From these propositions he thus satisfactorily accounts for single vision by both eyes. "If the question be concerning an object at the concurrence of the optic axes, it is seen single, because its two similar appearances, in regard to size, shape, and colour, are seen by both eyes in one and the same direction, or, if you will, in two directions, which coincide with each other through the whole of their extent. It therefore matters not whether the distance be truly or falsely estimated; whether the object be thought to touch our eyes, or to be infinitely remote. And hence we have a reason, which no other theory of visible direction affords, why objects appeared single to the young gentleman mentioned by Mr Chefelden, immediately after his being couched, and before he could have learned to judge of distance by sight.

"When two similar objects are placed in the optic axes, one in each, at equal distances from the eyes, they will appear in the same place, and therefore one, for the same reason that a truly single object, in the concurrence of the optic axes, is seen single.

"To finish this part of my subject, it seems only necessary to determine, whether the dependence of visible direction upon the actions of the muscles of the eyes.

Of vision.

Of Vision. eyes be established by nature, or by custom. But facts are here wanting. As far as they go, however, they serve to prove that it arises from an original principle of our constitution. For Mr Cheselden's patient saw objects single, and consequently in the same directions with both eyes, immediately after he was couched; and persons affected with squinting from their earliest infancy see objects in the same directions with the eye they have never been accustomed to employ, as they do with the other they have constantly used."

The author removes many difficulties, and obviates the objections to which his theory may seem most liable. The whole work deserves to be attentively studied by every optician; and we therefore recommend it to the perusal of our readers.

We are indebted to Dr Jurin for the following curious experiments, to determine whether an object seen by both eyes appears brighter than when seen with one only.

He laid a slip of clean white paper directly before him on the table, and applying the side of a book close to his right temple, so as that the book was advanced considerably more forward than his face, he held it in such a manner, as to hide from his right eye that half of the paper which lay to his left hand, while the left half of the paper was seen by both eyes, without any impediment.

Then looking at the paper with both eyes, he observed it to be divided, from the top to the bottom, by a dark line, and the part which was seen with one eye only was manifestly darker than that which was seen with both eyes; and applying the book to his left temple, he found, by the result of the experiment, that both his eyes were of equal goodness.

He then endeavoured to find to what degree this excess of brightness amounted; and comparing it with the appearance of an object illuminated partly by one candle and partly by two, he was surprised to find that an object seen with two eyes is by no means twice as luminous as when it is seen with one only; and after a number of trials, by which he made the proportion less and less continually, he found, that when one paper was illuminated by a candle placed at the distance of three feet, and another paper by the same candle at the same distance, and by another candle at the distance of 11 feet, the former seen with both eyes and the latter with one eye only, appeared to be of equal whiteness; so that an object seen by both eyes appears brighter than when it is seen with one only by about a 13th part. But he acknowledges, that it is difficult to make this experiment exactly.

He then proceeded to enquire, whether an object seen with both eyes appears any thing larger than when seen with one only; but he concluded that it did not, except on account of some particular circumstances, as in the case of the binocular telescope and the concave speculum.

M. du Tour maintains, that the mind attends to no more than the image made in one eye at a time; and produces several curious experiments in favour of this hypothesis, which had also been maintained by Kepler and almost all the first opticians. But, as M. Buffon observes, it is a sufficient answer to this hypothesis, how ingeniously soever it may be supported, that we see more distinctly with two eyes than with one; and that

when a round object is near us, we plainly see more of the surface in one case than in the other. There are also other facts which clearly prove the contrary of what is maintained by M. du Tour.

With respect to single vision with two eyes, Dr Hartley observes, that it deserves particular attention, that the optic nerves of men, and such other animals as look the same way with both eyes, unite in the *cella turcica* in a ganglion, or little brain, as one may call it, peculiar to themselves: and that the associations between synchronous impressions on the two retinas must be made sooner and cemented stronger on this account; also that they ought to have a much greater power over one another's images, than in any other part of the body. And thus an impression made on the right eye alone, by a single object, may propagate itself into the left, and there raise up an image almost equal in vividness to itself; and consequently when we see with one eye only, we may, however, have pictures in both eyes.

A curious deception in vision, arising from the use of both eyes, was observed and accounted for by Dr Smith. It is a common observation, he says, that objects seen with both eyes appear more vivid and stronger than they do to a single eye; especially when both of them are equally good. A person not short-sighted may soon be convinced of this fact, by looking attentively at objects that are pretty remote, first with one eye and then with both. This observation gave occasion to the construction of the binocular telescope, in the use of which the phenomenon is still more striking.

Besides this, our author observes, that there is another phenomenon observable with this instrument, which is very remarkable. In the foci of the two telescopes there are two equal rings, as usual, which terminate the pictures of the objects there formed, and consequently the visible area of the objects themselves. These equal rings, by reason of the equal eye-glasses, appear equal, and equally distant when seen separately by each eye: but when they are seen with both eyes, they appear much larger, and more distant also; and the objects seen through them do also appear much larger, though circumscribed by their united rings, in the same places as when they were seen separately.

He observes, that the phenomenon of the enlarged circle of the visible area in the binocular telescope, may be seen very plainly in looking at distant objects through a pair of spectacles, removed from the eyes about four or five inches, and held steady at that distance. The two innermost of the four apparent rings, which hold the glasses will then appear united in one larger and more distant ring than the two outermost, which will hardly be visible unless the spectacles be farther removed.

A curious circumstance relating to the effect of one eye upon the other, was noticed by M. Aepinus, who observed, that, when he was looking through a hole made in a plate of metal, about the 10th part of a line in diameter, with his left eye, both the hole itself appeared larger, and also the field of view seen through it was more extended, whenever he shut his right eye; and both these effects were more remarkable when that eye was covered with his hand. He found considerable difficulty in measuring this augmentation of the apparent

only one.

Of Vision.

apparent diameter of the hole, and of the field of view; but at length he found, that, when the hole was half an inch, and the tablet which he viewed through it was three feet from his eye, if the diameter of the field when both his eyes were open was 1, it became 1½ when the other eye was shut, and nearly 2 when his hand was laid upon it.

164

When one eye is closed, the pupil of the other is enlarged.

Upon examining this phenomenon, it presently appeared to depend upon the enlargement of the pupil of one eye when the other is closed, the physical or anatomical cause of which he did not pretend to assign; but he observes, that it is wisely appointed by divine Providence, in order that when one eye fails, the field of view in the other may be extended. That this effect should be more sensible when the eye is covered with the hand, is owing, he observes, to the eye lids not being impervious to the light. But the enlargement of the pupil does not enlarge the field of view, except in looking through a hole, as in this particular case; and therefore persons who are blind of one eye can derive no advantage from this circumstance. Before we applaud the wisdom of Providence in any part of the constitution of nature, we should be very sure that we do not mistake concerning the effects of that constitution.

A great deal has been written by Gassendi, Le Clerc, Muschenbroek, and Du Tour, concerning the place to which we refer an object viewed by one or both eyes. But the most satisfactory account of this matter that we have met with, the reader will find in Dr Wells's Essay above quoted, which will teach any person how to satisfy himself by experiment with respect to visible position and visible motion.

#### § 4. Of the Appearance of Objects seen through Media of different Forms.

165

The various appearances of objects seen through media of different Forms stated and illustrated.

For the more easy apprehension of what relates to this subject, we shall premise the five following particulars, which either have been already mentioned, or follow from what has been before laid down.

1. That as each point of an object, when viewed by the naked eye, appears in its proper place, and as that place is always to be found in the line in which the axis of a pencil of rays flowing from it enters the eye, or else in the line which Dr Wells calls the common axis; we from hence acquire an habit of judging the point to be situated in that line: and, because the mind is unacquainted with what refractions the rays suffer before they enter the eye, therefore, in cases where they are diverted from their natural course, by passing through any medium, it judges the point to be in that line produced back in which the axis of a pencil of rays flowing from it is situated the instant they enter the eye, and not in that it was in before refraction. We shall therefore, in what follows, suppose the apparent place of an object, when seen through a refracting medium, to be somewhere in that line produced back in which the axis of a pencil of rays flowing from it proceeds after they have passed through the medium.

2. That we are able to judge, though imperfectly, of the distance of an object by the degree of divergency, wherein the rays flowing from the same point of the object enter the pupil of the eye, in cases, where that divergency is considerable; but because in what

follows it will be necessary to suppose an object, when seen through a medium whereby its apparent distance is altered, to appear in some determinate situation, in those cases where the divergency of the rays at their entrance into the eye is considerable, we will suppose the object to appear where those lines which they describe in entering, if produced back, would cross each other: though it must not be asserted, that this is the precise distance; because the brightness, distinctness, and apparent magnitude of the object, on which its apparent distance in some measure depends, will also suffer an alteration by the refraction of the rays in passing through that medium.

3. That we estimate the magnitude of an object by that of the optic angle.

4. That vision is the brighter, the greater the number of rays is which enter the pupil. And,

5. That, in some cases, the apparent brightness, distinctness, and magnitude of an object, are the only means whereby our judgment is determined in estimating the distance of it.

PROP. I. An object placed within a medium terminated by a plane surface on that side which is next the eye, if the medium be denser than that in which the eye is (as we shall always suppose it to be, unless where the contrary is expressed), appears nearer to the surface of the medium than it is.

Thus, if  $A$  be a point of an object placed within the medium  $BDCE$  (fig. 5.), and  $Ab, Ac$  be two rays proceeding from thence, these rays passing out of a denser into a rarer medium, will be refracted from their respective perpendiculars  $bd, ce$ , and will enter the eye at  $H$ , suppose in the directions  $bf, cg$ : let then these lines be produced back till they meet in  $F$ ; this will be the apparent place of the point  $A$ : and because the refracted rays  $bf, cg$  will diverge more than the incident ones  $Ab, Ac$ , it will be nearer to the points  $b$  and  $c$  than the point  $A$ ; and as the same is true of each point in the object, the whole will appear to an eye at  $H$ , nearer to the surface  $BC$  than it is.

From hence it is, that when one end of a straight stick is put under water, and the stick is held in an oblique position, it appears bent at the surface of the water; viz. because each point that is under water appears nearer the surface, and consequently higher than it is.

From hence likewise it is, that an object at the bottom of a vessel may be seen when the vessel is filled with water, though it be so placed with respect to the eye, that it cannot be seen when the vessel is empty. To explain this, let  $ABCD$  (fig. 6.) represent a vessel, and let  $E$  be an object lying at the bottom of it. This object, when the vessel is empty, will not be seen by an eye at  $F$ , because  $HB$ , the upper part of the vessel, will obstruct the ray  $EH$ ; but when it is filled with water to the height  $GH$ , the ray  $EK$  being refracted at the surface of the water into the line  $KF$ , the eye at  $F$  shall see the object by means of that.

In like manner, an object situated in the horizon appears above its true place, upon account of the refraction of the rays which proceed from it in their passage through the atmosphere of the earth. For, first, if the object be situated beyond the limits of the atmosphere, its rays in entering it will be refracted towards the

Appearance of Objects seen through Media of different Forms.

the perpendicular; that is, towards a line drawn from the point where they enter, to the centre of the earth, which is the centre of the atmosphere: and as they pass on, they will be continually refracted the same way, because they are all along entering a denser part, the centre of whose convexity is still the same point; upon which account the line they describe will be a curve bending downwards: and therefore none of the rays that come from that object can enter an eye upon the surface of the earth, except what enter the atmosphere higher than they need to do if they could come in a right line from the object: consequently the object must appear above its proper place. Secondly, if the object be placed within the atmosphere, the case is still the same; for the rays which flow from it must continually enter a denser medium whose centre is below the eye: and therefore being refracted towards the centre, that is, downwards as before, those which enter the eye must necessarily proceed as from some point above the object; wherefore the object will appear above its proper place.

From hence it is, that the sun, moon, and stars, appear above the horizon, when they are just below it; and higher than they ought to do, when they are above it: Likewise distant hills, trees, &c. seem to be higher than they are.

Further, the lower these object are in the horizon, the greater is the obliquity with which the rays which flow from them enter the atmosphere, or pass from the rarer into the denser parts of it; and therefore they appear to be the more elevated by refraction: upon which account the lower parts of them are apparently more elevated than the other. This makes their upper and under parts seem nearer than they are; as is evident from the sun and moon, which appear of an oval form when they are in the horizon, their horizontal diameters appearing of the same length they would do if the rays suffered no refraction, while their vertical ones are shortened thereby.

PROP. II. An object seen through a medium terminated by plane and parallel surfaces, appears nearer, brighter, and larger, than with the naked eye.

For instance, let AB (fig. 7.) be the object, CDEF the medium, and GH the pupil of an eye, which is here drawn large to prevent confusion in the figure. And, 1st, let RK, RL, be two rays proceeding from the point R, and enter the denser medium at K and L; these rays will here by refraction be made to diverge less, and to proceed afterwards, suppose in the lines Ka, Lb; at a and b, where they pass out of the denser medium, they will be as much refracted the contrary way, proceeding in the lines ac, bd, parallel to their first direction. Produce these lines back till they meet in e: this will be the apparent place of the point R; and it is evident from the figure, that it must be nearer the eye than that point; and because the same is true of all other pencils flowing from the object AB, the whole will be seen in the situation fg, nearer to the eye than the line AB. 2d, As the rays RK, RL, would not have entered the eye, but have passed by it in the directions Kr, Lt, had they not been refracted in passing through the medium, the object appears brighter. 3d, The rays Ab, Bi, will be refracted at b and i into the less converging lines bk, il, and at the other surface into Ml,

parallel to Ab and Bi produced; so that the extremities of the object will appear in the lines Ml, Ml produced, viz. in f and g, and under as large an angle fMg, as the angle AgB under which an eye at g would have seen it had there been no medium interposed to refract the rays; and therefore it appears larger to the eye at GH, being seen through the interposed medium, than otherwise it would have done. But it is here to be observed, that the nearer the point e appears to the eye on account of the refraction of the rays RK, RL, the shorter is the image fg, because it is terminated by the lines Mf and Mg, upon which account the object is made to appear less; and therefore the apparent magnitude of an object is not much augmented by being seen through a medium of this form.

Farther, it is apparent from the figure, that the effect of a medium of this form depends wholly upon its thickness; for the distance between the lines Rr and ec, and consequently the distance between the points e and R, depends upon the length of the line Ka: Again, the distance between the lines AM and fM depends on the length of the line bk; but both Ku and kb depend on the distance between the surfaces CE and DF, and therefore the effect of this medium depends upon its thickness.

PROP. III. An object seen through a convex lens, appears larger, brighter, and more distant, than with the naked eye.

To illustrate this, let AB (fig. 8.) be the object, CD the lens, and EF the eye. 1. From A and B, the extremities of the object, draw the lines AYr, BXr, crossing each other in the pupil of the eye; the angle ArB comprehended between these lines, is the angle under which the object would be seen with the naked eye. But by the interposition of a lens of this form, whose property is to render converging rays more so, the rays AY and BX will be made to cross each other before they reach the pupil. There the eye at E will not perceive the extremities of the object by means of these rays (for they will pass it without entering), but by some others which must fall without the points Y and X, or between them; but if they fall between them, they will be made to concur sooner than they themselves would have done; and therefore, if the extremities of the object could not be seen by them, it will much less be seen by these. It remains therefore, that the rays which will enter the eye from the points A and B after refraction, must fall upon the lens without the points Y and X; let then the rays AO and BP be such. These after refraction entering the eye at r, the extremities of the object will be seen in the line rQ, rT, produced, and under the optic angle QrT, which is larger than ArB, and therefore the apparent magnitude of the object will be increased. 2. Let GHI be a pencil of rays flowing from the point G; as it is the property of this lens to render diverging rays less diverging, parallel, or converging, it is evident that some of those rays, which would proceed on to F and E, and miss the eye, were they to suffer no refraction in passing through the lens, will now enter it; by which means the object will appear brighter. 3. As to the apparent distance of the object, that will vary according to the situation of it with respect to the focus of parallel rays of the lens.

1. Then

1. Then, let us suppose the object placed so much nearer the lens than its focus of parallel rays, that the refracted rays KE and LF, though rendered less diverging by passing through it, may yet have a considerable degree of divergency, so that we may be able to form a judgment of the distance of the object thereby. In this case, the object ought to appear where EK, FL, produced back concur; which, because they diverge less than the rays GH, GI, will be beyond G, that is, at a greater distance from the lens than the object is. But because both the brightness and magnitude of the object will at the same time be augmented, prejudice will not permit us to judge it quite so far off as the point where those lines meet, but somewhere between that point and its proper place.

2. Let the object be placed in the focus of parallel rays, then will the rays KE and LF become parallel; and though in this case the object would appear at an immense distance, if that distance were to be judged of by the direction of the rays KE and LF, yet upon account of the brightness and magnitude of it, we shall not think it much farther from us than if it were seen by the naked eye.

3. If the object be situated beyond the focus of parallel rays, as in BA (fig. 9.), the rays flowing from thence and falling upon the lens CD, will be collected into their respective foci at *a* and *b*, and the intermediate points, *m*, *n*, &c. and will there form an image of the object AB; and after crossing each other in the several points of it, as expressed in the figure, will pass on diverging as from a real object. Now if an eye be situated at *c*, where Ac, Bc, rays proceeding from the extreme point of the object, make not a much larger angle AcB, than they would do if there were no lens interposed, and the rays belonging to the same pencil do not converge so much as those which the eye would receive if it were placed nearer to *a* or *b*, the object upon these accounts appearing very little larger or brighter than with the naked eye, is seen nearly in its proper place; but if the eye recedes a little way towards *ab*, the object then appearing both brighter and larger, seems to approach the lens: which is an evident proof of what has been so often asserted, viz. that we judge of the distance of an object in some measure by its brightness and magnitude; for the rays converge the more the farther the eye recedes from the lens; and therefore if we judged of the distance of the object by the direction of the rays which flow from it, we ought in this case to conceive it at a greater distance, than when the rays were parallel, or diverged at their entrance into the eye.

That the object should seem to approach the lens in this case, was a difficulty that exceedingly puzzled the learned Barrow, and which he pronounces insuperable, and not to be accounted for by any theory we have of vision. Molineux also leaves it to the solution of others, as that which will be inexplicable, till a more intimate knowledge of the visive faculty, as he expresses it, be obtained by mortals.

They imagined, that seeing an object appears farther off, the less the rays diverge which fall upon the eye. If they should proceed parallel to each other, it ought to appear exceeding remote; and if they should converge, it should then appear more distant still: the reason of this was, because the looked upon the ap-

parent place of an object, as owing only to the direction of the rays whatever it was, and not at all to its apparent magnitude or splendor.

Perhaps it may proceed from our judging of the distance of an object in some measure by its magnitude, that that deception of sight commonly observed by travellers may arise; viz. that upon the first appearance of a building larger than usual, as a cathedral church, or the like, it generally seems nearer to them, than they afterwards find it to be.

PROP. IV. If an object be placed farther from a convex lens than its focus of parallel rays, and the eye be situated farther from it, on the other side than the place where the rays of the several pencils are collected into their respective foci, the object appears inverted, and pendulous in the air, between the eye and the lens.

To explain this, let AB (fig. 9.) represent the object, CD the lens, and let the rays of the pencil ACD be collected in *a*, and those of BCD in *b*, forming there an inverted image of the object AB, and let the eye be placed in F: it is apparent from the figure, that some of the refracted rays which pass through each point of the image will enter the eye as from a real object in that place; and therefore the object AB will appear there, as the proposition asserts. But we are so little accustomed to see objects in this manner, that it is very difficult to perceive the image with one eye; but if both eyes are situated in such a manner, that rays flowing from each point of the image may enter both, as at G and H, and we direct our optic axes to the image, it is easy to be perceived.

If the eye be situated in *a* or *b*, or very near them on either side, the object appears exceedingly confused; viz. if at *d*, the rays which proceed from the same point of the object converge so very much, and if at *e*, they diverge so much, that they cannot be collected together upon the retina, but fall upon it as if they were the axes of so many distinct pencils coming thro' every point of the lens; wherefore little more than one single point of the object is seen at a time, and that appears all over the lens; from whence nothing but confusion arises.

If the lens be so large that both eyes may be applied to it, as in *b* and *k*, the object will appear double; for it is evident from the figure, that the rays which enter the eye at *b* from either extremity of the object A or B, do not proceed as from the same point with that from whence those which enter the other at *k* seem to flow; the mind therefore is here deceived, and looks upon the object as situated in two different places, and therefore judges it to be double.

PROP. V. An object seen through a concave lens appears nearer, smaller, and less bright, than with the naked eye.

Thus, let AB (fig. 10.) be the object, CD the pupil of an eye, and EF, the lens. Now, as it is the property of a lens of this form to render diverging rays more so, and converging ones less so, the diverging rays GH, GI, proceeding from the point G, will be made to diverge more, and so to enter the eye as from some nearer point *g*; and the rays AH, BI, which converge, will be made to converge less, and to enter the eye as from the points *a* and *b*; wherefore the objects will appear in the situation *agb*, less

Reflection  
of Light.

and nearer than without the lens. Farther, as the rays which proceed from G are rendered more diverging, some of them will be made to pass by the pupil of the eye, which otherwise would have entered it, and therefore each point of the object will appear less bright.

PROP. VI. An object seen through a polygonous glass, that is, such as is terminated by several plain surfaces, is multiplied thereby.

Plate  
CCCLVIII

For instance, let A (fig. 11.) be an object, and BC a polygonous glass terminated by the plain surfaces BD, DE, &c. and let the situation of the eye F be such, that the rays AB being refracted in passing through the glass, may enter it in the direction BF, and the rays AC in the direction CF. Then will the eye, by means of the former, see the object in G, and by the latter in H; and by means of the rays AI, the object will appear also in its proper situation A.

### SECT. III. Of the Reflection of Light.

171

Some portion of light always reflected from transparent bodies.

WHEN a ray of light falls upon any body, however transparent, the whole of it never passes through the body, but some part is always driven back or reflected from it; and it is by this reflected light that all bodies which have no light of their own become visible to us. Of that part of the ray which enters, another part is also reflected from the second surface, or that which is farthest from the luminous body. When this part arrives again at the first surface, part of it is reflected back from that surface; and thus it continues to be reflected between the two surfaces, and to pass backwards and forwards within the substance of the medium, till some part is totally extinguished and lost. Besides this inconsiderable quantity, however, which is lost in this manner, the second surface often reflects much more than the first; insomuch that, in certain positions, scarce any rays will pass through both sides of the medium. A very considerable quantity is also unaccountably lost or extinguished at each reflecting surface; insomuch that no body, however transparent, can transmit all the rays which fall upon it; neither, tho' it be ever so well fitted for reflection, will it reflect them all.

#### § I. Of the Cause of Reflection.

THE reflection of light is by no means so easily accounted for as the refraction of the same fluid. This property, as we have seen in the last section, may be accounted for in a satisfactory manner by the supposition of an attractive power diffused throughout the medium, and extending a very little way beyond it; but with regard to the reflection of light, there seems to be no satisfactory hypothesis hitherto invented. Of the principal opinions on this subject Mr Rowning hath given us the following account.

I. It was the opinion of philosophers, before Sir Isaac Newton discovered the contrary, that light is reflected by impinging upon the solid parts of bodies. But that it is not so, is clear for the following reasons.

And first, it is not reflected at the first surface of a body by impinging against it.

For it is evident, that, in order to the due and

regular reflection of light, that is, that the reflected rays should not be dispersed and scattered one from another, there ought to be no rasures or unevenness in the reflecting surface large enough to bear a sensible proportion to the magnitude of a ray of light; because if the surface abounds with such, the reflected rays will rather be scattered like a parcel of pebbles thrown upon a rough pavement, than reflected with that regularity with which light is observed to be from a well polished surface. Now those surfaces, which to our senses appear perfectly smooth and well polished, are far from being so; for to polish, is no other than to grind off the larger eminences and protuberances of the metal with the rough and sharp particles of sand, emery, or putty, which must of necessity leave behind them an infinity of rasures and scratches, which, though inconsiderable with regard to the former roughnesses, and too minute to be discerned by us, must nevertheless bear a large proportion to, if not vastly exceed, the magnitude of the particles of light.

Secondly, it is not reflected at the second surface by Nor at the second.

That it is not reflected by impinging upon the solid particles which constitute this second surface, is sufficiently clear from the foregoing argument; the second surfaces of bodies being as incapable of a perfect polish as the first: and it is farther confirmed from hence, viz. that the quantity of light reflected differs according to the different density of the medium behind the body. And that it is not reflected by impinging upon the particles which constitute the surface of the medium behind it, is evident, because the strongest reflection of all at the second surface of a body, is when there is a vacuum behind it. This therefore wants no farther proof.

II. It has been thought by some, that it is reflected at the first surface of a body, by a repulsive force equally diffused over it; and at the second, by an attractive force.

1. If there be a repulsive force diffused over the surface of bodies that repels rays of light at all times, then, since by increasing the obliquity of a ray we diminish its perpendicular force (which is that only whereby it must make its way through this repulsive force), however weakly that force may be supposed to act, rays of light may be made to fall with so great a degree of obliquity on the reflecting surface, that there shall be a total reflection of them there, and not one particle of light be able to make its way through: which is contrary to observation; the reflection of light at the first surface of a transparent body being never total in any obliquity whatever. The hypothesis therefore in this particular must be false.

2. As to the reflection at the second surface by the attractive force of the body; this may be considered in two respects: first, when the reflection is total; secondly, when it is partial.

And first, in cases where the reflection is total, the cause of it is undoubtedly that same attractive force by which light would be refracted in passing out of the same body. This is manifest from that analogy which is observable between the reflection of light at this second surface, and its refraction there. For otherwise, what can be the reason that the total reflection should begin just when the obliquity of the incident

172  
Light is not reflected by impinging on the solid parts of bodies at the first surface,

Cause of  
Reflection.

cident ray, at its arrival at the second surface, is such that the refracted angle ought to be a right one; or when the ray, were it not to return in reflection, ought to pass on parallel to the surface, without going from it? For in this case it is evident, that it ought to be returned by this very power; and in such manner that the angle of reflection shall be equal to the angle of incidence; just as a stone thrown obliquely from the earth, after it is so far turned out of its course by the attraction of the earth, as to begin to move horizontally, or parallel to the surface of the earth, is then by the same power made to return in a curve similar to that which is described in its departure from the earth, and so falls with the same degree of obliquity that it was thrown with.

177  
Objected  
to.

But, secondly, as to the reflection at the second surface, when it is partial; an attractive force uniformly spread over it, as the maintainers of this hypothesis conceive it to be, can never be the cause thereof. Because it is inconceivable, that the same force, acting in the same circumstances in every respect, can sometimes reflect the violet coloured rays and transmit the red, and at other times reflect the red and transmit the violet.

We have stated this objection, because it is our business to conceal no plausible opinions: but it is not valid; for in each colour, the reflection takes place at that angle, and no other, where the refraction of *that* ray would make it parallel to the posterior surface.

This partial reflection and refraction is a great difficulty in all the attempts which have been made to give a mechanical explanation of the phenomena of optics. It is equally a desideratum in that explanation which was proposed by Huygens, and, since his time, revived by Euler, by means of the undulations of an elastic fluid, although a vague consideration of undulatory motions seems to offer a very specious analogy. But a *rigid* application of such *knowledge* as we have acquired of such motions, will convince any unprejudiced mathematician, that the phenomena of undulation are essentially dissimilar to the phenomena of light. The inflection of light, and its refraction, equally demonstrate that light *is acted on* by moving forces in a direction perpendicular to the surface; and it is equally demonstrable that such forces must, in proper circumstances, produce reflections precisely such as we observe. The only difficulty is to show how there can be forces which produce both reflection and refraction, in circumstances which are similar. The fact is, that such effects are produced: The first logical inference is, that with respect to the light which is reflected and that which is refracted, the circumstances are *not* similar; and our attention should be directed to the discovery of that dissimilarity. All the phenomena of combined reflection and refraction should be examined and classed according to their generality, not doubting but that these points of resemblance will lead to the discovery of their causes. Now the experiments of Mr Bouguer show that bodies differ extremely in their powers of thus separating light by reflection and refraction, some of them reflecting much more at a given angle than others. It is not therefore a *general property of light* to be partly reflected and partly refracted, but a *distinctive* property of *different* bodies; and since we see that they

possess it in *different* degrees, we are authorised to conclude that some bodies *may want it altogether*. We may therefore expect some success by considering how bodies are affected by light, as well as how light is affected by bodies. Now, in all the phenomena of the material world we find bodies connected by mutual forces. We know no case where a body A tends towards a body B, or, in common language, is attracted by it, without, at the same time, the body B tending towards A. This is observed in the phenomena of magnetism, electricity, gravitation, corpuscular attraction, impulse, &c. We should therefore conclude from analogy, that as bodies change the motion of light, light also changes the motion of bodies; and that the particles near the surface are put into vibration by the passage of light through among them. Suppose a parcel of cork-balls all hanging as pendulums in a symmetrical order, and that an electrified ball passes through the midst of them; it is very easy to show that it may proceed through this assemblage in various directions with a sinuated motion, and without touching any of them, and that its ultimate direction will have a certain inclination to its primary direction, depending on the outline of the assemblage, just as is observed in the motion of light; and, in the mean time, the cork-balls will be variously agitated. Just so must it happen to the particles of a transparent body, if we suppose that they act on the particles of light by mutual attractions and repulsions.

Cause of  
Reflection.178  
The objec-  
tion obvia-  
ted.

An attentive consideration of what happens here will show us that the superficial particles will be much more agitated than the rest; and thus a stratum be produced, which, in any instant, will act on those particles of light which are then approaching them in a manner different from that in which they will act on similarly situated particles of light, which come into the place of the first in the following moment, when these acting particles of the body have (by their motion of vibration) changed their own situation. Now it is clearly understood, that in all motions of vibration, such as the motions of pendulums, there is a moment when the body is in its natural situation, as when the pendulum is in the vertical line. This *may* happen in the same instant in each atom of the transparent body. The particles of light which *then* come within the sphere of action may be wholly reflected; in the next moment, particles of light in the very situation of the first may be refracted.

Then will arise a separation of light; and as this will depend on the manner in which the particles of bodies are agitated by it during its passage, and as this again will depend on the nature of the body, that is on the law of action of those forces which connect the particles with each other, and with the particles of light, it will be different in different bodies. But in all bodies there will be this general resemblance, that the separation will be most copious in great obliquities of incidence, which gives the repulsive forces more time for action, while it diminishes the perpendicular force of the light. Such a resemblance between the phenomena and the legitimate consequences of the assumption (the agitation of the parts of the body), gives us some authority for assigning this as the cause; nor can the assumption

Cause of  
Reflection.

tion be called *gratuitous*. To suppose that the particles of the transparent body *are not thus agitated*, would be a most gratuitous contradiction of a law of nature to which we know no other exception.

Thus the objection raised in n° 132, is obviated, because the reflection and refraction is not here conceived as simultaneous, but as successive.

179  
Another  
Hypothesis

III. Some being apprehensive of the insufficiency of a repulsive and attractive force diffused over the surfaces of bodies and acting uniformly, have supposed, that, by the action of light upon the surface of bodies, the matter of these bodies is put into an undulatory motion; and that where the surface of it is subsiding light is transmitted, and in those places where it is rising light is reflected. But to overlook the objections which we have just made to this theory of undulation, we have only to observe, that, were it admitted, it seems not to advance us one jot farther; for in those cases, suppose where red is reflected and violet transmitted, how comes it to pass that the red impinges only on those parts when the waves are rising, and the violet when they are subsiding?

180  
Sir I. Newton's  
Hypothesis;

IV. The next hypothesis that we shall take notice of, is that remarkable one of Sir Isaac Newton's fits of easy reflection and transmission, which we shall now explain and examine.

That author, as far as we can apprehend his meaning in this particular, is of opinion, that light in its passage from the luminous body, is disposed to be alternately reflected by and transmitted through any refracting surface it may meet with; that these dispositions (which he calls *fits of easy reflection and easy transmission*) return successively at equal intervals; and that they are communicated to it at its first emission out of the luminous body it proceeds from, probably by some very subtle and elastic substance diffused through the universe, and that in the following manner. As bodies falling into water, or passing through the air, cause undulations in each, so the rays of light may excite vibrations in this elastic substance. The quickness of which vibrations depending on the elasticity of the medium (as the quickness of the vibrations in the air, which propagate sound, depend solely on the elasticity of the air, and not upon the quickness of those in the sounding body) the motion of the particles of it may be quicker than that of the rays; and therefore, when a ray at the instant it impinges upon any surface, is in that part of a vibration of this elastic substance which conspires with its motion, it may be easily transmitted; and when it is in that part of a vibration which is contrary to its motion, it may be reflected. He farther supposes, that when light falls upon the surface of a body, if it be not in a fit of easy transmission, every ray is there put into one, so that when they come at the other side (for this elastic substance, easily pervading the pores of bodies, is capable of the same vibrations within the body as without it), the rays of one colour shall be in a fit of easy transmission, and those of another in a fit of easy reflection, according to the thickness of the body, the intervals of the fits being different in rays of a different kind. This seems to account for the different colours of the bubble and thin plate of air and water, as is obvious enough; and likewise for the reflection of light at the second surface of a

thicker body; for the light reflected from thence is also observed to be coloured, and to form rings according to the different thickness of the body, when not intermixed and confounded with other light, as will appear from the following experiment. If a piece of glass be ground concave on one side and convex on the other, both its concavity and convexity having one common centre; and if a ray of light be made to pass through a small hole in a piece of paper held at that common centre, and be permitted to fall on the glass; besides those rays which are regularly reflected back to the hole again, there will be others reflected to the paper, and form coloured rings surrounding the hole, not unlike those occasioned by the reflection of light from thin plates.

It is ever with extreme reluctance, that we venture to call in question the doctrines of Newton; but to his theory of reflection there is this insuperable objection, that it explains nothing, unless the *cause* of the fits of more easy reflection and transmission be held as legitimate, namely, that *they are produced by the undulations of another elastic fluid, incomparably more subtle than light*, acting upon it in the way of impulse. The fits themselves are *matters of fact*, and no way different from what we have endeavoured to account for: but to admit this theory of them would be to transgress every rule of philosophising, as we have shown them to be susceptible of explanation from acknowledged optical laws.

## § 2. Of the Laws of Reflection.

THE fundamental law of the reflection of light, is, that in all cases the angle of reflection is equal to the angle of incidence. This is found by experiment to be the case, and besides may be demonstrated mathematically from the laws of percussion in bodies perfectly elastic. The axiom therefore holds good in every case of reflection, whether it be from plane surfaces or spherical ones, and that whether they are convex or concave; and hence the seven following propositions relating to the reflection of light from plane and spherical surfaces may be deduced.

I. Rays of light reflected from a plane surface have the same degree of inclination to one another that their respective incident ones have.—For the angle of reflection of each ray being equal to that of its respective incident one, it is evident, that each reflected ray will have the same degree of inclination to that portion of the surface from whence it is reflected that its incident one has: but it is here supposed, that all those portions of surface from whence the rays are reflected, are situated in the same plain; consequently the reflected rays will have the same degree of inclination to each other that their incident ones have, from whatever part of the surface they are reflected.

II. Parallel rays reflected from a concave surface are rendered converging.—To illustrate this, let AF CD, EB, (fig. 1.) represent three parallel rays falling upon the concave surface FB, whose centre is C. To the points F and B draw the lines CF, CB; these being drawn from the centre, will be perpendicular to the surface at those points. The incident ray CD also passing through the centre, will be perpendicular to the surface, and therefore will return after reflection in the same line; but the oblique rays AF and

Plate  
CCCLIX.  
183  
Laws of reflection  
from a concave surface.

Laws of  
Reflection.

and EB will be reflected into the lines FM and BM, situated on the contrary side of their respective perpendicular CF and CB. They will therefore proceed converging after reflection towards some point, as M, in the line CD.

III. Converging rays falling on the like surface, are made to converge more.—For, every thing remaining as above, let GF, HF, be the incident rays. Now, because these rays have larger angles of incidence than the parallel ones AF and EB in the foregoing case, their angles of reflection will also be larger than those of the others; they will therefore converge after reflection, suppose in the lines FN and BN, having their point of concurrence N farther from the point C than M, that to which the parallel rays AF and EB converged to in the foregoing case; and their precise degree of convergency will be greater than that wherein they converged before reflection.

IV. Diverging rays falling upon the like surface, are, after reflection, parallel, diverging, or converging. If they diverge from the focus of parallel rays, they then become parallel; if from a point nearer to the surface than that, they will diverge, but in a less degree than before reflection; if from a point between that and the centre, they will converge after reflection, and that to some point on the contrary side of the centre, but situated farther from it than the point from which they diverged. If the incident rays diverge from a point beyond the centre, the reflected ones will converge to one on the other side of it, but nearer to it than the point they diverged from; and if they diverge from the centre, they will be reflected thither again.

1. Let them diverge in the lines MF, MB, proceeding from E, the focus of parallel rays; then, as the parallel rays AF and EB were reflected into the lines FM and BM (by Prop. II.), these rays will now on the contrary be reflected into them.

2. Let them diverge from N, a point nearer to the surface than the focus of parallel rays, they will then be reflected into the diverging lines FG and BH which the incident rays GF and HB described that were shewn to be reflected into them in the foregoing proposition; but the degree wherein they diverge will be less than that wherein they diverged before reflection.

3. Let them proceed diverging from X, a point between the focus of parallel rays and the centre; they then make less angles of incidence than the rays MF and MB, which became parallel by reflection: they will consequently have less angles of reflection, and proceed therefore converging towards some point, as Y; which point will always fall on the contrary side of the centre, because a reflected ray always falls on the contrary side of the perpendicular with respect to that on which its incident one falls; and of consequence it will be farther distant from the centre than X.

4. If the incident ones diverge from Y, they will, after reflection, converge to X; those which were the incident rays in the former case being the reflected ones in this. And lastly,

5. If the incident rays proceed from the centre, they fall in with their respective perpendiculars; and for that reason are reflected thither again.

V. parallel rays reflected from a convex surface are rendered diverging.—For, let AB, GD, EF, (fig. 2,) be three parallel rays falling upon the convex surface BF, whose centre of convexity is C, and let one of them, viz. GD, be perpendicular to the surface. Through B, D, and F, the points of reflection, draw the lines CV, CG, and CT; which, because they pass through the centre, will be perpendicular to the surface, at these points. The incident ray GD being perpendicular to the surface, will return after reflection in the same line, but the oblique ones AB and EF in the lines BK and FL, situated on the contrary side of their respective perpendiculars BV and FT. They will therefore diverge, after reflection, as from some point M in the line GD produced; and this point will be in the middle between D and C.

VI. Diverging rays reflected from the like surface are rendered more diverging.—For, every thing remaining as above, let GB, GF, be the incident rays. These having larger angles of incidence than the parallel ones AB and EF in the preceding case, their angles of reflection will also be larger than theirs: they will therefore diverge after reflection, suppose in the lines BP and FQ, as from some point N, farther from C than the point M; and the degree wherein they will diverge will be greater than that wherein they diverged before reflection.

VII. Converging rays reflected from the like surface, are parallel, converging, or diverging. If they tend towards the focus of parallel rays, they then become parallel: if to a point nearer the surface than that, they converge, but in a less degree than before reflection; if to a point between that and the centre, they will diverge after reflection, as from some point on the contrary side of the centre, but situated farther from it than the point they converged to: if the incident rays converge to a point beyond the centre, the reflected ones will diverge as from one on the contrary side of it, but nearer to it than the point to which the incident ones converged; and if the incident rays converge towards the centre, the reflected ones will proceed as from thence.

1. Let them converge in the lines KB and LF, tending towards M, the focus of parallel rays; then, as the parallel rays AB, EF were reflected into the lines BK and FL (by Prop. V.), those rays will now on the contrary be reflected into them.

2. Let them converge in the lines PB, QF, tending towards N a point nearer the surface than the focus of parallel rays, they will then be reflected into the converging lines BG and FG, in which the rays GB, GF proceeded that were shown to be reflected into them by the last proposition: but the degree wherein they will converge will be less than that wherein they converged before reflection.

3. Let them converge in the lines RB and SF proceeding towards X, a point between the focus of parallel rays and the centre: their angles of incidence will then be less than those of the rays KB and LF, which became parallel after reflection: their angles of reflection will therefore be less; on which account they must necessarily diverge, suppose in the lines BH and FI, for some point, as Y; which point (by Prop. IV.) will fall on the contrary side of the centre

Laws of  
Reflection.

Plate  
CCCLIX.

184  
From a convex surface.

Laws of  
Reflection.

centre with respect to  $X$ , and will be farther from it than that.

4. If the incident rays tend towards  $Y$ , the reflected ones will diverge as from  $X$ ; those which were the incident ones in one case being the reflected ones in the other.

5. Lastly, if the incident rays converge towards the centre, they fall in with their respective perpendiculars; on which account they proceed after reflection as from the centre.

We have already observed, that in some cases there is a very great reflection from the second surface of a transparent body. The degree of inclination necessary to cause a total reflection of a ray at the second surface of a medium, is that which requires that the refracted angle (supposing the ray to pass out there) should be equal to or greater than a right one; and consequently it depends on the refractive power of the medium through which the ray passes, and is therefore different in different media. When a ray passes through glass surrounded with air, and is inclined to its second surface under an angle of 42 degrees or more, it will be wholly reflected there. For, as 11 is to 17 (the ratio of refraction out of glass into air), so is the sine of an angle of 42 degrees to a fourth number that will exceed the sine of a right angle. From hence it follows, that when a ray of light arrives at the second surface of a transparent substance with as great or a greater degree of obliquity than that which is necessary to make a total reflection, it will there be all returned back to the first: and if it proceeds towards that with as great an obliquity as it did towards the other (which it will do if the surfaces of the medium be parallel to each other), it will there be all reflected again, &c. and will therefore never get out, but pass from side to side, till it be wholly suffocated and lost within the body.—From hence may arise an obvious inquiry, how it comes to pass, that light falling very obliquely upon a glass window from without, should be transmitted into the room. In answer to this it must be considered, that however obliquely a ray falls upon the surface of any medium whose sides are parallel (as those of the glass in a window are), it will suffer such a degree of refraction in entering there, that it shall fall upon the second with a less obliquity than that which is necessary to cause a total reflection. For instance, let the medium be glass, as supposed in the present case: then, as 17 is to 11 (the ratio of refraction out of air into glass), so is the sine of the largest angle of incidence with which a ray can fall upon any surface to the sine of a less angle than that of total reflection. And therefore, if the sides of the glass be parallel, the obliquity with which a ray falls upon the first surface, cannot be so great, but that it shall pass the second without suffering a total reflection there.

When light passes out of a denser into a rarer medium, the nearer the second medium approaches the first in density (or more properly in its refractive power), the less of it will be refracted in passing from one to the other; and when their refracting powers are equal, all of it will pass into the second medium.

185 The preceding propositions demonstrated in the following manner.

PROP. I. Of the reflection of rays from a plane surface.

“When rays fall upon a plane surface, if they di-

verge, the focus of the reflected rays will be at the same distance behind the surface, that the radiant point before it: if they converge, it will be at the same distance before the surface that the imaginary focus of the incident rays is behind it.”

This proposition admits of two cases.

CASE 1. Of diverging rays.

DEM. Let  $AB$ ,  $AC$ , (fig. 3.) be two diverging rays incident on the plane surface  $DE$ , the one perpendicularly, the other obliquely: the perpendicular one  $AB$  will be reflected to  $A$ , proceeding as from some point in the line  $AB$  produced; the oblique one  $AC$  will be reflected into some line as  $CF$ , such that the point  $G$ , where the line  $FG$  produced intersects the line  $AB$  produced also, shall be at an equal distance from the surface  $DE$  with the radiant  $A$ . For the perpendicular  $CH$  being drawn,  $ACH$  and  $HCF$  will be the angles of incidence and reflection; which being equal, their complements  $ACB$  and  $FCE$  are so too: but the angle  $BCG$  is equal to  $FCE$ , as being vertical to it: therefore in the triangles  $ABC$  and  $GBC$  the angles at  $C$  are equal, the side  $BC$  is common, and the angles at  $B$  are also equal to each other, as being right ones; therefore the lines  $AB$  and  $BG$ , which respect the equal angles at  $C$ , are also equal; and consequently the point  $G$ , the focus of the incident rays  $AB$ ,  $AC$ , is at the same distance behind the surface, that the point  $A$  is before it. *Q. E. D.*

CASE 2. Of converging rays.

This is the converse of the former case. For supposing  $FC$  and  $AB$  to be two converging incident rays,  $CA$  and  $BA$  will be the reflected ones (the angles of incidence in the former case being now the angles of reflection, and *vice versa*), having the point  $A$  for their focus; but this, from what was demonstrated above, is at an equal distance from the reflecting surface with the point  $G$ , which in this case is the imaginary focus of the incident rays  $FC$  and  $AB$ .

Obs. It is not here, as in the refraction of rays in passing through a plane surface, where some of the refracted rays proceed as from one point, and some as from another: but they all proceed after reflection as from one and the same point, however obliquely they may fall upon the surface; for what is here demonstrated of the ray  $AC$  holds equally of any other, as  $AI$ ,  $AK$ , &c.

The case of parallel rays incident on a plane surface is included in this proposition: for in that case we are to suppose the radiant to be at an infinite distance from the surface, and then by the proposition the focus of the reflected rays will be so too; that is, the rays will be parallel after reflection, as they were before.

PROP. II. Of the reflection of parallel rays from a spherical surface.

“When parallel rays are incident upon a spherical surface, the focus of the reflected rays will be the middle point between the centre of convexity and the surface.”

This proposition admits of two cases.

CASE 1. Of parallel rays falling upon a convex surface.

DEM. Let  $AB$ ,  $DH$ , (fig. 4.) represent two parallel rays incident on the convex surface  $BH$ , the one perpendicularly, the other obliquely; and let  $C$  be the centre of convexity; suppose  $HE$  to be the reflected ray of the oblique incident one  $DH$  proceeding as from  $F$ ,

Laws of  
Reflection.

Plate  
CCCLIX.

Laws of Reflection.

Laws of Reflection.

a point in the line AB produced. Through the point H draw the line CI, which will be perpendicular to the surface at that point; and the angles DHI and IHE, being the angles of incidence and reflection, will be equal. To the former of these, the angle HCF is equal, the lines AC and DH being parallel; and to the latter the angle CHF, as being vertical; wherefore the triangle CFH is isosceles, and consequently the sides CF and FH are equal: but supposing BH to vanish, FH is equal to FB; and therefore upon this supposition FC and FB are equal, that is, the focus of the reflected rays is the middle point between the centre of convexity and the surface. *Q. E. D.*

CASE 2. Of parallel rays falling upon a concave surface.

Plate CCCLIX.

DEM. Let AB, DH, (fig. 5.) be two parallel rays incident, the one perpendicularly, the other obliquely, on the concave surface BH, whose centre of concavity is C. Let BF and HF be the reflected rays meeting each other in F; this will be the middle point between B and C. For drawing through C the perpendicular CH, the angles DHC and FHC, being the angles of incidence and reflection, will be equal, to the former of which the angle HCF is equal, as alternate; and therefore the triangle CFH is isosceles. Wherefore CF and FH are equal: but if we suppose BH to vanish, FB and FH are also equal, and therefore CF is equal to FB; that is, the focal distance of the reflected rays is the middle point between the centre and the surface. *Q. E. D.*

Obs. It is here observable, that the farther the line DH, either in fig. 4. or 5. is taken from AB, the nearer the point F falls to the surface. For the farther the point H recedes from B, the larger the triangle CFH will become; and consequently, since it is always an isosceles one, and the base CH, being the radius, is everywhere of the same length, the equal legs CF and FH will lengthen; but CF cannot grow longer unless the point F approach towards the surface. And the farther H is removed from B, the faster F approaches to it.

This is the reason, that whenever parallel rays are considered as reflected from a spherical surface, the distance of the oblique one from the perpendicular one is taken so small with respect to the focal distance of that surface, that without any physical error it may be supposed to vanish.

186  
Reflected rays from a spherical surface never proceed from the same point.

From hence it follows, that if a number of parallel rays, as AB, CD, EG, &c. fall upon a convex surface, (as fig. 6.) and if BA, DK, the reflected rays of the incident ones AB, CD, proceed as from the point F, those of the incident ones CD, EG, viz. DK, GL, will proceed as from N, those of the incident ones EG, HI, as from O, &c. because the farther the incident ones CD, EG, &c. are from AB, the nearer to the surface are the points F, f, f, in the line BF, from which they proceed after reflection; so that properly the foci of the reflected rays BA, DK, GL, &c. are not in the line AB produced, but in a curve line passing through the points F, N, O, &c.

The same is applicable to the case of parallel rays reflected from a concave surface, as expressed by the pricked lines on the other half of the figure, where FQ, RS, TV, are the incident rays; QF, Sf, Vf, the reflected ones, intersecting each other in the points

X, Y, and F; so that the foci of those rays are not in the line FB, but in a curve passing through those points.

Had the surface BH in fig. 4. or 5. been formed by the revolution of a parabola about its axis having its focus in the point F, all the rays reflected from the convex surface would have proceeded as from the point F, and those reflected from the concave would have fallen upon it, however distant their incident ones AB, DH, might have been from each other. For in the parabola, all lines drawn parallel to the axis make angles with the tangents to the points where they cut the parabola (that is, with the surface of the parabola) equal to those which are made with the same tangents by lines drawn from thence to the focus; therefore, if the incident rays describe those parallel lines, the reflected ones will necessarily describe these other, and so will all proceed as from, or meet in, the same point.

PROP. III. Of the reflection of diverging and converging rays from a spherical surface.

“When rays fall upon any spherical surface, if they diverge, the distance of the focus of the reflected rays from the surface is to the distance of the radiant point from the same (or, if they converge, to that of the imaginary focus of the incident rays), as the distance of the focus of the reflected rays from the centre is to the distance of the radiant point (or imaginary focus of the incident rays) from the same.”

187  
Rays proceeding from one point and falling on a parabolic concave surface are all reflected from one point.

188  
Proportional distance of the focus of rays reflected from a spherical surface.

This proposition admits of ten cases.

CASE 1. Of diverging rays falling upon a convex surface.

DEM. Let RB, RD (fig. 7.) represent two diverging rays flowing from the point R as from a radiant, and falling the one perpendicularly, the other obliquely, on the convex surface BD, whose centre is C. Let DE be the reflected ray of the incident one RD, produce ED to F, and through R draw the line RH parallel to FE till it meets CD produced in H. Then will the angle RHD be equal to EDH the angle of reflection, as being alternate to it, and therefore equal also to RDH which is the angle of incidence; wherefore the triangle DRH is isosceles, and consequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar, (or, to express it in Euclid's way, the sides of the triangle RHC are cut proportionably, 2 Elem. 6.): and therefore FD is to RH, or its equal RD, as CF to CR; but BD vanishing, FD and RD differ not from FB and RB: wherefore FB is to RB also, as CF to CR; that is, the distance of the focus from the surface is to the distance of the radiant point from the same, as the distance of the focus from the centre is to the distance of the radiant from thence. *Q. E. D.*

CASE 2. Of converging rays falling upon a concave surface.

DEM. Let KD and CB be the converging incident rays having their imaginary focus in the point R, which was the radiant in the foregoing case. Then as RD was in that case reflected into DE, KD will in this be reflected into DF; for, since the angles of incidence in both cases are equal, as they are by being vertical, the angles of reflection will be so too; so that F will be the focus of the reflected rays: but it

was

**Laws of Reflection.** was there demonstrated, that  $FB$  is to  $RB$  as  $CF$  to  $CR$ ; that is, the distance of the focus from the surface is to the distance (in this Case) of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same. *Q. E. D.*

**CASE 3.** Of converging rays falling upon a convex surface, and tending to a point between the focus of parallel rays and the centre.

**DEM.** Let  $BD$  (fig. 8.) represent a convex surface whole centre is  $C$ , and whose focus of parallel rays is  $P$ ; and let  $AB, KD$ , be two converging rays incident upon it, and having their imaginary focus at  $R$ , a point between  $P$  and  $C$ . Now because  $KD$  tends to a point between the focus of parallel rays and the centre, the reflected ray  $DE$  will diverge from some point on the other side the centre, suppose  $F$ ; as explained above (p. 308.) under prop. 7. Through  $D$  draw the perpendicular  $CD$ , and produce it to  $H$ ; then will  $KDH$  and  $HDE$  be the angles of incidence and reflection, which being equal, their vertical ones  $RDC$  and  $CDF$  will be so too, and therefore the vertex of the triangle  $RDF$  is bisected by the line  $DC$ : wherefore (3 El. 6.)  $FD$  and  $DR$ , or  $BD$  vanishing,  $FB$  and  $BR$  are to reach other as  $FC$  to  $CR$ ; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident ones, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

**CASE 4.** Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the centre.

**DEM.** Let  $RB, RD$ , (fig. 8.) be the diverging rays incident upon the concave surface  $BD$ , having their radiant point in the point  $R$ , the imaginary focus of the incident rays in the foregoing case. Then as  $KD$  was in that case reflected into  $DE$ ,  $RD$  will now be reflected into  $DF$ . But it was there demonstrated, that  $FB$  and  $RB$  are to each other as  $CF$  to  $CR$ ; that is, the distance of the focus is to that of the radiant as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

The angles of incidence and reflection being equal, it is evident, that if, in any case, the reflected ray be made the incident one, the incident will become the reflected one; and therefore the four following cases may be considered respectively as the converse of the four foregoing; for in each of them the incident rays are supposed to coincide with the reflected ones in the other. Or they may be demonstrated independently of them as follows.

**CASE 5.** Of converging rays falling upon a convex surface, and tending to a point nearer the surface than the focus of parallel rays.

**DEM.** Let  $ED, RB$  (fig. 7.) be the converging rays incident upon the convex surface  $BD$  whose centre is  $C$ , and focus of parallel rays is  $P$ ; and let the imaginary focus of the incident rays be at  $F$ , a point between  $B$  and  $P$ ; and let  $DR$  be the reflected ray. From  $C$  and  $R$  draw the lines  $CH, RH$ , the one passing through  $D$ , the other parallel to  $FE$ . Then will the angle  $KMD$  be equal to  $HDE$  the angle of incidence, as alternate to it; and therefore

equal to  $HDR$ , the angle of reflection: wherefore the triangle  $HDR$  is isosceles, and consequently  $DR$  is equal to  $RH$ . Now the lines  $FD$  and  $RH$  being parallel, the triangles  $FDC$  and  $RHC$  are similar; and therefore  $RH$ , or  $RD$  is to  $FD$  as  $CR$  to  $CF$ : but  $BD$  vanishing,  $RD$  and  $FD$  coincide with  $RB$  and  $FB$ , wherefore  $RB$  is to  $FB$  as  $CR$  to  $CF$ ; that is, the distance of the focus from the surface is to the distance of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same. *Q. E. D.*

**CASE 6.** Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the surface.

**DEM.** Let  $FD$  and  $FB$  represent two diverging rays flowing from the point  $F$  as a radiant, which was the imaginary focus of the incident rays in the foregoing case. Then as  $ED$  was in that case reflected into  $DR$ ,  $FD$  will be reflected into  $DK$  (for the reason mentioned in Case 2.), so that the reflected ray will proceed as from the point  $R$ : but it was demonstrated in the case immediately foregoing, that  $RB$  is to  $FB$  as  $CR$  to  $CF$ ; that is, the distance of the focus from the surface is to that of the radiant from the same, as the distance of the former from the centre is to that of the latter from the same. *Q. E. D.*

**CASE 7.** Of converging rays falling upon a convex surface, and tending towards a point beyond the centre.

**DEM.** Let  $AB, ED$  (fig. 8.) be the incident rays tending to  $F$ , a point beyond the centre  $C$ , and let  $DK$  be the reflected ray of the incident one  $ED$ . Then because the incident ray  $ED$  tends to a point beyond the centre, the reflected ray  $DK$  will proceed as from one on the contrary side, suppose  $R$ ; as explained above under Prop. VII. Through  $D$  draw the perpendicular  $CD$ , and produce it to  $H$ . Then will  $EDH$  and  $HDK$  be the angles of incidence and reflection; which being equal, their vertical ones  $CDF$  and  $CDR$  will be so too: consequently the vertex of the triangle  $FDR$  is bisected by the line  $CD$ : wherefore,  $RD$  is to  $DF$ , or (3 Elem. 6.)  $BD$  vanishing,  $RB$  is to  $BF$  as  $RC$  to  $CF$ ; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident rays, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

**CASE 8.** Of diverging rays falling upon a concave surface, and proceeding from a point beyond the centre.

**DEM.** Let  $FB, FD$ , be the incident rays having their radiant in  $F$ , the imaginary focus of the incident rays in the foregoing case. Then as  $ED$  was in that case reflected into  $DK$ ,  $FD$  will now be reflected into  $DR$ ; so that  $R$  will be the focus of the reflected rays. But it was demonstrated in the foregoing case, that  $RB$  is to  $FB$  as  $RC$  to  $CF$ ; that is, the distance of the focus of the reflected rays from the surface is to the distance of the radiant from the same, as the distance of the focus of the reflected rays from the centre is to the distance of the radiant from thence. *Q. E. D.*

The two remaining cases may be considered as the converse of those under Prop. II. (p. 309, 310.), because the

Laws of Reflection. the incident rays in these are the reflected ones in them; or they may be demonstrated in the same manner with the foregoing, as follows.

CASE 9. Converging rays falling upon a convex surface, and tending to the focus of parallel rays, become parallel after reflection.

Plate  
CCCLIX.

DEM. Let ED, RB (fig. 7.) represent two converging rays incident on the convex surface BD, and tending towards F, which we will now suppose to be the focus of parallel rays; and let DR be the reflected ray, and C the centre of convexity of the reflecting surface. Through C draw the line CD, and produce it to H, drawing RH parallel to ED produced to F. Now it has been demonstrated (Case 5. where the incident rays are supposed to tend to the point F), that RB is to FB as RC to CF; but F in this Case being supposed to be the focus of parallel rays, it is the middle point between C and B (by Prop. II.), and therefore FB and FC are equal; and consequently the two other terms in the proportion, viz. RB and RC, must be so too; which can only be upon the supposition that R is at an infinite distance from B; that is, that the reflected rays BR and DR be parallel. Q. E. D.

CASE 10. Diverging rays falling upon a concave surface, and proceeding from the focus of parallel rays, become parallel after reflection.

DEM. Let RD, RB (fig. 8.), be two diverging rays incident upon the concave surface BD, as supposed in Case 4. where it was demonstrated that FB is to RB as CF to CR. But in the present case RB and CR are equal, because R is supposed to be the focus of parallel rays; therefore FB and FC are so too: which cannot be unless F be taken at an infinite distance from B; that is, unless the reflected rays BF and DF be parallel. Q. E. D.

OBS. It is here observable, that in the case of diverging rays falling upon a convex surface (see fig. 7.), the farther the point D is taken from B, the nearer the point F, the focus of the reflected rays, approaches to B, while the radiant R remains the same. For it is evident from the curvature of a circle, that the point D (fig. 9.) may be taken so far from B, that the reflected ray DE shall proceed as from F, G, H, or even from B, or from any point between B and R; and the farther it is taken from B, the faster the point from which it proceeds approaches towards R: as will easily appear if we draw several incident rays with their respective reflected ones, in such manner that the angles of reflection may be all equal to their respective angles of incidence, as is done in the figure. The like is applicable to any of the other cases of diverging or converging rays incident upon a spherical surface. This is the reason, that when rays are considered as reflected from a spherical surface, the distance of the oblique rays from the perpendicular one is taken so small, that it may be supposed to vanish.

From hence it follows, that if a number of diverging rays are incident upon the convex surface BD at the several points B, D, D, &c. they shall not proceed after reflection as from any point in the line RB produced, but as from a curve line passing through the several points F, f, f, &c. The same is applicable in all the other cases.

Laws of Reflection. Had the curvature BD (fig. 7.) been hyperbolic, having its foci in R and F; then R being the radiant (or the imaginary focus of incident rays), F would have been the focus of the reflected ones, and vice versa, however distant the points B and D might be taken from each other. In like manner, had the curve BD (fig. 8.) been elliptical, having its foci in F and R, the one of these being made the radiant (or imaginary focus of incident rays), the other would have been the focus of reflected ones, and vice versa. For both in the hyperbola and ellipsis, lines drawn from each of their foci through any point make equal angles with the tangent to that point. Therefore, if the incident rays proceed to or from one of their foci, the reflected ones will all proceed as from or to the other. So that, in order that diverging or converging rays may be accurately reflected to or from a point, the reflecting surface must be formed by the revolution of an *hyperbola* about its longer axis, when the incident rays are such, that their radiant or imaginary focus of incident rays shall fall on one side of the surface, and the focus of the reflected ones on the other: when they are both to fall on the same side, it must be formed by the revolution of an *ellipsis* about its longer axis. However, upon account of the great facility with which spherical surfaces are formed in comparison of that with which surfaces formed by the revolution of any of the conic sections about their axes are made, the latter are very rarely used. Add to this another inconvenience, viz. that the foci of these curves being mathematical points, it is but one point of the surface of an object that can be placed in any of them at a time; so that it is only in theory that surfaces formed by the revolution of these curves about their axes render reflection perfect.

Now, because the focal distance of rays reflected from a spherical surface cannot be found by the analogy laid down in the third proposition, without making use of the quantity sought; we shall here give an instance whereby the method of doing it in all others will readily appear.

PROB. Let it be required to find the focal distance of diverging rays incident upon a convex surface, whose radius of convexity is 5 parts, and the distance of the radiant from the surface is 20.

SOL. Call the focal distance sought  $x$ ; then will the distance of the focus from the centre be  $5 - x$ , and that of the radiant from the same 25. therefore by prop. 3. we have the following proportion, viz.  $x : 20 :: 5 - x : 25$ ; and multiplying extremes together and means together, we have  $25x = 100 - 20x$ , which, after due reduction, gives  $x = \frac{100}{45}$ .

If in any case it should happen that the value of  $x$  should be a negative quantity, the focal point must then be taken on the contrary side of the surface to that on which it was supposed that it would fall in stating the problem.

If letters instead of figures had been made use of in the foregoing solution, a general theorem might have been raised, to have determined the focal distance of reflected rays in all cases whatever. See this done in Suppl. to *Gregory's Optics*, 2d edit. p. 112.

Because it was, in the preceding section, observed; that different incident rays though tending to or from one point, would after refraction proceed to or from different

The Ap-  
pearance  
of Bodies  
seen by Re-  
flection.

different points, a method was there inserted of determining the distinct point which each separate ray entering a spherical surface converges to, or diverges from, after refraction: the same has been observed here with regard to rays reflected from a spherical surface (see Obs. in Case 2. and Case 10.) But the method of determining the distinct point to or from which any given incident ray proceeds after reflection, is much more simple. It is only necessary to draw the reflected ray such, that the angle of reflection may be equal to the angle of incidence, which will determine the point it proceeds to or from in any case whatever.

§ 3. *Of the Appearance of Bodies seen by Light reflected from plane and spherical Surfaces.*

WHATEVER has been said concerning the appearance of bodies seen by refracted light through lenses, respects also the appearance of bodies seen by reflection. But besides these, there is one thing peculiar to images by reflection, viz. that each point in the representation of an object made by reflection appears situated somewhere in an infinite right line that passes through its correspondent point in the object, and is perpendicular to the reflecting surface.

The truth of this appears sufficiently from the propositions formerly laid down: in each of which, rays flowing from any radiant point, are shown to proceed after reflection to or from some point in a line that passes through the said radiant, and is perpendicular to the reflecting surface. For instance (fig. 1.), rays flowing from Y are collected in X, a point in the perpendicular CD, which, being produced, passes through Y: again (fig. 2.), rays flowing from G, proceed, after reflection, as from N, a point in the perpendicular CD, which, being produced, passes through G; and so of the rest.

This observation, however, except where an object is seen by reflection from a plain surface, relates only to those cases where the representation is made by means of such rays as fall upon the reflecting surface with a very small degree of obliquity; because such as fall at a considerable distance from the perpendicular, proceed not after reflection as from any point in that perpendicular, but as from other points situated in a certain curve, as hath already been explained; upon which account these rays are neglected, as making a confused and deformed representation. And therefore it is to be remembered, that however the situation of the eye with respect to the object and reflecting surface may be represented in the following figures, it is to be supposed as situated in such a manner with respect to the object, that rays flowing from thence and entering it after reflection, may be such only as fall with a very small degree of obliquity upon the surface; that is, the eye must be supposed to be placed almost directly behind the object, or between it and the reflecting surface. The reason why it is not always so placed, is only to avoid confusion in the figures.

I. When an object is seen by reflection from a plane surface, the image of it appears at the same distance behind the surface that the object is placed before it, of the same magnitude therewith, and directly opposite to it.

VOL. XIII.

To explain this, let AB (fig. 10.) represent an object seen by reflection from the plain surface SV; and let the rays AF, AG, be so inclined to the surface, that they shall enter an eye at H after reflection; and let AE be perpendicular to the surface: then by the observation just mentioned, the point A will appear in some part of the line AE produced, suppose I; that is, the oblique rays AF and AG will proceed after reflection as from that point; and further, because the reflected rays FH, GK, will have the same degree of inclination to one another that their incident ones have, that point must necessarily be at the same distance from the surface that the point A is; the representation therefore of the point A will be at the same distance behind the surface that the point itself is before it, and directly opposite to it: consequently, since the like may be shewn of the point B, or of any other, the whole image IM will appear at the same distance behind the surface that the object is before it, and directly opposite to it; and because the lines AI, BM, which are perpendicular to the plain surface, are for that reason parallel to each other, it will also be of the same magnitude therewith.

II. When an object is seen by reflection from a convex surface, its image appears nearer to the surface, and less than the object.

Let AB (fig. 12.) represent the object, SV a reflecting surface whose centre of convexity is C: and let the rays AF, AG, be so inclined to the surface, that after reflection therefrom, they shall enter the eye at H: and let AE be perpendicular to the surface; then will the oblique rays AF, AG, proceed after reflection as from some point in the line AE produced, suppose from I; which point, because the reflected rays will diverge more than the incident ones, must be nearer to the surface than to the point A. And since the same is also true of the rays which flow from B, or any other point, the representation IM will be nearer to the surface than the object; and because it is terminated by the perpendiculars AE and BF, which incline to each other, as concurring at the centre, it will also appear less.

III. When an object is seen by reflection from a concave surface, the representation of it is various, both with regard to its magnitude and situation, according as the distance of the object from the reflecting surface is greater or less.

1. When the object is nearer to the surface than its focus of parallel rays, the image falls on the opposite side of the surface, is more distant from it, and larger than the object.

Thus, let AB (fig. 13.) be the object, SV the reflecting surface, F the focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE, CR, which will be perpendicular to the surface; and let the rays AR, AG, be incident upon such points of it that they shall be reflected into an eye at H. Now, because the radiant points A and B are nearer the surface than F the focus of parallel rays, the reflected rays will diverge, and will therefore proceed as from some points on the opposite side of the surface; which points, by the observation laid down at the beginning of this section, will be in the perpendiculars AE, BR, produced, suppose in I and M: but they will diverge in a less

R r

degree

ent Sur-  
faces.

degree than their incident ones (see the proposition just referred to); and therefore the said points will be farther from the surface than the points A and B. The image therefore will be on the opposite side of the surface with respect to the object: it will be more distant than it; and consequently being terminated by the perpendicular CI and CM, it will also be larger.

2. When the object is placed in the focus of parallel rays, the reflected rays enter the eye parallel; in which case the image ought to appear at an infinite distance behind the reflecting surface: but the representation of it, for the like reasons that were given in the foregoing case, being large and distinct, we judge it not much farther from the surface than the image.

3. When the object is placed between the focus of parallel rays and the centre, the image falls on the opposite side of the centre, is larger than the object, and in an inverted position.

Thus let AB (fig. 14.) represent the object, SV the reflecting surface, F its focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE and CN, which will be perpendicular to the surface; and let AR, AG, be a pencil of rays flowing from A. These rays proceeding from a point beyond the focus of parallel rays, will after reflection converge towards some point on the opposite side of the centre, which will fall upon the perpendicular EC produced, but at a greater distance from C than the radiant A from which they diverged. For the same reason, rays flowing from B will converge to a point in the perpendicular NC produced, which shall be farther from C than the point B; from whence it is evident, that the image IM is larger than the object AB, that it falls on the contrary side of the centre, and that their positions are inverted with respect to each other.

4. If the object be placed beyond the centre of convexity, the image is then formed between the centre and the focus of parallel rays, is less than the object, and its position is inverted.

This proposition is the converse of the foregoing: for as in that case rays proceeding from A were reflected to I, and from B to M; so rays flowing from I and M will be reflected to A and B; if therefore an object be supposed to be situated beyond the centre in IM, the image of it will be formed in AB between that and the focus of parallel rays, will be less than the object, and inverted.

5. If the middle of the object be placed in the centre of convexity of the reflecting surface, the object and its image will be coincident; but the image will be inverted with respect to the object.

That the place of the image and the object should be the same in this case needs little explication; for the middle of the object being in the centre, rays flowing from thence will fall perpendicularly upon the surface, and therefore necessarily return thither again; so that the middle of the image will be coincident with the middle of the object. But that the image should be inverted is perhaps not so clear. To explain this, let AB (fig. 15.) be the object, having its middle point C in the centre of the reflecting sur-

face SV; through the centre and the point R draw the line CR, which will be perpendicular to the reflecting surface; join the points AR and BR, and let AR represent a ray flowing from A; this will be reflected into RB: for C being the middle point between A and B, the angles ARC and CRB are equal; and a ray from B will likewise be reflected to A; and therefore the position of the image will be inverted with respect to that of the object.

In this proposition it is to be supposed, that the object AB is so situated with respect to the reflecting surface, that the angle ACR may be right; for otherwise the angles ARC and BRC will not be equal, and part of the image will therefore fall upon the object and part off.

6. If in any of the three last cases, in each of which the image is formed on the same side of the reflecting surface with the object, the eye be situated farther from the surface than the place where the image falls, the rays of each pencil, crossing each other in the several points of the image, will enter the eye as from a real object situated there; so that the image will appear pendulous in the air between the eye and the reflecting surface, and in the position wherein it is formed, viz. inverted with respect to the object, in the same manner that an image formed by refracted light appears to an eye placed beyond it; which was fully explained under Prop. IV. (p. 304.), and therefore needs not be repeated.

But as what relates to the appearance of the object when the eye is placed nearer to the surface than the image, was not there fully inquired into, that point shall now be more strictly examined under the following case, which equally relates to refracted and reflected light.

7. If the eye be situated between the reflecting surface and the place of the image, the object is then seen beyond the surface; and the farther the eye recedes from the surface towards the place of the image, the more confused, larger, and nearer, the object appears.

To explain this, let AB (fig. 16.) represent the object; IM its image, one of whose points M is formed by the concurrence of the reflected rays DM, EM, &c. which before reflection came from B; the other, I, by the concurrence of DI, EI, &c. which came from A: and let  $ab$  be the pupil of an eye, situated between the surface DP and the image. This pupil will admit the rays H  $a$ , K  $b$ ; which, because they are tending towards I, are such as came from A, and therefore the point A will appear diffused over the space RS. In like manner the pupil will also receive into it the reflected rays K  $a$  and L  $b$ , which, because they are tending towards M, by supposition came from C; and therefore the point A will be seen spread as it were over the space TV, and the object will seem to fill the space RV; but the representation of it will be confused, because the intermediate points of the object being equally enlarged in appearance, there will not be room for them between the points S and T, but they will coincide in part one with another: for instance, the appearance of that point in the object, whose representation falls upon  $c$  in the image, will fill the space  $mn$ ; and so of the rest. Now, if the same pupil

ent Sur-  
faces.

Plate

ent Surfa-  
ces.

pupil be removed into the situation  $e$ , the reflected rays  $Ee$  and  $Gf$  will then enter the eye, and therefore one extremity of the object will appear to cover the space  $XY$ ; and because the rays  $Of$  and  $Le$  will also enter it in their progress towards  $M$ , the point  $B$ , from whence they came, will appear to cover  $ZV$ ; the object therefore will appear larger and more confused than before. And when the eye recedes quite to the image, it sees but one single point of the object, and that appears diffused all over the reflecting surface: for instance, if the eye recedes to the point  $M$ , then rays flowing from the point  $B$  enter it upon whatever part of the surface they fall; and so for the rest. The object also appears nearer to the surface the farther the eye recedes from it towards the place of the image; probably because, as the appearance of the object becomes more and more confused, its place is not so easily distinguished from that of the reflecting surface itself, till at last when it is quite confused (as it is when the eye is arrived at  $M$ ) they both appear as one, the surface assuming the colour of the object.

193  
The ap-  
parent  
magnitude  
of an object  
seen by re-  
flection  
from a con-  
cave sur-  
face.

As to the precise apparent magnitude of an object seen after this manner, it is such that the angle it appears under shall be equal to that which the image of the same object would appear under were we to suppose it seen from the same place: that is, the apparent object (for such we must call it to distinguish it from the image of the same object) and the image subtend equal angles at the eye.

DEM. Here we must suppose the pupil of the eye to be a point only, because the magnitude of that causes small alteration in the apparent magnitude of the object; as we shall see by and by. Let then the point  $a$  represent the pupil, then will the extreme rays that can enter it be  $Ha$  and  $Ka$ ; the object therefore will appear under the angle  $HaK$ , which is equal to its vertical one  $MaI$ , under which the image  $IM$  would appear were it to be seen from  $a$ . Again, if the eye be placed in  $f$ , the object appears under the angle  $GfO$  equal to  $IfM$ , which the image subtends at the same place, and therefore the apparent object and image of it subtend equal angles at the eye.

Q. E. D.

Now if we suppose the pupil to have any sensible magnitude, such, suppose, that its diameter may be  $ab$ ; then the object seen by the eye in that situation will appear under the angle  $HAL$ , which is larger than the angle  $HaK$ , under which it appeared before; because the angle at  $X$  is nearer than the angle at  $a$ , to the line  $IM$ , which is a subtense common to them both.

From this proposition it follows, that, were the eye close to the surface at  $K$ , the real and apparent object would be seen under equal angles (for the real object appears from that place under the same angle that the image does, as will be shown at the end of this section): therefore, when the eye is nearer to the image than that point, the image will subtend a larger angle at it than the object does; and consequently, since the image and apparent object subtend equal angles at the eye, the apparent object must necessarily be seen under a larger angle than the object itself, wherever the eye be placed, between the surface and the image.

As each point in the representation of an object made by reflection is situated somewhere in a right line that passes through its correspondent point in the object, and is perpendicular to the reflecting surface, as was shown in the beginning of this section; we may from hence deduce a most easy and expeditious method of determining both the magnitude and situation of the image in all cases whatever. Thus,

Through the extremities of the object  $AB$  and the centre  $C$  (fig. 17, 18, or 19.) draw the lines  $AC$   $BC$ , and produce them as the case requires; these lines will be perpendicular to the reflecting surface, and therefore the extremities of the image will fall upon them. Through  $F$  the middle point of the object and the centre, draw the line  $FC$ , and produce it till it passes through the reflecting surface; this will also be perpendicular to the surface. Through  $G$ , the point where this line cuts the surface, draw the lines  $AG$  and  $BG$ , and produce them this way or that, till they cross the former perpendiculars; and where they cross, there  $I$  and  $M$  the extremities of the image will fall. For supposing  $AG$  to be a ray proceeding from the point  $A$  and falling upon  $G$ , it will be reflected to  $B$ ; because  $FA$  is equal to  $FB$ , and  $FG$  is perpendicular to the reflecting surface; and therefore the representation of the point  $A$  will be in  $BG$  produced as well as in  $AC$ ; consequently it will fall on the point  $I$ , where they cross each other. Likewise the ray  $BG$  will for the same reason be reflected to  $A$ ; and therefore the representation of the point  $B$  will be in  $AG$  produced, as well as in some part of  $BC$ , that is in  $M$  where they cross. From whence the proposition is clear.

Plate  
CCCLIX.

If it happens that the lines will not cross which way soever they are produced, as in (fig. 20.), then is the object in the focus of parallel rays of that surface, and has no image formed in any place whatever. For in this case the rays  $AH$ ,  $AG$ , flowing from the point  $A$ , become parallel after reflection in the lines  $HC$ ,  $GB$ , and therefore do not flow as to or from any point: in like manner, rays flowing from  $B$  are reflected into the parallel lines  $KB$  and  $GA$ ; so that no representation can be formed by such reflection.

From hence we learn another circumstance relating to the magnitude of the image made by reflection; viz. that it subtends the same angle at the vertex of the reflecting surface that the object does. This appears by inspection of the 17th, 18th, or 19th figure; in each of which the angle  $IGM$ , which the image subtends at  $G$  the vertex of the reflecting surface, is equal to the angle  $AGB$ , which the object subtends at the same place; for in the two first of those figures they are vertical, in the third they are the same. And,

Farther, the angle  $ICM$ , which the image subtends at the centre, is also equal to the angle  $ACB$  which the object subtends at the same place; for in the two first figures they are the same, in the last they are vertical to each other.

From whence it is evident, that the object and its image are to each other in diameter, either as their respective distances from the vertex of the reflecting surface, or as their distances from the centre of the same.

Light differently refrangible.

Plate  
CCCLIX.

IV. As objects are multiplied by being seen through transparent media, whose surfaces are properly disposed, so they may also by reflecting surfaces. Thus,

1. If two reflecting surfaces be disposed at right angles, as the surfaces AB, BC, (fig. 21.), an object at D may be seen by an eye at E, after one reflection at F, in the line EF produced; after two reflections, the first at G, the second at H, in the line EH produced; and also after one reflection made at A, in the line EA produced.

2. If the surfaces be parallel, as AB, CD, (fig. 22.), and the object be placed at E and the eye at F, the object will appear multiplied an infinite number of times: thus, it may be seen in the line FG produced, after one reflection at G; in the line FH produced after two reflections, the first at I, the second at H; and also in FP produced, after several successive reflections of the ray EL, at the points L, M, N, O, and P: and so on *in infinitum*. But the greater the number of reflections are, the weaker their representation will be.

#### SECT. IV. *Of the different Refrangibility of Light.*

As this property of light solves a great number of the phenomena which could not be understood by former opticians, we shall give an account of it in the words of Sir Isaac Newton, who first discovered it; especially as his account is much more full, clear, and perspicuous, than those of succeeding writers.

Plate  
CCCLIX.

"In a very dark chamber, at a round hole F (fig. 1.), about one third of an inch broad made in the shutter of a window, I placed a glass prism ABC, whereby the beam of the sun's light SF, which came in at that hole, might be refracted upwards, toward the opposite wall of the chamber, and there form a coloured image of the sun, represented at TP. The axis of the prism (that is the line passing through the middle of the prism, from one end of it to the other end, parallel to the edge of the refracting angle) was in this and the following experiments perpendicular to the incident rays. About this axis I turned the prism slowly, and saw the refracted light on the wall, or coloured image of the sun, first to descend, and then to ascend. Between the descent and ascent, when the image seemed stationary, I stopped the prism and fixed it in that posture.

"Then I let the refracted light fall perpendicularly upon a sheet of white paper, MN, placed at the opposite wall of the chamber, and observed the figure and dimensions of the solar image, PT, formed on the paper by that light. This image was oblong, and not oval, but terminated by two rectilinear and parallel sides and two semicircular ends. On its sides it was bounded pretty distinctly; but on its ends very confusedly and indistinctly, the light there decaying and vanishing by degrees. At the distance of  $18\frac{1}{2}$  feet from the prism the breadth of the image was about  $2\frac{1}{4}$  inches, but its length was about  $10\frac{1}{4}$  inches, and the length of its rectilinear sides about eight inches, and ACB, the refracting angle of the prism, whereby so great a length was made, was  $6\frac{1}{4}$  degrees. With a less angle the length of the image was less, the breadth remaining the same. It is farther to be observed, that the rays went on in straight lines from the prism to the image,

and therefore at their going out of the prism had all that inclination to one another from which the length of the image proceeded. This image PT was coloured, and the more eminent colours lay in this order from the bottom at T to the top at P; red, orange, yellow, green, blue, indigo, violet; together with all their intermediate degrees in a continual succession perpetually varying."

Our author concludes from this experiment, and many more to be mentioned hereafter, "that the light of the sun consists of a mixture of several sorts of coloured rays, some of which at equal incidences are more refracted than others, and therefore are called *more refrangible*. The red at T, being nearest to the place Y, where the rays of the sun would go directly if the prism was taken away, is the least refracted of all the rays; and the orange, yellow, green, blue, indigo, and violet, are continually more and more refracted, as they are more and more diverted from the course of the direct light. For by mathematical reasoning he has proved, that when the prism is fixed in the posture abovementioned, so that the place of the image shall be the lowest possible, or at the limit between its descent and ascent, the figure of the image ought then to be round like the spot at Y, if all the rays that tended to it were equally refracted. Therefore, seeing by experience it is found that this image is not round, but about five times longer than broad, it follows that all the rays are not equally refracted. And this conclusion is farther confirmed by the following experiments.

"In the sun beam SF (fig. 2.), which was propagated into the room thro' the hole in the window-shutter EG, at the distance of some feet from the hole, I held the prism ABC in such a posture, that its axis might be perpendicular to that beam: then I looked through the prism upon the hole F, and turning the prism to and fro about its axis to make the image *p t* of the hole ascend and descend, when between its two contrary motions it seemed stationary, I stopped the prism; in this situation of the prism, viewing through it the said hole F, I observed the length of its refracted image *p t* to be many times greater than its breadth; and that the most refracted part thereof appeared violet at *p*; the least refracted red, at *t*; and the middle parts indigo, blue, green, yellow, and orange, in order. The same thing happened when I removed the prism out of the sun's light, and looked through it upon the hole shining by the light of the clouds beyond it. And yet if the refraction of all the rays were equal according to one certain proportion of the sines of incidence and refraction, as is vulgarly supposed the refracted image ought to have appeared round, by the mathematical demonstration abovementioned. So then by these two experiments it appears, that in equal incidences there is a considerable inequality of refractions."

For the discovery of this fundamental property of light, which has opened the whole mystery of colours, we see our author was not only beholden to the experiments themselves, which many others had made before him, but also to his skill in geometry; which was absolutely necessary to determine what the figure of the refracted image ought to be upon the old principle of an equal refraction of all the rays; but having

ferently  
refrang-  
ible.

Plate  
CCCLX.

ving thus made the discovery, he contrived the following experiment to prove it at sight.

"In the middle of two thin boards, *DE de*, (fig. 3.), I make a round hole in each, at *G*, and *g*, a third part of an inch in diameter; and in the window shut a much larger hole being made, at *F*, to let into my darkened chamber a large beam of the sun's light, I placed a prism, *ABC*, behind the shut in that beam, to refract it towards the opposite wall; and close behind this prism I fixed one of the boards *DE*, in such a manner that the middle of the refracted light might pass through the hole made in it at *G*, and the rest be intercepted by the board. Then at the distance of about 12 feet from the first board, I fixed the other board, *de*, in such manner that the middle of the refracted light, which came through the hole in the first board, and fell upon the opposite wall, might pass through the hole *g* in this other board *de*, and the rest being intercepted by the board, might paint upon it the coloured spectrum of the sun. And close behind this board I fixed another prism *abc*, to refract the light which came through the hole *g*. Then I returned speedily to the first prism *ABC*, and by turning it slowly to and fro about its axis, I caused the image which fell upon the second board *de*, to move up and down upon that board, that all its parts might pass successively through the hole in that board, and fall upon the prism behind it. And in the mean time I noted the places, *M*, *N*, on the opposite wall, to which that light after its refraction in the second prism did pass; and by the difference of the places at *M* and *N*, I found that the light, which being most refracted in the first prism *ABC*, did go to the blue end of the image, was again more refracted by the second prism *abc*, than the light which went to the red end of that image. For when the lower part of the light which fell upon the second board *de*, was cast through the hole *g*, it went to a lower place *M* on the wall; and when the higher part of that light was cast through the same hole *g*, it went to a higher place *N* on the wall; and when any intermediate part of the light was cast through that hole, it went to some place in the wall between *M* and *N*. The unchanged position of the holes in the boards made the incidence of the rays upon the second prism to be the same in all cases. And yet in that common incidence some of the rays were more refracted and others less; and those were more refracted in this prism, which by a greater refraction in the first prism were more turned out of their way; and therefore, for their constancy of being more refracted, are deservedly called *more refrangible*."

195  
Reflected  
light diffe-  
rently re-  
frangible.

Our author shows also, by experiments made with convex glasses, that lights (reflected from natural bodies) which differ in colour, differ also in degrees of refrangibility; and that they differ in the same manner as the rays of the sun do.

"The sun's light consists of rays differing in reflexivity, and those rays are more reflexible than others which are more refrangible. A prism, *ABC* (fig. 4), whose two angles, at its base *BC*, were equal to one another and half right ones, and the third at *A* a right one, I placed in a beam *FM* of the sun's light, let into a dark chamber through a hole *F* one third part of an inch broad. And turning the prism slowly about its axis until the light which went through one of its

angles *ACB*, and was refracted by it to *G* and *H*, began to be reflected into the line *MN* by its base *BC*, at which till then it went out of the glass; I observed that those rays, as *MH*, which had suffered the greatest refraction, were sooner reflected than the rest. To make it evident that the rays which vanished at *H* were reflected into the beam *MN*, I made this beam pass through another prism *VXY*, and being refracted by it to fall afterwards upon a sheet of white paper *pt* placed at some distance behind it, and there by that refraction to paint the usual colours at *pt*. Then causing the first prism to be turned about its axis according to the order of the letters *ABC*, I observed that when those rays *MH*, which in this prism had suffered the greatest refraction, and appeared blue and violet, began to be totally reflected, the blue and violet light on the paper which was most refracted in the second prism received a sensible increase at *p*, above that of the red and yellow at *t*: and afterwards, when the rest of the light, which was green, yellow, and red, began to be totally reflected and vanished at *G*, the light of those colours at *t*, on the paper *pt*, received as great an increase as the violet and blue had received before. Which puts it past dispute, that those rays became first of all totally reflected at the base *BC*, which before at equal incidences with the rest upon the base *BC* had suffered the greatest refraction. I do not here take notice of any refractions made in the sides *AC*, *AB*, of the first prism, because the light enters almost perpendicularly at the first side, and goes out almost perpendicularly at the second; and therefore suffers none, or so little, that the angles of incidence at the base *BC* are not sensibly altered by it; especially if the angles of the prism at the base *BC* be each about 40 degrees. For the rays *FM* begin to be totally reflected when the angle *CMF* is about 50 degrees, and therefore they will then make a right angle of 90 degrees with *AC*.

Light dif-  
ferently  
refrang-  
ible.

"It appears also from experiments, that the beam of light *MN*, reflected by the base of the prism, being augmented first by the more refrangible rays and afterwards by the less refrangible, is composed of rays differently refrangible.

"The light whose rays are all alike refrangible, I call *simple*, *homogeneous*, and *similar*; and that whose rays are some more refrangible than others, I call *compound*, *heterogeneous*, and *dissimilar*. The former light I call *homogeneous*, not because I would affirm it so in all respects; but because the rays which agree in refrangibility agree at least in all their other properties which I consider in the following discourse.

"The colours of homogeneous lights I call *primary*, *homogeneous*, and *simple*; and those of heterogeneous lights, *heterogeneous* and *compound*. For these are always compounded of homogeneous lights, as will appear in the following discourse.

196,  
Colours  
simple or  
compound,

"The homogeneous light and rays which appear red, or rather make objects appear so, I call *rubrific* or *red-making*; those which make objects appear yellow, green, blue, and violet, I call *yellow-making*, *green-making*, *blue-making*, *violet making*; and so of the rest. And if at any time I speak of light and rays as coloured or endowed with colours, I would be understood to speak not philosophically and properly, but grossly, and according to such conceptions as vulgar people

Lightdifferently refrangible.

people in seeing all these experiments would be apt to frame. For the rays, to speak properly, are not coloured. In them there is nothing else than a certain power and disposition to stir up a sensation of this or that colour. For as sound, in a bell or musical string or other sounding body, is nothing but a trembling motion, and in the air nothing but that motion propagated from the object, and in the sensorium it is a sense of that motion under the form of sound; so colours in the object are nothing but a disposition to reflect this or that sort of rays more copiously than the rest: in rays they are nothing but their dispositions to propagate this or that motion into the sensorium; and in the sensorium they are sensations of those motions under the forms of colours. See CHROMATICS.

197  
Why the image of the sun, by heterogeneous rays passing through a prism, is oblong.  
Plate  
CCCLIX.

"By the mathematical proposition abovementioned, it is certain that the rays which are equally refrangible do fall upon a circle answering to the sun's apparent disk, which will also be proved by experiment by and by. Now let AG (fig. 5.) represent the circle which all the most refrangible rays, propagated from the whole disk of the sun, would illuminate and paint upon the opposite wall if they were alone; EL the circle, which all the least refrangible rays would in like manner illuminate if they were alone; BH, CI, DK, the circles which so many intermediate sorts would paint upon the wall, if they were singly propagated from the sun in successive order, the rest being intercepted; and conceive that there are other circles without number, which innumerable other intermediate sorts of rays would successively paint upon the wall, if the sun should successively emit every sort apart. And seeing the sun emits all these sorts at once, they must all together illuminate and paint innumerable equal circles; of all which, being according to their degrees of refrangibility placed in order in a continual series, that oblong spectrum PT is composed, which was described in the first experiment.

"Now if these circles, whilst their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of the heterogeneous rays, would be proportionably diminished. Let the circles AG, BH, CI, &c. remain as before; and let *ag*, *bh*, *ci*, &c. be so many less circles lying in a like continual series, between two parallel right lines *ae* and *gl*, with the same distances between their centres, and illuminated with the same sorts of rays: that is, the circle *ag* with the same sort by which the corresponding circle AG was illuminated; and the rest of the circles *bh*, *ci*, *dk*, *el* respectively with the same sorts of rays by which the corresponding circles BH, CI, DK, EL, were illuminated. In the figure PT, composed of the great circles, three of those, AG, BH, CI, are so expanded into each other, that three sorts of rays, by which those circles are illuminated, together with innumerable other sorts of intermediate rays, are mixed at QR in the middle of the circle BH. And the like mixture happens throughout almost the whole length of the figure PT. But in the figure *pt*, composed of the less circles the three less circles *ag*, *bh*, *ci*, which answer to those three greater, do not extend into one another; nor are there anywhere mingled so much as any two of the three sorts of rays by which those circles are illuminated, and which in the figure PT are all of them in

termingled at QR. So then, if we would diminish the mixture of the rays, we are to diminish the diameters of the circles. Now these would be diminished if the sun's diameter, to which they answer, could be made less than it is, or (which comes to the same purpose) if without doors, at a great distance from the prism towards the sun, some opaque body were placed with a round hole in the middle of it to intercept all the sun's light, except so much as coming from the middle of his body could pass through that hole to the prism. For so the circles AG, BH, and the rest, would not any longer answer to the whole disk of the sun, but only to that part of it which could be seen from the prism through that hole; that is, to the apparent magnitude of that hole viewed from the prism. But that these circles may answer more distinctly to that hole, a lens is to be placed by the prism to cast the image of the hole (that is, every one of the circles AG, BH, &c.) distinctly upon the paper at PT; after such a manner, as by a lens placed at a window the pictures of objects abroad are cast distinctly upon a paper within the room. If this be done, it will not be necessary to place that hole very far off, no not beyond the window. And therefore, instead of that hole, I used the hole in the window-shut as follows.

"In the sun's light let into my darkened chamber through a small round hole in my window-shut, at about 10 or 12 feet from the window, I placed a lens MN (fig. 6.), by which the image of the hole F might be distinctly cast upon a sheet of white paper placed at I. Then immediately after the lens I placed a prism ABC, by which the trajected light might be refracted either upwards or sideways, and thereby the round image which the lens alone did cast upon the paper at I, might be drawn out into a long one with parallel sides, as represented at *pt*. This oblong image I let fall upon another paper at about the same distance from the prism as the image at I, moving the paper either towards the prism or from it, until I found the just distance where the rectilinear sides of the image *pt* become most distinct. For in this case the circular images of the hole, which compose that image, after the manner that the circles *ag*, *bh*, *ci*, &c. do the figure *pt*, were terminated most distinctly, and therefore extended into one another the least that they could, and by consequence the mixture of the heterogeneous rays was now the least of all. The circles *ag*, *bh*, *ci*, &c. which compose the image *pt*, are each equal to the circle at I; and therefore, by diminishing the hole F, or by removing the lens farther from it, may be diminished at pleasure, whilst their centres keep the same distances from each other. Thus, by diminishing the breadth of the image *pt*, the circles of heterogeneous rays that compose it may be separated from each other as much as you please. Yet instead of the circular hole F, it is better to substitute an oblong hole shaped like a parallelogram, with its length parallel to the length of the prism. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image *pt* will be as simple as before, or simpler: and the image being much broader, is therefore fitter to have experiments tried in its light than before.

"Homogeneous light is refracted regularly without any dilatation, splitting, or shattering of the rays; and the

Lightdifferently refrangible.

Light differently refrangible.

198 The image of the sun, by simple and homogeneous light; circular.

the confused vision of objects seen through refracting bodies by heterogeneous light, arises from the different refrangibility of several sorts of rays. This will appear by the experiments which will follow. In the middle of a black paper I made a round hole about a fifth or a sixth part of an inch in diameter. Upon this paper I caused the spectrum of homogeneous light, described in the former article, so to fall that some part of the light might pass through the hole in the paper. This transmitted part of the light I refracted with a prism placed behind the paper; and letting this refracted light fall perpendicularly upon a white paper, two or three feet distant from the prism, I found that the spectrum formed on the paper by this light was not oblong, as when it is made in the first experiment, by refracting the sun's compound light, but was, so far as I could judge by my eye, perfectly circular, the length being nowhere greater than the breadth; which shows that this light is refracted regularly without any dilatation of the rays, and is an ocular demonstration of the mathematical proposition mentioned above.

"In the homogeneous light I placed a paper circle of a quarter of an inch in diameter; and in the sun's unrefracted, heterogeneous, white light, I placed another paper circle of the same bigness; and going from these papers to the distance of some feet, I viewed both circles through a prism. The circle illuminated by the sun's heterogeneous light appeared very oblong, as in the second experiment, the length being many times greater than the breadth. But the other circle illuminated with homogeneous light appeared circular, and distinctly defined, as when it is viewed by the naked eye; which proves the whole proposition mentioned in the beginning of this article.

199 Vision more distinct in homogeneous than in heterogeneous light.

"In the homogeneous light I placed flies and such like minute objects, and viewing them through a prism I saw their parts as distinctly defined as if I had viewed them with the naked eye. The same objects placed in the sun's unrefracted heterogeneous light, which was white, I viewed also through a prism, and saw them most confusedly defined, so that I could not distinguish their smaller parts from one another. I placed also the letters of a small print one while in the homogeneous light and then in the heterogeneous; and viewing them through a prism, they appeared in the latter case so confused and indistinct that I could not read them; but in the former, they appeared so distinct that I could read readily, and thought I saw them as distinct as when I viewed them with my naked eye: in both cases, I viewed the same objects through the same prism, at the same distance from me, and in the same situation. There was no difference but in the lights by which the objects were illuminated, and which in one case was simple, in the other compound; and therefore the distinct vision in the former case, and confused in the latter, could arise from nothing else than from that difference in the lights. Which proves the whole proposition.

"In these three experiments, it is farther very re-

remarkable, that the colour of homogeneous light, was never changed by the refraction. And as these colours were not changed by refractions, so neither were they by reflections. For all white, grey, red, yellow, green, blue, violet bodies, as paper, ashes, red lead, orpiment, indigo, bice, gold, silver, copper, grass, blue flowers, violets, bubbles of water tinged with various colours, peacocks feathers, the tincture of lignum nephriticum, and such like, in red homogeneous light appeared totally red, in blue light totally blue, in green light totally green, and so of other colours. In the homogeneous light of any colour they all appeared totally of that same colour; with this only difference that, some of them reflected that light more strongly, others more faintly. I never yet found any body which by reflecting homogeneous light could sensibly change its colour.

"From all which it is manifest, that if the sun's light consisted of but one sort of rays, there would be but one colour in the world, nor would it be possible to produce any new colour by reflections and refractions; and by consequence, that the variety of colours depends upon the composition of light.

"The solar image  $pt$ , formed by the separated rays in the 5th experiment, did in the progress from its end  $p$ , on which the most refrangible rays fell, unto its end  $t$ , on which the least refrangible rays fell, appear tinged with this series of colours; violet, indigo, blue, green, yellow, orange, red, together with all their intermediate degrees in a continual succession perpetually varying; so that there appeared as many degrees of colours as there were sorts of rays differing in refrangibility. And since these colours could not be changed by refractions nor by reflections, it follows, that all homogeneous light has its proper colour answering to its degree of refrangibility.

"Every homogeneous ray considered apart is refracted, according to one and the same rule; so that its sine of incidence is to its sine of refraction in a given ratio: that is, every different coloured ray has a different ratio belonging to it. This our author has proved by experiment, and by other experiments has determined by what numbers those given ratios are expressed. For instance, if an heterogeneous white ray of the sun emerges out of glass into air; or, which is the same thing, if rays of all colours be supposed to succeed one another in the same line AC, and AD (fig. 15): their common sine of incidence in glass be divided into 50 equal parts, then EF and GH, the sines of refraction into air, of the least and most refrangible rays, will be 77 and 78 such parts respectively. And since every colour has several degrees, the sines of refraction of all the degrees of red will have all intermediate degrees of magnitude from 77 to  $77\frac{1}{2}$ , of all the degrees of orange from  $77\frac{1}{2}$  to  $77\frac{3}{4}$ , of yellow from  $77\frac{3}{4}$  to  $77\frac{1}{2}$ , of green from  $77\frac{1}{2}$  to  $77\frac{1}{4}$ , of blue from  $77\frac{1}{4}$  to  $77\frac{1}{8}$ , of indigo from  $77\frac{1}{8}$  to  $77\frac{1}{16}$ , and of violet from  $77\frac{1}{16}$  to 78."

200 Every homogeneous ray is refracted according to one and the same rule.

Plate CCCLX.

SECT. I *The Application of the foregoing Theory to several natural Phenomena.*§ 1. *Of the Rainbow.*

201  
Knowledge  
of the na-  
ture of the  
rainbow a  
modern dis-  
covery.

THIS beautiful phenomenon hath engaged the attention of all ages. By some nations it hath been deified; though the more sensible part always looked upon it as a natural appearance, and endeavoured, however imperfectly, to account for it. The observations of the ancients and philosophers of the middle ages concerning the rainbow were such as could not have escaped the notice of the most illiterate husbandmen who gazed at the sky; and their various hypotheses deserve no notice. It was a considerable time even after the dawn of true philosophy in this western part of the world, before we find any discovery of importance on this subject. Maurolycus was the first who pretended to have measured the diameters of the two rainbows with much exactness; and he reports, that he found that of the inner bow to be 45 degrees, and that of the outer bow 56; from which Descartes takes occasion to observe, how little we can depend upon the observations of those who were not acquainted with the cause of the appearances.

One *Glichtovius* (the same, it is probable, who distinguished himself by his opposition to Luther, and who died in 1543) had maintained, that the second bow is the image of the first, as he thought was evident from the inverted order of the colours. For, said he, when we look into the water, all the images that we see reflected by it are inverted with respect to the objects themselves; the tops of the trees, for instance, that stand near the brink, appearing lower than the roots.

202  
Approach  
towards it  
made by  
Fletcher of  
Breslau.

That the rainbow is opposite to the sun, had always been observed. It was, therefore, natural to imagine, that the colours of it were produced by some kind of reflection of the rays of light from drops of rain, or vapour. The regular order of the colours was another circumstance that could not have escaped the notice of any person. But, notwithstanding mere reflection had in no other case been observed to produce colours, and it could not but have been observed that refraction is frequently attended with that phenomenon, yet no person seems to have thought of having recourse to a proper refraction in this case, before one *Fletcher* of Breslau, who in a treatise which he published in 1571, endeavoured to account for the colours of the rainbow by means of a double refraction and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the spectator. He seems to have overlooked the reflection at the farther side of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature to bring the ray of the sun to the eye of the spectator. That he should think of two refractions, was the ne-

cessary consequence of his supposing that the ray entered the drop at all. This supposition, therefore, was all the light that he threw upon the subject. B. Porta supposed that the rainbow is produced by the refraction of light in the whole body of rain or vapour, but not in the separate drops.

After all, it was a man whom no writers allow to have had any pretensions to philosophy, that hit upon this curious discovery. This was Antonio De Dominis, bishop of Spalatro, whose treatise *De Radiis Visus et Lucis*, was published by J. Bartolus in 1611. He first advanced, that the double reflection of Fletcher, with an intervening reflection, was sufficient to produce the colours of the bow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent reflection. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner surface, is from thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent, so as to come directly to the eye. To verify this hypothesis, this person (no philosopher as he was) proceeded in a very sensible and philosophical manner. For he procured a small globe of solid glass, and viewing it when it was exposed to the rays of the sun, in the same manner in which he had supposed that the drops of rain were situated with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order.

Thus the circumstances in which the colours of the rainbow were formed, and the progress of a ray of light through a drop of water were clearly understood; but philosophers were a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed nothing but the doctrine of the different refrangibility of the rays of light, which was a discovery reserved for the great Sir Isaac Newton, could furnish a complete solution of this difficulty. De Dominis supposed that the red rays were those which had traversed the least space in the inside of a drop of water, and therefore retained more of their native force, and consequently, striking the eye more briskly, gave it a stronger sensation; that the green and blue colours were produced by those rays, the force of which had been, in some measure, obtunded in passing through a greater body of water; and that all the intermediate colours were composed (according to the hypothesis which generally prevailed at that time) of a mixture of these three primary ones. That the different colours were caused by some difference in the impulse of light upon the eye, and the greater or less impression that was thereby made upon it, was an opinion which had been adopted by many persons, who had ventured to depart from the authority of Aristotle.

Afterwards the same De Dominis observed, that all the rays of the same colour must leave the drop of water in a part similarly situated with respect to the eye,

in

de Dominis  
bishop of  
Spalatro.

Of the  
Rainbow.

in order that each of the colours may appear in a circle, the centre of which is a point of the heavens, in a line drawn from the sun through the eye of the spectator. The red rays, he observed, must issue from the drop nearest to the bottom of it, in order that the circle of red may be the outermost, and therefore the most elevated in the bow.

Notwithstanding De Dominis conceived so justly of the manner in which the inner rainbow is formed, he was far from having as just an idea of the cause of the exterior bow. This he endeavoured to explain in the very same manner in which he had done the interior, viz. by one reflection of the light within the drop, preceded and followed by a refraction; supposing only that the rays which formed the exterior bow were returned to the eye by a part of the drop lower than that which transmitted the red of the interior bow. He also supposed that the rays which formed one of the bows came from the superior part of the sun's disk, and those which formed the other from the inferior part of it. He did not consider, that upon those principles, the two bows ought to have been contiguous; or rather, that an indefinite number of bows would have had their colours all intermixed; which would have been no bow at all.

When Sir Isaac Newton discovered the different refrangibility of the rays of light, he immediately applied his new theory of light and colours to the phenomena of the rainbow, taking this remarkable object of philosophical inquiry where De Dominis and Descartes, for want of this knowledge, were obliged to leave their investigations imperfect. For they could give no good reason why the bow should be coloured, and much less could they give any satisfactory account of the orders in which the colours appear.

204  
The true  
cause of the  
colours of  
the rain-  
bow.

Plate  
CCCLX.

If different particles of light had not different degrees of refrangibility, on which the colours depend, the rainbow, besides being much narrower than it is, would be colourless; but the different refrangibility of differently coloured rays being admitted, the reason is obvious, both why the bow should be coloured, and also why the colours should appear in the order in which they are observed. Let *a* (fig. 8.) be a drop of water, and *S* a pencil of light; which, on its leaving the drop of water, reaches the eye of the spectator. This ray, at its entrance into the drop, begins to be decomposed into its proper colours; and upon leaving the drop, after one reflection and a second refraction, it is farther decomposed into as many small differently-coloured pencils as there are primitive colours in the light. Three of them only are drawn in this figure, of which the blue is the most, and the red the least refracted.

The doctrine of the different refrangibility of light enables us to give a reason for the size of a bow of each particular colour. Newton, having found that the lines of refraction of the most refrangible and least refrangible rays, in passing from rain-water into air, are in the proportion of 183 to 182, when the sine of incidence is 158, calculated the size of the bow; and he found, that if the sun was only a physical point, without sensible magnitude, the breadth of the inner bow would be 2 degrees; and if to this 30' was added for the apparent diameter of the sun, the whole breadth would be  $2\frac{1}{2}$  degrees. But as the outermost

VOL. XIII.

colours, especially the violet, are extremely faint, the breadth of the bow will now in reality appear to exceed two degrees. He finds, by the same principles, that the breadth of the exterior bow, if it was everywhere equally vivid, would be  $4^{\circ} 20'$ . But in this case there is a greater deduction to be made, on account of the faintness of the light of the exterior bow; so that, in fact, it will not appear to be more than 3 degrees broad.

The principal phenomena of the rainbow are all explained on Sir Isaac Newton's principles in the following propositions.

*When the rays of the sun fall upon a drop of rain and enter into it, some of them, after one reflection and two refractions, may come to the eye of a spectator who has his back towards the sun, and his face towards the drop.*

205  
Explana-  
tion of the  
phenomena  
of rainbow  
on the prin-  
ciples of  
Newton.

IF XY (fig. 9.) is a drop of rain, and the sun shines upon it in any lines *sf*, *sd*, *sa*, &c most of the rays will enter into the drop; some few of them only will be reflected from the first surface; those rays which are reflected from thence do not come under our present consideration, because they are never retracted at all. The greatest part of the rays then enter the drop, and those passing on to the second surface, will most of them be transmitted through the drop; but neither do those rays which are thus transmitted fall under our present consideration, since they are not reflected. For the rays, which are described in the proposition, are such as are twice refracted and once reflected. However, at the second surface, or hinder part of the drop, at *pg*, some few rays will be reflected, whilst the rest are transmitted: those rays proceed in some such lines as *nr*, *nq*; and coming out of the drop in the lines *rv*, *qt*, may fall upon the eye of a spectator, who is placed anywhere in those lines, with his face towards the drop, and consequently with his back towards the sun, which is supposed to shine upon the drop in the lines *sf*, *sd*, *sa*, &c. These rays are twice refracted and once reflected; they are refracted when they pass out of the air into the drop; they are reflected from the second surface, and are refracted again when they pass out of the drop into the air.

*When rays of light reflected from a drop of rain come to the eye, those are called effectual which are able to excite a sensation.*

*When rays of light come out of a drop of rain, they will not be effectual, unless they are parallel and contiguous.*

THERE are but few rays that can come to the eye at all: for since the greatest part of those rays which enter the drop XY (fig. 9.) between *X* and *a*, pass out of the drop through the hinder surface *pg*; only few are reflected from thence, and come out through the nearer surface between *a* and *y*. Now, such rays as emerge, or come out of the drop, between *a* and *Y*, will be ineffectual, unless they are parallel to one another, as *rv* and *qt* are; because such rays as come out diverging from one another will be so far asunder when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be

S f

sufficient

Of the  
Rainbow.Of the  
Rainbow.

sufficient to excite any sensation. But even rays, which are parallel, as  $rv$ ,  $qt$ , will not be effectual, unless there are several of them contiguous or very near to one another. The two rays  $rv$  and  $qt$  alone will not be perceived, though both of them enter the eye; for so very few rays are not sufficient to excite a sensation.

*When rays of light come out of a drop of rain after one reflection, those will be effectual which are reflected from the same point, and which entered the drop near to one another.*

Plate  
CCCLX.

ANY rays, as  $sb$  and  $cd$ , (fig. 10.) when they have passed out of the air into a drop of water, will be refracted towards the perpendiculars  $bl$ ,  $dl$ ; and as the ray  $sb$  falls farther from the axis  $av$  than the ray  $cd$ ,  $sb$  will be more refracted than  $cd$ ; so that these rays, though parallel to one another at their incidence, may describe the lines  $be$  and  $de$  after refraction, and be both of them reflected from one and the same point  $e$ . Now all rays which are thus reflected from one and the same point, when they have described the lines  $ef$ ,  $eg$ , and after reflection emerge at  $f$  and  $g$ , will be so refracted, when they pass out of the drop into the air, as to describe the lines  $fb$ ,  $gi$ , parallel to one another. If these rays were to return from  $e$  in the lines  $eb$ ,  $ed$ , and were to emerge at  $b$  and  $d$ , they would be refracted into the lines of their incidence  $bs$ ,  $dc$ . But if these rays, instead of being returned in the lines  $eb$ ,  $ed$ , are reflected from the same point  $e$  in the lines  $eg$ ,  $ef$ , the lines of reflection  $eg$  and  $ef$  will be inclined both to one another, and to the surface of the drop; just as much as the lines  $eb$  and  $ed$  are. First  $eb$  and  $eg$  make just the same angle with the surface of the drop: for the angle  $bex$ , which  $eb$  makes with the surface of the drop, is the complement of incidence, and the angle  $gev$ , which  $eg$  makes with the surface, is the complement of reflection; and these two are equal to one another. In the same manner we might prove, that  $ed$  and  $ef$  make equal angles with the surface of the drop. Secondly, The angle  $bed$  is equal to the angle  $feg$ ; or the reflected rays  $eg$ ,  $ef$ , and the incident rays  $be$ ,  $de$ , are equally inclined to each other. For the angle of incidence  $bel$  is equal to the angle of reflection  $gel$ , and the angle of incidence  $dcl$  is equal to the angle of reflection  $fel$ ; consequently the difference between the angles of incidence is equal to the difference between the angles of reflection, or  $bel - dcl = gel - fel$ , or  $bed = gef$ . Since therefore either the lines  $eg$ ,  $ef$ , or the lines  $eb$ ,  $ed$ , are equally inclined both to one another and to the surface of the drop; the rays will be refracted in the same manner, whether they were to return in the lines  $eb$ ,  $ed$ , or are reflected in the lines  $eg$ ,  $ef$ . But if they were to return in the lines  $eb$ ,  $ed$ , the refraction, when they emerge at  $b$  and  $d$ , would make them parallel. Therefore, if they are reflected from one and the same point  $e$  in the lines  $eg$ ,  $ef$ , the refraction, when they emerge at  $g$  and  $f$ , will likewise make them parallel.

But though such rays as are reflected from the same point in the hinder part of a drop of rain, are parallel to one another when they emerge, and so have one condition that is requisite towards making them effectual, yet there is another condition necessary; for rays,

that are effectual, must be contiguous as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, those only will be contiguous which enter it nearly at the same place.

Let  $XY$  (fig. 9.) be a drop of rain,  $ag$  the axis or diameter of the drop, and  $sa$  a ray of light that comes from the sun and enters the drop at the point  $a$ . This ray  $sa$ , because it is perpendicular to both the surfaces, will pass straight through the drop in the line  $agb$  without being refracted; but any collateral rays, such as those that fall about  $sb$ , as they pass through the drop, will be made to converge to their axis, and passing out at  $n$  will meet the axis at  $b$ : rays which fall farther from the axis than  $sb$ , such as those which fall about  $sc$ , will likewise be made to converge; but then their focus will be nearer to the drop than  $b$ . Suppose therefore  $i$  to be the focus to which the rays that fall about  $sc$  will converge, any ray  $sc$ , when it has described the line  $co$  within the drop, and is tending to the focus  $i$ , will pass out of the drop at the point  $o$ . The rays that fall upon the drop about  $sd$ , more remote still from the axis, will converge to a focus still nearer than  $i$ , as suppose at  $k$ . These rays therefore go out of the drop at  $p$ . The rays, that fall still more remote from the axis, as  $se$ , will converge to a focus nearer than  $k$ , as suppose at  $l$ ; and the ray  $se$ , when it has described the line  $eo$  within the drop, and is tending to  $l$ , will pass out at the point  $o$ . The rays that fall still more remote from the axis will converge to a focus still nearer. Thus the ray  $sf$  will after refraction converge to a focus at  $m$ , which is nearer than  $l$ ; and having described the line  $fn$  within the drop, it will pass out to the point  $n$ . Now here we may observe, that as any rays  $sb$  or  $sc$ , fall farther above the axis  $sa$ , the points  $n$ , or  $o$ , where they pass out behind the drop, will be farther above  $g$ ; or that, as the incident ray rises from the axis  $sa$ , the arc  $gn$  increases, till we come to some ray  $sd$ , which passes out of the drop at  $p$ ; and this is the highest point where any ray that falls upon the quadrant or quarter  $ax$  can pass out: for any rays  $se$ , or  $sf$ , that fall higher than  $sd$ , will not pass out in any point above  $p$ , but at the points  $o$  or  $n$ , which are below it. Consequently, tho' the arc  $gnop$  increases, whilst the distance of the incident ray from the axis  $sa$  increases, till we come to the ray  $sd$ ; yet afterwards, the higher the ray falls above the axis  $sa$ , this arc  $pang$  will decrease.

We have hitherto spoken of the points on the hinder part of the drop, where the rays pass out of it; but this was for the sake of determining the points from whence those rays are reflected, which do not pass out behind the drop. For, in explaining the rainbow, we have no farther reason to consider those rays which go through the drop; since they can never come to the eye of a spectator placed anywhere in the lines  $rv$  or  $qt$  with his face towards the drop. Now, as there are many rays which pass out of the drop between  $g$  and  $p$ , so some few rays will be reflected from thence; and consequently the several points between  $g$  and  $p$ , which are the points where some of the rays pass out of the drop, are likewise the points of reflection for the rest which do not pass out. Therefore, in respect of those rays which are reflected, we may call  $gp$  the arc of reflection; and may say, that this arc

of

Of the  
Rainbow.Of the  
Rainbow.

of reflection increases, as the distance of the incident ray from the axis  $sa$  increases, till we come to the ray  $sd$ ; the arc of reflection is  $gn$  for the ray  $sb$ , it is  $go$  for the ray  $sc$ ; and  $gp$  for the ray  $sd$ . But after this, as the distance of the incident ray from the axis  $sa$  increases, the arc of reflection decreases; for  $og$  less than  $pg$  is the arc of reflection for the ray  $se$ , and  $ng$  is the arc of reflection for the ray  $sf$ .

From hence it is obvious, that some one ray, which falls above  $sd$ , may be reflected from the same point with some other ray which falls below  $sd$ . Thus, for instance, the ray  $sb$  will be reflected from the point  $n$ , and the ray  $sf$  will be reflected from the same point: and consequently, when the reflected rays  $nr$ ,  $nq$ , are refracted as they pass out of the drop at  $r$  and  $q$ , they will be parallel, by what has been shown in the former part of this proposition. But since the intermediate rays, which enter the drop between  $sf$  and  $sb$ , are not reflected from the same point  $n$ , these two rays alone will be the parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And consequently these rays  $rv$ ,  $qt$ , though they are parallel after they emerge at  $r$  and  $q$ , will not be contiguous, and for that reason will not be effectual; the ray  $sd$  is reflected from  $p$ , which has been shown to be the limit of the arc of reflection; such rays as fall just above  $sd$ , and just below  $sd$ , will be reflected from nearly the same point  $p$ , as appears from what has been already shown. These rays therefore will be parallel, because they are reflected from the same point  $p$ ; and they will likewise be contiguous, because they all of them enter the drop at one and the same place very near to  $d$ . Consequently, such rays as enter the drop at  $d$ , and are reflected from  $p$  the limit of the arc of reflection, will be effectual; since, when they emerge at the fore part of the drop between  $a$  and  $y$ , they will be both parallel and contiguous.

If we can make out hereafter that the rainbow is produced by the rays of the sun which are thus reflected from drops of rain as they fall whilst the sun shines upon them, this proposition may serve to show us, that this appearance is not produced by any rays that fall upon any part, and are reflected from any part of those drops: since this appearance cannot be produced by any rays but those which are effectual; and effectual rays must always enter each drop at one certain place in the fore-part of it, and must likewise be reflected from one certain place in the hinder surface.

*When rays that are effectual emerge from a drop of rain after one reflection and two refractions, those which are most refrangible will, at their emerſion, make a leſs angle with the incident rays than thoſe do which are leaſt refrangible; and by this means the rays of different colours will be ſeparated from one another.*

Plate  
CCCLX.

LET  $fb$  and  $gi$  (fig. 10.) be effectual violet rays emerging from the drop at  $fg$ ; and  $fn$ ,  $gp$ , effectual red rays emerging from the same drop at the same place. Now, though all the violet rays are parallel to one another, because they are supposed effectual, and though all the red rays are likewise parallel to one another for the same reason; yet the violet rays will not be parallel to the red rays. These rays, as they have different colours, and different degrees of re-

frangibility, will diverge from one another; any violet ray  $gi$ , which emerges at  $g$ , will diverge from any red ray  $gp$ , which emerges at the same place. Now, both the violet ray  $gi$ , and the red ray  $gp$ , as they pass out of the drop of water into the air, will be refracted from the perpendicular  $lo$ . But the violet ray is more refrangible than the red one; and for that reason  $gi$ , or the refracted violet ray, will make a greater angle with the perpendicular than  $gp$  the refracted red ray; or the angle  $ig o$  will be greater than the angle  $pg o$ . Suppose the incident ray  $sb$  to be continued in the direction  $sk$ , and the violet ray  $ig$  to be continued backward in the direction  $ik$ , till it meets the incident ray at  $k$ . Suppose likewise the red ray  $pg$  to be continued backwards in the same manner, till it meets the incident ray at  $w$ . The angle  $iks$  is that which the violet ray, or most refrangible ray at its emerſion, makes with the incident ray; and the angle  $pws$  is that which the red ray, or least refrangible ray at its emerſion, makes with the incident ray. The angle  $iks$  is less than the angle  $pws$ . For, in the triangle,  $gwk$ ,  $gws$ , or  $pws$ , is the external angle at the base, and  $gkw$  or  $iks$  is one of the internal opposite angles; and either internal opposite angle is less than the external angle at the base. (Euc. b. I. prop. 16.) What has been shown to be true of the rays  $gi$  and  $gp$  might be shown in the same manner of the rays  $fb$  and  $fn$ , or of any other rays that emerge respectively parallel to  $gi$  and  $gp$ . But all the effectual violet rays are parallel to  $gi$ , and all the effectual red rays are parallel to  $gp$ . Therefore the effectual violet rays at their emerſion make a less angle with the incident ones than the effectual red ones. And for the same reason, in all the other sorts of rays, those which are most refrangible, at their emerſion from a drop of rain after one reflection, will make a less angle with the incident rays, than those do which are least refrangible.

Or otherwise: When the rays  $gi$  and  $gp$  emerge at the same point  $g$ , as they both come out of water into air, and consequently are refracted from the perpendicular, instead of going straight forwards in the line  $eg$  continued, they will both be turned round upon the point  $g$  from the perpendicular  $go$ . Now it is easy to conceive, that either of these lines might be turned in this manner upon the point  $g$  as upon a centre, till they became parallel to  $sb$  the incident ray. But if either of these lines or rays were refracted so much from  $go$  as to become parallel to  $sb$ , the ray so much refracted, would, after emerſion, make no angle with  $sk$ , because it would be parallel to it. And consequently that ray which is most turned round upon the point  $g$ , or that ray which is most refrangible, will after emerſion be nearest parallel to the incident ray, or will make the least angle with it. The same may be proved of all other rays emerging parallel to  $gi$  and  $gp$  respectively or of all effectual rays; those which are most refrangible will after emerſion make a less angle with the incident rays, than those do which are least refrangible.

But since the effectual rays of different colours make different angles with  $sk$  at their emerſion, they will be separated from one another: so that if the eye was placed in the beam  $fgbi$ , it would receive only rays of one colour from the drop  $xagv$ ; and if it was placed

Of the  
Rainbow.

in the beam  $fgnp$ , it would receive only rays of some other colour.

The angle  $swp$ , which the least refrangible or red rays make with the incident ones when they emerge so as to be effectual, is found by calculation to be 42 degrees 2 minutes. And the angle  $ski$ , which the most refrangible rays make with the incident ones when they emerge so as to be effectual, is found to be 40 degrees 17 minutes. The rays which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between 42 degrees 2 minutes, and 40 degrees 17 minutes.

*If a line is supposed to be drawn from the centre of the sun through the eye of the spectator, the angle which any effectual rays, after two refractions and one reflection, makes with the incident ray, will be equal to the angle which it makes with that line.*

Plate  
CCCLX.

LET the eye of the spectator be at  $i$ , (fig. 10.) and let  $qt$  be the line supposed to be drawn from the centre of the sun through the eye of the spectator; the angle  $git$ , which any effectual ray makes with this line, will be equal to the angle  $iks$ , which the same ray makes with the incident ray  $sb$  or  $sk$ . If  $sb$  is a ray coming from the centre of the sun, then since  $qt$  is supposed to be drawn from the same point, these two lines, upon account of the remoteness of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line  $ki$  crossing these two parallel lines will make the alternate angles equal. (Euc. b. I. prop. 29.) Therefore  $kis$  or  $git$  is equal to  $ski$ .

*When the sun shines upon the drops of rain as they are falling, the rays that come from those drops to the eye of a spectator, after one reflection and two refractions, produce the primary rainbow.*

206  
Two rain-  
bows seen  
at once.

If the sun shines upon the rain as it falls, there are commonly seen two bows, as AFB, CHD, (fig. 11.); or if the cloud and rain does not reach over that whole side of the sky where the bows appear, then only a part of one or of both bows is seen in that place where the rain falls. Of these two bows, the innermost AFB is the more vivid of the two, and this is called the *primary bow*. The outer part TFY of the primary bow is red, the inner part VEX is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppose the spectator's eye to be at O, and let LOP be an imaginary line drawn from the centre of the sun through the eye of the spectator: if a beam of light S coming from the sun falls upon any drop F; and the rays that emerge at F in the line FO, so as to be effectual, make an angle FOP of 42° 2' with the line LP; then these effectual rays make an angle of 42° 2' with the incident rays, by the preceding proposition, and consequently these rays will be red, so that the drop F will appear red. All the other rays, which emerge at F, and would be effectual if they fell upon the eye are, refracted more than the red ones, and consequently will pass above the eye. If a beam of light S falls upon the drop E; and the rays that emerge at E in the line EO, so as to be effectual, make an angle EOP of 40° 17' with the line LP; then these effectual rays make likewise an angle of

Of the  
Rainbow.

40° 17' with the incident rays, and the drop E will appear of a violet colour. All the other rays, which emerge at E, and would be effectual if they came to the eye, are refracted less than the violet ones, and therefore pass below the eye. The intermediate drops between F and E will for the same reasons be of the intermediate colours.

Thus we have shown why a set of drops from F to E, as they are falling, should appear of the primary colours, red, orange, yellow, green, blue, indigo, and violet. It is not necessary that the several drops, which produce these colours, should all of them fall at exactly the same distance from the eye. The angle FOP, for instance, is the same whether the distance of the drop from the eye is OF, or whether it is in any other part of the line OF something nearer to the eye. And whilst the angle FOP is the same, the angle made by the emerging and incident rays, and consequently the colour of the drop, will be the same. This is equally true of any other drop. So that although in the figure the drops F and E are represented as falling perpendicularly one under the other, yet this is not necessary in order to produce the bow.

But the coloured line FE, which we have already accounted for, is only the breadth of the bow. It still remains to be shown, why not only the drop F should appear red, but why all the other drops quite from A to B in the arc ATFYB should appear of the same colour. Now it is evident, that wherever a drop of rain is placed, if the angle which the effectual rays make with the line LP is equal to the angle FOP, that is, if the angle which the effectual rays make with the incident rays is 42° 2', any of those drops will be red, for the same reason that the drop F is of this colour.

If FOP was to turn round upon the line OP, so that one end of this line should always be at the eye, and the other be at P opposite to the sun; such a motion of this figure would be like that of a pair of compasses turning round upon one of the legs OP with the opening FOP. In this revolution the drop F would describe a circle, P would be the centre, and ATFYB would be an arc in this circle. Now since, in this motion of the line and drop OF, the angle made by FO with OP, that is, the angle FOP, continues the same; if the sun was to shine upon this drop as it revolves, the effectual rays would make the same angle with the incident rays, in whatever part of the arc ATFYB the drop was to be. Therefore, whether the drop is at A, or at T, or at Y, or at B, or wherever else it is in this whole arc, it would appear red, as it does at F. The drops of rain, as they fall, are not indeed turned round in this manner: but then, as innumerable of them are falling at once in right lines from the cloud, whilst one drop is at F, there will be others at Y, at T, at B, at A, and in every other part of the arc ATFYB: and all these drops will be red for the same reason that the drop F would have been red, if it had been in the same place. Therefore, when the sun shines upon the rain as it falls, there will be a red arc ATFYB opposite to the sun. In the same manner, because the drop E is violet, we might prove that any other drop, which, whilst it is falling, is in any part of the arc AVEXB, will be violet; and consequently, at the same time that the red arc ATFYB appears, there will like-  
wise

Of the  
Rainbow.

wife be a violet arc *AVEXB* below or within it. *FE* is the distance between these two coloured arcs; and from what has been said, it follows, that the intermediate space between these two arcs will be filled up with arcs of the intermediate colours, orange, yellow, blue, green, and indigo. All these coloured arcs together make up the primary rainbow.

*The primary rainbow is never a greater arc than a semicircle.*

Plate  
CCCLX.  
207  
Why the  
arc of the  
primary  
rainbow is  
never  
greater  
than a semi-  
circle.

SINCE the line *LOP* is drawn from the sun through the eye of the spectator, and since *P* (fig. 9.) is the centre of the rainbow: it follows, that the centre of the rainbow is always opposite to the sun. The angle *FOP* is an angle of  $42^{\circ} 2'$ , as was observed, or *F* the highest part of the bow is  $42^{\circ} 2'$  from *P* the centre of it. If the sun is more than  $42^{\circ} 2'$  high, *P* the centre of the rainbow, which is opposite to the sun, will be more than  $42^{\circ} 2'$  below the horizon; and consequently *F* the top of the bow, which is only  $42^{\circ} 2'$  from *P*, will be below the horizon; that is, when the sun is more than  $42^{\circ} 2'$  high, no primary rainbow will be seen. If the sun is something less than  $42^{\circ} 2'$  high, then *P* will be something less than  $42^{\circ} 2'$  below the horizon; and consequently *F*, which is only  $42^{\circ} 2'$  from *P*, will be just above the horizon; that is, a small part of the bow at this height of the sun will appear close to the ground opposite to the sun. If the sun is  $20^{\circ}$  high, then *P* will be  $20^{\circ}$  below the horizon; and *F* the top of the bow, being  $42^{\circ} 2'$  from *P*, will be  $22^{\circ} 2'$  above the horizon; therefore, at this height of the sun, the bow will be an arc of a circle whose centre is below the horizon; and consequently that arc of the circle which is above the horizon, or the bow, will be less than a semicircle. If the sun is in the horizon, then *P*, the centre of the bow, will be in the opposite part of the horizon; *F*, the top of the bow, will be  $42^{\circ} 2'$  above the horizon; and the bow itself, because the horizon passes through the centre of it, will be a semicircle. More than a semicircle can never appear; because if the bow was more than a semicircle, *P* the centre of it must be above the horizon; but *P* is always opposite to the sun, therefore *P* cannot be above the horizon, unless the sun is below it; and when the sun is set or is below the horizon, it cannot shine upon the drops of rain as they fall; and consequently, when the sun is below the horizon, no bow at all can be seen.

*When the rays of the sun fall upon a drop of rain, some of them, after two reflections and two refractions, may come to the eye of a spectator, who has his back towards the sun and his face towards the drop.*

IF *HGW* (fig. 12.) is a drop of rain, and parallel rays coming from the sun, as *zv*, *yw*, fall upon the lower part of it, they will be refracted towards the perpendiculars *vl*, *wl*, as they enter into it, and will describe some such lines as *vb*, *wi*. At *b* and *i* great part of these rays will pass out of the drop; but some of them will be reflected from thence in the lines *bf*, *ig*. At *f* and *g* again, great part of the rays that were reflected thither will pass out of the drop. But these rays will not come to the eye of a spectator at *o*. However, here again all the rays will not pass out; but some few will be reflected from *f* and *g*, in

some such lines as *fd*, *gb*; and these, when they emerge out of the drop of water into the air at *b* and *d* will be refracted from the perpendiculars, and, describing the lines *dt*, *bo*, may come to the eye of the spectator who has his back towards the sun and his face towards the drop.

*Those rays, which are parallel to one another after they have been once refracted and once reflected in a drop of rain, will be effectual when they emerge after two refractions and two reflections.*

No rays can be effectual, unless they are contiguous and parallel. From what was said, it appears, that when rays come out of a drop of rain contiguous to one another, either after one or after two reflections, they must enter the drop nearly at one and the same place. And if such rays as are contiguous are parallel after the first reflection, they will emerge parallel, and therefore will be effectual. Let *zv* and *yw* be contiguous rays which come from the sun, and are parallel to one another when they fall upon the lower part of the drop, suppose these rays to be refracted at *v* and *w*, and to be reflected at *b* and *i*; if they are parallel to one another, as *bf*, *gi*, after this first reflection, then, after they are reflected a second time from *f* and *g*, and refracted a second time as they emerge at *d* and *b*, they will go out of the drop parallel to one another in the lines *dt* and *bo*, and will therefore be effectual.

The rays *zv*, *yw*, are refracted towards the perpendiculars *vl*, *wl*, when they enter the drop, and will be made to converge. As these rays are very oblique, their focus will not be far from the surface *vw*. If this focus is at *k*, the rays, after they have passed the focus, will diverge from thence in the directions *kb*, *ki*; and if *ki* is the principal focal distance of the concave reflecting surface *bi*, the reflected rays *bf*, *ig*, will be parallel. These rays *ef*, *ig*, are reflected again from the concave surface *fg*, and will meet in a focus at *e*, so that *ge* will be the principal focal distance of this reflecting surface *fg*. And because *bi*, and *fg* are parts of the same sphere, the principal focal distances *ge* and *ki* will be equal to one another. When the rays have passed the focus *e*, they will diverge from thence in the lines *ed*, *eb*: and we are to show, that when they emerge at *d* and *b*, and are refracted there, they will become parallel.

Now if the rays *vk*, *wk*, when they have met at *k*, were to be turned back again in the directions *kv*, *kw*, and were to emerge at *v* and *w*, they would be refracted into the lines of their incidence, *vz*, *wy*, and therefore would be parallel. But since *ge* is equal to *ik*, as has already been shown, the rays *ed*, *eb*, that diverge from *e*, fall in the same manner upon the drop at *d* and *b*, as the rays *kv*, *kw*, would fall upon it at *v* and *w*; and *ed*, *eb*, are just as much inclined to the refracting surface *db*, as *kv*, *kw*, would be to the surface *vw*. From hence it follows, that the rays *ed*, *eb*, emerging at *d* and *b*, will be refracted in the same manner, and will have the same direction in respect to one another, as *kv*, *kw*, would have. But *kv* and *kw* would be parallel after refraction. Therefore *ed* and *eb* will emerge in lines *dp*, *bo*, so as to be parallel to one another, and consequently so as to be effectual.

Of the  
Rainbow.

Of the  
Rainbow.

When rays that are effectual emerge from a drop of rain after two reflections and two refractions, those which are most refrangible will at their emergence make a greater angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another.

Plate  
CCCLX.

IF rays of different colours, which are differently refrangible, emerge at any point  $b$  (fig. 12), these rays will not be all of them equally refracted from the perpendicular. Thus, if  $bo$  is a red ray, which is of all others the least refrangible, and  $bm$  is a violet ray, which is of all others the most refrangible; when these two rays emerge at  $b$ , the violet ray will be refracted more from the perpendicular  $bx$  than the red ray, and the refracted angle  $xbm$  will be greater than the refracted angle  $xbo$ . From hence it follows, that these two rays, after emergence, will diverge from one another. In like manner, the rays that emerge at  $d$  will diverge from one another; a red ray will emerge in the line  $dp$ , a violet ray in the line  $dt$ . So that though all the effectual red rays of the beam  $bdmt$  are parallel to one another, and all the effectual red rays of the beam  $bdop$  are likewise parallel to one another, yet the violet rays will not be parallel to the red ones, but the violet beam will diverge from the red beam. Thus the rays of different colours will be separated from one another.

This will appear farther, if we consider what the proposition affirms, That any violet or most refrangible ray will make a greater angle with the incident rays, than any red or least refrangible ray makes with the same incident rays. Thus if  $yw$  is an incident ray,  $bm$  a violet ray emerging from the point  $b$ , and  $bo$  a red ray emerging from the same point; the angle which the violet ray makes with the incident one is  $ym$ , and that which the red ray makes with it is  $yo$ . Now  $ym$  is a greater angle than  $yo$ . For in the triangle  $brs$  the internal angle  $brs$  is less than  $bsy$  the external angle at the base. (Eucl. B. I. prop. 16.) But  $ym$  is the complement of  $brs$  or of  $bry$  to two right ones, and  $yo$  is the complement of  $bsy$  to two right ones. Therefore, since  $bry$  is less than  $bsy$ , the complement of  $bry$  to two right angles will be greater than the complement of  $bsy$  to two right angles; or  $ym$  will be greater than  $yo$ .

Or otherwise: Both the rays  $bo$  and  $bm$ , when they are refracted in passing out of the drop at  $b$ , are turned round upon the point  $b$  from the perpendicular  $bx$ . Now either of these lines  $bo$  or  $bm$  might be turned round in this manner, till it made a right angle with  $yw$ . Consequently, that ray which is most turned round upon  $b$ , or which is most refracted, will make an angle with  $yw$  that will be nearer to a right one than that ray makes with it which is least turned round upon  $b$ , or which is least refracted. Therefore that ray which is most refracted will make a greater angle with the incident ray than that which is refracted.

But since the emerging rays, as they are differently refrangible, make different angles with the same incident ray  $yw$ , the refraction which they suffer at emergence will separate them from one another.

The angle  $ym$ , which the most refrangible or violet rays make with the incident ones, is found by cal-

culatation to be  $54^{\circ} 7'$ ; and the angle  $yo$ , which the least refrangible or red rays make with the incident ones, is found to be  $50^{\circ} 57'$ : the angles, which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between  $54^{\circ} 7'$  and  $50^{\circ} 57'$ .

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator; the angle which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes that line.

IF  $yw$  (fig. 12.) is an incident ray,  $bo$  an effectual ray, and  $qn$  a line drawn from the centre of the sun through  $o$  the eye of the spectator; the angle  $yso$ , which the effectual ray makes with the incident ray, is equal to  $son$  the angle which the same effectual ray makes with the line  $qn$ . For  $yw$  and  $qn$ , considered as drawn from the centre of the sun, are parallel;  $bo$  crosses them, and consequently makes the alternate angles  $yso$ ,  $son$ , equal to one another. Eucl. B. I. Prop. 29.

When the sun shines upon the drops of rain as they are falling, the rays that come from these drops to the eye of a spectator, after two reflections and two refractions, produce the secondary rainbow.

THE secondary rainbow is the outermost CHD, fig. 11. When the sun shines upon a drop of rain  $H$ ; and the rays  $HO$ , which emerge at  $H$  so as to be effectual, make an angle  $HOP$  of  $54^{\circ} 7'$  with  $LOP$  a line drawn from the sun through the eye of the spectator; the same effectual rays will make likewise an angle of  $54^{\circ} 7'$  with the incident rays  $S$ , and the rays which emerge at this angle are violet ones, by what was observed above. Therefore, if the spectator's eye is at  $O$ , none but violet rays will enter it: for as all the other rays make a less angle with  $OP$ , they will fall above the spectator's eye. In like manner, if the effectual rays that emerge from the drop  $G$  make an angle of  $50^{\circ} 57'$  with the line  $OP$ , they will likewise make the same angle with the incident rays  $S$ ; and consequently from the drop  $G$  to the spectator's eye at  $O$ , no rays will come but red ones; for all the other rays, making a greater angle with the line  $OP$ , will fall below the eye at  $O$ . For the same reason, the rays emerging from the intermediate drops between  $H$  and  $G$ , and coming to the spectator's eye at  $O$ , will emerge at intermediate angles, and therefore will have the intermediate colours. Thus, if there are seven drops from  $H$  to  $G$  inclusively, their colours will be violet, indigo, blue, green, yellow, orange, and red. This coloured line is the breadth of the secondary rainbow.

Now, if  $HOP$  was to turn round upon the line  $OP$ , like a pair of compasses upon one of the legs  $OP$  with the opening  $HOP$ , it is plain from the supposition, that, in such a revolution of the drop  $H$ , the angle  $HOP$  would be the same, and consequently the emerging rays would make the same angle with the incident ones. But in such a revolution the drop would describe a circle of which  $P$  would be the centre, and  $CNHRD$  an arc. Consequently, since, when the drop is at  $N$ , or at  $R$ , or anywhere else in that arc, the emerging rays make the same angle with the incident ones as when the drop is at  $H$ , the colour of the drop will

Rainbow.

will be the same to an eye placed at O, whether the drop is at N, or at H, or at R, or anywhere else in that arc. Now, though the drop does not thus turn round as it falls, and does not pass through the several parts of this arc, yet, since there are drops of rain falling everywhere at the same time, when one drop is at H, there will be another at R, another at N, and others in all parts of the arc; and these drops will all of them be violet-coloured, for the same reason that the drop H would have been of this colour if it had been in any of those places. In like manner, as the drop G is red when it is at G, it would likewise be red in any part of the arc CWGQD; and so will any other drop, when, as it is falling, it comes to any part of that arc. Thus as the sun shines upon the rain, whilst it falls, there will be two arcs produced, a violet coloured one CNHRD, and a red one CWGQD; and for the same reasons the intermediate space between these two arcs will be filled up with arcs of the intermediate colours. All these arcs together make up the secondary rainbow.

*The colours of the secondary rainbow are fainter than those of the primary rainbow; and are ranged in the contrary order.*

209  
Why the  
colours of  
the second-  
ary rain-  
bow are  
fainter than  
those of the  
primary,  
and ranged  
in a con-  
trary order

THE primary rainbow is produced by such rays as have been only once reflected; the secondary rainbow is produced by such rays as have been twice reflected. But at every reflection some rays pass out of the drop of rain without being reflected; so that the oftener the rays are reflected, the fewer of them are left. Therefore the colours of the secondary bow are produced by fewer rays, and consequently will be fainter, than the colours of the primary bow.

In the primary bow, reckoning from the outside of it, the colours are ranged in this order; red, orange, yellow, green, blue, indigo, violet. In the secondary bow, reckoning from the outside, the colours are violet, indigo, blue, green, yellow, orange, red. So that the red, which is the outermost or highest colour in the primary bow, is the innermost or lowest colour in the secondary one.

Now the violet rays, when they emerge so as to be effectual after one reflection, make a less angle with the incident rays than the red ones; consequently the violet rays make a less angle with the lines OP (fig. 11.) than the red ones. But, in the primary rainbow, the rays are only once reflected, and the angle which the effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops, or violet arc, in the primary bow, will be nearer to the centre of the bow than the red drops or red arc; that is, the innermost colour in the primary bow will be violet, and the outermost colour will be red. And, for the same reason, through the whole primary bow, every colour will be nearer to the centre P, as the rays of that colour are more refrangible.

Plate  
CCCLX.

But the violet rays, when they emerge so as to be effectual after two reflections, make a greater angle with the incident rays than the red ones; consequently the violet rays will make a greater angle with the line OP, than the red ones. But in the secondary rainbow the rays are twice reflected, and the angle which effectual rays make with OP is the distance of the co-

loured drop from P the centre of the bow. Therefore the violet drops or violet arc in the secondary bow will be farther from the centre of the bow than the red drops or red arc; that is, the outermost colour in the secondary bow will be violet, and the innermost colour will be red. And, for the same reason, through the whole secondary bow, every colour will be further from the centre P, as the rays of that colour are more refrangible.

objects.

### § 2. Of Coronas, Parhelia, &c.

UNDER the articles CORONA and PARHELION a pretty full account is given of the different hypotheses concerning these phenomena, and likewise of the method by which these hypotheses are supported, from the known laws of refraction and reflection; to which therefore, in order to avoid repetition, we must refer.

### § 3. Of the apparent Place, Distance, Magnitude, and Motion of Objects.

PHILOSOPHERS in general had taken for granted, that the place to which the eye refers any visible object seen by reflection or refraction, is that in which the visual ray meets a perpendicular from the object upon the reflecting or refracting plane. But this method of judging of the place of objects was called in question by Dr Barrow, who contended that the arguments brought in favour of the opinion were not conclusive. These arguments are, that the images of objects appear straight in a plane mirror, but curved in a convex or concave one: that a straight thread, when partly immersed perpendicularly in water, does not appear crooked as when it is obliquely plunged into the fluid; but that which is within the water seems to be a continuation of that which is without. With respect to the reflected image, however, of a perpendicular right line from a convex or concave mirror, he says, that it is not easy for the eye to distinguish the curve that it really makes; and that, if the appearance of a perpendicular thread, part of which is plunged in water, be closely attended to, it will not favour the common hypothesis. If the thread is of any shining metal, as silver, and viewed obliquely, the image of the part immersed will appear to detach itself sensibly from that part which is without the water, so that it cannot be true that every object appears to be in the same place where the refracted ray meets the perpendicular; and the same observation, he thinks, may be extended to the case of reflection. According to this writer, we refer every point of an object to the place from which the pencils of light, that give us the image of it, issue, or from which they would have issued if no reflecting or refracting substance intervened. Pursuing this principle, he proceeds to investigate the place in which the rays issuing from each of the points of an object, and which reach the eye after one reflection or refraction, meet; and he found, that if the refracting surface was plane, and the refraction was made from a denser medium into a rarer, those rays would always meet in a place between the eye and a perpendicular to the point of incidence. If a convex mirror be used, the case will be the same; but if the mirror be plane, the rays will meet in the perpendicular, and beyond it if it be con-

cave. He also determined, according to these principles, what form the image of a right line will take, when it is presented in different manners to a spherical mirror, or when it is seen through a refracting medium.

The appa-  
rent place,  
&c. of  
objects.

Probable as Dr Barlow thought the maxim which he endeavoured to establish, concerning the supposed place of visible objects, he has the candour to mention an objection to it, and to acknowledge that he was not able to give a satisfactory solution of it. It is this. Let an object be placed beyond the focus of a convex lens; and if the eye be close to the lens, it will appear confused, but very near to its true place. If the eye be a little withdrawn, the confusion will increase, and the object will seem to come nearer; and when the eye is very near the focus, the confusion will be exceedingly great, and the object will seem to be close to the eye. But in this experiment the eye receives no rays but those that are converging; and the point from which they issue is so far from being nearer than the object, that it is beyond it; notwithstanding which, the object is conceived to be much nearer than it is, though no very distinct idea can be formed of its precise distance. It may be observed, that in reality, the rays falling upon the eye in this case in a manner quite different from that in which they fall upon it in other circumstances, we can form no judgment about the place from which they issue. This subject was afterwards taken up by Berkeley, Smith, Montucla, and others.

211  
M. de la  
Hire's ob-  
servations.

M. de la Hire made several valuable observations concerning the distance of visible objects, and various other phenomena of vision, which are well worth our notice. He also took particular pains to ascertain the manner in which the eye conforms itself to the view of objects placed at different distances. He enumerates five circumstances, which assist us in judging of the distance of objects, namely, their apparent magnitude, the strength of the colouring, the direction of the two eyes, the parallax of the objects, and the distinctness of their small parts. Painters, he says, can only take advantage of the two first mentioned circumstances, and therefore pictures can never perfectly deceive the eye; but in the decorations of theatres, they, in some measure, make use of them all. The size of objects, and the strength of their colouring, are diminished in proportion to the distance at which they are intended to appear. Parts of the same object which are to appear at different distances, as columns in an order of architecture, are drawn upon different planes, a little removed from one another, that the two eyes may be obliged to change their direction, in order to distinguish the parts of the nearer plane from those of the more remote. The small distance of the planes serves to make a small parallax, by changing the position of the eye; and as we do not preserve a distinct idea of the quantity of parallax, corresponding to the different distances of objects, it is sufficient that we perceive there is a parallax, to be convinced that these planes are distant from one another, without determining what that distance is; and as to the last circumstance, viz. the distinctness of the small parts of objects, it is of no use in discovering the deception, on account of the false light that is thrown upon these decorations.

To these observations concerning deceptions of sight, we shall add a similar one of M. le Cat, who

took notice that the reason why we imagine objects to be larger when they are seen through a mist, is the dimness or obscurity with which they are then seen; this circumstance being associated with the idea of great distance. This he says is confirmed by our being surprised to find, upon approaching such objects, that they are so much nearer to us, as well as so much smaller than we had imagined.

Among other cases concerning vision, which fell under the consideration of M. de la Hire, he mentions one which is of difficult solution. It is when a candle, in a dark place, and situated beyond the limits of distinct vision, is viewed through a very narrow chink in a card; in which case a considerable number of candles, sometimes so many as six, will be seen along the chink. This appearance he attributes to small irregularities in the surface of the humours of the eye, the effect of which is not sensible when rays are admitted into the eye through the whole extent of the pupil, and consequently one principal image effaces a number of small ones; whereas, in this case, each of them is formed separately, and no one of them is so considerable as to prevent the others from being perceived at the same time.

There are few persons, M. de la Hire observes, who have both their eyes perfectly equal, not only with respect to the limits of distinct vision, but also with respect to the colour with which objects appear tinged when they are viewed by them, especially if one of the eyes has been exposed to the impression of a strong light. To compare them together in this respect, he directs us to take two thin cards, and to make in each of them a round hole of a third or a fourth of a line in diameter, and, applying one of them to each of the eyes, to look through the holes on a white paper, equally illuminated; when a circle of the paper will appear to each of the eyes, and, placing the cards properly, these two circles may be made to touch one another, and thereby the appearance of the same object to each of the eyes may be compared to the greatest advantage. To make this experiment with the greatest exactness, it is necessary, he says, that the eyes be kept shut some time before the cards be applied to them.

M. de la Hire first endeavoured to explain the cause of those dark spots which seem to float before the eyes, especially those of old people. They are most visible when the eyes are turned towards an uniform white object, as the snow in the open field. If they be fixed when the eye is so, this philosopher supposed that they were occasioned by extravasated blood upon the retina. But he thought that the moveable spots were occasioned by opaque matter floating in the aqueous humour of the eye. He thought the vitreous humour was not sufficiently limpid for this purpose.

By the following calculation, M. de la Hire gives us an idea of the extreme sensibility of the optic nerves. One may see very easily, at the distance of 4000 toises, the sail of a wind-mill, 6 feet in diameter; and the eye being supposed to be an inch in diameter, the picture of this sail, at the bottom of the eye, will be  $\frac{1}{8000}$  of an inch, which is less than the 666th part of a line, and is about the 66th part of a common hair, or the 8th part of a single thread of silk. So small, therefore, must one of the fibres of the optic nerve be, which he

says

Apparent place, &c. of objects. says is almost inconceivable, since each of these fibres is a tube that contains spirits. If birds perceive distant objects as well as men, which he thinks very probable, he observes that the fibres of their optic nerves must be much finer than ours.

213 Berkeley's account of the judgment formed concerning distance by confused vision. The person who first took much notice of Dr Barrow's hypothesis was the ingenious Dr Berkely, bishop of Cloyne, who distinguished himself so much by the objections which he started to the reality of a material world, and by his opposition to the Newtonian doctrine of fluxions. In his Essay towards a New Theory of Vision, he observes, that the circle formed upon the retina, by the rays which do not come to a focus, produce the same confusion in the eye, whether they cross one another before they reach the retina, or tend to do it afterwards; and therefore that the judgment concerning distance will be the same in both the cases, without any regard to the place from which the rays originally issued; so that in this case, as, by receding from the lens, the confusion, which always accompanies the nearness of an object, increases, the mind will judge that the object comes nearer.

214 Smith's account. But, says Dr Smith, if this be true, the object ought always to appear at a less distance from the eye than that at which objects are seen distinctly, which is not the case: and to explain this appearance, as well as every other in which a judgment is formed concerning distance, he maintains, that we judge of it by the apparent magnitude of objects only, or chiefly; so that, since the image grows larger as we recede from the lens through which it is viewed, we conceive the object to come nearer. He also endeavours to show, that, in all cases in which glasses are used, we judge of distance by the same simple rule; from which he concludes universally, that the apparent distance of an object seen in a glass is to its apparent distance seen by the naked eye as the apparent magnitude to the naked eye is to its apparent magnitude in the glass.

215 Objected to by Mr Robins. But that we do not judge of distance merely by the angle under which objects are seen, is an observation as old as Alhazen, who mentions several instances, in which, though the angles under which objects appear be different, the magnitudes are universally and instantaneously deemed not to be so. And Mr Robins clearly shows the hypothesis of Dr Smith to be contrary to fact in the most common and simple cases. In microscopes, he says, it is impossible that the eye should judge the object to be nearer than the distance at which it has viewed the object itself, in proportion to the degree of magnifying. For when the microscope magnifies much, this rule would place the image at a distance, of which the sight cannot possibly form any opinion, as being an interval from the eye at which no object can be seen. In general, he says, he believes, that whoever looks at an object through a convex glass, and then at the object itself without the glass, will find it to appear nearer in the latter case, though it be magnified in the glass; and in the same trial with the concave glass, though by the glass the object be diminished, it will appear nearer through the glass than without it.

But the most convincing proof that the apparent distance of the image is not determined by its apparent magnitude, is the following experiment. If a double convex glass be held upright before some luminous

object, as a candle, there will be seen two images, one erect, and the other inverted. The first is made simply by reflection from the nearest surface, the second by reflection from the farther surface, the rays undergoing a refraction from the first surface both before and after the reflection. If this glass has not too short a focal distance, when it is held near the object, the inverted image will appear larger than the other, and also nearer; but if the glass be carried off from the object, though the eye remain as near to it as before, the inverted image will diminish so much faster than the other, that, at length, it will appear very much less than it, but still nearer. Here, says Mr Robins, two images of the same object are seen under one view, and their apparent distances immediately compared; and here it is evident, that those distances have no necessary connection with the apparent magnitude. He also shows how this experiment may be made still more convincing, by sticking a piece of paper on the middle of the lens, and viewing it through a short tube.

M. Bouguer adopts the general maxim of Dr Barrow, in supposing that we refer objects to the place from which the pencils of rays seemingly converge at their entrance into the pupil. But when rays issue from below the surface of a vessel of water, or any other refracting medium, he finds that there are always two different places of this seeming convergence; one of them of the rays that issue from it in the same vertical circle, and therefore fall with different degrees of obliquity upon the surface of the refracting medium; and another, of those that fall upon the surface with the same degree of obliquity, entering the eye laterally with respect to one another. Sometimes, he says, one of these images is attended to by the mind, and sometimes the other, and different images may be observed by different persons. An object plunged in water affords an example, he says, of this duplicity of images.

If BA b (fig. 1.) be part of the surface of water, and the object be at O, there will be two images of it in two different places; one at G, on the caustic by refraction, and the other at E, in the perpendicular AO, which is as much a caustic as the other line. The former image is visible by the rays ODM, O dm, which are one higher than the other, in their progress to the eye: whereas the image at E is made by the rays ODM, O ef, which enter the eye laterally. This, says he, may serve to explain the difficulty of Father Tacquet, Barrow, Smith, and many other authors, and which Newton himself considered as a very difficult problem, though it might not be absolutely insoluble.

G. W. Kraft has ably supported the opinion of Dr Barrow, that the place of any point, seen by reflection from the surface of any medium, is that in which rays issuing from it, infinitely near to one another, would meet; and considering the case of a distant object, viewed in a concave mirror, by an eye very near to it, when the image, according to Euclid and other writers, would be between the eye and the object, and the rule of Dr Barrow cannot be applied; he says that in this case the speculum may be considered as a plane, the effect being the same, only the image is more obscure.

Apparent place, &c. of objects.

of objects.

217  
Dr Porter-  
field's view  
of this sub-  
ject.

Dr Porterfield gives a distinct and comprehensive view of the natural methods of judging concerning the distance of objects.

The conformation of the eye, he observes, can be of no use to us with respect to objects that are placed without the limits of distinct vision. As the object, however, does then appear more or less confused, according as it is more or less removed from those limits, this confusion afflicts the mind in judging of the distance of the object; it being always esteemed so much the nearer, or the farther off, by how much the confusion is greater. But this confusion hath its limits, also, beyond which it can never extend; for when an object is placed at a certain distance from the eye, to which the breadth of the pupil bears no sensible proportion, the rays of light that come from a point in the object, and pass the pupil, are so little diverging that they may be considered as parallel. For a picture on the retina will not be sensibly more confused, though the object be removed to a much greater distance.

The most universal, and frequently the most sure means of judging of the distance of objects is, he says, the angle made by the optic axis. For our two eyes are like two different stations, by the assistance of which distances are taken; and this is the reason why those persons who are blind of one eye, so frequently miss their mark in pouring liquor into a glass, snuffing a candle, and such other actions as require that the distance be exactly distinguished. To convince ourselves of the usefulness of this method of judging of the distance of objects, he directs us to suspend a ring in a thread, so that its side may be towards us, and the hole in it to the right and left hand; and taking a small rod, crooked at the end, retire from the ring two or three paces, and having with one hand covered one of our eyes, to endeavour with the other to pass the crooked end of the rod through the ring. This, says he, appears very easy; and yet, upon trial, perhaps once in 100 times we shall not succeed, especially if we move the rod a little quickly.

Our author observes, that by persons recollecting the time when they began to be subject to the mistakes abovementioned, they may tell when it was that they lost the use of one of their eyes; which many persons are long ignorant of, and which may be a circumstance of some consequence to a physician\*. The use of this second method of judging of distances De Chales limited to 120 feet; beyond which, he says, we are not sensible of any difference in the angle of the optic axis.

A third method of judging of the distance of objects, consists in their apparent magnitudes, on which so much stress was laid by Dr Smith. From this change in the magnitude of the image upon the retina, we easily judge of the distance of objects, as often as we are otherwise acquainted with the magnitude of the objects themselves; but as often as we are ignorant of the real magnitude of bodies, we can never, from their apparent magnitude, form any judgment of their distance.

From this we may see why we are so frequently deceived in our estimates of distance, by any extraordinary magnitudes of objects seen at the end of it; as, in travelling towards a large city, or a castle, or a cathedral church, or a mountain larger than ordinary,

we fancy them to be nearer than we find them to be. This also is the reason why animals, and all small objects, seen in valleys, contiguous to large mountains, appear exceedingly small. For we think the mountain nearer to us than if it were smaller; and we should not be surprized at the smallness of the neighbouring animals, if we thought them farther off. For the same reason, we think them exceedingly small, when they are placed upon the top of a mountain, or a large building; which appear nearer to us than they really are, on account of their extraordinary size.

Dr Jurin clearly accounts for our imagining objects, when seen from a high building, to be smaller than they are, and smaller than we fancy them to be when we view them at the same distance on level ground. It is, says he, because we have no distinct idea of distance in that direction, and therefore judge of things by their pictures upon the eye only; but custom will enable us to judge rightly even in this case.

Let a boy, says he, who has never been upon any high building, go to the top of the monument, and look down into the street; the object seen there, as men and horses, will appear so small as greatly to surprise him. But 10 or 20 years after, if in the mean time he has used himself now and then to look down from that and other great heights, he will no longer find the same objects to appear so small. And if he was to view the same objects from such heights as frequently as he sees them upon the same level with himself in the streets, he supposes that they would appear to him just of the same magnitude from the top of the monument, as they do from a window one story high. For this reason it is, that statues placed upon very high buildings ought to be made of a larger size than those which are seen at a nearer distance; because all persons, except architects, are apt to imagine the height of such buildings to be much less than it really is.

The fourth method by which Dr Porterfield says that we judge of the distance of objects, is the force with which their colour strikes upon our eyes. For if we be assured that two objects are of a similar and like colour, and that one appears more bright and lively than the other, we judge that the brighter object is the nearer of the two.

The fifth method consists in the different appearance of the small parts of objects. When these parts appear distinct, we judge that the object is near; but when they appear confused, or when they do not appear at all, we judge that it is at a greater distance. For the image of any object, or part of an object, diminishes as the distance of it increases.

The sixth and last method by which we judge of the distance of objects is, that the eye does not represent to our mind one object alone, but at the same time all those that are placed betwixt us and the principal object, whose distance we are considering; and the more this distance is divided into separate and distinct parts, the greater it appears to be. For this reason, distances upon uneven surfaces appear less than upon a plane: for the inequalities of the surfaces, such as hills, and holes, and rivers, that lie low and out of sight either do not appear, or hinder the parts that lie behind them from appearing; and so the whole apparent distance is diminished by the parts that do not

acies of vi-  
sion ex-  
plained.

not appear in it. This is the reason that the banks of a river appear contiguous to a distant eye, when the river is low and not seen.

Dr Porterfield very well explains several fallacies in vision depending upon our mistaking the distances of objects. Of this kind, he says, is the appearance of parallel lines, and long vistas consisting of parallel rows of trees; for they seem to converge more and more as they are farther extended from the eye. The reason of this, he says, is because the apparent magnitudes of their perpendicular intervals are perpetually diminishing, while, at the same time, we mistake their distance. Hence we may see why, when two parallel rows of trees stand upon an ascent, whereby the more remote parts appear farther off than they really are, because the line that measures the length of the vistas now appears under a greater angle than when it was horizontal, the trees, in such a case, will seem to converge less, and sometimes, instead of converging, they will be thought to diverge.

For the same reason that a long vista appears to converge more and more the farther it is extended from the eye, the remoter parts of a horizontal walk or a long floor will appear to ascend gradually; and objects placed upon it, the more remote they are the higher they will appear, till the last be seen on a level with the eye; whereas the ceiling of a long gallery appears to descend towards a horizontal line, drawn from the eye of the spectator. For this reason, also, the surface of the sea, seen from an eminence, seems to rise higher and higher the farther we look; and the upper parts of high buildings seem to stoop, or incline forwards over the eye below, because they seem to approach towards a vertical line proceeding from the spectator's eye; so that statues on the top of such buildings, in order to appear upright, must recline, or bend backwards.

Our author also shows the reason why a windmill, seen from a great distance, is sometimes imagined to move the contrary way from what it really does, by our taking the nearer end of the sail for the more remote. The uncertainty we sometimes find in the course of the motion of a branch of lighted candles, turned round at a distance, is owing, he says, to the same cause; as also our sometimes mistaking a convex for a concave surface, more especially in viewing seals and impressions with a convex glass or a double microscope; and lastly, that, upon coming in a dark night into a street, in which there is but one row of lamps, we often mistake the side of the street they are on.

Far more light was thrown upon this curious subject by M. Bouguer.

220  
Great light  
thrown up-  
on this sub-  
ject by M.  
Bouguer.

The proper method of drawing the appearance of two rows of trees that shall appear parallel to the eye, is a problem which has exercised the ingenuity of several philosophers and mathematicians. That the apparent magnitude of objects decreases with the angle under which they are seen, has always been acknowledged. It is also acknowledged, that it is only by custom and experience that we learn to form a judgment both of magnitudes and distances. But in the application of these maxims to the abovementioned problem, all persons, before M. Bouguer, made use of the real distance instead of the apparent one; by

which only the mind can form its judgment. And it is manifest, that, if any circumstances contribute to make the distance appear otherwise than it is in reality, the apparent magnitude of the object will be affected by it; for the same reason, that, if the magnitude be misapprehended, the idea of the distance will vary.

For want of attending to this distinction, Tacquet pretended to demonstrate, that nothing can give the idea of two parallel lines (rows of trees for instance) to an eye situated at one of their extremities, but two hyperbolical curves, turned the contrary way; and M. Varignon maintained, that in order to make a vista appear of the same width, it must be made narrower, instead of wider, as it recedes from the eye.

M. Bouguer observes, that very great distances, and those that are considerably less than they, make nearly the same impression upon the eye. We, therefore, always imagine great distances to be less than they are; and for this reason the ground plan of a long vista always appears to rise. The visual rays come in a determinate direction; but as we imagine that they terminate sooner than they do, we necessarily conceive that the place from which they issue is elevated. Every large plane, therefore, as AB (fig. 2.) viewed by an eye at O, will seem to lie in such a direction as *Ab*; and consequently lines, in order to appear truly parallel on the plane AB, must be drawn so as that they would appear parallel on the plane *Ab*, and be from thence projected to the plane AB.

To determine the inclination of the apparent ground-plan *Ab* to the true ground-plan AB, our ingenious author directs us to draw upon a piece of level ground two straight lines of a sufficient length (for which purpose lines fastened to small sticks are very convenient), making an angle of 3 or 4 degrees with one another. Then a person, placing himself within the angle, with his back towards the angular point, must walk backwards and forwards till he can fancy the lines to be parallel. In this situation, a line drawn from the point of the angle through the place of his eye, will contain the same angle with the true ground-plan which this does with the apparent one.

M. Bouguer then shows other more geometrical methods of determining this inclination; and says, that by these means he has often found it to be 4 or 5 degrees, though sometimes only 2 or 2½ degrees. The determination of this angle, he observes, is variable; depending upon the manner in which the ground is illuminated and the intensity of the light. The colour of the soil is also not without its influence, as well as the particular conformation of the eye, by which it is more or less affected by the same degree of light, and also the part of the eye on which the object is painted. When, by a slight motion of his head, he contrived, that certain parts of the soil, the image of which fell towards the bottom of his eye, should fall towards the top of the retina, he always thought that this apparent inclination became a little greater.

But what is very remarkable, and what he says he can assure his reader may be depended upon, is, that if he look towards a rising ground, the difference between the apparent ground-plan and the true one will be much more considerable, so that they will sometimes make an angle of 25 or 30 degrees. Of this he

had made frequent observations. Mountains, he says, begin to be inaccessible when their sides make an angle from 35 to 37 degrees with the horizon, as then it is not possible to climb them but by means of stones or shrubs, to serve as steps to fix the feet on. In these cases, both he and his companions always agreed that the apparent inclination of the side of the mountain was 60 or 70 degrees.

These deceptions are represented in fig. 3. in which, when the ground plan AM, or AN, are much inclined, the apparent ground-plan Am, or An, makes a very large angle with it. On the contrary, if the ground dips below the level, the inclination of the apparent to the true ground-plan diminishes, till, at a certain degree of the slope, it becomes nothing at all; the two plans AP and Ap being the same, so that parallel lines drawn upon them would always appear so. If the inclination below the horizon is carried beyond the situation AP, the error will encrease; and what is very remarkable, it will be on the contrary side; the apparent plan Ar being always below the true plan AR, so that if a person would draw upon the plan AR lines that shall appear parallel to the eye, they must be drawn converging, and not diverging, as is usual on the level ground; because they must be the projections of two lines imagined to be parallel, on the plan Ar, which is more inclined to the horizon than AR.

These remarks, he observes, are applicable to different planes exposed to the eye at the same time. For if BH, fig. 4. be the front of a building, at the distance of AB from the eye, it will be reduced in appearance to the distance Ab; and the front of the building will be bb, rather inclined towards the spectator, unless the distance be inconsiderable.

After making a great number of observations upon this subject, our author concludes, that when a man stands upon a level plane, it does not seem to rise sensibly but at some distance from him. The apparent plane, therefore, has a curvature in it, at that distance, the form of which is not very easy to determine; so that a man standing upon a level plane, of infinite extent, will imagine that he stands in the centre of a basin. This is also, in some measure, the case with a person standing upon the level of the sea.

He concludes with observing, that there is no difficulty in drawing lines according to these rules, so as to have any given effect upon the eye, except when some parts of the prospect are very near the spectator, and others very distant from him; because, in this case, regard must be had to the conical or conoidal figure of a surface. A right line passing at a small distance from the observer, and below the level of his eye, in that case almost always appears sensibly curved at a certain distance from the eye; and almost all figures in this case are subject to some complicated optical alteration to which the rules of perspective have not as yet been extended. If a circle be drawn near our feet, and within that part of the ground which appears level to us, it will always appear to be a circle, and at a very considerable distance it will appear an ellipse; but between these two situations, it will not appear to be either the one or the other, but will be like one of those ovals of Descartes, which is more curved on one of its sides than the other.

On these principles a parterre, which appears dis-

torted when it is seen in a low situation, appears perfectly regular when it is viewed from a balcony or any other eminence. Still, however, the apparent irregularity takes place at a greater distance, while the part that is near the spectator is exempt from it. If AB, fig. 5. be the ground plane, and Aa be a perpendicular, under the eye, the higher it is situated, at O, to the greater distance will T, the place at which the plane begins to have an apparent ascent along Tb, be removed.

All the varieties that can occur with respect to the visible motion of objects, are thus succinctly summed up by Dr Porterfield under eleven heads.

1. An object moving very swiftly is not seen, unless it be very luminous. Thus a cannon-ball is not seen if it is viewed transversely: but if it be viewed according to the line it describes, it may be seen, because its picture continues long on the same place of the retina; which, therefore, receives a more sensible impression from the object.

2. A live coal swung briskly round in a circle appears a continued circle of fire, because the impressions made on the retina by light, being of a vibrating, and consequently of a lasting nature, do not presently perish, but continue till the coal performs its whole circuit, and returns again to its former place.

3. If two objects, unequally distant from the eye, move with equal velocity, the more remote one will appear the slower; or, if their celerities be proportional to their distances, they will appear equally swift.

4. If two objects, unequally distant from the eye, move with unequal velocities in the same direction, their apparent velocities are in a ratio compounded of the direct ratio of their true velocities, and the reciprocal one of their distances from the eye.

5. A visible object moving with any velocity appears to be at rest, if the space described in the interval of one second be imperceptible at the distance of the eye. Hence it is that a near object moving very slowly, as the index of a clock, or a remote one very swiftly, as a planet, seems to be at rest.

6. An object moving with any degree of velocity will appear at rest, if the space it runs over in a second of time be to its distance from the eye as 1 to 1400.

7. The eye proceeding straight from one place to another, a lateral object, not too far off, whether on the right or left, will seem to move the contrary way.

8. The eye proceeding straight from one place to another, and being sensible of its motion, distant objects will seem to move the same way, and with the same velocity. Thus, to a person running eastwards, the moon on his right hand appears to move the same way, and with equal swiftness; for, by reason of its distance, its image continues fixed upon the same place of the retina, from whence we imagine that the object moves along with the eye.

9. If the eye and the object move both the same way, only the eye much swifter than the object, the last will appear to go backwards.

10. If two or more objects move with the same velocity, and a third remain at rest, the moveable ones will appear fixed, and the quiescent in motion the contrary

Apparent  
place, &c.  
of objects.

contrary way. Thus clouds moving very swiftly, their parts seem to preserve their situation, and the moon to move the contrary way.

11. If the eye be moved with great velocity, lateral objects at rest appear to move the contrary way. Thus to a person sitting in a couch, and riding briskly through a wood, the trees seem to retire the contrary way; and to people in a ship, &c. the shores seem to recede.

221  
Dr Porter-  
field's ac-  
count of  
objects ap-  
pearing to  
move to a  
giddy per-  
son when  
he and they  
are both at  
rest.

At the conclusion of these observations, our author endeavours to explain another phenomenon of motion, which, though very common and well known, had not, as far as he knew, been explained in a satisfactory manner. It is this: If a person turns swiftly round, without changing his place, all objects about will seem to move round in a circle the contrary way; and this deception continues not only while the person himself moves round, but, which is more surprising, it also continues for some time after he ceases to move, when the eye, as well as the object, is at absolute rest.

The reason why objects appear to move round the contrary way, when the eye turns round, is not so difficult to explain: for though, properly speaking, motion is not seen, as not being in itself the immediate object of sight; yet by the sight we easily know when the image changes its place on the retina, and thence conclude that either the object, the eye, or both, are moved. But by the sight alone we can never determine how far this motion belongs to the object, how far to the eye, or how far to both. If we imagine the eye at rest, we ascribe the whole motion to the object, though it be truly at rest. If we imagine the object at rest, we ascribe the whole motion to the eye, though it belongs entirely to the object; and when the eye is in motion, though we are sensible of its motion, yet, if we do not imagine that it move so swiftly as it really does, we ascribe only a part of the motion to the eye, and the rest of it we ascribe to the object, though it be truly at rest. This last, he says, is what happens in the present case, when the eye turns round; for though we are sensible of the motion of the eye, yet we do not apprehend that it moves so fast as it really does; and therefore the bodies about appear to move the contrary way, as is agreeable to experience.

But the great difficulty still remains, viz. Why, after the eye ceases to move, objects should, for some time, still appear to continue in motion, though their pictures on the retina be truly at rest, and do not at all change their place. This, he imagined, proceeds from a mistake we are in with respect to the eye, which, though it be absolutely at rest, we nevertheless conceive as moving the contrary way to that in which it moved before; from which mistake, with respect to the motion of the eye, the objects at rest will appear to move the same way which the eye is imagined to move; and, consequently, will seem to continue their motion for some time after the eye is at rest.

222  
Dr Wells  
accounts  
for this phe-  
nomenon.

This is ingenious, but perhaps not just. An account of this matter, which seems to us more satisfactory, has been lately given to the public by Dr Wells. "Some of the older writers upon optics (says this able philosopher) imagined the vivise spirits to be contained in the head, as water is in a

vessel; which, therefore, when once put in motion by the rotation of our bodies, must continue in it for some time after this has ceased; and to this real circular movement of the vivise spirits, while the body is at rest, they attributed the apparent motions of objects in giddiness. Dechalefs saw the weakness of this hypothesis; and conjectured, that the phenomenon might be owing to a real movement of the eyes; but produced no fact in proof of his opinion. Dr Porterfield, on the contrary, supposed the difficulty of explaining it to consist in showing, why objects at rest appear in motion to an eye which is also at rest. The solution he offered of this representation of the phenomenon, is not only extremely ingenious, but is I believe the only probable one which can be given. It does not apply, however, to the fact which truly exists; for I shall immediately show, that the eye is not at rest, as he imagined. The last author I know of who has touched upon this subject is Dr Darwin. His words are, 'When any one turns round rapidly on one foot till he becomes dizzy, and falls upon the ground, the spectra of the ambient objects continue to present themselves in rotation, or appear to liberate, and he seems to behold them for some time in motion.' I do not indeed pretend to understand his opinion fully; but this much seems clear, that if such an apparent motion of the surrounding objects depends in any way upon their spectra, or the illusive representations of those objects, occasioned by their former impressions upon the retinas, no similar motion would be observed, were we to turn ourselves round with our eyes shut, and not to open them till we became giddy; for in this case, as the surrounding objects could not send their pictures to the retinas, there would consequently be no spectra to present themselves afterward in rotation. But whoever will make the experiment, will find, that objects about him appear to be equally in motion when he has become giddy by turning himself round, whether this has been done with his eyes open or shut. I shall now venture to propose my own opinion upon this subject.

"If the eye be at rest, we judge an object to be in motion when its picture falls in succeeding times upon different parts of the retina; and if the eye be in motion, we judge an object to be at rest, as long as the change of the place of its picture upon the retina holds a certain correspondence with the change of the eye's position. Let us now suppose the eye to be in motion, while, from some disorder in the system of sensation, we are either without those feelings which indicate the various positions of the eye, or are not able to attend to them. It is evident, that in such a state of things an object at rest must appear to be in motion, since it sends in succeeding times its picture to different parts of the retina. And this seems to be what happens in giddiness. I was first led to think so from observing, that, during a slight fit of giddiness I was accidentally seized with, a coloured spot, occasioned by looking steadily at a luminous body, and upon which I happened at that moment to be making an experiment, was moved in a manner altogether independent of the positions I conceived my eyes to possess. To determine this point, I again produced the spot, by looking some time at the flame of a candle: then turning myself round till I became giddy, I suddenly discontinued this motion, and directed my eyes to

to the middle of a sheet of paper, fixed upon the wall of my chamber. The spot now appeared upon the paper, but only for a moment; for it immediately after seemed to move to one side, and the paper to the other, notwithstanding I conceived the position of my eyes to be in the mean while unchanged. To go on with the experiment, when the paper and spot had proceeded to a certain distance from each other, they suddenly came together again; and this separation and conjunction were alternately repeated a number of times, the limits of the separation gradually becoming less, till at length the paper and spot both appeared to be at rest, and the latter to be projected upon the middle of the former. I found also, upon repeating and varying the experiment a little, that when I had turned myself from left to right, the paper moved from right to left, and the spot consequently the contrary way; but that when I had turned from right to left, the paper would then move from left to right. These were the appearances observed while I stood erect. When I inclined, however, my head in such a manner as to bring the side of my face parallel to the horizon, the spot and paper would then move from each other, one upward and the other downward. But all these phenomena demonstrate, that there was a real motion in my eyes at the time I imagined them to be at rest; for the apparent situation of the spot, with respect to the paper, could not possibly have been altered, without a real change of the position of those organs. To have the same thing proved in another way, I desired a person to turn quickly round, till he became very giddy; then to stop himself, and look steadfastly at me. He did so, and I could plainly see, that although he thought his eyes were fixed, they were in reality moving in their sockets, first toward one side and then toward the other."

225  
A remark-  
able decep-  
tion ex-  
plained by  
M. le Cat.  
Plate  
CCCLXI.

M. Le Cat well explains a remarkable deception, by which a person shall imagine an object to be on the opposite side of a board, when it is not so, and also inverted and magnified. It is illustrated by fig. 6. in which D represents the eye, and CB a large black board, pierced with a small hole. E is a large white board, placed beyond it, and strongly illuminated; and *d* a pin, or other small object, held betwixt the eye and the first board. In these circumstances, the pin shall be imagined to be at F, on the other side of the board, where it will appear inverted and magnified; because what is in fact perceived, is the shadow of the pin upon the retina; and the light that is stopped by the upper part of the pin coming from the lower part of the enlightened board, and that which is stopped by the lower part coming from the upper part of the board, the shadow must necessarily be inverted with respect to the object.

There is a curious phenomenon relating to vision, which some persons have ascribed to the inflection of light, but which Mr Melville explains in a very different and very simple manner.

226  
A curious  
phenomenon  
explained by  
Mr Melville.

When any opaque body is held at the distance of three or four inches from the eye, so that a part of some more distant luminous object, such as the window, or the flame of a candle, may be seen by rays passing near its edge, if another opaque body, nearer to the eye, be brought across from the opposite side, the edge of the first body will seem to swell out-

wards, and meet the latter; and in doing so will intercept a portion of the luminous object that was seen before.

This appearance he explains in the following manner: Let AB (fig. 7.) represent the luminous object to which the sight is directed, CD the more distant opaque body, GH the nearer, and EF the diameter of the pupil. Join ED, FD, EG, FG, and produce them till they meet AB in K, N, M, and L. It is plain that the parts AN, MB, of the luminous object cannot be seen. But taking any point *a* between N and K, and drawing *aDd*, since the portion *dF* of the pupil is filled with light flowing from that point, it must be visible. Any point *b*, between *a* and K, must fill *fF*, a great proportion of the pupil, and therefore must appear brighter. Again, any point *c*, between *b* and K, must appear brighter than *b*, because it fills a greater portion *gF* with light. The point K itself, and every other point in the space KL, must appear very luminous, since they send entire pencils of rays EKF, ELF, to the eye; and the visible brightness of every point from L towards M, must decrease gradually, as from K to N; that is, the spaces KN, LM, will appear as dim shadowy borders, or fringes, adjacent to the edges of the opaque bodies.

When the edge G is brought to touch the right line KF, the penumbras unite; and as soon as it reaches NDF, the above phenomenon begins; for it cannot pass that right line without meeting some line *aDd*, drawn from a point between N and K, and, by intercepting all the rays that fall upon the pupil, render it invisible. In advancing gradually to the line KDE, it will meet other lines *bDd*, *cDd*, &c. and therefore render the points *b*, *c*, &c. from N to K, successively invisible; and therefore the edge of the fixed opaque body CD must seem to swell outwards, and cover the whole space NK; while GH, by its motion, covers MK. When GH is placed at a greater distance from the eye, CD continuing fixed, the space OP to be passed over in order to intercept NK is less; and therefore, with an equal motion of GH, the apparent swelling of CD must be quicker; which is found true by experience.

If ML represent a luminous object, and REFQ any plane exposed to its light, the space FQ will be entirely waded from the rays, and the space FE will be occupied by a penumbra, gradually darker, from E to F. Let now GH continue fixed, and CD move parallel to the plane EF; and as soon as it passes the line LF, it is evident that the shadow QF will seem to swell outwards; and when CD reaches ME, so as to cover with its shadow the space RE, QF, by its extension, will cover FE. This is found to hold true likewise by experiment.

#### § 4. Of the Concave Figure of the Sky.

THIS apparent concavity is only an optical deception founded on the incapacity of our organs of vision to take in very large distances.—Dr Smith, in his Complete System of Optics, hath demonstrated, that, if the surface of the earth was perfectly plane, the distance of the visible horizon from the eye would scarce exceed the distance of 5000 times the height of the eye above the ground, supposing the height of the eye between five and six feet: beyond this distance, all

surface.

Concavity  
of the Sky

Plate  
CCCLXI.  
fig. 8.

all objects would appear in the visible horizon. For, let OP be the height of the eye above the line PA drawn upon the ground; and if an object AB, equal in height to PO, be removed to a distance PA equal to 5000 times that height, it will hardly be visible by reason of the smallness of the angle AOB. Consequently any distance AC, how great soever, beyond A, will be invisible. For since AC and BO are parallel, the ray CO will always cut AB in some point D between A and B; and therefore the angle AOC or AOD, will always be less than AOB, and therefore AD or AC will be invisible. Consequently all objects and clouds, as CE and FG, placed at all distances beyond A, if they be high enough to be visible, or to subtend a bigger angle at the eye than AOB, will appear at the horizon AB; because the distance AC is invisible.

228  
Why a long  
row of ob-  
jects ap-  
pears circu-  
lar.

Hence, if we suppose a vast long row of objects; or a vast long wall ABZY (fig. 9.), built upon this plane, and its perpendicular distance OA from the eye at O to be equal to or greater than the distance OA of the visible horizon, it will not appear straight, but circular, as if it was built upon the circumference of the horizon *ac egy*; and if the wall be continued to an immense distance, its extreme parts YZ will appear in the horizon at *yz*, where it is cut by a line Oy parallel to the wall. For, supposing a ray YO, the angle YOy will become insensibly small. Imagine this infinite plane OAYy, with the wall upon it, to be turned about the horizontal line O like the lid of a box, till it becomes perpendicular to the other half of the horizontal plane LM<sub>y</sub>, and the wall parallel to it, like a vast ceiling over head; and then the wall will appear like the concave figure of the clouds overhead. But though the wall in the horizon appear in the figure of a semicircle, yet the ceiling will not, but much flatter. Because the horizontal plane was a visible surface, which suggested the idea of the same distances quite round the eye: but in the verticle plane extended between the eye and the ceiling, there is nothing that affects the sense with an idea of its parts but the common line Oy; consequently the apparent distances of the higher parts of the ceiling will be gradually diminished in ascending from that line. Now when the sky is quite overcast with clouds of equal gravities, they will all float in the air at equal heights above the earth, and consequently will compose a surface resembling a large ceiling, as flat as the visible surface of the earth. Its concavity therefore is not real, but apparent: and when the heights of the clouds are unequal, since their real shapes and magnitudes are all unknown, the eye can seldom distinguish the unequal distances of those clouds that appear in the same directions, unless when they are very near us, or are driven by contrary currents of the air. So that the visible shape of the whole surface remains alike in both cases. And when the sky is either partly overcast, or partly free from clouds, it is matter of fact that we retain much the same idea of its concavity as when it was quite overcast.

229  
Why the  
concavity  
of the sky  
appears less  
than a he-  
misphere.

The concavity of the heavens appears to the eye, which is the only judge of an apparent figure, to be a less portion of a spherical surface than a hemisphere. Dr Smith says, that the centre of the concavity is much below the eye; and by taking a medium among

several observations, he found the apparent distance of its parts at the horizon to be generally between three and four times greater than the apparent distance of its parts overhead. For let the arch ABCD represent the apparent concavity of the sky, O the place of the eye, OA and OC the horizontal and vertical apparent distances, whose proportion is required. First observe when the sun or the moon, or any cloud or star, is in such a position at B, that the apparent arches BA, BC, extended on each side of this object towards the horizon and zenith, seem equal to the eye; then taking the altitude of the object B with a quadrant, or a cross-staff, or finding it by astronomy from the given time of observation, the angle AOB is known. Drawing therefore the line OB in the position thus determined, and taking in it any point B at pleasure, in the vertical line CO produced downwards, seek the centre E of the circle ABC, whose arches BA, BC, intercepted between B and the legs of the right angle AOC, shall be equal to each other; then will this arch ABCD represent the apparent figure of the sky. For by the eye we estimate the distance between any two objects in the heavens by the quantity of sky that appears to lie between them; as upon earth we estimate it by the quantity of ground that lies between them. The centre E may be found geometrically by constructing a cubic equation, or as quickly and sufficiently exact by trying whether the chords BA, BC, of the arch ABC drawn by conjecture are equal, and by altering its radius BE till they are so. Now in making several observations upon the sun, and some others upon the moon and stars, they seemed to our author to bisect the verticle arch ABC at B, when their apparent altitudes or the angle AOB was about 23 degrees; which gives the proportion of OC to OA as 3 to 10 or as 1 to 3 $\frac{1}{3}$  nearly. When the sun was but 30 degrees high, the upper arch seemed always less than the under one; and, in our author's opinion, always greater when the sun was about 18 or 20 degrees high.

#### § 5. Of the Blue Colour of the Sky, and of Blue and Green Shadows.

THE opinions of ancient writers concerning the colour of the sky merit no notice. The first who gave any rational explanation was Fromondus. By him it was supposed, that the blueness of the sky proceeded from a mixture of the white light of the sun with the black space beyond the atmosphere, where there is neither refraction nor reflection. This opinion prevailed very generally even in modern times, and was maintained by Otto Guericke and all his contemporaries, who asserted that white and black may be mixed in such a manner as to make a blue. M. Bouguer had recourse to the vapours diffused through the atmosphere, to account for the reflection of the blue rays rather than any other. He seems however to suppose, that it arises from the constitution of the air itself, whereby the fainter coloured rays are incapable of making their way through any considerable tract of it. Hence he is of opinion, that the colour of the air is properly blue; to which opinion Dr Smith seems also to have inclined.

To this blue colour of the sky is owing the appearance of blue and green shadows in the mornings and evenings.

explanation.

evenings.—These were first taken notice of by M. Buffon in the month of July 1742, when he observed that the shadows of trees which fell upon a white wall were green. He was at that time standing upon an eminence, and the sun was setting in the cleft of a mountain, so that he appeared considerably lower than the horizon. The sky was clear, excepting in the west, which, though free from clouds, was lightly shaded with vapours, of a yellow colour, inclining to red. Then the sun itself was exceedingly red, and was seemingly at least four times as large as he appears to be at mid-day. In these circumstances, he saw very distinctly the shadows of the trees, which were 30 or 40 feet from the white wall, coloured with a light green, inclining to blue. The shadow of an arbour, which was three feet from the wall, was exactly drawn upon it, and looked as if it had been newly painted with verdegriſe. This appearance lasted near five minutes; after which it grew fainter, and vanished at the same time with the light of the sun.

The next morning, at sunrise, he went to observe other shadows, upon another white wall; but instead of finding them green, as he expected, he observed that they were blue, or rather of the colour of lively indigo. The sky was serene, except a slight covering of yellowish vapours in the east; and the sun arose behind a hill, so that it was elevated above his horizon. In these circumstances, the blue shadows were only visible three minutes; after which they appeared black, and in the evening of the same day he observed the green shadows exactly as before. Six days passed without his being able to repeat his observations, on account of the clouds; but the 7th day, at sunset, the shadows were not green, but of a beautiful sky-blue. He also observed, that the sky was in a great measure free from vapours at that time; and that the sun set behind a rock, so that it disappeared before it came to his horizon. Afterwards he often observed the shadows both at sunrise and sunset; but always observed them to be blue, though with a great variety of shades of that colour. He showed this phenomenon to many of his friends, who were as much surprised at it as he himself had been; but he says that any person may see a blue shadow, if he will only hold his finger before a piece of white paper at sunrise or sunset.

The first person who attempted to explain this phenomenon was the Abbé Mazeas, in a memoir of the society in Berlin for the year 1752. He observed, that when an opaque body was illuminated by the moon and a candle at the same time, and the two shadows were cast upon the same white wall, that which was enlightened by the candle was reddish, and that which was enlightened by the moon was blue. But, without attending to any other circumstances, he supposed the change of colour to be occasioned by the diminution of the light; but M. Melville, and M. Bouguer, both independent of one another, seem to have hit upon the true cause of this curious appearance, and which hath been already hinted at. The former of these gentlemen, in his attempts to explain the blue colour of the sky, observes, that since it is certain that no body assumes any particular colour, but because it reflects one sort of rays more abundantly

than the rest; and since it cannot be supposed that the constituent parts of pure air are gross enough to separate any colours of themselves; we must conclude with Sir Isaac Newton, that the violet and blue making rays are reflected more copiously than the rest, by the finer vapours diffused through the atmosphere, whose parts are not big enough to give them the appearance of visible opaque clouds. And he shows, that in proper circumstances, the bluish colour of the sky-light may be actually seen on bodies illuminated by it, as, he says, it is objected should always happen upon this hypothesis. For that if, on a clear cloudless day, a sheet of white paper be exposed to the sun's beams, when any opaque body is placed upon it, the shadow which is illuminated by the sky only will appear remarkably bluish compared with the rest of the paper, which receives the sun's direct rays.

M. Bouguer, who has taken the most pains with this subject, observes, that as M. Buffon mentions the shadows appearing green only twice, and that at all other times they were blue, this is the colour which they regularly have, and that the blue was changed into green by some accidental circumstance. Green, he says, is only a composition of blue and yellow, so that this accidental change may have arisen from the mixture of some yellow rays in the blue shadow; and that perhaps the wall might have had that tinge, so that the blue is the only colour for which a general reason is required. And this, he says, must be derived from the colour of pure air, which always appears blue, and which always reflects that colour upon all objects without distinction; but which is too faint to be perceived when our eyes are strongly affected by the light of the sun, reflected from other objects around us.

To confirm this hypothesis, he adds some curious observations of his own, in which this appearance is agreeably diversified. Being at the village of Boucholtz in July 1764, he observed the shadows projected on the white paper of his pocket-book, when the sky was clear. At half an hour past 6 in the evening, when the sun was about four degrees high, he observed that the shadow of his finger was of a dark grey, while he held the paper opposite to the sun; but when he inclined it almost horizontally, the paper had a bluish cast, and the shadow upon it was of a beautiful bright blue.

When his eye was placed between the sun and the paper laid horizontally, it always appeared of a bluish cast; but when he held the paper thus inclined between his eye and the sun, he could distinguish, upon every little eminence occasioned by the inequality of the surface of the paper, the principal of the prismatic colours. He also perceived them upon his nails, and upon the skin of his hand. This multitude of coloured points, red, yellow, green, and blue, almost effaced the natural colour of the objects.

At three quarters past six, the shadows began to be blue, even when the rays of the sun fell perpendicularly. The colour was the most lively when the rays fell upon it an angle of 45 degrees; but with a less inclination of the paper, he could distinctly perceive, that the blue shadow had a border of a stronger blue on that side which looked towards the sky, and a red border on that side which was turned towards the earth. To see these borders, the body that made the

this subject.

shadow

Different  
coloured  
shadows.

shadow was obliged to be placed very near the paper; and the nearer it was the more sensible was the red border. At the distance of three inches, the whole shadow was blue. At every observation, after having held the paper towards the sky, he turned it towards the earth, which was covered with verdure; holding it in such a manner, that the sun might shine upon it while it received the shadows of various bodies; but in this position he could never perceive the shadow to be blue or green at any inclination with respect to the sun's rays.

At seven o'clock, the sun being still about two degrees high, the shadows were of a bright blue, even when the rays fell perpendicularly upon the paper, but were the brightest when it was inclined at an angle of  $45^\circ$ . At this time he was surprised to observe, that a large tract of sky was not favourable to this blue colour, and that the shadow falling upon the paper placed horizontally was not coloured, or at least the blue was very faint. This singularity, he concluded, arose from the small difference between the light of that part of the paper which received the rays of the sun and that which was in the shade in this situation. In a situation precisely horizontal, the difference would vanish, and there could be no shadow. Thus too much or too little of the sun's light produced, but for different reasons, the same effect; for they both made the blue light reflected from the sky to become insensible. This gentleman never saw any green shadows, but when he made them fall on yellow paper. But he does not absolutely say, that green shadows cannot be produced in any other manner; and supposes, that if it was on the same wall that M. Buffon saw the blue shadows, seven days after having seen the green ones, the cause of it might be the mixture of yellow rays, reflected from the vapours, which he observes were of that colour.

236  
Blue shadows not  
confined to  
the mornings  
and evenings.

These blue shadows, our author observes, are not confined to the times of the sun-rising and sun-setting; on the 19th of July, when the sun has the greatest force, he observed them at three o'clock in the afternoon, but the sun shone through a mist at that time.

If the sky is clear, the shadows begin to be blue; when, if they be projected horizontally, they are eight times as long as the height of the body that produces them, that is, when the centre of the sun is  $7^\circ 8'$  above the horizon. This observation, he says, was made in the beginning of August.

Besides these coloured shadows, which are produced by the interception of the direct rays of the sun, our author observed others similar to them at every hour of the day, in rooms into which the light of the sun was reflected from some white body, if any part of the clear sky could be seen from the place, and all unnecessary light was excluded as much as possible. Observing these precautions, he says that the blue shadows may be seen at any hour of the day, even with the direct light of the sun; and that this colour will disappear in all those places of the shadow from which the blue sky cannot be seen.

All the observations that our author made upon the yellow or reddish borders of shadows above-mentioned, led him to conclude, that they were occasioned by the interception of the sky-light, whereby part of the

Vol. XIII.

shadow was illuminated either by the red rays reflected from the clouds, when the sun is near the horizon, or from some terrestrial bodies in the neighbourhood. This conjecture is favoured by the necessity he was under of placing any body near the paper, in order to produce this bordered shadow, as he says it is easily demonstrated, that the interception of the sky-light can only take place when the breadth of the opaque body is to its distance from the white ground on which the shadow falls, as twice the sine of half the amplitude of the sky to its cosine.

At the conclusion of his observations on these blue shadows, he gives a short account of another kind of them, which, he does not doubt, have the same origin. These he often saw early in the spring when he was reading by the light of a candle in the morning, and consequently the twilight mixed with that of his candle. In these circumstances, the shadow that was made by intercepting the light of his candle, at the distance of about six feet, was of a beautiful and clear blue, which became deeper as the opaque body which made the shadow was brought nearer to the wall, and was exceedingly deep at the distance of a few inches only. But wherever the day-light did not come, the shadows were all black without the least mixture of blue.

§ 6. *Of the Irradiations of the Sun's Light appearing through the interstices of the Clouds.*

THIS is an appearance which every one must have observed when the sky was pretty much overcast with clouds at some distance from each other. At that time several large beams of light, something like the appearance of the light of the sun admitted into a smoky room, will be seen generally with a very considerable degree of divergence, as if the radiant point was situated at no great distance above the clouds. Dr Smith observes that this appearance is one of those which serve to demonstrate that very high and remote objects in the heavens do not appear to us in their real shapes and positions, but according to their perspective projections on the apparent concavity of the sky. He acquaints us, that though these beams are generally seen diverging, as represented in fig. 11. it is not always the case. He himself, in particular, once saw them converging towards a point diametrically opposite to the sun: for, as near as he could conjecture, the point to which they converged was situated as much below the horizon as the sun was then elevated above the opposite part of it. This part is represented by the line  $zDz$ , and the point below it in opposition to the sun is  $E$ ; towards which all the beams  $vz$ ,  $vt$ , &c. appeared to converge.

"Observing (says our author) that the point of convergence was opposite to the sun, I began to suspect that this unusual phenomenon was but a case of the usual apparent divergence of the beams of the sun from his apparent place among the clouds, as represented in fig. 11. I say an apparent divergence; for though nothing is more common than for rays to diverge from a luminous body, yet the divergence of these beams in such large angles is not real, but apparent. Because it is impossible for the direct rays of the sun to cross one another at any point of the apparent concavity of the sky, in a greater angle than about half a degree. For

the diameter of the earth being so extremely small, in comparison to the distance of the sun, as to subtend an angle at any point of his body of but 20 or 22 seconds at most; and the diameter of our visible horizon being extremely smaller than that of the earth; it is plain, that all the rays which fall upon the horizon from any given point of the sun, must be inclined to each other in the smallest angles imaginable: the greatest of them being as much smaller than that angle of 22 seconds, as the diameter of the visible horizon is smaller than that of the earth. All the rays that come to us from any given point of the sun may therefore be considered as parallel to each other; as the rays  $eBg$  from the point  $e$ , or  $fBb$  from the opposite point  $f$ ; and consequently the rays of these two pencils that come from opposite points of the sun's real diameter, and cross each other in the sun's apparent place  $B$  among the clouds, can constitute no greater an angle with each other than about half a degree; this angle of their intersection  $eBf$  being the same as the sun would appear under to an eye placed among the clouds at  $B$ , or (which is much the same) to an eye at  $O$  upon the ground. Because the sun's real distance  $OS$  is inconceivably greater than his apparent distance  $OB$ . Therefore the rays of the sun, as  $Bg$ ,  $Bb$ , do really diverge from his apparent place  $B$  in no greater angles  $gBb$  than about half a degree. Nevertheless they appear to diverge from the place  $B$  in all possible angles, and even in opposite directions. Let us proceed then to an explanation of this apparent divergence, which is not self-evident by any means; though at first sight we are apt to think it is, by not distinguishing the vast difference between the true and apparent distances of the sun.

Fig. 11.

"What I am going to demonstrate is this. Supposing all the rays of the sun to fall accurately parallel to each other upon the visible horizon, as they do very nearly, yet in both cases they must appear to diverge in all possible angles. Let us imagine the heavens to be partly overcast with a specious bed of broken clouds,  $v, v, v$ , &c. lying parallel to the plane of the visible horizon, here represented by the line  $AOD$ ; and when the sun's rays fall upon these clouds in the parallel lines  $s v, s v$ , &c. let some of them pass through their intervals in the lines  $v t, v t$ , &c. and fall upon the plane of the horizon at the places  $t, t$ , &c. And since the rest of the incident rays  $s v, s v$ , are supposed to be intercepted from the place of the spectator at  $O$  by the cloud  $x$ , and from the intervals between the transmitted rays  $v t, v t$ , &c. by the clouds  $v, v$ , &c. a small part of these latter rays  $v t, v t$ , when reflected every way from some certain kind of thin vapours floating in the air, may undoubtedly be sufficient to affect the eye with an appearance of lights and shades, in the form of bright beams in the places  $v t, v t$ , &c. and of dark ones in the intervals between them; just as the like beams of light and shade appear in a room by reflections of the sun's rays from a smoky or dusty air within it; the lights and shades being here occasioned by the transmission of the rays through some parts of the window, and by their interruption at other parts.

Fig. 14.

"Now, if the apparent concavity of this bed of clouds  $v, v$ , to the eye at  $O$ , be represented by the arch  $ABCD$ , and be cut in the point  $B$  by the line  $OBx$  drawn parallel to the beams  $t v$ ; it will be evident by

the rules of perspective, that these long beams will not appear in their real places, but upon the concave  $AB$   $CD$  diverging every way from the place  $B$ , where the sun himself appears, or the cloud  $x$  that covers his body, as represented separately in full view in fig. 11.

"And for the same reason, if the line  $BO$  be produced towards  $E$ , below the plane of the horizon  $AOD$ , and the eye be directed towards the region of the sky directly above  $E$ , the lower ends of the same real beams  $v t, v t$ , will now appear upon the part  $DE$  of this concave; and will seem to converge towards the point  $E$ , situated just as much below the horizon as the opposite point  $B$  is above it: which is separately represented in full view in fig. 12.

"For if the beams  $v t, v t$ , be supposed to be visible throughout their whole lengths, and the eye be directed in a plane perpendicular to them, here represented by the line  $OF$ ; they and their intervals will appear broadest in and about this plane, because these parts of them are the nearest to the eye; and therefore their remoter parts and intervals will appear gradually narrower towards the opposite ends of the line  $BE$ . As a farther illustration of this matter, we may conceive the spectator at  $O$  to be situated upon the top of so large a descent  $OHI$  towards a remote valley  $IK$ , and the sun to be so very low, that the point  $E$ , opposite to him, may be seen above the horizon of this shady valley. In this case it is manifest, that the spectators at  $O$  would now see these beams converging so far as to meet each other at the point  $E$  in the sky itself.

"I do not remember to have ever seen any phenomenon of this kind by moon-light; not so much as of beams diverging from her apparent place. Probably her light is too weak after reflections from any kind of vapours, to cause a sensible appearance of lights and shades so as to form these beams. And in the unusual phenomenon I well remember, that the converging sun-beams towards the point below the horizon were not quite so bright and strong as those usually are that diverge from him; and that the sky beyond them appeared very black (several showers having passed that way), which certainly contributed to the evidence of this appearance. Hence it is probable that the thinness and weakness of the reflected rays from the vapours opposite to the sun, is the chief cause that this appearance is so very uncommon in comparison to that other of diverging beams. For as the region of the sky round about the sun is always brighter than the opposite one, so the light of the diverging beams ought also to be brighter than that of the converging ones. For, though rays are reflected from rough unpolished bodies in all possible directions, yet it is a general observation, that more of them are reflected forwards obliquely, than are reflected more directly backwards. Besides, in the present case, the incident rays upon the opposite region to the sun, are more diminished by continual reflections from a longer tract of the atmosphere, than the incident rays upon the region next the sun.

"The common phenomenon of diverging beams, I think, is more frequent in summer than in winter, and also when the sun is lower than when higher up; probably because the lower vapours are denser, and therefore more strongly reflective than the higher; because the lower sky-light is not so bright as the upper;

per; because the air is generally quieter in the mornings and evenings than about noon-day; and lastly, because many sorts of vapours are exhaled in greater plenty in summer than in winter, from many kinds of volatile vegetables; which vapours, when the air is cooled and condensed in the mornings and evenings, may become dense enough to reflect a sensible light."

§ 7. *Of the Illumination of the Shadow of the Earth by the refraction of the Atmosphere.*

242  
Why the  
moon is vi-  
sible when  
totally  
eclipsed.

THE ancient philosophers, who knew nothing of the refractive power of the atmosphere, were very much perplexed to account for the body of the moon being visible when totally eclipsed. At such times she generally appears of a dull red colour, like tarnished copper, or of iron almost red-hot. This, they thought, was the moon's native light, by which she became visible when hid from the brighter light of the sun. Plutarch indeed, in his discourse upon the face of the moon, attributes this appearance to the light of the fixed stars reflected to us by the moon; but this must be by far too weak to produce that effect. The true cause of it is the scattered beams of the sun bent into the earth's shadow by refractions through the atmosphere in the following manner.

Plate  
CCCLXII.  
fig. 1.

"Let the body of the sun, says Dr Smith, be represented by the greater circle  $ab$ , and that of the earth by the lesser one  $cd$ ; and let the lines  $ace$  and  $bde$  touch them both on their opposite sides, and meet in  $e$  beyond the earth; then the angular space  $ced$  will represent the conic figure of the earth's shadow, which would be totally deprived of the sun's rays, were none of them bent into it by the refractive power of the atmosphere. Let this power just vanish at the circle  $hi$ , concentric to the earth, so that the rays  $ah$  and  $bi$ , which touch its opposite sides, may proceed unrefracted, and meet each other at  $k$ . Then the two nearest rays to these that flow within them, from the same points  $a$  and  $b$ , being refracted inwards through the margin of the at-

mosphere, will cross each other at a point  $l$ , somewhat nearer to the earth than  $k$ ; and in like manner, two opposite rays next within the two last will cross each other at a point  $m$ , somewhat nearer to the earth than  $l$ , having suffered greater refractions, by passing through longer and denser tracts of air lying somewhat nearer to the earth. The like approach of the successive intersections  $k, l, m$ , is to be understood of innumerable couples of rays, till you come to the intersection  $n$  of the two innermost; which we may suppose just to touch the earth at the points  $o$  and  $p$ . It is plain then, that the space bounded by these rays  $on, np$ , will be the only part of the earth's shadow wholly deprived of the sun's rays. Let  $fmq$  represent part of the moon's orbit when it is nearest to the earth, at a time when the earth's dark shadow  $onp$  is the longest: in this case I will show that the ratio of  $tm$  to  $tn$  is about 4 to 3; and consequently that the moon, though centrally eclipsed at  $m$ , may yet be visible by means of those scattered rays above-mentioned, first transmitted to the moon by refraction through the atmosphere, and from thence reflected to the earth.

Illumina-  
tion of the  
Shadow of  
the Earth.

"For let the incident and emergent parts  $aq, rn$ , of the ray  $aqorn$ , that just touches the earth at  $o$ , be produced till they meet at  $u$ , and let  $agu$  produced meet the axis  $st$  produced in  $x$ ; and joining  $us$  and  $um$ , since the refractions of an horizontal ray passing from  $o$  to  $r$ , or from  $o$  to  $q$ , would be alike and equal, the external angle  $nux$  is double the quantity of the usual refraction of an horizontal ray; and the angle  $aus$  is the apparent measure of the sun's semidiameter seen from the earth; and the angle  $ust$  is that of the earth's semidiameter  $tu$  seen from the sun (called his *horizontal parallax*); and lastly, the angle  $umt$  is that of the earth's semidiameter seen from the moon (called her *horizontal parallax*); because the elevation of the point  $u$  above the earth is too small to make a sensible error in the quantity of these angles; whose measures by astronomical tables are as follow:

Fig. 2.

The sun's least apparent semidiameter	= ang. $aus = 15' - 50''$
The sun's horizontal parallax	= ang. $ust = 00 - 10$
<hr/>	
Their difference* is	= ang. $txu = 15 - 40$
Double the horizontal refraction	= ang. $nux = 67 - 30$
<hr/>	
Their sum† is	= ang. $tnu = 83 - 10$
The moon's greatest horizontal parallax	= ang. $tmu = 62 - 10$

\* Encl. I.  
prop. 32.

† Ibid.

Therefore (by a preceding prop.) we have  $tm:tn::$  (ang.  $tnu:ang. tmu::83'-10'':62'-10'':$ ) 4:3 in round numbers; which was to be proved. It is easy to collect from the moon's greatest horizontal parallax of  $62'-10''$ , that her least distance  $tm$  is about  $55\frac{1}{2}$  semidiameters of the earth; and therefore the greatest length  $tn$  of the dark shadow, being three quarters of  $tm$ , is about  $41\frac{1}{2}$  semidiameters.

"The difference of the last mentioned angles  $tnu, tmu$ , is  $mun=21'$ , that is, about two thirds of  $31'-40''$ , the angle which the whole diameter of the sun subtends at  $u$ . Whence it follows, that the middle point  $m$  of the moon centrally eclipsed, is illuminated by rays which come from two thirds of every diameter of the sun's disk, and pass by one side of the earth; and also by rays that come from the opposite

two thirds of every one of the said diameters, and pass by the other side of the earth. This will appear by conceiving the ray  $aqorn$  to be inflexible, and its middle point  $o$  to slide upon the earth, while the part  $rn$  is approaching to touch the point  $m$ ; for then the opposite part  $qa$  will trace over two thirds of the sun's diameter. The true proportion of the angles  $num, aus$ , could not be preserved in the scheme, by reason of the sun's immense distance and magnitude with respect to the earth.

"Having drawn the line  $atu$ , it is observable, that all the incident rays, as  $aq, an$ , flowing from any one point of the sun to the circumference of the earth, will be collected to a focus  $a$ , whose distance  $ta$  is less than  $tm$  in the ratio of 62 to 67 nearly; and thus an image of the sun will be formed at  $a\beta$ , whose rays

Fig. 3.

U u 2

us

Measures  
of light.

Measures.  
of Light.

will diverge upon the moon. For the angle  $tau$  is the difference of the angles  $xu$ ,  $uat$  found above; and  $ta : tm :: \text{ang. } tmu : \text{ang. } tau :: 62' - 10'' : 67' - 30''$ .

"The rays that flow next above  $aq$  and  $ax$ , by passing through a thinner part of the atmosphere, will be united at a point in the axis  $ata$  somewhat farther from the earth than the last focus  $a$ ; and the same may be said of the rays that pass next above these, and so on; whereby an infinite series of images of the sun will be formed, whose diameters and degrees of brightness will increase with their distances from the earth.

243  
Why the  
moon ap-  
pears duller  
when eclipsed  
in her  
perigee  
than in her  
apogee.

"Hence it is manifest why the moon eclipsed in her perigee is observed to appear always duller and darker than in her apogee. The reason why her colour is always of the copper kind between a dull red and orange, I take to be this. The blue colour of a clear sky shows manifestly that the blue-making rays are more copiously reflected from pure air than those of any other colour; consequently they are less copiously transmitted through it among the rest that come from the sun, and so much the less as the tract of air through which they pass is the longer. Hence the common colour of the sun and moon is whitest in the meridian, and grows gradually more inclined to diluted yellow, orange, and red, as they descend lower, that is, as the rays are transmitted through a longer tract of air; which tract being still lengthened in passing to the moon and back again, causes a still greater loss of the blue-making rays in proportion to the rest; and so the resulting colour of the transmitted rays must lie between a dark orange and red, according to Sir Isaac Newton's rule for finding the result of a mixture of colours. We have an instance of the reverse of this case in leaf-gold, which appears yellow by reflected and blue by transmitted rays. The circular edge of the shadow in a partial eclipse appears red; because the red-making rays are the least refracted of all others, and consequently are left alone in the conical surface of the shadow, all the rest being refracted into it.

#### § 8. Of the Measures of Light.

THAT some luminous bodies give a stronger, and others a weaker light, and that some reflect more light than others, was always obvious to mankind; but no person, before M. Bouguer, hit upon a tolerable method of ascertaining the proportion that two or more lights bear to one other. The methods he most commonly used were the following.

244  
M. Bou-  
guer's con-  
trivances  
for measur-  
ing light.  
Plate  
CCCLXII.

He took two pieces of wood or pasteboard EC and CD (fig. 4.), in which he made two equal holes P and Q, over which he drew pieces of oiled or white paper. Upon these holes he contrived that the light of the different bodies he was comparing should fall; while he placed a third piece of pasteboard FC, so as to prevent the two lights from mixing with one another. Then placing himself sometimes on one side, and sometimes on the other, but generally on the opposite side of this instrument, with respect to the light, he altered their position till the papers in the two holes appeared to be equally enlightened. This being done, he computed the proportion of their light by the squares of the distances at which the luminous bodies were placed from the objects. If, for instance, the

distances were as three and nine, he concluded that the light they gave were as nine and eighty-one. Where any light was very faint, he sometimes made use of lenses, in order to condense it; and he inclosed them in tubes or not as his particular application of them required.

To measure the intensity of light proceeding from the heavenly bodies, or reflected from any part of the sky, he contrived an instrument which resembles a kind of portable camera obscura. He had two tubes, of which the inner was black, fastened at their lower extremities by a hinge C, (fig. 5.) At the bottom of these tubes were two holes, R and S, three or four lines in diameter, covered with two pieces of fine white paper. The two other extremities had each of them a circular aperture, an inch in diameter; and one of the tubes consisted of two, one of them sliding into the other, which produced the same effect as varying the aperture at the end. When this instrument is used, the observer has his head, and the end of the instrument C, so covered, that no light can fall upon his eye, besides that which comes through the two holes S and R, while an assistant manages the instrument, and draws out or shortens the tube DE, as the observer directs. When the two holes appear equally illuminated, the intensity of the lights is judged to be inversely as the squares of the tubes.

In using this instrument, it is necessary that the object should subtend an angle larger than the aperture A or D, seen from the other end of the tube; for otherwise, the lengthening of the tube has no effect. To avoid, in this case, making the instrument of an inconvenient length, or making the aperture D too narrow, he has recourse to another expedient. He constructs an instrument, represented (fig. 6.), consisting of two object-glasses, AE and DF, exactly equal, fixed in the ends of two tubes six or seven feet, or, in some cases, 10 or 12 feet long, and having their foci at the other ends. At the bottom of these tubes B, are two holes, three or four lines in diameter, covered with a piece of white paper; and this instrument is used exactly like the former.

If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object-glasses; and then the remaining surface of the two glasses will give the proportion of their lights. But for this purpose, the central parts of the glass must be covered in the same proportion with the parts near the circumference, leaving the aperture such as is represented (fig. 7.), because the middle part of the glass is thicker and less transparent than the rest.

If all the objects to be observed lie nearly in the same direction, our author observes, that these two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficient for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a *heliometer*, or *astrometer*.

Our author observes, that it is not the absolute quantity, but only the intensity of the light, that is measured by these two instruments, or the number of rays, in proportion to the surface of the luminous body; and it is of great importance that these two things be

245  
These in-  
struments  
measure  
only the  
intensity of  
light.  
be

Measures  
of Light.

be distinguished. The intensity of light may be very great, when the quantity, and its power of illuminating other bodies, may be very small, on account of the smallness of its surface; or the contrary may be the case, when the surface is large.

Having explained these methods which M. Bouguer took to measure the different proportions of light, we shall subjoin in this place a few miscellaneous examples of his application of them.

It is observable, that when a person stands in a place where there is a strong light, he cannot distinguish objects that are placed in the shade: nor can he see any thing upon going immediately into a place where there is very little light. It is plain, therefore, that the action of a strong light upon the eye, and also the impression which it leaves upon it, makes it insensible to the effect of a weaker light. M. Bouguer had the curiosity to endeavour to ascertain the proportion between the intensities of the two lights in this case; and by throwing the light of two equal candles upon a board, he found that the shadow made by intercepting the light of one of them, could not be perceived by his eye, upon the place enlightened by the other, at little more than eight times the distance; from whence he concluded, that when one light is eight times eight, or 64 times less than another, its presence or absence will not be perceived. He allows, however, that the effect may be different on different eyes; and supposes that the boundaries in this case, with respect to different persons, may lie between 60 and 80.

Applying the two tubes of his instrument, mentioned above, to measure the intensity of the light reflected from different parts of the sky: he found, that when the sun was 25 degrees high, the light was four times stronger at the distance of eight or nine degrees from his body, than it was at 31 or 32 degrees. But what struck him the most was to find, that when the sun is 15 or 20 degrees high, the light decreases on the same parallel to the horizon to 110 or 120 degrees, and then increases again to the place exactly opposite to the sun.

The light of the sun, our author observes, is too strong, and that of the stars too weak, to determine the variation of their light at different altitudes: but as, in both cases, it must be in the same proportion with the diminution of the light of the moon in the same circumstances, he made his observations on that luminary, and found, that its light at  $19^{\circ} 16'$ , is to its light at  $66^{\circ} 11'$ , as 1681 to 2500; that is, the one is nearly two thirds of the other. He chose those particular altitudes, because they are those of the sun at the two solstices at Croisic, where he then resided. When one limb of the moon touched the horizon of the sea, its light was 2000 times less than at the altitude of  $66^{\circ} 11'$ . But this proportion he acknowledges must be subject to many variations, the atmosphere near the earth varying so much in its density. From this observation he concludes, that at a medium light is diminished in the proportion of about 2500 to 1681, in traversing 7469 toises of dense air.

Lastly, our accurate philosopher applied his instrument to the different parts of the sun's disk, and found that the centre is considerably more luminous than the extremities of it. As near as he could make the ob-

servation, it was more luminous than a part of the disk  $\frac{1}{4}$ ths of the semidiameter from it, in the proportion of 35 to 28; which, as he observes, is more than in the proportion of the sines of the angles of obliquity. On the other hand, he observes, that both the primary and secondary planets are more luminous at their edges than near their centres.

The comparison of the light of the sun and moon is a subject that has frequently exercised the thoughts of philosophers; but we find nothing but random conjectures, before our author applied his accurate measures in this case. In general, the light of the moon is imagined to bear a much greater proportion to that of the sun than it really does; and not only are the imaginations of the vulgar, but those of philosophers also, imposed upon with respect to it. It was a great surprise to M. de la Hire to find that he could not, by the help of any burning mirror, collect the beams of the moon in a sufficient quantity to produce the least sensible heat. Other philosophers have since made the like attempts with mirrors of greater power, though without any greater success; but this will not surprise us, when we see the result of M. Bouguer's observations on this subject.

In order to solve this curious problem concerning the comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day-time, and the other in the night following, when the moon was at her mean distance from the earth; and, after many trials, he concluded that the light of the sun is about 300,000 times greater than that of the moon; which is such a disproportion, that, as he observes, it can be no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning glasses. For the largest of them will not encrease the light 1000 times; which will still leave the light of the moon, in the focus of the mirror, 300 times less than the intensity of the common light of the sun.

To this account of the proportion of light which we actually receive from the moon, it cannot be displeasing to the reader, if we compare it with the quantity which would have been transmitted to us from that opaque body, if it reflected all the light it receives. Dr Smith thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as 1 to about 90,900, if no rays were lost at the moon.

In the first place, he supposes that the moon, en-  
lightened by the sun, is as luminous as the clouds are at  
a medium. He therefore supposed the light of the sun  
to be equal to that of a whole hemisphere of clouds, or  
as many moons as would cover the surface of the hea-  
vens. But on this Dr Priestley observes, that it is true,  
the light of the sun shining perpendicularly upon any  
surface would be equal to the light reflected from the  
whole hemisphere, if every part reflected all the light  
that fell upon it; but the light that would in fact be  
received from the whole hemisphere (part of it being  
received obliquely) would be only one-half as much  
as would be received from the whole hemisphere, if  
every part of it shone directly upon the surface to be  
illuminated.

In his Remarks, par. 97, Dr Smith demonstrates his method of calculation in the following manner.

“ Let

Plate  
CCCLXII  
fig. 8.

"Let the little circle  $cf dg$  represent the moon's body half enlightened by the sun, and the great circle  $acb$ , a spherical shell concentric to the moon, and touching the earth;  $ab$ , any diameter of that shell perpendicular to a great circle of the moon's body, represented by its diameter  $cd$ ;  $e$  the place of the shell receiving full moon-light from the bright hemisphere  $fdg$ . Now, because the surface of the moon is rough like that of the earth, we may allow that the sun's rays, incident upon any small part of it, with any obliquity, are reflected from it every way alike, as if they were emitted. And therefore if the segment  $df$  shone alone, the points  $a, e$ , would be equally illuminated by it; and likewise if the remaining bright segment  $dg$  shone alone, the points  $be$  would be equally illuminated by it. Consequently, if the light at the point  $a$  was increased by the light at  $b$ , it would become equal to the full moon-light at  $e$ . And conceiving the same transfer to be made from every point of the hemispherical surface  $bbik$  to their opposite points in the hemisphere  $kaeb$ , the former hemisphere would be left quite dark, and the latter would be uniformly illuminated with full moon-light; arising from a quantity of the sun's light, which, immediately before its incidence on the moon, would uniformly illuminate a circular plane equal to a great circle of her body, called her *disk*. Therefore the quantities of light being the same upon both surfaces, the density of the sun's incident light is to the density of full moon-light, as that hemispherical surface  $beb$  is to the said disk; that is, as any other hemispherical surface whose centre is at the eye, to that part of it which the moon's disk appears to possess very nearly, because it subtends but a small angle at the eye: that is, as radius of the hemisphere to the versed sine of the moon's apparent semidiameter, or as 10,000,000 to

$\frac{2}{3}$  or as 90,400 to 1: taking the moon's mean

horizontal diameter to be  $16' 7''$ .

"Strictly speaking, this rule compares moon-light at the earth with day-light at the moon; the medium of which, at her quadratures, is the same as our day-light; but is less at her full in the duplicate ratio of 365 to 366, or thereabout, that is of the sun's distances from the earth and full moon: and therefore full-moon light would be to our day-light as about 1 to 90,000, if no rays were lost at the moon.

"Secondly, I say that full-moon light is to any other moon light as the whole disk of the moon to the part that appears enlightened, considered upon a plane surface. For now let the earth be at  $b$ , and let  $dl$  be perpendicular to  $fg$ , and  $gm$  to  $cd$ : then it is plain, that  $gl$  is equal to  $dm$ ; and that  $gl$  is equal to a perpendicular section of the sun's rays incident upon the arch  $dg$ , which at  $b$  appears equal to  $dm$ ; the eye being unable to distinguish the unequal distances of its parts. In like manner, conceiving the moon's surface to consist of innumerable physical circles parallel to  $cf dg$ , as represented at  $A$ , the same reason holds for every one of these circles as for  $cf dg$ . It follows then, that the bright part of the surface visible at  $b$ , when reduced to a flat as represented at  $B$ , by the crescent  $pdqmp$ , will be equal and similar to a perpendicular section of all the rays incident on that

part, represented at  $C$  by the crescent  $pgqlp$ . Now the whole disk being in proportion to this crescent, as the quantities of light incident upon them; and the light falling upon every rough particle, being equally rarified in diverging to the eye at  $b$ , considered as equidistant from them all; it follows, that full moon-light is to this moon-light as the whole disk  $pdqc$  to the crescent  $pdqmp$ .

"Therefore, by compounding this ratio with that in the former remark, day-light is to moon-light as the surface of an hemisphere whose centre is at the eye, to the part of that surface which appears to be possessed by the enlightened part of the moon.

Mr Michell made his computation in a much more simple and easy manner, and in which there is less danger of falling into any mistake. Considering the distance of the moon from the sun, and that the density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun's light, as that distance, in proportion to its density at the surface of the sun; and in this manner he found, that if the moon reflected all the light it receives from the sun, it would only be the 45,000th part of the light we receive from the greater luminary. Admitting, therefore, that moon-light is only a 300,000th part of the light of the sun, Mr Michell concludes, that it reflects no more than between the 6th and 7th part of what falls upon it.

#### SECT. IV. Of Aberration.

THE great practical use of the science of optics is to aid human sight; but it has been repeatedly observed during the progress of this article, that in constructing dioptrical instruments for this purpose, great difficulties, arise from the aberration of light. It has been shown, page 288, &c. how to determine the concurrence of any refracted ray  $PF$  with the ray  $RVCF$  (figs. 5, 6, &c. Plate CCCLV.) which passes through the centre  $C$ , and therefore falls perpendicularly on the spherical surface at the vertex  $V$ , and suffers no refraction. This is the conjugate focus to  $R$  for the two rays  $RP$ ,  $RV$ , and for another ray flowing from  $R$  and falling on the surface at an equal distance on the opposite side to  $P$ . In short, it is the conjugate focus for all the rays flowing from  $R$  and falling on the spherical surface in the circumference of a circle described by the revolution of the point  $P$  round the axis  $RVCF$ ; that is, of all the rays which occupy the conical surface described by the revolution of  $RP$ , and the refracted rays occupy the conical surface produced by the revolution of  $PF$ .

But no other rays flowing from  $R$  are collected at  $F$ ; for it appeared in the demonstration of that proposition, that rays incident at a greater distance from the axis  $RC$  were collected at a point between  $C$  and  $F$ ; and then the rays which are incident on the whole arch  $PC$ , or the spherical surface generated by its revolution round  $RC$ , although they all cross the axis  $RC$ , are diffused over a certain portion of it, by what has been called the aberration of figure. It is called also (but improperly) the aberration from the geometrical focus, by which is meant the focus of an infinitely slender pencil of rays, of which the middle ray (or axis of the pencil) occupies the lens  $RC$ , and suffers

Of Aberration.

250

Mr Michell's calculation.

251

Theory of aberration.

Fig. 9.

Of Aberration, suffers no refraction. But there is no such focus. But if we make  $mRV = nRC : mRV = VC : VF$ , the point F is called the geometrical focus, and is the remotest limit from C of all the foci (equally geometrical) of rays flowing from R. The other limit is easily determined by constructing the problem for the extreme point of the given arch.

It is evident from the construction, that while the point of incidence P is near to V, the line CK increases but very little, and therefore CF diminishes little, and the refracted rays are but little diffused from F; and therefore they are much denser in its vicinity than any other point of the axis. It will soon be evident that they are incomparably denser. It is on this account that the point F has been called the conjugate focus  $\kappa\alpha\tau' \xi\epsilon\chi\eta$ , to R, and the geometrical focus and the diffusion has been called *aberration*. A geometrical point R is thus represented by a very small circle (or physical point as it is improperly called) at F, and F has drawn the chief attention. And as, in the performance of optical instruments, it is necessary that this extended representation of a mathematical point R be very small, that may not sensibly interfere with the representations of the points adjacent to R, and thus cause indistinct vision, a limit is thus set to the extent of the refracting surface which must be employed to produce this representation. But this evidently diminishes the quantity of light, and renders the vision *obscure*, though distinct. Artists have therefore endeavoured to execute refracting surfaces of forms not spherical, which collect accurately to one point the light issuing from another, and the mathematicians have furnished them with forms having this property; but their attempts have been fruitless. Spherical surfaces are the only ones which can be executed with accuracy. All are done by grinding the refracting substance in a mould of proper materials. When this is spherical, the two work themselves, with moderate attention, into an exact sphere; because if any part is more prominent than another, it is ground away, and the whole gets of necessity one curvature. And it is astonishing to what degree of accuracy this is done. An error of the millionth part of an inch would totally destroy the figure of a mirror of an inch focal distance, so as to make it useless for the coarsest instrument. Therefore all attempts to make other figures are given up. Indeed other reasons make them worse than spherical, even when accurately executed. They would not collect to accurate focuses the rays of oblique pencils.

It is evident from these observations, that the theory of aberrations is absolutely necessary for the successful construction of optical instruments; and it must be acceptable to the reader to have a short account of it in this place. Enough shall be said here to show the general nature and effects of it in optical instruments, and in some of the more curious phenomena of nature. Under the article TELESCOPE the subject will be resumed, in such a manner as to enable the reader who possesses a very moderate share of mathematical knowledge, not only to understand how aberrations are increased and diminished, but also how, by a proper employment of contrary aberrations, their hurtful effects may be almost entirely removed in all important cases. And the manner in which the sub-

ject shall be treated in the present general sketch, will have the advantage of pointing out at the same time the maxims of construction of the greatest part of optical instruments, which generally produce their effects by means of pencils of rays which are either out of the axis altogether, or are oblique to it; cases which are seldom considered in elementary treatises of optics.

Let PV $\pi$  (fig. 1.) be a spherical surface of a refracting substance (glass for instance), of which C is the centre, and let an indefinitely slender pencil of rays AP  $\alpha\beta$  be incident on it, in a direction parallel to a ray CV passing through the centre. It is required to determine the focus  $f$  of this pencil.

Let AP be refracted into PF. Draw CI, CR the sines of incidence and refraction, and CP the radius. Draw RB perpendicular to CP, and B $f$  parallel to AP or CV. I say, first,  $f$  is the focus of the indefinitely slender pencil, or more accurately speaking,  $f$  is the remotest limit from P of the concurrence of rays with PF, refracted by points lying without the arch VP, or the nearest limit for rays incident between V and P.

Draw the radius C $p$ c', the line  $pf$ ; and draw  $pg$  parallel to P $f$ , and P $o$  perpendicular to P $f$ . It is evident, that if  $f$  be the focus,  $c'pf$  is the angle of refraction corresponding to the angle of incidence  $\alpha pC$ . as C'P $f$  is the angle corresponding to APC. Also PC $p$  is the increment of the angle of incidence, and the angle  $c'pg$  is equal to the sum of the angle C'P $f$  and C'C $c$  and the angle  $gpf$  is equal to the angle  $pfP$ . Therefore  $c'pf = C'Pf + P, C, p + Pfp$ . Therefore PC $p$  + P $fp$  is the corresponding increment of the angle of refraction. Also, because RP $o$  = CP $p$  (being right angles) the angle  $pP $o$  = RPC, and P $o$  : P $p$  = PR : PC.$

Therefore, by a preceding Lemma in this article, Page 280, we have PC $p$  + P $fp$  : PC $p$  = tan. ref. : tan. incid. = &c. T, R : T, I; and P $fp$  : PC $p$  = T, R — T, I : T, I, = diff. : T, I; but P $fp$  : PC $p$  =  $\frac{P_o}{P_f} : \frac{P_p}{P_c} = \frac{PR}{P_f}$   $\frac{PC}{P_c}$  = PR : P $f$ , = DR : DB (because DP is parallel to B $f$  by construction) = tan. CPR — tan. CPI : tan. CPI. Now CPI is the angle of incidence; and therefore CPR is the angle properly corresponding to it as an angle of refraction, and the point  $f$  is properly determined.

Hence the following rule: As the difference of the tangents of incidence and refraction is to the tangent of incidence, so is the radius of the surface multiplied by the cosine of refraction to the distance of the focus of an infinitely slender pencil of parallel incident rays.

N. B. We here consider the cosine of refraction as a number. This was first done by the celebrated Leonhard Euler, and is one of the greatest improvements in mathematics which this century can boast of. The sines, tangents, secants, &c. are considered as fractional numbers, of which the radius is unity. Thus, CP  $\times$

fin.  $30^\circ$ , is the same thing with  $\frac{1}{2}$  CP, or  $\frac{CP}{2}$ . And in like manner CB, drawn perpendicular to the axis  $\times$  fin.  $19^\circ 28' 16'' 32'''$ , is the same thing with  $\frac{1}{3}$  of CB. Also  $\frac{CB}{\cos. 60^\circ}$  is the same thing with twice CB, &c.

In

CCCLXIII.252  
How to remedy the evils of aberration.

Of Aberra-  
tion.

In this manner,  $BE = BC \times \sin. BCE$ , and also  $BE = CE \times \tan. BCE$ , and  $CB = CE \times \sec. BCE$ , &c. &c. This manner of considering the lines which occur in geometrical constructions is of immense use in all parts of mixed mathematics; and no where more remarkably than in optics, the most beautiful example of them. Of this an important instance shall now be given.

*Corol. 1.* The distance  $FG$  of this lateral focus from the axis  $CV$  (that is, from the line drawn through the centre parallel to the incident light) is proportional to the cube of the semi-aperture  $PH$  of the spherical surface.

For  $FG = BE$ . Now  $BE = CB \times \sin. BCE = CB \times \sin. CPA$ ; and  $CB = RC \times \cos. RCB = RC \times \sin. CPR$ , and  $RC = CP \times \sin. CPR$ : Therefore  $BE = PC \times \sin.^2 CPR \times \sin. PCA = PC \times \sin.^4 refr. \times \sin. incid.$  but  $\sin.^2 refr. = \frac{m^2}{n^2} \sin.^2 incid.$  Therefore, finally,

$BE$ , or  $FG = PC \times \frac{m^2}{n^2} \times \sin.^3 incid$ : But  $PC \sin. incid.$

is evidently  $PH$  the semi-aperture; therefore the proposition is manifest.

*Corol. 2.* Now let this slender pencil of rays be incident at the vertex  $V$ . The focus will now be a point  $F$  in the axis, determined by making  $CV : CF = m : n$ . Let the incident pencil gradually recede from the axis  $CF$ , still, however, keeping parallel to it. The focus  $f$  will always be found in a curve line  $DC'F$ , so constituted that the ordinate  $G$  will be as the cube of the line  $PH$ , perpendicular to the axis intercepted between the axis and that point of the surface which is cut by a tangent to the curve in  $f$ .

All the refracted rays will be tangents to this curve, and the adjacent rays will cross each other in these lateral foci  $f$ ; and will therefore be incomparably more dense along the curve than any where within its area. This is finely illustrated by receiving on white paper the light of the sun refracted through a globe or cylinder of glass filled with water. If the paper is held parallel to the axis of the cylinder, and close to it, the illuminated part will be bounded by two very bright parallel lines, where it is cut by the curve; and these lines will gradually approach each other as the paper is withdrawn from the vessel, till they coalesce into one very bright line at  $F$ , or near it. If the paper be held with its end touching the vessel, and its plane nearly perpendicular to the axis, the whole progress at the curve will be distinctly seen.

As such globes were used for burning-glasses, the point of greatest condensation (which is very near but not exactly in  $F$ ) was called the *focus*. When these curves were observed by Mr Tschirnhaufs, he called them *caustics*; and those formed by refraction he called *diacaustics*, to distinguish them from the *catacaustics* formed by reflection.

It is somewhat surprising, that these curves have been so little studied since the time of Tschirnhaufs. The doctrine of aberrations has indeed been considered in a manner independent of their properties. But whoever considers the progress of rays in the eye piece of optical instruments, will see that the knowledge of the properties of diacaustic curves determines directly, and almost accurately, the foci and images that are formed there. For, let the object-glass of a telescope or microscope be of any dimensions, the pencils inci-

dent on the eye-glasses are almost all of this evanescent bulk. These advantages will be shown in their proper places; and we proceed at present to extend our knowledge of aberrations in general, first considering the aberrations of parallel incident rays.

Abiding by the instance represented by the figure, it is evident that the caustic will touch the surface in a point  $\phi$ , so situated that  $c\phi : \phi\chi = mv : n$ . The refracted ray  $\phi\phi$  will touch the surface, and will cross the axis in  $\phi$ , the nearest limit of diffusion along the axis. If the surface is of smaller extent, as  $PV$ , the caustic begins at  $f$ , when the extreme refracted ray  $Pf$  touches the caustic, and crosses the axis in  $F'$ , and the opposite branch of the caustic in  $K$ . If there be drawn an ordinate  $KO\frac{1}{2}$  to the caustic, it is evident that the whole light incident on the surface  $PVn$  passes through the circle whose diameter is  $K\frac{1}{2}$ , and that the circle is the smallest space which receives all the refracted light.

It is of great importance to consider the manner in which the light is distributed over the surface of this circle of smallest diffusion; for this is the representation of one point of the infinitely distant radiant object. Each point of a planet, for instance, is represented by this little circle; and as the circles representing the different adjacent points must interfere with each other, an indistinctness must arise similar to what is observed when we view an object through a pair of spectacles which do not fit the eye. The indistinctness must be in proportion to the number of points whose circles of diffusion interfere: that is, to the area of these circles, provided that the light is uniformly diffused over them: but if it be very rare at the circumference, the impression made by the circles belonging to the adjacent points must be less sensible. Accordingly, Sir Isaac Newton, supposing it incomparably rarer at the circumference than towards the centre, affirms, that the indistinctness of telescopes arising from the spherical figure of the object-glass was some thousand times less than that arising from the unequal refrangibility of light; and therefore, that the attempts to improve them by diminishing or removing this aberration were needless, while the distinctness from unequal refrangibility remained. It is surprising, that a philosopher so eminent for sagacity and for mathematical knowledge, should have made such a mistake, and unfortunate that the authority of his great name hindered others from examining the matter, trusting to his assertion, that the light was so rare at the border of this circle. His mistake is surprising, because the very nature of a caustic should have showed him, that the light was infinitely dense at the borders of the circle of smallest diffusion. The first person who detected this oversight of the British philosopher was the Abbe Bossovich, who, in a dissertation published at Vienna in 1767, showed, by a very beautiful analysis, that the distribution was extremely different from what Newton had asserted, and that the superior indistinctness arising from unequal refrangibility was incomparably less than he had said. We shall attempt to make this delicate and interesting matter conceivable by those who have but small mathematical preparation.

Let the curve  $DVZCI$  *ævd* (fig. 2.) be the caustic (magnified),  $EI$  its axis,  $I$  the focus of central rays,  $B$  the focus of extreme rays, and  $IB$  the line contain-

Plate  
CCCLXIII

Of Aberra-  
tion. ing the foci of all the intermediate rays, and CO  $\epsilon$  the diameter of the circle of smallest diffusion.

It is plain, that from the centre O there can be drawn two rays OV, Ov, touching the caustic in V, v. Therefore the point O will receive the ray EO, which passes through the vertex of the refracting surface, and all the rays which are incident on the circumference of a circle described on the refracting surface by the extremity of the ray OV, or Ov. The density of the light at O will therefore be indefinitely great.

From the point C there can be drawn two rays; one of them CX touching the caustic in C, and the other C, touching it at d on the opposite side. The rays which touch the caustic in the immediate vicinity of C, both in the arch CV and the arch CI will cut OC in points indefinitely near to each other; because their distance from each other in the line OC will be to their uniform distance on the refracting surface as the distance between their points of contact with the caustic to the distance of these points from the refracting surface. Here therefore at C the density of the light will also be indefinitely great.

From any point H, lying between O and C, may be drawn three rays. One of them, LHT, P, touching the arch CD of the caustic in T, cutting the refracting surface in P, and the axis in L: another, tHp, touching the arch CI of the caustic in t. The third is H $\pi$  $\pi$ , touching the arch cd of the opposite branch of the caustic in  $\pi$ .

It will greatly assist our conceptions of this subject, if we consider a ray of light from the refracting surface as a thread attached at I of this figure, or at F of fig. 1. and gradually unlapped from the caustic DVCI on one side, and then lapped on the opposite branch I  $\epsilon$  v d; and attend to the point of its intersection with the diameter  $\epsilon$ OC of the circle of smallest diffusion.

Therefore, 1. let the ray be first supposed to pass through the refracting surface at F, the right hand extremity of the aperture. The thread is then folded up on the whole right hand branch ICVD of the caustic; and if the straight part of it FD be produced, it will cut the diameter of the circle of smallest diffusion in the opposite extremity  $\epsilon$ . Or suppose a ruler in place of the thread, applied to the caustic at D and to the refracting surface at F, the part of it D $\epsilon$ , which is detached from the caustic, cuts CO $\epsilon$  in the point  $\epsilon$ . 2. Now suppose the ruler to revolve gradually, its extremity moving across the arch FAf of the refracting surface while the edge is applied to the caustic; the point of contact with the caustic will shift gradually down the branch DV of the caustic, while its edge passes across the line  $\epsilon$ C; and when the point of contact arrives at V, the extremity will be at Y on the refracting surface, and the intersection of the edge will be at O. 3. Continuing the motion, the point of contact shifts from V to Z, the extremity from Y to Q', and the intersection from O to Q, so

that  $OQ = \frac{OC^2}{2}$ , as will presently appear. 4. After this, the point of contact will shift from Z to C, the extremity from Q' to X, halfway from F to A, as will soon be shown, and the intersection from Q to C. 5. The point of contact will now shift from C down to I, the extremity will pass from X to A, and the intersection will go back from C to O. 6. The

ruler must now be applied to the other branch of the caustic I  $\epsilon$  v d, and the point of contact will ascend from I to  $\epsilon$ , the extremity will pass from A to x, half way to f from A, and the intersection from O to  $\epsilon$ . 7. The point of contact will ascend from C to z, the extremity passes from x to q', and the intersection from

C to q,  $Oq^2$  being  $= \frac{Oc^2}{2}$ . 8. While the contact of the ruler and caustic shifts from z to v, the extremity shifts from q' to y, and the intersection from q to O. 9. The contact rises from v to d, the extremity passes from y to f, and the intersection from O to C; and then the motion across the refracting surface is completed, the point of contact shifting down from D to I, along the branch DVZCI, and then ascending along the other branch I  $\epsilon$  v d, while the intersection passes from  $\epsilon$  to C, back again from C to  $\epsilon$ , and then back again from  $\epsilon$  to C, where it ends, having thrice passed through every intermediate point of  $\epsilon$ C.

We may form a notion of the density of the light in any point H, by supposing the incident light of uniform density at the refracting surface, and attending to the configuration of the rays in the circle of smallest diffusion. Their vicinity may be estimated both in the direction of the radii OH, and in the direction of the circumference described by its extremity H, during its revolution round the axis; and the density must be conceived as proportional to the number of originally equidistant rays, which are collected into a spot of given area. These have been collected from a corresponding spot or area of the refracting surface; and as the number of rays is the same in both, the density at H will be to the density of the refracting surface, as the area occupied of the refracting surface to the corresponding area at H. The vicinity of the rays in the direction of the radius depends on the proportion between PT and TH. For the ray adjacent to PTH may be supposed to cross it at the point of contact T; and therefore the uniform distance between them at the surface of that medium is to the distance between the same rays at H as the distance of T from the refracting surface to its distance from H. Therefore the number of rays which occupy a tenth of an inch, for example, of the radius AP, is to the number which would occupy a tenth of an inch at H as TH to TP; and the radial density at P is to the radial density at H also as TH to TP. In the next place, the circumferential density at P is to that at H as the radius AP to the radius OH. For supposing the figure to turn round its axis Af, the point P of the refracting surface will describe a circumference whose radius is AP, and H will describe a circumference whose radius is OH; and the whole rays which pass through the first circumference pass also thro' the last; and therefore their circumferential densities will be in the inverse proportion of the spaces into which they are collected. Now the radius AP is to the radius OH as AL to OL; and circumferences have the same proportion with their radii. Therefore the circumferential density at P is to that in H as AL to OL inversely; and it was found that the radial density was as AN to ON inversely, being as TH to TP, which are very nearly in this ratio. Therefore the absolute density (or number of rays collected in a given space) at P will be to that at H, in the ratio compounded of these ratios; that is, in the ratio of ON  $\times$  OL to AN  $\times$  AL. But as NL bears but a very small ratio to AN or AL,

Of Aberra-  
tion.

$AN \times A^2$  may be taken as equal to  $AO^2$  without any sensible error. It never differs from it in telescopes 100th part, and is generally incomparably smaller. Therefore the density at H may be considered as proportional to  $ON \times OL$  inversely. And it will afterwards appear that  $NS = \frac{1}{2}OL$ . Therefore the density at H is inversely as  $ON \times NS$ .

Now describe a circle on the diameter OS, and draw  $NT\phi$  cutting the circumference  $N\phi^2 = ON \times NS$ , and the density at H is as  $N\phi^2$  inversely. This gives us a very easy estimation of the density, viz. draw a line from the point of contact of the ray which touches the part VC of the caustic, and the density is in the inverse subduplicate ratio of the part of this line intercepted between the axis and the circumference  $S\phi O$ . It will afterwards appear that the density corresponding to this ray is one half of the density corresponding to all the three: or a better expression will be had for the density at H by drawing  $R\beta$  perpendicular to  $R\phi$ , and  $\beta o$  perpendicular to  $\phi\beta$ , making  $\phi R$  in  $o$ ; then  $\phi o$  is as  $\frac{I}{\phi N^2}$ , or is proportional to the density, as is evident.

When H is at O, N is at S, and  $\phi o$  is infinite. As H moves from O, N descends, and  $\phi o$  diminishes, till H comes to Q, and T to  $z$ , and  $\phi$  to  $\zeta$ , and  $o$  to R. When H moves from Q towards C, T descends below  $z$ ,  $\phi o$  again increases, till it is again infinite, when H is at C, T at C, and N at O.

Thus it appears, without any minute consideration, that the light has a density indefinitely great in the centre O; that the density decreases to a minimum in some intermediate point Q, and then increases again to infinity at the margin C. Hence it follows, that the indistinctness arising from the spherical figure of the refracting surfaces is incomparably greater than Newton supposed; and that the valuable discovery of Mr Dollond of achromatic lenses, must have failed of answering his fond expectations, if his very method of producing them had not, at the same time, enabled him to remove that other indistinctness by employing contrary aberrations. And now, since the discoveries by Dr Blair of substances which disperse the different colours in the same proportions, but very different degrees, has enabled us to employ much larger portions of the sphere than Mr Dollond could introduce into his object-glasses, it becomes absolutely necessary to study this matter completely, in order to discover and ascertain the amount of the errors which perhaps unavoidably remain.

255  
Contrary  
aberrations  
correct  
each other.

This slight sketch of the most simple case of aberration, namely, when the incident rays are parallel, will serve to give a general notion of the subject; and the reader can now see how contrary aberrations may be employed in order to form an ultimate image which shall be as distinct as possible. For let it be proposed to converge parallel rays accurately to the focus F (fig. 3.) by the refraction of spherical surfaces of which V is the vertex. Let PV be a convex lens of such a form that rays flowing from F and passing through it immediately round the vertex V are collected to the conjugate focus R, while the extreme ray FP, incident on the margin of the lens P, is converged to  $r$ , nearer to V, having the longitudinal aberration  $Rr$ . Let  $pV$  be a plano-concave lens, of such sphericity

that a ray  $Ap$ , parallel to the axis CV, and incident on the point  $p$ , as far from its vertex V as P in the other lens is from its vertex, is dispersed from  $r$ , the distance  $pV$  being equal to  $rV$ , while the central rays are dispersed from P, as far from V as R is from V. It is evident, that if these lenses be joined as in fig. 4. a ray  $A^2p$ , parallel to the common axis CV, will be collected at the distance VF equal to VF in the fig. 4. and that rays passing through both lenses in the neighbourhood of the axis will be collected at the same point F.

Of the  
Multiply-  
ing glaſs.

This compound lens is said to be without spherical aberration; and it is true that the central and the extreme rays are collected in the same point F: but the rays which fall on the lens between the centre and margin are a little diffused from F, and it is not possible to collect them all to one point. For in the rules for computing the aberration, quantities are neglected which do not preserve (in different apertures) the same ratio to the quantities retained. The diffusion is least when the aberration is corrected, not for the very extremity, but for a certain intermediate point (varying with the aperture, and having no known ratio to it); and when this is done the compound lens is in its state of greatest perfection, and the remaining aberration is quite insensible.

This subject will be resumed under the article TELESCOPE, and prosecuted as far as the construction of optical instruments requires.

#### SECT. IV. Of Optical Instruments.

OF the mechanism of optical instruments particular accounts are given in this work under their respective denominations. These it would be improper to repeat: but as it belongs to the science of optics to explain, by the laws of refraction and reflection, the several phenomena which those instruments exhibit, we must in this place enumerate the instruments themselves, omitting entirely, or stating very briefly, such facts as are stated at large in other places. In this enumeration we shall begin with the *multiplying-glass*, not because it is first in importance, but that it may not intervene between instruments more useful, and which have a mutual relation to one another.

##### § 1. The Multiplying-glass.

THE multiplying-glass is made by grinding down the round side  $bik$  (fig. 1.) of a plano-convex glass AB, into several flat surfaces, as  $bb$ ,  $bld$ ,  $dk$ . An object C will not appear magnified when seen through this glass by the eye at H; but it will appear multiplied into as many different objects as the glass contains plane surfaces. For, since rays will flow from the object C to all parts of the glass, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray  $giH$ , falling perpendicularly on the middle surface, will go through the glass to the eye without suffering any refraction; and will therefore show the object in its true place at C: whilst a ray  $ab$  flowing from the same object, and falling obliquely on the plane surface  $bb$ , will be refracted in the direction  $be$ , by passing through the glass; and, upon leaving it, will go on to the eye in the direction  $eH$ ; which will

Fig. 4.

A vertical line with points A, C, and F. A horizontal line intersects the vertical line at point V. A point P is marked on the horizontal line to the left of V. A line segment connects P and F. A small circle is centered at V. A small circle is also centered at C. A small circle is also centered at F. A small circle is also centered at A. A small circle is also centered at P.

Backara.

Plate  
Mirrors.

cause the same object  $C$  to appear also at  $E$ , in the direction of the ray  $Hc$ , produced in the right line  $Hcn$ . And the ray  $cd$ , flowing from the object  $C$ , and falling obliquely on the plane surface  $dk$ , will be refracted, (by passing through the glass, and leaving it at  $f$ ) to the eye at  $H$ ; which will cause the same object to appear at  $D$ , in the direction  $Hfm$ .—If the glass be turned round the line  $g/H$ , as an axis, the object  $C$  will keep its place, because the surface  $bld$  is not removed; but all the other objects will seem to go round  $C$ , because the oblique planes, on which the rays  $abcd$  fall, will go round by the turning of the glass.

## § 2. Mirrors.

It has been elsewhere observed, that of mirrors there are three principally used in optical experiments (See CATOPTICS, Sect. I.); the plane mirror, the spherical convex mirror, and the spherical concave mirror. Of these the plane mirror first claims our attention, as it is more common, and undoubtedly more ancient, than the other two. It has been said (*ubi supra*), that the image reflected by this mirror appears as far behind the surface as the object is before it; that the image will appear of the same size, and in the same position with the object; that every such mirror will reflect an image of twice its own length and breadth; and that in certain circumstances it will reflect several images of the same object. For these phenomena it is our business in this place to account by the laws of reflection.

Plate  
CCCLXIV.

Let  $AB$  (fig. 2.) be an object placed before the reflecting surface  $ghi$  of the plane mirror  $CD$ ; and let the eye be at  $o$ . Let  $Ab$  be a ray of light flowing from the top  $A$  of the object, and falling upon the mirror at  $b$ , and  $bm$  be a perpendicular to the surface of the mirror at  $b$ ; the ray  $Ab$  will be reflected from the mirror to the eye at  $o$ , making an angle  $mbo$  equal to the angle  $Abm$ : then will the top of the image  $E$  appear to the eye in the direction of the reflected ray  $ob$  produced to  $E$ , where the right line  $ApE$ , from the top of the object, cuts the right line  $obE$ , at  $E$ . Let  $Bi$  be a ray of light proceeding from the foot of the object at  $B$  to the mirror at  $i$ ; and  $ni$  a perpendicular to the mirror from the point  $i$ , where the ray  $Bi$  falls upon it: this ray will be reflected in the line  $io$ , making an angle  $nio$  equal to the angle  $Bin$ , with that perpendicular, and entering the eye at  $o$ ; then will the foot  $F$  of the image appear in the direction of the reflected ray  $oi$ , produced to  $F$ , where the right line  $BF$  cuts the reflected ray produced to  $F$ . All the other rays that flow from the intermediate points of the object  $AP$ , and fall upon the mirror between  $b$  and  $i$ , will be reflected to the eye at  $o$ ; and all the intermediate points of the image  $EF$  will appear to the eye in the direction of these reflected rays produced. But all the rays that flow from the object, and fall upon the mirror above  $b$ , will be reflected back above the eye at  $o$ ; and all the rays that flow from the object, and fall upon the mirror below  $i$ , will be reflected back below the eye at  $o$ ; so that none of the rays that fall above  $b$ , or below  $i$ , can be reflected to the eye at  $o$ ; and the distance between  $b$  and  $i$  is equal to half the length of the object  $AB$ .

Hence it appears, that if a man sees his whole

image in a plane looking-glass, the part of the glass that reflects his image must be just half as long and half as broad as himself, let him stand at any distance from it whatever; and that his image must appear just as far behind the glass as he is before it. Thus, the man  $AB$  (fig. 3.) viewing himself in the plane mirror  $CD$ , which is just half as long as himself, sees his whole image as at  $EF$ , behind the glass, exactly equal to his own size. For a ray  $AC$  proceeding from his eye whole at  $A$ , and falling perpendicularly upon the surface of the glass at  $C$ , is reflected back to his eye, in the same line  $CA$ ; and the eye of his image will appear at  $E$ , in the same line produced to  $E$ , beyond the glass. and a ray  $BD$ , flowing from his foot, and falling obliquely on the glass at  $D$ , will be reflected as obliquely on the other side of the perpendicular  $adD$ , in the direction  $DA$ ; and the foot of his image will appear at  $F$ , in the direction of the reflected ray  $AD$ , produced to  $F$ , where it is cut by the right line  $BGF$ , drawn parallel to the right line  $ACE$ . Just the same as if the glass were taken away, and a real man stood at  $F$ , equal in size to the man standing at  $B$ : for to his eye at  $A$ , the eye of the other man at  $E$  would be seen in the direction of the line  $ACE$ ; and the foot of the man at  $F$  would be seen by the eye  $A$ , in the direction of the line  $ADF$ .

If the glass be brought nearer the man  $AB$ , as suppose to  $cb$ , he will see his image as at  $CDG$ : for the reflected ray  $CA$  (being perpendicular to the glass) will show the eye of the image as at  $C$ ; and the incident ray  $Bb$ , being reflected in the line  $bA$ , will show the foot of his image as at  $G$ ; the angle of reflection  $abA$  being always equal to the angle of incidence  $Bba$ : and so of all the intermediate rays from  $A$  to  $B$ . Hence, if the man  $AB$  advances towards the glass  $CD$ , his image will approach towards it; and if he recedes from the glass, his image will also recede from it.

If the object be placed before a common looking-glass, and viewed obliquely, three, four, or more images of it will appear behind the glass.

To explain this, let  $ABCD$  (fig. 11.) represent the glass; and let  $EF$  be the axis of a pencil of rays flow. ing from  $E$ , a point in an object situated there. The rays of this pencil will in part be reflected at  $F$ , suppose into the line  $FG$ . What remains will (after refraction at  $F$ , which we do not consider here) pass on to  $H$ ; from whence (on account of the quicksilver which is spread over the second surface of glasses of this kind to prevent any of the rays from being transmitted there) they will be strongly reflected to  $K$ , where part of them will emerge and enter an eye at  $L$ . By this means one representation of the said point will be formed in the line  $EL$  produced, suppose in  $M$ ; Again, another pencil, whose axis is  $EN$ , first reflected at  $N$ , then at  $O$ , and afterwards at  $P$ , will form a second representation of the same point at  $Q$ : And thirdly, another pencil, whose axis is  $ER$ , after reflection at the several points  $R$ ,  $S$ ,  $H$ ,  $T$ ,  $V$ , successively, will exhibit a third representation of the same point at  $X$ ; and so on *in infinitum*. The same being true of each point in the object, the whole will be represented in the like manner; but the representations will be faint, in proportion to the number of reflections the rays suffer, and the length of their progress within the glass.

Concave and Convex Mirrors. glaſs. We may add to theſe another representation of the ſame object in the line LO produced, made by ſuch of the rays as fall upon O, and are from thence reflected to the eye at L.

This experiment may be tried by placing a candle before the glaſs as at E, and viewing it obliquely, as from L.

2. *Of Concave and Convex Mirrors.* The effects of theſe in magnifying and diminiſhing objects have been already in general explained; but for the better underſtanding the nature of reflecting teleſcopes, it will ſtill be proper to ſubjoin the following particular deſcription of the effects of concave ones.

Plate CCCLXIV. When parallel rays (fig. 4.), as *d f c*, *C m b*, *e l c*, fall upon a concave mirror AB (which is not tranſparent, but has only the ſurface *A b B* of a clear poliſh), they will be reflected back from that mirror, and meet in a point *m*, at half the diſtance of the ſurface of the mirror from C the centre of its concavity; for they will be reflected at as great an angle from a perpendicular to the ſurface of the mirror, as they fell upon it with regard to that perpendicular, but on the other ſide thereof. Thus, let C be the centre of concavity of the mirror *A b B*; and let the parallel rays *d f a*, *C m b*, and *e l c*, fall upon it at the points *a*, *b*, and *c*. Draw the lines *C i a*, *C m b*, and *C h c*, from the centre C to theſe points; and all theſe lines will be perpendicular to the ſurface of the mirror, becauſe they proceed thereto like ſo many radii or ſpokes from its centre. Make the angle *C a b* equal to the angle *d a C*, and draw the line *a m b*, which will be the direction of the ray *d f a*, after it is reflected from the point *a* of the mirror: ſo that the angle of incidence *d a C* is equal to the angle of reflection *C a b*; the rays making equal angles with the perpendicular *C i a* on its oppoſite ſides.

Draw alſo the perpendicular *C h c* to the point *c*, where the ray *e l c* touches the mirror; and having made the angle *C c i* equal to the angle *C c e*, draw the line *c m i*, which will be the courſe of the ray *e l c*, after it is reflected from the mirror.

The ray *C m b* paſſing through the centre of concavity of the mirror, and falling upon it at *b*, is perpendicular to it; and is therefore reflected back from it in the ſame line *b m C*.

All theſe reflected rays meet in the point *m*; and in that point the image of the body which emits the parallel rays *d a*, *C b*, and *e c*, will be formed; which point is diſtant from the mirror equal to half the radius *b m C* of its concavity.

The rays which proceed from any celeftial object may be eſteemed parallel at the earth; and therefore the image of that object will be formed at *m*, when the reflecting ſurface of the concave mirror is turned directly towards the object. Hence, the focus *m* of parallel rays is not in the centre of the mirror's concavity, but half way between the mirror and that centre.

The rays which proceed from any remote terreſtrial object are nearly parallel at the mirror: not ſtrictly ſo, but come diverging to it, in ſeparate pencils, or as it were bundles of rays, from each point of the ſide of the object next the mirror; and therefore they will not be converged to a point at the diſtance of half the radius of the mirror's concavity from its reflecting ſur-

face, but into ſeparate points at a little greater diſtance from the mirror. And the nearer the object is to the mirror, the farther theſe points will be from it; and an inverted image of the object will be formed in them, which will ſeem to hang pendant in the air; and will be ſeen by an eye placed beyond it (with regard to the mirror) in all reſpects like the object, and as diſtinct as the object itſelf.

Let *A c B* (fig. 5.) be the reflecting ſurface of a mirror, whoſe centre of concavity is at C; and let the upright object DE be placed beyond the centre C, and ſend out a conical pencil of diverging rays from its upper extremity D, to every point of the concave ſurface of the mirror *A c B*. But to avoid confuſion, we only draw three rays of that pencil, as *DA*, *D c*, *DB*.

From the centre of concavity C, draw the three right lines *CA*, *C c*, *CB*, touching the mirror in the ſame points where the foreſaid rays touch it; and all theſe lines will be perpendicular to the ſurface of the mirror. Make the angle *C A d* equal to the angle *D A C*, and draw the right line *A d* for the courſe of the reflected ray *DA*: make the angle *C c d* equal to the angle *D c C*, and draw the right line *c d* for the courſe of the reflected ray *D c*: make alſo the angle *C B d* equal to the angle *D B C*, and draw the right line *B d* for the courſe of the reflected ray *BD*. All theſe reflected rays will meet in the point *d*, where they will form the extremity *d* of the inverted image *e d*, ſimilar to the extremity D of the upright object DE.

If the pencil of rays *E f*, *E g*, *E h*, be alſo continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from D, they will all meet at the point *e* by reflection, and form the extremity *e* of the image *e d*, ſimilar to the extremity E of the object DE.

And as each intermediate point of the object, between D and E, ſends out a pencil of rays in like manner to every part of the mirror, the rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities *e* and *d* of the image; and ſo the whole image will be formed, not at *i*, half the diſtance of the mirror from its centre of concavity C, but at a greater diſtance, between *i* and the object DE; and the image will be inverted with reſpect to the object.

This being well underſtood, the reader will eaſily ſee how the image is formed by the large concave mirror of the reflecting teleſcope, when he comes to the deſcription of that inſtrument:

When the object is more remote from the mirror than its centre of concavity C, the image will be leſs than the object, and between the object and mirror: when the object is nearer than the centre of concavity, the image will be more remote and bigger than the object. Thus, if ED be the object, *d e* will be its image: For, as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it; on account of the leſſer or greater divergency of the pencils of rays which proceed from the object: for the leſs they diverge, the ſooner they are converged to points by reflection; and the more they

Concave and Convex Mirrors. 259 Aerial images formed by concave mirrors.

Micro-  
scopes.

they diverge, the farther they must be reflected before they meet.

If the radius of the mirror's concavity, and the distance of the object from it, be known, the distance of the image from the mirror is found by this rule: Divide the product of the distance and radius by double the distance made less by the radius, and the quotient is the distance required.

If the object be in the centre of the mirror's concavity, the image and object will be coincident, and equal in bulk.

If a man places himself directly before a large concave mirror, but farther from it than its centre of concavity, he will see an inverted image of himself in the air, between him and the mirror, of a less size than himself. And if he holds out his hand towards the mirror, the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the centre of concavity; and he will imagine he may shake hands with his image. If he reaches his hand farther, the hand of the image will pass by his hand, and come between his hand and his body; and if he moves his hand towards either side, the hand of the image will move towards the other; so that whatever way the object moves, the image will move the contrary.

All the while a bystander will see nothing of the image, because none of the reflected rays that form it enter his eyes.

### § 3. Microscopes.

Under the word MICROSCOPE a copious detail has been given of the construction of those instruments as they are now made by the most eminent artists. In that article it fell not within our plan to treat scientifically of their magnifying powers: these can be explained only by the laws of refraction and reflection, which we shall therefore apply to a few microscopes, leaving our readers to make the application themselves to such others as they may choose to analyse by optical principles.

The first and simplest of all microscopes is nothing more than a very small globule of glass, or a convex lens whose focal distance is extremely short. The magnifying power of this microscope is thus ascertained by Dr Smith. "A minute object  $pq$ , seen distinctly through the glass  $AE$  by the eye put close to it, appears so much greater than it would to the naked eye, placed at the least distance  $qL$  from whence it appears sufficiently distinct, as this latter distance  $qL$  is greater than the former  $qE$ . For having put your eye close to the glass  $EA$ , in order to see as much of the object as possible at one view, remove the object  $pq$  to and fro till it appear most distinctly, suppose at the distance  $Eq$ . Then conceiving the glass  $AE$  to be removed, and a thin plate, with a pin-hole in it, to be put in its place, the object will appear distinct, and as large as before, when seen through the glass, only not so bright. And in this latter case it appears so much greater than it does to the naked eye at the distance  $qL$ , either with the pin-hole or without it, as the angle  $pEq$  is greater than the angle  $pLq$ , or as the latter distance  $qL$  is greater than the former  $qE$ . Since the interposition of the glass has no other effect than to render the appearance distinct, by helping the eye to

increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye. As the human eye is so constructed, as, for reasons already assigned, to have distinct vision only when the rays which fall upon it are parallel or nearly so; it follows, that if the eye be so perfect as to see distinctly by pencils of parallel rays falling upon it, the distance  $Eq$ , of the object from the glass, is then the focal distance of the glass. Now, if the glass be a small round globule, of about  $\frac{1}{15}$ th of an inch diameter, its focal distance  $Eq$ , being three quarters of its diameter, is  $\frac{1}{20}$ th of an inch; and if  $qL$  be eight inches, the distance at which we usually view minute objects, this globule will magnify in the proportion of 8 to  $\frac{1}{20}$ th, or of 160 to 1.

2. *The Double or Compound Microscope* (fig. 8.) consists of an object-glass  $cd$ , and an eye-glass  $ef$ . The small object  $ab$  is placed at a little greater distance from the glass  $cd$  than its principal focus; so that the pencils of rays flowing from the different points of the object, and passing through the glass, may be made to converge, and unite in as many points between  $g$  and  $b$ , where the image of the object will be formed: which image is viewed by the eye through the eye-glass  $ef$ . For the eye-glass being so placed, that the image  $gh$  may be in its focus, and the eye much about the same distance on the other side, the rays of each pencil will be parallel after going out of the eye-glass, as at  $e$  and  $f$ , till they come to the eye at  $k$ , where they will begin to converge by the refractive power of the humours; and after having crossed each other in the pupil, and passed through the crystalline and vitreous humours, they will be collected into points on the retina, and form the large inverted image  $AB$  thereon.

By this combination of lenses, the aberration of the light from the figure of the glass, which in a globule of the kind abovementioned is very considerable, is in some measure corrected. This appeared so sensibly to be the case, even to former opticians, that they very soon began to make the addition of another lens. The instrument, however, receives a considerable improvement by the addition of a third lens. For, says Mr Martin, it is not only evident from the theory of this aberration, that the image of any point is rendered less confused by refraction through two lenses than by an equal refraction through one; but it also follows, from the same principle, that the same point has its image still less confused when formed by rays refracted through three lenses than by an equal refraction through two; and therefore a third lens added to the other two will contribute to make the image more distinct, and consequently the instrument more complete. At the same time the field of view is amplified, and the use of the microscope rendered more agreeable, by the addition of the other lens. Thus also we may allow a somewhat larger aperture to the object-lens, and thereby increase the brightness of objects, and greatly heighten the pleasure of viewing them. For the same reason, Mr Martin has proposed a four-glass microscope, which answers the purposes of magnifying and of distinct vision still more perfectly.

The magnifying power of double microscopes is ca-

Fig. 9.

fly understood, thus: The glass L, next the object PQ is very small, and very much convex, and consequently its focal distance LF is very short; the distance LQ of the small object PQ is but a little greater than LF: Greater it must be, that the rays flowing from the object may converge after passing through the glass, and, crossing one another, form an image of the object; and it must be but a little greater, that the image  $pq$  may be at a great distance from the glass, and consequently may be much larger than the object itself. This picture  $pq$  being viewed through a convex glass AE, whose focal distance is  $qE$ , appears distinct as in a telescope. Now the object appears magnified upon two accounts; first, because, if we viewed its picture  $pq$  with the naked eye, it would appear as much greater than the object, at the same distance, as it really is greater than the object, or as much as  $Lq$  is greater than  $LQ$ : and, secondly, because this picture appears magnified through the eye-glass as much as the least distance at which it can be seen distinctly with the naked eye, is greater than  $qE$ , the focal distance of the eye-glass. For example, if this latter ratio be five to one, and the former ratio of  $Lq$  to  $LQ$  be 20 to 1; then, upon both accounts, the object will appear 5 times 20, or 100 times greater than to the naked eye.

Fig. 10. represents the section of a compound microscope with three lenses. By the middle one GK the pencils of rays coming from the object-glass are refracted so as to tend to a focus at O; but being intercepted by the proper eye-glass DF, they are brought together at I, which is nearer to that lens than its proper focus at L; so that the angle DIF, under which the object now appears, is larger than DLF, under which it would have appeared without this additional glass; and consequently the object is more magnified in the same proportion. Dr Hooke tells us, that, in most of his observations, he made use of a double microscope with this broad middle-glass when he wanted to see much of an object at one view, and taking it out when he would examine the small parts of an object more accurately; for the fewer refractions there are, the more bright and clear the object appears.

261  
The magnifying power of Dr Smith's microscope.

Having in the historical part of this article given a practical account of the construction of Dr Smith's double reflecting microscope, it may not be improper in this place to ascertain its magnifying power. This we shall do from the author himself, because his symbols, being general, are applicable to such microscopes of all dimensions: and though the mere practical reader may perhaps be at first sight puzzled by them, yet, if he will substitute any particular numbers for  $m$  and  $n$ , &c. he may ascertain with ease the magnifying power of such a microscope of these particular dimensions.

Between the centre E and principal focus T of a concave speculum ABC, whose axis is EQTC, place an object PQ; and let the rays flowing from it be reflected from the speculum AB towards an image  $p q$ ; but before they unite in it, let them be received by a convex speculum  $abc$ , and thence be reflected, through a hole BC in the vertex of the concave, to a second image  $\omega x$ , to be viewed through the eye-glass L.

The object may be situated between the specula C, &c; or, which is better, between the principal focus  $t$

and vertex  $e$  of the convex one, a small hole being made in its vertex for the incident rays to pass through.

Microscope.

In both cases we have TQ, TE, Tq, continual proportionals in some given ratio, suppose of 2 to  $n$ ; and also  $t q$ ,  $tc$ ,  $tx$ , continual proportionals in some other given ratio, suppose of 1 to  $m$ . Then if  $d$  be the usual distance at which we view minute objects distinctly with the naked eye, and  $\omega l$  the focal distance of the least eye-glass, through which the object appears sufficiently bright and distinct, it will be magnified in the ratio of  $mnd$  to  $\omega l$ .

For the object PQ, and its first image  $p q$ , are terminated on one side by the common axis of the specula, and on the other by a line PE $p$ , drawn through the centre E of the concave ABC. Likewise the images  $p q$  and  $\omega x$  are terminated by the common axis and by the line  $ep\omega$  drawn through the centre  $e$  of the convex  $abc$ . Hence, by the similar triangles  $\omega ne$ ,  $p q e$ , and also  $p q E$ , PQE, we have  $\omega x : p q :: ne : qe :: m : 1$ , and  $p q : PQ :: qE : QE :: n : 1$ ; and consequently  $\omega x : PQ :: mn : 1$ , whence  $\omega x = mn \times PQ$ . Now if  $l$  be the focal distance of the eye-glass L, the points P, Q, of the object, are seen through it by the rays of two pencils emerging parallel to the lines  $\omega l$ ,  $xl$ , respectively; that is, PQ appears under an

Eucl.v.12

angle equal to  $\omega lx$ , which is as  $\frac{\omega x}{l} = \frac{mnPQ}{l}$  and to the naked eye at the distance  $d$  from PQ, it appears under an angle PoQ which is as  $\frac{PQ}{d}$ , and therefore is magnified in the ratio of these angles, that is, of  $mnd$  to  $\omega l$ .

Corol. Having the numbers  $m$ ,  $n$ ,  $d$ , to find an eye-glass which shall cause the microscope to magnify M times in diameter, take  $\omega l = \frac{mnd}{M}$ . For the apparent magnitude is to the true as  $M : 1 :: mnd : \omega l$ .

262

We shall conclude this part of our subject with the following easy method of ascertaining the magnifying power of such microscopes as are most in use.

The apparent magnitude of any object, as must appear from what hath been already delivered, is measured by the angle under which it is seen; and this angle is greater or smaller according as the object is near to or far from the eye; and of consequence the less the distance at which it can be viewed the larger it will appear. The naked eye is unable to distinguish any object brought exceedingly near it: but looking through a convex lens, however near the focus of that lens be, there an object may be distinctly seen; and the smaller the lens is, the nearer will be its focus, and in the same proportion the greater will be its magnifying power. From these principles it is easy to find the reason why the first or greatest magnifiers are so extremely minute; and also to calculate the magnifying power of any convex lens employed in a single microscope: For as the proportion of the natural light is to the focus, such will be its power of magnifying. If the focus of a convex lens, for instance, be at one inch, and the natural light at eight inches, which is the common standard, an object may be seen through that lens at one inch distance from the eye, and will appear in its diameter eight times larger than

262  
An easy method of ascertaining the magnifying power of the most common microscopes.

scopes.

than it does to the naked eye: but as the object is magnified every way, in length as well as in breadth, we must square this diameter to know how much it really is enlarged; and we then find that its superficies is magnified 64 times.

Again, suppose a convex lens whose focus is only one-tenth of an inch distant from its centre; as in eight inches the common distance of distinct vision with the naked eye, there are 80 such tenths, an object may be seen through this glass 80 times nearer than with the naked eye. It will, of consequence, appear 80 times longer, and as much broader, than it does to common sight; and therefore is 6400 times magnified. If a convex glass be so small that its focus is only  $\frac{1}{80}$  of an inch distant, we find that eight inches contains 160 of these twentieth-parts; and of consequence the length and breadth of any object seen through such a lens will be magnified 160 times, and the whole surface 25,600 times. As it is an easy matter to melt a drop or globule of a much smaller diameter than a lens can be ground, and as the focus of a globule is no farther off than a quarter of its own diameter, it must of consequence magnify to a prodigious degree. But this excessive magnifying power is much more than counterbalanced by its admitting so little light, want of distinctness, and showing such a minute part of the object to be examined; for which reason, these globules, though greatly in vogue some time ago, are now almost entirely rejected. Mr Leeuwenhoek, as has been already observed, made use only of single microscopes consisting of convex lenses, and left to the Royal Society a legacy of 26 of those glasses. Accordingly to Mr Folke's description of these, they were all exceedingly clear, and showed the object very bright and distinct; "which (says Mr Folke) must be owing to the great care this gentleman took in the choice of his glass, his exactness in giving it the true figure, and afterwards, among many, reserving only such for his use as upon trial he found to be most excellent. Their powers of magnifying are different, as different objects may require: and as on the one hand, being all ground glasses, none of them are so small, or consequently magnify to

so great a degree, as some of those drops frequently used in other microscopes; yet, on the other hand, the distinctness of these very much exceeds what I have met with in glasses of that sort. And this was what Mr Leeuwenhoek ever proposed to himself; rejecting all those degrees of magnifying in which he could not so well obtain that end. For he informs us in one of his letters, that though he had above 40 years by him glasses of an extraordinary smallness, he had made but very little use of them; as having found, in a long course of experience, that the most considerable discoveries were to be made with such glasses as, magnifying but moderately, exhibited the object with the greatest brightness and distinction."

In a single microscope, if you want to learn the magnifying power of any glass, no more is necessary than to bring it to its true focus, the exact place whereof will be known by an object's appearing perfectly distinct and sharp when placed there. Then, with a pair of small compasses, measure, as nearly as you can, the distance from the centre of the glass to the object you was viewing, and afterwards applying the compasses to any ruler, with a diagonal scale of the parts of an inch marked on it, you will easily find how many parts of an inch the said distance is. When that is known, compute how many times those parts of an inch are contained in eight inches, the common standard of sight, and that will give you the number of times the diameter is magnified: squaring the diameter will give the superficies; and if you would learn the solid contents, it will be shown by multiplying the superficies by the diameter.

The superficies of one side of an object only can be seen at one view; and to compute how much that is magnified, is most commonly sufficient; but sometimes it is satisfactory to know how many minute objects are contained in a larger: as suppose we desire to know how many animalcules are contained in the bulk of a grain of sand: and to answer this, the cube, as well as the surface, must be taken into the account. For the greater satisfaction of those who are not much versed in these matters, we shall here subjoin the following

Micro-  
scopes.

TABLE.

TABLE of the MAGNIFYING POWERS of CONVEX GLASSES, employed in *Single Microscopes*, according to the distance of their focus; Calculated by the scale of an inch divided into 100 parts. Showing how many times the DIAMETER, the SUPERFICIES, and the CUBE of an OBJECT, is magnified, when viewed through such glasses, to an eye whose natural sight is at eight inches, or 800 of the 1000th-parts of an inch.

		1	800	640,000	512,000,000

The greatest magnifier in Mr Leeuwenhoek's cabinet of microscopes, presented to the Royal Society, had its focus, as nearly as can well be measured, at one-twentieth of an inch distance from its centre; and consequently magnifies the diameter of an object 160 times, and the superficies 25,600. But the greatest magnifier in Mr Wilson's single microscopes, as they are now made, has usually its focus at no farther distance than about the 50th part of an inch; whereby it has a power of enlarging the diameter of an object 400, and its superficies 160,000 times.

264  
The magnifying power of the solar microscope calculated differently from that of others.

The magnifying power of the solar microscope must be calculated in a different manner; for here the difference between the focus of the magnifier and the distance of the screen or sheet whereon the image of the object is cast, is the proportion of its being magnified. Suppose, for instance, the lens made use of has its focus at half an inch, and the screen is placed at the distance of five feet, the object will then appear magnified in the proportion of five feet to half an inch: and as in five feet there are 120 half inches, the diameter will be magnified 120 times, and the superficies 14,400 times; and, by putting the screen at farther distances, you may magnify the object almost as much as you please; But Mr Baker advises to regard distinctness more than bigness, and to place the screen just at that distance where the object is seen most distinct and clear.

With regard to the double reflecting microscope, Mr Baker observes, that the power of the object-lens is indeed greatly increased by the addition of two eye-glasses; but as no object-lens can be used with them of so minute a diameter, or which magnifies of itself near so much as those that can be used alone, the glasses of this microscope, upon the whole magnify, little or nothing more than those of Mr Wilson's single

one; the chief advantages arising from a combination of lenses being the sight of a larger field or portion of an object magnified in the same degree.

#### § 4. Telescopes.

##### I. THE REFRACTING TELESCOPE.

AFTER what has been said concerning the structure of the compound microscope, and the manner in which the rays pass through it to the eye, the nature of the astronomical telescope will easily be understood; for it differs from the microscope only in that the object is placed at so great a distance from it, that the rays of the same pencil, flowing from thence, may be considered as falling parallel to one another upon the object-glass; and therefore the image made by that glass is looked upon as coincident with its focus of parallel rays.

1. This will appear very plain from the 12th figure, in which AB is the object emitting the several pencils of rays Acd, Bcd, &c. but supposed to be at so great a distance from the object-glass cd, that the rays of the same pencil may be considered as parallel to each other; they are therefore supposed to be collected into their respective foci at the points m and p, situated at the focal distance of the object-glass cd. Here they form an image E, and crossing each other proceed diverging to the eye-glass hg; which being placed at its own focal distance from the points m and p, the rays of each pencil, after passing through that glass, will become parallel among themselves; but the pencils themselves will converge considerably with respect to one another, even so as to cross at e, very little farther from the glass hg than its focus; because, when they entered the glass, their axes were almost parallel, as coming through the object-glass at the point k, to

265

whole

Refracting  
Telescope.

266  
Magnify-  
ing power  
of.

whose distance the breadth of the eye-glass in a long telescope bears very small proportion. So that the place of the eye will be nearly at the focal distance of the eye-glass, and the rays of each respective pencil being parallel among themselves, and their axes crossing each other in a larger angle than they would do if the object were to be seen by the naked eye, vision will be distinct, and the object will appear magnified.

The power of magnifying in this telescope is as the focal length of the object glass to the focal length of the eye-glass.

DEM. In order to prove this, we may consider the angle  $A\angle B$  as that under which the object would be seen by the naked eye; for in considering the distance of the object, the length of the telescope may be omitted, as bearing no proportion to it. Now the angle under which the object is seen by means of the telescope is  $g\angle h$ , which is to the other  $A\angle B$ , or its equal  $g\angle k$ , as the distance from the centre of the object-glass to that of the eye-glass. The angle, therefore, under which an object appears to an eye assisted by a telescope of this kind, is to that under which it would be seen without it, as the focal length of the object-glass to the focal length of the eye-glass.

It is evident from the figure, that the visible area, or space which can be seen at one view when we look through this telescope, depends on the breadth of the eye-glass, and not of the object-glass; for if the eye-glass be too small to receive the rays  $gm$ ,  $ph$ , the extremities of the object could not have been seen at all: a larger breadth of the object-glass conduces only to the rendering each point of the image more luminous by receiving a larger pencil of rays from each point of the object.

267  
Objects  
seen thro',  
inverted.

It is in this telescope as in the compound microscope, where we see, when we look through it, not the object itself, but only an image of it at  $CED$ : now that image being inverted with respect to the object, as it is, because the axes of the pencils that flow from the object cross each other at  $k$ , objects seen through a telescope of this kind necessarily appear inverted.

This is a circumstance not at all regarded by astronomers: but for viewing objects upon the earth, it is convenient that the telescope should represent them in their natural posture; to which use the telescope with three eye-glasses, as represented fig. 13. is peculiarly adapted, and the progress of the rays through it from the object to the eye is as follows:

Plate

jects erect.

$AB$  is the object sending out the several pencils  $Ac$ ,  $Bc$ , &c. which passing through the object-glass  $cd$ , are collected into their respective foci in  $CD$ , where they form an inverted image. From hence they proceed to the first eye-glass  $ef$ , whose focus being at  $l$ , the rays of each pencil are rendered parallel among themselves, and their axes, which were nearly parallel before, are made to converge and cross each other: the second eye-glass  $gh$ , being so placed that its focus shall fall upon  $m$ , renders the axes of the pencils which diverge from thence parallel, and causes the rays of each, which were parallel among themselves, to meet again at its focus  $EF$  on the other side, where they form a second image inverted with respect to the former, but erect with respect to the object. Now this image being seen by the eye at  $ab$  through the eye-glass  $ih$ , affords a direct representation of the object, and under the same angle that the first image  $CD$

Vol. XIII.

would have appeared, had the eye been placed at  $l$ , supposing the eye-glasses to be of equal convexity; and therefore the object is seen equally magnified in this as in the former telescope, that is, as the focal distance of the object-glass to that of any one of the eye-glasses, and appears erect.

If a telescope exceeds 20 feet, it is of no use in viewing objects upon the surface of the earth; for if magnifies above 90 or 100 times, as those of that length usually do, the vapours which continually float near the earth in great plenty, will be so magnified as to render vision obscure.

2. The Galilean Telescope with the concave eye-glass is constructed as follows:

$AB$  (fig. 1.) is an object sending forth the pencils of rays  $ghi$ ,  $klm$ , &c. which, after passing through the object-glass  $cd$ , tend towards  $eEf$  (where we will suppose the focus of it to be), in order to form an inverted image there as before; but in their way to it are made to pass through the concave glass  $no$ , so placed that its focus may fall upon  $E$ , and consequently the rays of the several pencils which were converging towards those respective focal points  $e$ ,  $E$ ,  $f$ , will be rendered parallel among themselves: but the axes of those pencils crossing each other at  $F$ , and diverging from thence, will be rendered more diverging, as represented in the figure. Now these rays entering the pupil of an eye, will form a large and distinct image  $ab$  upon the retina, which will be inverted with respect to the object, because the axis of the pencils cross in  $F$ . The object of course will be seen erect, and the angle under which it will appear will be equal to that which the lines  $aF$ ,  $bF$ , produced back through the eye-glass form at  $F$ .

It is evident, that the less the pupil of the eye is, the less is the visible area seen through a telescope of this kind; for a less pupil would exclude such pencils as proceed from the extremities of the object  $AB$ , as is evident from the figure. This is an inconvenience that renders this telescope unfit for many uses; and is only to be remedied by the telescope with the convex eye-glasses, where the rays which form the extreme parts of the image are brought together in order to enter the pupil of the eye, as explained above.

It is apparent also, that the nearer the eye is placed to the eye-glass of this telescope, the larger is the area seen through it; for, being placed close to the glass, as in the figure, it admits rays that come from  $A$  and  $B$ , the extremities of the object, which it could not if it was placed farther off.

The degree of magnifying in this telescope is in the same proportion with that in the other, viz. as the focal distance of the object-glass is to the focal distance of the eye-glass.

For there is no other difference but this, viz. that as the extreme pencils in that telescope were made to converge and form the angle  $g\angle h$  (fig. 12.), or  $in\angle k$  (fig. 13.), the axes are now made to diverge and form the angle  $aF\angle b$  (fig. 1.); which angles, if the concave glass in one has an equal refractive power with the convex one in the other, will be equal, and therefore each kind will exhibit the object magnified in the same degree.

There is a defect in all these kinds of telescopes, not to be remedied in a single lens by any means whatever, which was thought only to arise from hence,

*viz.* that spherical glasses do not collect rays to one and the same point. But it was happily discovered by Sir Isaac Newton that the imperfection of this sort of telescope, so far as it arises from the spherical form of the glasses, bears almost no proportion to that which is owing to the different refrangibility of light. This diversity in the refraction of rays is about a 28th part of the whole; so that the object-glass of a telescope cannot collect the rays which flow from any one point in the object into a less room than the circular space whose diameter is about the 56th part of the breadth of the glass.

To show this, let  $AB$  (fig. 2.) represent a convex lens; and let  $CDF$  be a pencil of rays flowing from the point  $D$ ; let  $H$  be the point at which the least refrangible rays are collected to a focus; and  $I$ , that where the most refrangible concur. Then, if  $IH$  be the 28th part of  $EH$ ,  $IK$  will be a proportionable part of  $EC$  (the triangles  $HIK$  and  $HEC$  being similar): consequently  $LK$  will be the 28th part of  $FC$ . But  $MN$  will be the least space into which the rays will be collected, as appears by their progress represented in the figure. Now  $MN$  is but about half of  $KL$ ; and therefore it is about the 56th part of  $CF$ : so that the diameter of the space into which the rays are collected will be about the 56th part of the breadth of that part of the glass through which the rays pass; which was to be shown.

Since therefore each point of the object will be represented in so large a space, and the centres of those spaces will be contiguous, because the points in the object the rays flow from are so; it is evident, that the image of an object made by such a glass must be a most confused representation, though it does not appear so when viewed through an eye-glass that magnifies in a moderate degree; consequently the degree of magnifying in the eye-glass must not be too great with respect to that of the object-glass, lest the confusion become sensible.

Notwithstanding this imperfection, a dioptrical telescope may be made to magnify in any given degree, provided it be of sufficient length; for the greater the focal distance of the object glass is, the less may be the proportion which the focal distance of the eye-glass may bear to that of the object glass, without rendering the image obscure. Thus, an object-glass, whose focal distance is about four feet, will admit of an eye-glass whose focal distance shall be little more than an inch, and consequently will magnify almost 48 times; but an object-glass of 40 feet focus will admit of an eye-glass of only four inches focus, and will therefore magnify 120 times; and an object-glass of 100 feet focus will admit of an eye-glass of little more than six inches focus, and will therefore magnify almost 200 times.

The reason of this disproportion in their several degrees of magnifying is to be explained in the following manner: Since the diameter of the spaces, into which rays flowing from the several points of an object are collected, are as the breadth of the object-glass, it is evident that the degree of confusedness in the image is as the breadth of that glass; for the degree of confusedness will only be as the diameters or breadth of those spaces, and not as the spaces themselves. Now the focal length of the eye glass, that is,

its power of magnifying, must be as that degree; for, if it exceeds it, it will render the confusedness sensible; and therefore it must be as the breadth or diameter of the object glass. The diameter of the object-glass, which is as the square-root of its aperture or magnitude, must be as the square-root of the power of magnifying in the telescope; for unless the aperture itself be as the power of magnifying, the image will want light: the square-root of the power of magnifying will be as the square-root of the focal distance of the object-glass; and therefore the focal distance of the eye-glass must be only as the square-root of that of the object glass. So that in making use of an object glass of a longer focus, suppose, than one that is given, you are not obliged to apply an eye glass of a proportionably longer focus than what would suit the given object-glass, but such an one only whose focal distance shall be to the focal distance of that which will suit the given object-glass, as the square root of the focal length of the object-glass you make use of, is to the square-root of the focal length of the given one. And this is the reason that longer telescopes are capable of magnifying in a greater degree than shorter ones, without rendering the object confused or coloured.

3. But the inconveniency of very long telescopes is so great, that different attempts have been made to remove it. Of these, the most successful have been by Dollond and Blair: and the general principles upon which these eminent opticians proceeded have been mentioned in the historical part of this article, and in the preceding section. The public will soon be favoured with a fuller account of Dr Blair's discovery from his own pen; and of Dollond's, it may be sufficient to observe, in addition to what has been already said, that the object-glasses of his telescopes are composed of three distinct lenses, two convex and one concave; of which the concave one is placed in the middle, as is represented in fig. 3. where  $a$  and  $c$  show the two convex lenses, and  $bb$  the concave one, which is by the British artists placed in the middle. The two convex ones are made of London crown glass, and the middle one of white flint glass; and they are all ground to spheres of different radii, according to the refractive powers of the different kinds of glass and the intended focal distance of the object-glass of the telescope. According to Boscovich, the focal distance of the parallel rays for the concave lens is one-half, and for the convex glass one-third of the combined focus. When put together, they refract the rays in the following manner. Let  $ab, ab$  (fig. 4.), be two red rays of the sun's light falling parallel on the first convex lens  $c$ . Supposing there was no other lens present but that one, they would then be converged into the lines  $bc, be$ , and at last meet in the focus  $g$ . Let the lines  $gb, gb$ , represent two violet rays falling on the surface of the lens. These are also refracted, and will meet in a focus; but as they have a greater degree of refrangibility than the red rays, they must of consequence converge more by the same power of refraction in the glass, and meet sooner in a focus, suppose at  $r$ .—Let now the concave lens  $dd$  be placed in such a manner as to intercept all the rays before they come to their focus. Were this lens made of the same materials, and ground to the same radius with the convex one, it

would

Reflecting  
Telescope.

would have the same power to cause the rays diverge that the former had to make them converge. In this case, the red rays would become parallel, and move on in the line  $oo$ ; But the concave lens being made of flint glass, and upon a shorter radius, has a greater refractive power, and therefore they diverge a little after they come out of it; and if no third lens was interposed, they would proceed diverging in the lines  $opt, opt$ ; but, by the interposition of the third lens  $ovo$ , they are again made to converge, and meet in a focus somewhat more distant than the former, as at  $x$ . By the concave lens the violet rays are also refracted, and made to diverge: but having a greater degree of refrangibility, the same power of refraction makes them diverge somewhat more than the red ones; and thus, if no third lens was interposed, they would proceed in such lines as  $lmn, lmn$ . Now as the differently coloured rays fall upon the third lens with different degrees of divergence, it is plain, that the same power of refraction in that lens will operate upon them in such a manner as to bring them all together to a focus very nearly at the same point. The red rays, it is true, require the greatest power of refraction to bring them to a focus; but they fall upon the lens with the least degree of divergence. The violet rays, though they require the least power of refraction, yet have the greatest degree of divergence; and thus all meet together at the point  $x$ , or very nearly so.

Plate  
CCCLXV.

But, though we have hitherto supposed the refraction of the concave lens to be greater than that of the convex ones, it is easy to see how the errors occasioned by the first lens may be corrected by it, though it should have even a less power of refraction than the convex one. Thus, let  $ab, ab$  (fig. 5.), be two rays of red light falling upon the convex lens  $c$ , and refracted into the focus  $q$ ; set also  $gb, gb$ , be two violet rays converged into a focus at  $r$ ; it is not necessary, in order to their convergence into a common focus at  $x$ , that the concave lens should make them *diverge*: it is sufficient if the glass has a power of dispersing the violet rays somewhat more than the red ones; and many kinds of glass have this power of dispersing some kinds of rays, without a very great power of refraction. It is better, however, to have the object-glass composed of three lenses; because there is then another correction of the aberration by means of the third lens; and it might be impossible to find two lenses, the errors of which would exactly correct each other. It is also easy to see, that the effect may be the same whether the concave glass is a portion of the same sphere with the others or not; the effect depending upon a combination of certain circumstances, of which there is an infinite variety.

By means of this correction of the errors arising from the different refrangibility of the rays of light, it is possible to shorten dioptric telescopes considerably, and yet leave them equal magnifying powers. The reason of this is, that the errors arising from the object-glass being removed, those which are occasioned by the eye glass are inconsiderable: for the error is always in proportion to the length of the focus in any glass; and in very long telescopes it becomes exceedingly great, being no less than  $\frac{1}{4}$ th of the whole; but in glasses of a few inches focus it becomes trifling. Refracting telescope, which go by the name of *Dol-*

*lond's*, are therefore now constructed in the following manner. Let AB (fig. 6.) represent an object glass composed of three lenses as above described, and converging the rays 1, 2, 3, 4, &c. to a very distant focus as at  $x$ . By means of the interposed lens CD, however, they are converged to one much nearer, as at  $y$ , where an image of the object is formed. The rays diverging from thence fall upon another lens EF, where the pencils are rendered parallel, and an eye placed near that lens would see the object magnified and very distinct. To enlarge the magnifying power still more, however, the pencils thus become parallel are made to fall upon another at GH; by which they are again made to converge to a distant focus: but, being intercepted by the lens IK, they are made to meet at the nearer one  $z$ ; whence diverging to LM, they are again rendered parallel, and the eye at N sees the object very distinctly.

From an inspection of the figure it is evident, that Dollond's telescope thus constructed is in fact two telescopes combined together; the first ending with the lens EF, and the second with LM. In the first we do not perceive the object itself, but the image of it formed at  $y$ ; and in the second we perceive only the image of that image formed at  $z$ . Nevertheless such telescopes are exceedingly distinct, and represent objects so clearly as to be preferred, in viewing terrestrial things, even to reflectors themselves. The latter indeed have greatly the advantage in their powers of magnifying, but they are much deficient in point of light. Much more light is lost by reflection than by refraction: and as in these telescopes the light must unavoidably suffer two reflections, a great deal of it is lost; nor is this loss counterbalanced by the greater aperture which these telescopes will bear, which enables them to receive a greater quantity of light than the refracting ones. The metals of reflecting telescopes also are very much subject to tarnish, and require much more dexterity to clean them than the glasses of refractors; which makes them more troublesome and expensive, though for making discoveries in the celestial regions they are undoubtedly the only proper instruments which have been hitherto constructed. If Dr Blair indeed shall be so fortunate as discover a vitreous substance of the same powers with the fluid in the compound object glass of his telescope (and from his abilities and perseverance we have every thing to hope), a refracting telescope may be constructed superior for every purpose to the best reflector.

## II. THE REFLECTING TELESCOPE.

THE inconveniences arising from the great length of refracting telescopes, before Dollond's discovery, are sufficiently obvious; and these together with the difficulties occasioned by the different refrangibility of light, induced Sir Isaac Newton to turn his attention to the subject of reflection, and endeavour to realize the ideas of himself and others concerning the possibility of constructing telescopes upon that principle.—The instrument which he conceived is represented, fig. 7. where ABCD is a large tube, open at AD and closed at BC, and of a length at least equal to the distance of the focus from the metallic spherical concave speculum GH placed at the end BC. The rays EG, FH, &c. proceeding from a remote object PR, intersect

275  
Gregorian  
telescope.

intersect one another somewhere before they enter the tube, so that  $EG$ ,  $eg$  are those that come from the lower part of the object, and  $fh$ ,  $FH$  from its upper part: these rays, after falling on the speculum  $GH$ , will be reflected, so as to converge and meet in  $mn$ , where they will form a perfect image of the object. — But as this image cannot be seen by the spectator, they are intercepted by a small plane metallic speculum  $KK$ , intersecting the axis at an angle of  $45^\circ$ , by which the rays tending to  $mn$  will be reflected towards a hole  $LL$  in the side of the tube, and the image of the object will thus be formed in  $qS$ ; which image will be less distinct, because some of the rays which would otherwise fall on the concave speculum  $GH$ , are intercepted by the plane speculum: nevertheless it will appear in a considerable degree distinct, because the aperture  $AD$  of the tube, and the speculum  $GH$  are large. In the lateral hole  $LL$  is fixed a convex lens, whose focus is at  $Sq$ ; and therefore this lens will refract the rays that proceed from any point of the image, so as at their exit they will be parallel, and those that proceed from the extreme points  $Sq$  will converge after refraction, and form an angle at  $O$ , where the eye is placed; which will see the image  $Sq$ , as if it were an object, through the lens  $LL$ ; consequently the object will appear enlarged, inverted, bright, and distinct. In  $LL$  lenses of different convexities may be placed, which by being moved nearer to the image or farther from it, would represent the object more or less magnified, provided that the surface of the speculum  $GH$  be of a perfectly spherical figure. If, in the room of one lens  $LL$ , three lenses be disposed in the same manner with the three eye glasses of the refracting telescope, the object will appear erect, but less distinct than when it is observed with one lens. On account of the position of the eye in this telescope, it is extremely difficult to direct the instrument towards any object. Huygens, therefore, first thought of adding to it a small refracting telescope, the axis of which is parallel to that of the reflector. This is called a *finder*, or *director*. The Newtonian telescope is also furnished with a suitable apparatus for the commodious use of it.

274  
Its magni-  
fying  
power.

Plate  
CCCLXV.

In order to determine the magnifying power of this telescope, it is to be considered that the plane speculum  $KK$  is of no use in this respect. Let us then suppose, that one ray proceeding from the object coincides with the axis  $GLA$  (fig. 8.) of the lens and speculum; let  $bb$  be another ray proceeding from the lower extreme of the object, and passing through the focus  $I$  of the speculum  $KH$ : this will be reflected in the direction  $bId$ , parallel to the axis  $GLA$ , and falling on the lens  $dLd$ , will be refracted to  $G$ ; so that  $GL$  will be equal to  $LI$ , and  $dG = dI$ . To the naked eye the object would appear under the angle  $Ibi = bIA$ ; but by means of the telescope it appears under the angle  $dGL = dIL = Idi$ : and the angle  $Idi$  is to the angle  $Ibi :: bI : Id$ ; consequently the apparent magnitude by the telescope is to that by the naked eye as the distance of the focus of the speculum from the speculum, to the distance of the focus of the lens from the lens.

The Newtonian telescope was still inconvenient. Notwithstanding the contrivance of Huygens, objects were by it found with difficulty. The telescope of

Gregory, therefore, soon obtained the preference, to which for most purposes it is justly intitled, as the reader will perceive from the following construction.

Let  $TYT$  (fig. 9.) be a brass tube, in which  $LdD$  is a metallic concave speculum, perforated in the middle at  $X$ ; and  $EF$  a less concave mirror, so fixed by the arm or strong wire  $RT$ , which is moveable by means of a long screw on the outside of the tube, as to be moved nearer to or farther from the larger speculum  $LdD$ , its axis being kept in the same line with that of the great one. Let  $AB$  represent a very remote object, from each part of which issue pencils of rays, e. g.  $cd$ ,  $CD$ , from  $A$  the upper extreme of the object, and  $il$ ,  $iI$ , from the lower part  $B$ ; the rays  $IL$ ,  $CD$  from the extremes crossing one another before they enter the tube. These rays, falling upon the larger mirror  $LD$ , are reflected from it into the focus  $KH$ , where they form an inverted image of the object  $AB$ , as in the Newtonian telescope. From this image the rays, issuing as from an object, fall upon the small mirror  $EF$ , the centre of which is at  $e$ ; so that after reflection they would meet in their foci at  $QQ$ , and there form an erect image. But since an eye at that place could see but a small part of an object, in order to bring rays from more distant parts of it into the pupil, they are intercepted by the plano-convex lens  $MN$ , by which means a smaller erect image is formed at  $PV$ , which is viewed through the meniscus  $SS$  by an eye at  $O$ . This meniscus both makes the rays of each pencil parallel, and magnifies the image  $PV$ . At the place of this image all the foreign rays are intercepted by the perforated partition  $ZZ$ . For the same reason the hole near the eye  $O$  is very narrow. When nearer objects are viewed by this telescope, the small speculum  $EF$  is removed to a greater distance from the larger  $LD$ , so that the second image may be always formed in  $PV$ ; and this distance is to be adjusted (by means of the screw on the outside of the great tube) according to the form of the eye of the spectator. It is also necessary, that the axis of the telescope should pass through the middle of the speculum  $EF$ , and its centre, the centre of the speculum  $LL$ , and the middle of the hole  $X$ , the centres of the lenses  $MN$ ,  $SS$ , and the hole near  $O$ . As the hole  $X$  in the speculum  $LL$  can reflect none of the rays issuing from the object, that part of the image which corresponds to the middle of the object must appear to the observer more dark and confused than the extreme parts of it. Besides, the speculum  $EF$  will also intercept many rays proceeding from the object; and therefore, unless the aperture  $TT$  be large, the object must appear in some degree obscure.

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus of the great one, where the first image  $KH$  is formed, but a little beyond it (with respect to the eye), as at  $n$ ; the consequence of which is, that the rays of the pencils will not be parallel after reflection from the small mirror, but converge so as to meet in points about  $QqQ$ , where they would form a larger upright image than  $PV$ , if the glass  $R$  was not in their way; and this image might be viewed by means of a single eye-glass properly placed between the image and the eye: but then the field of view would be less, and consequently

Reflecting  
Telescope.

276  
Its magni-  
fying  
power.

quently not so pleasant; for which reason, the glass R is still retained, to enlarge the scope or area of the field.

To find the magnifying power of this telescope, multiply the focal distance of the great mirror by the distance of the small mirror from the image next the eye, and multiply the focal distance of the small mirror by the focal distance of the eye-glass: then divide the product of the former multiplication by the product of the latter, and the quotient will express the magnifying power.

One great advantage of the reflecting telescope is, that it will admit of an eye-glass of a much shorter focal distance than a refracting telescope will; and consequently it will magnify so much the more: for the rays are not coloured by reflection from a concave mirror, if it be ground to a true figure, as they are by passing through a convex glass, let it be ground ever so true.

The nearer an object is to the telescope, the more its pencils of rays will diverge before they fall upon the great mirror, and therefore they will be the longer of meeting in points after reflection; so that the first image KHI will be formed at a greater distance from the large mirror, when the object is near the telescope, than when it is very remote. But as this image must be formed farther from the small mirror than its principal focus  $n$ , this mirror must be always set at a greater distance from the large one, in viewing near objects, than in viewing remote ones. And this is done by turning the screw on the outside of the tube, until the small mirror be so adjusted, that the object (or rather its image) appears perfect.

In looking through any telescope towards an object, we never see the object itself, but only that image of it which is formed next the eye in the telescope. For if a man holds his finger or a stick between his bare eye and an object, it will hide part (if not the whole) of the object from his view: But if he ties a stick across the mouth of a telescope before the object-glass, it will hide no part of the imaginary object he saw through the telescope before, unless it covers the whole mouth of the tube: for all the effect will be, to make the object appear dimmer, because it intercepts part of the rays. Whereas, if he puts only a piece of wire across the inside of the tube, between the eye-glass and his eye, it will hide part of the object which he thinks he sees; which proves, that he sees not the real object, but its image. This is also confirmed by means of the small mirror EF, in the reflecting telescope, which is made of opaque metal, and stands directly between the eye and the object towards which the telescope is turned; and will hide the whole object from the eye at O, if the two glasses ZZ and SS are taken out of the tube.

Great improvements have been lately made in the construction of both reflecting and refracting telescopes, as well as in the method of applying these instruments to the purposes for which they are intended. These, however, fall not properly under the science of optics, as sifter oppositions occur of giving a full account of them, as well as of the magic lantern, camera obscura, &c. under other articles of our multifarious work. See CATOPTICS, DIOPTRICS, SPECULUM,

and TELESCOPE. We shall conclude this article with some observations

*On the different Merits of Microscopes and Telescopes, compared with one another; how far we may reasonably depend on the Discoveries made by them, and what hopes we may entertain of further Improvements.*

THE advantages arising from the use of microscopes and telescopes depend, in the first place, upon their property of magnifying the minute parts of objects, so that they can by that means be more distinctly viewed by the eye; and, secondly, upon their throwing more light into the pupil of the eye than what is done without them. The advantages arising from the magnifying power would be extremely limited, if they were not also accompanied by the latter: for if the same quantity of light is spread over a large portion of surface, it becomes proportionably diminished in force; and therefore the objects, though magnified, appear proportionably dim. Thus, though any magnifying glass should enlarge the diameter of the object 10 times, and consequently magnify the surface 100 times, yet if the focal distance of the glass was about eight inches (provided this was possible), and its diameter only about the size of the pupil of the eye, the object would appear 100 times more dim when we looked through the glass, than when we beheld it with our naked eyes; and this, even on a supposition that the glass transmitted all the light which fell upon it, which no glass can do. But if the focal distance of the glass was only four inches, though its diameter remained as before, the inconvenience would be vastly diminished, because the glass could then be placed twice as near the object as before, and consequently would receive four times as many rays as in the former case, and therefore we would see it much brighter than before. Going on thus, still diminishing the focal distance of the glass, and keeping its diameter as large as possible, we will perceive the object more and more magnified, and at the same time very distinct and bright. It is evident, however, that with regard to optical instruments of the microscopic kind, we must sooner or later arrive at a limit which cannot be passed. This limit is formed by the following particulars. 1. The quantity of light lost in passing through the glass. 2. The diminution of the glass itself, by which it receives only a small quantity of rays. 3. The extreme shortness of the focal distance of great magnifiers, whereby the free access of the light to the object which we wish to view is impeded; and consequently the reflection of the light from it is weakened. 4. The aberrations of the rays, occasioned by their different refrangibility.

To understand this more fully, as well as to see how far these obstacles can be removed, let us suppose the lens made of such a dull kind of glass that it transmits only one half of the light which falls upon it. It is evident that such a glass, of four inches focal distance, and which magnifies the diameter of an object twice, still supposing its own breadth equal to that of the pupil of the eye, will show it four times magnified in surface, but only half as bright as if it was seen by the naked eye at the usual distance; for the light which falls upon the eye from the object at eight inches distance, and likewise the surface of the object in its natural

compared.

Micro-  
scopes and  
Telescopes  
compared.

natural size, being both represented by 1, the surface of the magnified object will be 4, and the light which makes that magnified object visible only 2; because though the glass receives four times as much light as the naked eye does at the usual distance of distinct vision, yet one half is lost in passing through the glass. The inconvenience in this respect can therefore be removed only as far as it is possible to increase the clearness of the glass, so that it shall transmit nearly all the rays which fall upon it; and how far this can be done hath not yet been ascertained.

The second obstacle to the perfection of microscopic glasses is the small size of great magnifiers, by which, notwithstanding their near approach to the object, they receive a smaller quantity of rays than might be expected. Thus, suppose a glass of only  $\frac{1}{4}$ th of an inch focal distance; such a glass would increase the visible diameter 80 times, and the surface 6400 times. If the breadth of the glass could at the same time be preserved as great as that of the pupil of the eye, which we shall suppose  $\frac{1}{2}$ th of an inch, the object would appear magnified 6400 times, at the same time that every part of it would be as bright as it appears to the naked eye. But if we suppose that this magnifying glass is only  $\frac{1}{2}$ th of an inch in diameter, it will then only receive  $\frac{1}{4}$ th of the light which otherwise would have fallen upon it; and therefore, instead of communicating to the magnified object a quantity of illumination equal to 6400, it would communicate only one equal to 1600, and the magnified object would appear four times as dim as it does to the naked eye. This inconvenience, however, is still capable of being removed, not indeed by increasing the diameter of the lens, because this must be in proportion to its focal distance, but by throwing a great quantity of light on the object. Thus, in the abovementioned example, if four times the quantity of light which naturally falls upon it could be thrown upon the object, it is plain that the reflection from it would be four times as great as in the natural way; and consequently the magnified image, at the same time that it was as many times magnified as before, would be as bright as when seen by the naked eye. In transparent objects this can be done very effectually by a concave speculum, as in the reflecting microscope already described: but in opaque objects the case is somewhat more doubtful; neither do the contrivances for viewing these objects seem entirely to make up for the deficiencies of the light from the smallness of the lens and shortness of the focus.—When a microscopic lens magnifies the diameter of an object 40 times, it hath then the utmost possible magnifying power, without diminishing the natural brightness of the object.

The third obstacle arises from the shortness of the focal distance in large magnifiers: but in transparent objects, where a sufficient quantity of light is thrown on the object from below, the inconvenience arises at last from straining the eye which must be placed nearer the glass than it can well bear; and this entirely supercedes the use of magnifiers beyond a certain degree.

The fourth obstacle arises from the different refrangibility of the rays of light, and which frequently causes such a deviation from truth in the appearances of things, that many people have imagined themselves to have

made surprising discoveries, and have even published them to the world; when in fact they have been only as many optical deceptions, owing to the unequal refractions of the rays. For this there seems to be no remedy, except the introduction of achromatic glasses into microscopes as well as telescopes. How far this is practicable, hath not yet been tried; but when these glasses shall be introduced (if such introduction is practicable), microscopes will then undoubtedly have received their ultimate degree of perfection.

With regard to telescopes, those of the refracting kind have evidently the advantage of all others, where the aperture is equal, and the aberrations of the rays are corrected according to Mr Dollond's method; because the image is not only more perfect, but a much greater quantity of light is transmitted than what can be reflected from the best materials hitherto known. Unluckily, however, the imperfections of the glass set a limit to these telescopes, as hath already been observed, so that they cannot be made above three feet and an half long. On the whole, therefore, the reflecting telescopes are preferable in this respect, that they may be made of dimensions greatly superior; by which means they can both magnify to a greater degree, and at the same time throw much more light into the eye.

With regard to the powers of telescopes, however, they are all of them exceedingly less than what we would be apt to imagine from the number of times which they magnify the object. Thus, when we hear of a telescope which magnifies 200 times, we are apt to imagine, that, on looking at any distant object through it, we should perceive it as distinctly as we would with our naked eye at the 200th part of the distance. But this is by no means the case; neither is there any theory capable of directing us in this matter: we must therefore depend entirely on experience.

The best method of trying the goodness of any telescope is by observing how much farther off you are able to read with it than you can with the naked eye. But that all deception may be avoided, it is proper to choose something to be read where the imagination cannot give any assistance, such as a table of logarithms, or something which consists entirely of figures; and hence the truly useful power of the telescope is easily known. In this way Mr Short's large telescope, which magnifies the diameter of objects 1200 times, is yet unable to afford sufficient light for reading at more than 200 times the distance at which we can read with our naked eye.

With regard to the form of reflecting telescopes, it is now pretty generally agreed, that when the Gregorian ones are well constructed, they have the advantage of those of the Newtonian form. One advantage evident at first sight is, that with the Gregorian telescope an object is perceived by looking directly through it, and consequently is found with much greater ease than in the Newtonian telescope, where we must look into the side. The unavoidable imperfection of the specula common to both, also gives the Gregorian an advantage over the Newtonian form. Notwithstanding the utmost care and labour of the workmen, it is found impossible to give the metals either a perfectly spherical or a perfectly parabolical form. Hence arises

some indistinctness of the image formed by the great speculum, which is frequently corrected by the little one, provided they are properly matched. But if this is not done, the error will be made much worse; and hence many of the Gregorian telescopes are far inferior to the Newtonian ones; namely, when the specula have not been properly adapted to each other. There is no method by which the workman can know the specula which will fit one another without a trial; and therefore there is a necessity for having many specula ready made of each sort, that in fitting up a telescope those may be chosen which best suit each other.

The brightness of any object seen through a telescope, in comparison with its brightness when seen by the naked eye, may in all cases be easily found by the following formula. Let  $n$  represent the natural distance of a visible object, at which it can be distinctly seen; and let  $d$  represent its distance from the object-glass of the instrument. Let  $m$  be the magnifying power of the instrument; that is, let the visual angle subtended at the eye by the object when at the distance  $n$ , and viewed without the instrument, be to the

visual angle produced by the instrument as 1 to  $m$ . Let  $a$  be the diameter of the object-glass, and  $p$  be that of the pupil. Let the instrument be so constructed, that no parts of the pencils are intercepted for want of sufficient apertures of the intermediate glasses. Lastly, let the light lost in reflection or refraction be neglected.

The brightness of vision through the instrument will

be expressed by the fraction  $\frac{an}{mpd}$ , the brightness of

natural vision being 1. But although this fraction may exceed unity, the vision through the instrument will not be brighter than natural vision. For, when this is the case, the pupil does not receive all the light transmitted through the instrument.

In microscopes,  $n$  is the nearest limits of distinct vision, nearly 8 inches. But a difference in this circumstance, arising from a difference in the eye, makes no change in the formula, because  $m$  changes in the same proportion with  $n$ .

In telescopes,  $n$  and  $d$  may be accounted equal, and the formula becomes  $\frac{a^2}{mp^2}$ .

## O P T

Optimates,  
Optio.

OPTIMATES, one of the divisions of the Roman people opposed to *populares*. It is not easy to ascertain the characteristic differences betwixt these two parties. Some say the optimates were warm supporters of the dignity of the chief magistrate, and promoters of the grandeur of the state, who cared not if the inferior members suffered, provided the commanding powers were advanced: Whereas the *populares* boldly stood up for the rights of the people, pleaded for larger privileges, and laboured to bring matters nearer to a level. In short, they resembled, according to this account, the court and country parties amongst the people of Great Britain.

Tully says, that the optimates were the best citizens, who wished to deserve the approbation of the better sort; and that the *populares* courted the favour of the populace, not so much considering what was right, as what would please the people and gratify their own thirst of vain glory and empty applause.

OPTIO, an officer in the Roman army, being an assistant or lieutenant to every centurion. The *optio* was so called because he was the choice or option of the centurion in latter times; at first, however, he had been chosen by the tribune, or chief commander of the legion. These *optiones* are also sometimes called *succenturiones* and *tergiductores*; the last name was given them because their post was in the rear of the company. Some authors make mention of *sub-optiones* or sub-lieutenants.

## O P U

It is proper however to add, that *optiones* were not peculiar to the camp, but were also used in a variety of other offices of life.

OPTION, the power or faculty of wishing or choosing; or the choice a person makes of any thing.

When a new suffragan bishop is consecrated, the archbishop of the province, by a customary prerogative, claims the collation of the first vacant benefice, or dignity, in that see, according as he shall choose; which choice is called the archbishop's *option*.

But in case the bishop dies, or is translated, before the present incumbent of the promotion chosen by the archbishop shall die or be removed, it is generally supposed that the option is void; inasmuch as the granter, singly and by himself, could not convey any right or title beyond the term of his continuance in that see. And if the archbishop dies before the avoidance shall happen, the right of filling up the vacancy shall go to his executors or administrators.

OPUNTIA, a species of cactus; see CACTUS. The fruit of the opuntia is remarkable for colouring the juices of living animals, though it appears not to be poisonous or even hurtful to the body. In a letter from Charleston in South Carolina, which was published in the 50th volume of the Philosophical Transactions, the author writes thus:—"As you desired, I tried the effects of the prickly pear in clearing the urine. A few days after your letter, I went down to one of the islands, and gathered some of the fruit, and

Option,  
Opuntia.

Or  
||  
Oracle.

and gave four of the pears to a child of three years of age, and six pears to one of five. The next morning I examined the urine of both, and it appeared of a very lively red colour, as if tart-wine had been mixed with water. I gave likewise six pears to a negro-wench, who was suckling an infant, and strictly forbade her to put the child to her breast for six or eight hours; and then taking some of her milk in a tea-cup, and setting it by for some hours, the cream had a reddish lustre, though it was very faint." From the same letter we learn, that the prickly pear grows in great abundance about Carolina; and also that the cochineal insects are found upon it, though no attempt, that we know of, has hitherto been made to cure them for use as the Spaniards do.

OR, the French word for gold, by which this metal is expressed in heraldry. In engraving it is denoted by small points all over the field or bearing. It may be supposed to signify of itself, *generosity*, *splendor*, or *solidity*; according to G. Leigh, if it is compounded with

Gul.	} it signifies	Courage.
Azu.		Trust.
Vor.		Joy.
Pur.		Charity.
Sab.		Constancy.

ORA, in antiquity, was a term equivalent to an ounce; but it has been much debated among our antiquaries, whether the ora, the mention of which so often occurs, was a coin, or only money of account. Dr Hickes observes, that the mode of reckoning money by marks and oras was never known in England till after the Danish settlements; and by examining the old nummulary estimates among the principal Gothic states upon the Baltic, it appears, that the ora and solidus were synonymous terms, and that the ora was the eighth part of the mark. From several of the Danish laws, it likewise appears, that the Danish ora, derived by corruption from *aureus*, was the same as the Frank solidus of twelve pence. As a weight, the ora was regarded as the uncia or unit, by which the Danish mark was divided; and in Doomsday-book the ora is used for the ounce, or the twelfth part of the nummulary Saxon pound, and the fifteenth of the commercial: as a coin, it was an aureus, or the Frank solidus of twelve pence. And from the accidental coincidence of the Frank aureus with the eighth part of their mark, the Danes probably took occasion to give it the new name of *ora*. There was another ora mentioned in the rolls of the 27th of Henry III. the value of which was sixteen pence; and this was probably derived from the half mancus of the Saxons. Such, in all appearance, was the original of these two oras; as there were no aurei of that period, to which these two denominations of money of sixteen and twelve pence can possibly be ascribed. It is observed farther, that the name *ora* distinguishes the gold coins in several parts of Europe to this day. The Portuguese moidore is nothing else but *moeda d'oro*, from the Latin *moneta de auro*; the French *Louis d'ores* come from the same use of the word, and owe their appellation to the ora. See Clarke on Coins.

ORACH. See ATRIPLEX.

Wild ORACH. See CHENOPODIUM.

ORACLE, among the heathens, was the answer

which the gods were supposed to give to those who consulted them upon any affair of importance. It is also used for the god who was thought to give the answer, and for the place where it was given.

Oracle.

The credit of oracles was so great, that in all doubts and disputes their determinations were held sacred and inviolable: whence vast numbers flocked to them for advice about the management of their affairs; and no business of any consequence was undertaken, scarce any peace concluded, any war waged, or any new form of government instituted, without the advice and approbation of some oracle. The answers were usually given by the intervention of the priest or priestess of the god who was consulted; and generally expressed in such dark and unintelligible phrases, as might be easily wrested to prove the truth of the oracle whatever was the event. It is not, therefore, to be wondered at, that the priests who delivered them were in the highest credit and esteem, and that they managed this reputation so as greatly to promote their own particular advantage. They accordingly allowed no man to consult the gods, before he had offered costly sacrifices, and made rich presents to them. And to keep up the veneration for their oracles, and to prevent their being taken unprepared, they admitted persons to consult the gods only at certain stated times; and sometimes they were so cautious, that the greatest personages could obtain no answer at all. Thus Alexander himself was peremptorily denied by the Pythia, or priestess of Apollo, till she was by downright force obliged to ascend the tripod; when, being unable to resist any longer, she cried out, *Thou art invincible*: and these words were accepted instead of a farther oracle.

Of the ambiguity of oracles, the following, out of a great many examples, may be mentioned. Cræsus having received from the Pythoneses this answer, That by passing the river Halys, he would destroy a great empire; he understood it to be the empire of his enemy, whereas he destroyed his own.—The oracle consulted by Pyrrhus gave him an answer, which might be equally understood of the victory of Pyrrhus, and the victory of the Romans his enemies:

*Aio te, Æcida, Romanos vincere posse.*

The equivocation lies in the construction of the Latin tongue, which cannot be rendered in English.—The Pythoneses advised Cræsus to guard against the mule. The king of Lydia understood nothing of the oracle, which denoted Cyrus descended from two different nations; from the Medes, by Mandana his mother, the daughter of Astyages; and from the Persians, by his father Cambyfes, whose race was by far less grand and illustrious.—Nero had for answer from the oracle of Delphos, that seventy-three might prove fatal to him. He believed he was safe from all danger till that age; but, finding himself deserted by every one, and hearing Galba proclaimed emperor, who was 73 years of age, he was sensible of the deceit of the oracle.

When men began to be better instructed by the lights philosophy had introduced into the world, the false oracles insensibly lost their credit. Chrysippus filled an entire volume with false or doubtful oracles. Oenomaus, to be revenged of some oracle that had deceived him, made a compilation of oracles, to show their

Oracle.

their ridiculous vanity. Eusebius has preserved some fragments of this criticism on oracles by Oenomaus. "I might (says Origen) have recourse to the authority of Aristotle and the Peripatetics, to make the Pythoness much suspected; I might extract from the writings of Epicurus and his sectators an abundance of things to discredit oracles; and I might show that the Greeks themselves made no great account of them."

The reputation of oracles was greatly lessened when they became an artifice of politics. Themistocles, with a design of engaging the Athenians to quit Athens, and to embark, in order to be in a better condition to resist Xerxes, made the pythoness deliver an oracle, commanding them to take refuge in wooden walls. Demosthenes said, that the Pythoness *Philipised*; to signify that she was gained over by Philip's presents.

The cessation of oracles is attested by several profane authors; as Strabo, Juvenal, Lucan, and others. Plutarch accounts for it, by saying, that the benefits of the gods are not eternal as themselves are; or that the genii, who presided over oracles, are subject to death; or that the exhalations of the earth had been exhausted. It appears that the last reason had been alleged in the time of Cicero, who ridicules it in his second book of Divination, as if the spirit of prophecy, supposed to be excited by subterraneous effluvia, had evaporated by length of time, as wine or pickle by being long kept.

Suidas, Nicephorus, and Cedrenus, relate, that Augustus, having consulted the oracle of Delphos, could obtain no other answer but this: "The Hebrew child whom all the gods obey, drives me hence, and sends me back to hell: get out of this temple without speaking one word." Suidas adds, that Augustus dedicated an altar in the Capitol, with this inscription, "To the eldest Son of God." Notwithstanding these testimonies, the answer of the oracle of Delphos to Augustus seems very suspicious. Cedrenus cites Eusebius for this oracle, which is not now found in his works; and Augustus's peregrination into Greece was 18 years before the birth of Christ.

Suidas and Cedrenus give an account also of an ancient oracle delivered to Thulis, a king of Egypt, which they say is well authenticated. The king having consulted the oracle of Serapis, to know if there ever was, or would be, one so great as himself, received this answer: "First, God, next the Word, and the Spirit with them. They are equally eternal, and make but one, whose power will never end. But thou, mortal, go hence, and think that the end of the life of man is uncertain."

Van Dale, in his treatise of oracles, does not believe that they ceased at the coming of Christ. He relates several examples of oracles consulted till the death of Theodosius the Great. He quotes the laws of the emperors Theodosius, Gratian, and Valentinian, against those who consulted oracles, as a certain proof that the superstition of oracles still subsisted in the time of those emperors.

According to others, the opinion of those who believe that demons had no share in the oracles, and that the coming of the Messiah made no change in

them, and the contrary opinion of those who pretend that the incarnation of the Word imposed a general silence on all oracles, should be equally rejected. They allege, that two sorts of oracles ought to be distinguished: the one dictated by the spirits of darkness, who deceived men by their obscure and doubtful answers; the other the pure artifice and cheat of the priests of false divinities. As to the oracles given out by demons, the reign of Satan was destroyed by the coming of the Saviour; truth shut the mouth of lies; but Satan continued his old craft among idolaters. All the devils were not forced to silence at the same time by the coming of the Messiah; it was on particular occasions that the truth of Christianity, and the virtue of Christians, imposed silence on the devils. St Athanasius tells the Pagans, that they have been witnesses themselves that the sign of the cross puts the devils to flight, silences oracles, and dissipates enchantments. This power of silencing oracles, and putting the devils to flight, is also attested by Arnobius, Lactantius, Prudentius, Minutius Felix, and several others. Their testimony is a certain proof that the coming of the Messiah had not imposed a general silence on oracles.

Plutarch relates, that the pilot Thamos heard a voice in the air, crying out, "The great Pan is dead;" whereupon Eusebius observes, that the accounts of the death of the demons were frequent in the reign of Tiberius, when Christ drove out the wicked spirits.

The same judgment, as is said, may be passed on oracles as on *possessions*. It was on particular occasions, by the divine permission, that the Christians cast out devils, or silenced oracles, in the presence, and even by the confession, of the Pagans themselves. And thus it is we should, it seems, understand the passages of St Jerom, Eusebius, Cyril, Theodoret, Prudentius, and other authors, who said that the coming of Christ had imposed silence on the oracles.

As to the second sort of oracles, which were pure artifices and cheats of the priests of false divinities, and which probably exceeded the number of those that immediately proceeded from demons, they did not cease till idolatry was abolished, though they had lost their credit for a considerable time before the coming of Christ. It was concerning this more common and general sort of oracles that Minutius Felix said, they began to discontinue their responses, according as men began to be more polite. But, however oracles were decried, impostors always found dupes, the grossest cheats having never failed.

Daniel discovered the imposture of the priests of Bel, who had a private way of getting into the temple to take away the offered meats, and who made the king believe that the idol consumed them.—Mundus, being in love with Paulina, the eldest of the priestesses of Isis, went and told her, that the god Anubis, being passionately fond of her, commanded her to give him a meeting. She was afterwards shut up in a dark room, where her lover Mundus, whom she believed to be the god Anubis, was concealed. This imposture having been discovered, Tiberius ordered those detestable priests and priestesses to be crucified, and with them Idea, Mundus's free-woman, who had conducted the whole intrigue. He also commanded the

Oracle.

Oracle.

the temple of Isis to be levelled with the ground, and her statue to be thrown into the Tiber; and as to Mundus, he contented himself with sending him into banishment.

Theophilus, bishop of Alexandria, not only destroyed the temples of the false gods, but discovered the cheats of the priests, by showing that the statues, some of which were of brass, and others of wood, were hollow within, and led into dark passages made in the wall.

Lucian, in discovering the impostures of the false prophet Alexander, says, that the oracles were chiefly afraid of the subtilties of the Epicureans and Christians. The false prophet Alexander sometimes feigned himself seized with a divine fury, and by means of the herb popewort, which he chewed, frothed at the mouth in so extraordinary a manner, that the ignorant people attributed it to the strength of the god he was possessed by. He had long before prepared a head of a dragon made of linen, which opened and shut its mouth by means of a horse-hair. He went by night to a place where the foundations of a temple were digging; and having found water, either of a spring, or rain that had settled there, he hid in it a goose-egg, in which he had inclosed a little serpent that had been just hatched. The next day, very early in the morning, he came quite naked into the street, having only a scarf about his middle, holding in his hand a scythe, and tossing about his hair as the priests of Cybele; then getting a-top of a high altar, he said that the place was happy to be honoured by the birth of a god.—Afterwards, running down to the place where he had hid the goose-egg, and going into the water, he began to sing the praises of Apollo and Æsculapius, and to invite the latter to come and show himself to men. With these words, he dips a bowl into the water, and takes out a mysterious egg, which had a god inclosed in it; and when he had it in his hand, he began to say that he held Æsculapius. Whilst all were eager to have a sight of this fine mystery, he broke the egg, and the little serpent starting out, twisted itself about his fingers.

These examples show clearly, that both Christians and Pagans were so far agreed as to treat the *greater number* of oracles as purely human impostures.—That, in fact, ALL of them were so, will be concluded by those who give equal credit to *dæmoniacal inspiration*, and *dæmoniacal possession*. The most ancient oracle was that of Dodona (see DODONA); but the most famous was that of Delphi, to which article we also refer for further particulars on this subject, so famous in Pagan antiquity. Another celebrated one was the oracle of Trophonius, in the neighbourhood of Lebadia, a city of Bœotia, which was held in high estimation. It received its name from Trophonius, brother of Agamedes, who lived in a subterraneous dwelling near Lebadia, and pretended to the faculty of foretelling future events. He died in his cave, and was deified as an oracular god. This oracle owed its reputation to one Saon.

Those who repaired to this cave for information, were required to offer certain sacrifices, to anoint themselves with oil, and to bathe in a certain river; They were then clothed in a linen robe, took a ho-

neyed cake in their hands, and descended into the subterraneous chamber by a narrow passage. Here it was that futurity was unfolded to them, either by visions or extraordinary sounds. The return from the cave was by the same passage, but the persons consulting were obliged to walk backwards. They generally came out astonished, melancholy, and dejected; hence the proverb, *ἐκ Τροφονίου μελαινέονται*. The priests on their return placed them on an elevated seat, called *the seat of Mnemosyne*, where an account was taken of what they had seen and heard. They were then conducted to the chapel of good Genius by their companions, where, by degrees, they recovered their usual composure and cheerfulness.

Besides these three principal oracles of Greece, it is proper to take notice of that of Amphiaraus at Oropus in Attica. It was so called from Amphiaraus, the son of Oicleus, a man skilled in magic, the interpretation of dreams, &c. and who after his death was deified and delivered oracles in a temple erected to his divinity. (See AMPHIARAUS.) They who applied to him for information, were to purify themselves, offer sacrifice, fast twenty-four hours, abstain from wine two days, and make an offering of a ram to Amphiaraus; on the skin of which they were to sleep, and see their destiny in a dream. Near the temple was Amphiaraus's fountain, which was sacred, and the waters of it forbidden to be used for ordinary purposes.

At Delos also there was an oracle of the Delian Apollo: in Milesia was that of the Branchidæ, with others of less note, which require not a particular description, such as that of the camps at Lacedæmon, that of Nabarcha, that of Chrysepolis, that of Claros in Ionia, that of Malles, that of Patarea, that of Pella, that of Phaselides, that of Sinope, that of Orpheus's head, &c.

Though the Romans consulted the Grecian oracles upon many occasions, and had few oracles in their own country; yet we must not omit mentioning the Cumæan oracles, which were delivered by the Sibyl of Cumæ. For an account of the Sibyls, see the article SIBYL. See also DÆMON and DÆMONIAC.

We have hitherto only considered the oracles of false gods, of which there was a far greater number than our limits permit us to observe, and before either Greeks or Romans had risen to any distinction. Oracle is in sacred history sometimes used for the mercy-seat, or the cover of the ark of the covenant; and by others it is taken for the sanctuary, or for the most holy place, wherein the ark was deposited.

Among the Jews we may distinguish several sorts of *real* oracles. They had first oracles that were delivered  *viva voce* ; as when God spake to Moses face to face, and as one friend speaks to another, (Numb. xii. 8.) Secondly, Prophetic dreams sent by God; as the dreams which God sent to Joseph, and which foretold his future greatness, (Gen. xxxvii. 5, 6.) Thirdly, Visions; as when a prophet in an ecstasy, being neither properly asleep nor awake, had supernatural revelations, (Gen. xv. 1. xvi. 2.) Fourthly, The oracle of Urim and Thummim, which was accompanied with the ephod or the pectoral worn by the high-priest, and which God had endued with the gift of foretelling things

Oracle.

things to come, (Numb. xii. 6. Joel ii. 28.) This manner of inquiring of the Lord was often made use of, from Joshua's time to the erection of the temple at Jerusalem. Fifthly, After the building of the temple, they generally consulted the prophets, who were frequent in the kingdoms of Judah and Israel. From Haggai, Zechariah, and Malachi, who are the last of the prophets that have any of their writings remaining, the Jews pretend that God gave them what they call *Bathcol*, the daughter of the voice, which was a supernatural manifestation of the will of God, which was performed either by a strong inspiration or internal voice, or else by a sensible and external voice, which was heard by a number of persons sufficient to bear testimony of it. For example, such was the voice that was heard at the baptism of Jesus Christ, saying, This is my beloved son, &c. (Matth. iii. 17.)

The scripture affords us examples likewise of profane oracles. Balaam, at the instigation of his own spirit, and urged on by his avarice, fearing to lose the recompense that he was promised by Balak king of the Moabites, suggests a diabolical expedient to this prince, of making the Israelites fall into idolatry and fornication (Numb. xxiv. 14. xxxi. 16.), by which he assures him of a certain victory, or at least of considerable advantage against the people of God.

Micaiah the son of Imlah, a prophet of the Lord, says (1 Kings xxii. 21, &c.), that he saw the Almighty sitting upon his throne, and all the host of heaven round about him; and the Lord said, Who shall tempt Ahab king of Israel, that he may go to war with Ramoth-gilead, and fall in the battle? One answered after one manner, and another in another. At the same time an evil spirit presented himself before the Lord and said, I will seduce him. And the Lord asked him How? To which Satan answered, I will go and be a lying spirit in the mouth of his prophets. And the Lord said, Go, and thou shalt prevail. This dialogue clearly proves these two things, *first*, that the devil could do nothing by his own power; and, *secondly*, that with the permission of God, he could inspire the false prophets, forcerers, and magicians, and make them deliver false oracles.

Respecting the cessation of profane oracles there have been a variety of opinions; some of which we have already remarked. It has been generally held, indeed, that oracles ceased at the birth of Jesus Christ: Yet some have endeavoured to maintain the contrary, by showing that they were in being in the days of Julian, commonly called *the Apostate*, and that this emperor himself consulted them; nay, farther, say they, history makes mention of several laws published by the Christian emperors Theodosius, Gratian, and Valentinian, to punish persons who interrogated them, even in their days; and that the Epicureans were the first who made a jest of this superstition, and exposed the roguery of its priests to the people. As we suspect most of the facts here asserted should be understood in a qualified sense, we shall endeavour to discuss this point of controversy in as few words as possible, although it is undoubtedly a matter of some consequence.

1<sup>st</sup>, The question, properly stated, is not, Whether oracles became extinct *immediately upon the birth of Christ*, or from the very moment he was born? but, If they fell gradually into disesteem and ceased, as

Christ and his gospel became known to mankind? And that they did so, is most certain from the concurrent testimonies of the fathers, which, who ever would endeavour to invalidate, may equally give up the most respectable traditions and relations of every kind.

2<sup>dly</sup>, But did not Julian, the apostate, consult these oracles? we answer in the negative: he had indeed recourse to magical operations, but it was because oracles had already ceased; for he bewailed the loss of them, and assigned pitiful reasons for it; which St Cyril has vigorously refuted, adding, that *he never could have offered such, but from an unwillingness to acknowledge, that when the world had received the light of Christ, the dominion of the devil was at an end.*

3<sup>dly</sup>, The Christian emperors do indeed seem to condemn the superstition and idolatry of those who were still for consulting oracles; but the edicts of those princes do not prove that oracles actually existed in their times, any more than that they ceased in consequence of their laws. It is certain that they were for the most part extinct before the conversion of Constantine.

4<sup>thly</sup>, Some Epicureans might make a jest of this superstition: however the Epicurean philosopher Celsus, in the 1<sup>st</sup> and 2<sup>d</sup> century of the church, was for crying up the excellency of several oracles, as appears at large from Origen's seventh book against him.

ORÆA, certain solemn sacrifices of fruits which were offered in the four seasons of the year, in order to obtain mild and temperate weather. They were offered to the goddesses who presided over the seasons, who attended upon the sun, and who received divine worship at Athens.

ORAL, something delivered by word of mouth, without being committed to writing; in which sense we say oral law, oral tradition, &c.

ORAN, a very strong and important town of Africa, in Barbary, and in the kingdom of Tremecen, with several forts, and an excellent harbour. It is seated partly on the side of a hill, and partly on a plain, about a stone-cast from the sea, almost opposite to Carthage in Spain. It is about a mile and an half in circumference, and well fortified, but commanded by the adjacent hills. It was taken by the Spaniards in 1509, and retaken by the Algerines in 1708, but in 1732 the Spaniards became masters of it, and have continued so ever since. E. Long. o. 8. N. Lat. 36. 2.

OURANG OUTANG. See SIMIA. Also COMPARATIVE ANATOMY, p. 250, ch. 1. sect. 2.

ORANGE, a famous city, and capital of a province of the same name, united to Dauphiny, with an university and a bishop's see, suffragan of Arles. It is seated in a fine large plain, watered by a vast number of little rivulets on the east side of the river Rhone. It is a very large ancient place, and was considerable in the time of the Romans, who adorned it with several buildings, of which there are still some ruins left, particularly of an amphitheatre, and a triumphal arch, which is almost entire, dedicated to Marius. This town was formerly much larger than it is at present, as appears from the traces of the ancient walls. The wall was in 1682 entirely demolished by order of Louis XIV. and the inhabitants were exposed to the fury of the soldiers. The town was restored to King William by the treaty of Ryfwick; but after his death

Orange.

death the French took it again, and expelled the protestant inhabitants. By the treaty of Utrecht it was confirmed to the crown of France, though the title is still retained in the house of Nassau. The title was first introduced into the family of Nassau by the marriage of Claude de Chalons, the prince of Orange's sister, with the count of Nassau, 1530. The principality is a very small district, it being only twelve miles in length and nine in breadth, and the revenue amounts to about 5000 l. a-year. The country is pleasant, and abounds with corn and fruit, but is exposed to violent winds. E. Long. 4. 49. N. Lat. 44. 9.

*Maurice Prince of ORANGE.* See MAURICE.

*ORANGE Tree*, in botany. See the article CITRUS.

—Orange-flowers are justly esteemed one of the finest perfumes; and though little used in medicine, yet the water distilled from them is accounted stomachic, cordial, and carminative. The fruit is cooling, and good in feverish disorders, and particularly in diarrheas. Orange-peel is an agreeable aromatic, proper to repair and strengthen the stomach, and gives a very grateful flavour to any infusions or tincture into whose compositions it enters. It is particularly useful in preparations of the bark; gives an agreeable warmth to the infusion: and according to Dr Percival, considerably increases its virtue.

In the philosophical Transactions, n° 114, there is a very remarkable account of a tree standing in a grove near Florence, having an *orange* stock, which had been so grafted upon, that it became in its branches, leaves, flower, and fruit; three formed: some emulating the orange, some the lemon or citron, and some partaking of both forms in one; and what was very remarkable, was, that these mixed fruits never produced any perfect seeds; sometimes there were no seeds at all in them, and sometimes only a few empty ones.

*ORANGE-Peel.* See CITRUS and *ORANGE-Tree*.

*ORANGE-dew*, a kind of dew which falls in the spring-time from the leaves of orange and lemon trees, which is extremely fine and subtle. M de la Hire observing this placed some flat pieces of glass under the leaves to receive it; and having procured some large drops of it, was desirous of discovering what it was. He soon found that it was not a merely aqueous fluid, because it did not evaporate in the air; and that it was not a resin, because it readily and perfectly mixed with water: it was natural then to suppose it a liquid gum; but neither did this, on examination prove to be the case; for being laid down on paper, it did not dry as the other liquid gums do. Its answering to none of these characters, and its being of the consistence of honey, and of a sweet sugar-like taste, gave a suspicion of its being a kind of manna; and whatever in the other trials had proved it not a resin, a gum, &c. all equally tends to prove that it is this substance.

*Orange-Sea*, in natural history, a name given by Count Marfigli to a very remarkable species of marine substance, which he denominates a *plant*. It is tough and firm in its structure, and in many things resembles the common fucus; but instead of growing into the branched form which the generality of those substances have, it is round and hollow, and in every respect resembles the shape of an orange. It has by way of root, some exceeding fine filaments, which fasten themselves to the rocks, or to shells, stones or any thing else that comes in the way. From these there grows no

pedicle; but the body of the orange, as it is called, is fastened by them to the rock, or other solid substance. The orange itself is usually of about three or four inches in diameter; and while in the sea, is full of water and even retains it when taken up. In this state it frequently weighs a pound and a half; but when the water is let out, and it is dried it becomes a mere membrane, weighing scarce any thing. It is best preserved, by stuffing it with cotton as soon as the water is let out of it, and then hanging it up to dry. Its surface is irregular and rough, and its colour a dusky green on the outside, and a clearer but somewhat bluish green within; and its thickness is about an eighth part of an inch. When viewed by the microscope, it is seen to be all over covered with small glandules, or rather composed of them for they stand so thick one by another as to leave no space between, and seem to make up the whole substance; so that it appears very like the rough shagreen skin used to cover toys. These are indeed so many hollow ducts, through which the sea-water finds a passage into the globe formed by this skin, and by this means it is kept always full and distended: on cutting it with a pair of scissars, the water immediately runs out, and the skins collapse; but there is something extremely remarkable in this, for the whole substance, near the wounded place, is in motion, and seems as if alive and sensible of the wound. The glandules are found full of water, and resembling small transparent bottles; and what goes to the structure of the plant beside these, is an assemblage of a vast number of filaments, all which are likewise hollow, and filled with a clear and transparent fluid.

There is another substance of this kind, mentioned and described by Count Marfigli. *Triumfeti*, and others, and called the *ramose* or branched orange. This is very much of the nature of the former; but, instead of consisting of one round globule, it is formed of several oblong ones, all joined together, and representing the branches of some of the fucuses, only they are shorter: and these are all hollow and full of water, in the same manner as the single globes of the common kind. This has, by way of root, certain fine and slender filaments, which fasten it to the stones or shells near which it is produced; and it is of a dusky greenish colour on the surface, of a fine bluish green within. The surface, viewed by the microscope appears rough, as in the other; and the glandules are of the same kind, and are always found full of clear water. See CORALLINES.

ORATION, in rhetoric, a speech or harangue, composed according to the rules of oratory, but spoken, in public. Orations may be reduced to three kinds viz. the demonstrative deliberative, and judicial. To the demonstrative kind belong panegyrics, genethliaca, epithalamia, congratulations, &c. To the deliberative kind belong persuasion, exhortation, &c. And to the judicial kind belong accusation, confutation, &c.

*Funeral Oration.* See FUNERAL Oration.

ORATOR, among the Romans, differed from a *patronus*: The latter was allowed only to plead causes on behalf of his clients; whereas the former might quit the forum and ascend the rostra or tribunal, to harangue the senate or the people. The orators had rarely a profound knowledge of the law, but they were eloquent, and their style was generally correct

Orator.Marfigli,  
Hist. de la  
Mer.

**Orator.** and concise. They were employed in causes of importance, instead of the common patrons. Orators, in the violence of elocution, used all the warmth of gesture, and even walked backwards and forwards with great heat and emotion. This it was which occasioned a witticism of Flavius Virginius, who asked one of those walking orators, *Quot millia passuum declamasset?* "How many MILES he had declaimed?" Similar to the Roman orators were the Grecian *Rhetores*. See **RHETORES**.

**Public ORATOR**, an office of very considerable dignity, and of some emolument in the English universities.

The public orator is the principal, and in many cases the only ostensible, agent, for the university in all those matters or forms which are merely external. He carries on or superintends all correspondences which are calculated to promote the dignity, or raise the utility, of the seminary which constitutes him. He has little to do, indeed with the internal government of the body, for which a variety of officers in different departments are appointed; but in all public affairs he is, as it were, the mouth of the whole; putting their deliberations into proper form, and communicating or publishing them, according to the intention of the university. Thus, if the whole university, or a committee appointed by them, or by statute, or by the will of any particular benefactor, have, after a comparative trial, adjudged a prize to any person or persons, it is the business of the public orator to inform the successful parties of the issue of the trial. Again, if for singular learning, or for any remarkable *good will* shown to the university by any person or persons, the *senate* or *convocation* are pleased to declare their grateful sense of it, either by conferring degrees, or otherwise as they think fit, the public orator is to notify this intention to the person or persons concerned; and so in other cases.

Another part of this public orator's business is to present young noblemen, or those who take *honorary* degrees, *tanquam nobiles*, to the vice-chancellor: this he does in a Latin speech, which, according to circumstances, is either short or long; and of which the subject is generally a defence of that particular statute

which allows the sons of noblemen, and some few others, to proceed to degrees before what is called the *statutable time*. In doing this, encomiums, often stronger than just, are made upon the learning and virtue of the noble candidate; a view is taken of the dignity of his ancient house; the honour is mentioned which has accrued to the university from the accession of such a member; and the oration concludes with promising great credit from his future conduct, as well as benefit from the influence of his rank in the state. These circumstances are deemed sufficient grounds for exempting the sons of noblemen from that tedious course of study through which the duller sons of commoners must all pass before they be thought worthy of academical honours.

**ORATORIO**, in the Italian music, a sort of sacred drama of dialogues; containing recitatives, duettos, trios, ritornellos, choruses, &c. The subjects of those pieces are usually taken from scripture, or the life of some saint, &c. The music for the oratorios should be in the finest taste and best chosen strains. These oratorios are greatly used at Rome in the time of Lent, and of late in England.

Menestrier attributes the origin of oratorios to the crusades, and says that the pilgrims returning from Jerusalem and the Holy Land, &c. composed songs, reciting the life and death of the Son of God, and the mysteries of the Christian faith, and celebrating the achievements and constancy of saints and martyrs. Others, with more probability, observe, that the oratorio was an avowed imitation of the opera, with only this difference that the foundation of it was always some religious or at least some moral subject. Crescimbeni ascribes its origin to San Filippo Neri, who was born at Florence in 1515, and who in his chapel, after sermons, and other devotions, in order to allure young people to pious offices, had hymns, psalms, and such like prayers, sung by one or more voices. Among these spiritual songs were dialogues; and these entertainments becoming more frequent, and improving every year, were the occasion that in the seventeenth century oratorios were first invented, so called from the place of their origin. See *Hawkins's History of Music*.

**Oratorio.**

## O R A T O R Y;

The art of speaking well upon any subject, in order to persuade.

### INTRODUCTION.

#### § 1 *Of the Rise and Progress of Oratory.*

**T**HE invention of oratory is by the Egyptians, and the fables of the poets, ascribed to Mercury. And it is well known, that the Greeks made their deities the authors likewise of other arts, and supposed that they presided over them. Hence they gave Mercury the titles of *Λογιστής* and *ἑρμῆς*, both which names come from words that signify "to speak." And Aristides calls eloquence *the gift of Mercury*; and for the same reason anciently the tongue was consecrated to him. He was likewise said to be the interpreter or

messenger of the gods; which office very well suited him, as he excelled in eloquence. Hence we read in the Sacred Writings, that when the people of Lystra took Barnabas and Paul for gods in human shape, because of that sudden and surprising cure which was wrought upon the lame man, they called Barnabas *Jupiter*, and Paul *Mercury*; for this reason, as the inspired writer tells us, "because he was the chief speaker," that is (as the spectators then thought), the interpreter or spokesman of Barnabas.

But to pass over these fictions of the heathen deities, let us hear what Quintillian says of the *origin* of this art; who seems to give a very probable account of it in the following passage. "The faculty of speech

(says

**I**  
The origin  
of the art  
of oratory.

(says he) we derive from nature (A); but the art from observation. For as in phytic, man, by seeing that some things promote health and others destroy it, formed the art upon those observations; in like manner, by perceiving that some things in discourse are said to advantage, and others not, they accordingly marked those things, in order to imitate the one and avoid the other. They also added some things from their own reason and judgment, which being confirmed by use, they began to teach others what they knew themselves." But no certain account can be given when or by whom, this method of observation first began to take place. And Aristotle supposes, not without reason, that the first lineaments of the art were very rude and imperfect. Pausanias, indeed, in his *Description of Greece*, tells us, that Pittheus, the uncle of Theseus, taught it at Trezene a city of Peloponnesus, and wrote a book concerning it; which he read himself, as it was published by one of Epidaurus. But as Pittheus lived about 1000 years before Pausanias, who flourished in the time of the emperor Hadrian, some are of opinion he might be imposed upon by the Epidaurian, who published this book under the name of *Pittheus*. But be that as it will, it is very reasonable to believe, that the Greeks had the principles of this art so early as the time of Pittheus. For Theseus his nephew lived not long before the taking of Troy, which, according to Sir Isaac Newton, happened 904 years before the birth of Christ; at which time Cicero thought it was in much esteem among them. "Homer (says he) would never have given Ulysses and Nestor in the Trojan wars so great commendations on account of their speeches (to one of whom he attributes force, and to the other sweetness of expression), if eloquence had not in those times been in great repute." And lest any one should imagine, that in those days they made use only of such helps as nature and practice could afford them, the same poet informs us, that Peleus sent Phoenix with his son Achilles to the Trojan war, to instruct him not only in the art of war, but likewise of eloquence. But who were the professors of this art for some ages following is not known. For Quintilian says, that afterwards Empedocles is the first upon record who attempted any thing concerning it. And he, by Sir Isaac Newton's account, flourished about 500 years after Troy was taken. At which time, as Cicero observes, men being now sensible of the powerful charms of oratory, and the influence it had upon the mind, there immediately arose several masters of it; the chief of whom are mentioned by Quintilian, who tells us, that "the oldest writers upon this art are Corax and Tisias, both of Sicily. After them came Gorgias of Leontium in the same island, who is said to have been the scholar of Empedocles and by reason of his great age (for he lived to be 109 years old) had many cotemporaries. Thrasymachus of Chalcedon, Prodicus of Cea, Protagoras of Abdera, Hippias of Elis, and Alcidas of Elea, lived in his

time; as likewise Antiphon, who first wrote orations, and also upon the art, and is said to have spoken admirably well in his own defence; and besides these, Polyarchus, and Theodore of Byzantium." These persons contributed different ways towards the improvement of the art. Corax and Tisias gave rules for methodizing a discourse, and adjusting its particular parts; as may be conjectured from Cicero's account of them, who says, "Though some had spoken well before their time, yet none with order and method." But Gorgias seems to have excelled all the rest in fame and reputation: for he was so highly applauded by all Greece, that a golden statue was erected to him at Delphos, which was a distinguishing honour conferred upon him only. And he is said to have been so great a master of oratory, that in a public assembly he would undertake to declaim immediately upon any subject, proposed to him. He wrote, as Cicero informs us, in the demonstrative or laudatory way; which requires most of the sublime, and makes what Diodorus Siculus says of him the more probable, that "he first introduced the strongest figures, members of periods opposite in sense, of an equal length, or ending with a like sound and other ornaments of that nature." And hence those figures, which give the greatest force and lustre to a discourse, were anciently called by his name. Cicero tells us further, that Thrasymachus, and Gorgias were the first who introduced numbers into prose, which Isocrates afterwards brought to perfection. Quintilian likewise mentions Protagoras, Gorgias Prodicus, and Thrasymachus, as the first who treated of common places, and showed the use of them for the invention of arguments. Nor must we omit Plato, whose elegant dialogue upon this subject is still extant, which he intitles *Gorgias*. For though he does not lay down the common rules of the art; yet he very well explains the nature of it, and maintains its true end and use against the generality of its professors, who had greatly perverted the original design of it. Thus by the study and industry of so many and ingenious and great men, the art of oratory was then carried to a considerable height among the Grecians. Though many of those who professed it in those times employed their skill rather to promote their own reputation and applause, than to serve the real interests of truth and virtue. "For they proposed in an arrogant manner (as Cicero says) to teach how a bad cause might be so managed, as to get the better of a good one." That is, they would undertake to charm the ears and strike the passions of their hearers in so powerful a manner, by sophistical reasonings, turns of wit, and fine language, as to impose falsehood upon them for truth; than which nothing could be either more dilingenuous in itself, or prejudicial to society.

But these who succeeded them seem to have consulted better, both for their own honour and that of their profession. Isocrates was the most renowned of

3 A 2

all

2  
Orators of  
Greece.

(A) If Quintilian meant that the human race speak an articulate language by nature or instinct, he certainly deceived himself (see LANGUAGE); but if his meaning was only that men have from nature a capability of speech, the observation is true but not of much value. Parrots and other birds have a capability of uttering articulate sounds.

all Gorgias's scholars, whom Cicero frequently extols with the highest commendations, as the greatest master and teacher of oratory: "whose school (as he says) like the Trojan horse, sent forth abundance of great men." Aristotle was chiefly induced to engage in this province from an emulation of his glory; and would often say in a verse of Sophocles, somewhat varied to his purpose.

To be silent it is a shame;  
While Isocrates gets such fame.

Quintilian says they both wrote upon the art, though there is no system of the former now extant. But that of Aristotle is esteemed the best and most complete of any in the Greek language. In this age the Grecian eloquence appeared in its highest perfection. Demosthenes was an hearer both of Isocrates and Plato, as also of Isæus (ten of whose orations are yet extant); and by the assistance of a surprising genius, joined with indefatigable industry, made that advantage of their precepts, that he has been always esteemed by the best judges the prince of Grecian orators. His great adversary and rival Æschines, after his banishment, is said to have gone to Rhodes, and employed his time there in teaching of rhetoric. Theodectes and Theophrastus, both of them scholars of Aristotle, imitated their master in writing upon the art. And from that time the philosophers, especially the stoics and peripatetics, applied themselves to lay down the rules of oratory; which Socrates had before separated from the province of a philosopher. And there is yet preserved a treatise upon this subject, which some have ascribed to Demetrius Phalereus the peripatetic, and scolar of Theophrastus, though others more probably to Dionysius of Halicarnassus. Quintilian mentions several other famous rhetoricians in the following ages, who were likewise writers; as Hermagoras, Athenæus, Apollonius Molon, Areus Cæcilius, Dionysius of Halicarnassus, Apollonius of Pergamus, and Theodore of Gadaro. But of these nothing now remains upon the subject of oratory, except some tracts of Dionysius, who flourished in the reign of Augustus Cæsar. Nor have there been wanting some eminent writers of this kind among the Greeks since the time of Quintilian; two of whom we cannot omit to mention, Hermogenes, and Longinus the author of the incomparable treatise *Of the Sublime*, a book which can scarce be too much commended or too often read.

3  
Rise and  
progress of  
oratory in  
Rome.

It was long before Rome received this art, and not without difficulty at first. The reason was, because the Romans were for several ages wholly addicted to military affairs, and to enlarge their territories; so that they not only neglected to cultivate learning, but thought the pursuit of it a thing of ill tendency, by diverting the minds of their youth from the cares and toils of war, to a more soft and indolent kind of life. Therefore so late as the year of their city 592, when by the industry of some Grecians the liberal arts began to flourish in Italy, a decree passed the senate, by which all philosophers and rhetoricians were ordered to depart out of Rome. But in a few years after, when Corneades, Critolaus, and Diogenes, who were not only philosophers but orators, came ambassadors from Athens to Rome. The Roman youth were so charmed with the eloquence of their languages, that

they could no longer be kept from pursuing the study of oratory. And by a further acquaintance with the Greeks, it soon gained such esteem, that persons of the first quality employed their time and pains to acquire it. And a young gentleman, who was ambitious to advance himself in the service of his country, could have little hopes of success, unless he had laid the foundation of his future prospects in that study.

Seneca tells us, that Lucius Plotinus, a Gaul, was the first who taught the art of oratory at Rome in Latin; which Cicero says, was while he was a boy; and when the most studious persons went to hear him he lamented that he could not go with them; being prevented by the regard he paid to the opinion of some of his friends, who thought that greater improvements were made by exercises in the Greek language under Grecian masters. Seneca adds, that this profession continued for some time in the hands of freedmen; and that the first Roman who engaged in it was Blandus of the equestrian order, who was succeeded by others; some of whose lives are yet extant, written by Suetonius, as many of the Grecians are by Philostratus and Eunapius. Quintilian likewise gives us the names of those among the Romans, who wrote upon the art. "The first (says he), as far as I can learn, who composed any thing upon this argument, was M. Cato the censor. After him Anthony the orator began upon this subject, which is the only work he has left, and that imperfect. Then followed some of less note. But he who carried eloquence to his highest pitch among us, was Cicero; who has likewise by his rules given the best plan both to practice and teach the art. After whom modesty would require us to mention no more, had he not told us himself, that his books of rhetoric slipped out of his hands while he was but a youth. And those lesser things, which many persons want, he has purposely omitted in his discourses of oratory. Cornificius wrote largely upon the same subject; Stertinus and Gallio the father, each of them something. But Celsus and Lennas were more accurate than Gallio; and in our times Virginius, Pliny, and Rutilius. And there are at this day some celebrated authors of the same kind, who, if they had taken in every thing, might have saved my pains." Time has since deprived us of most of the writers mentioned here by Quintilian. But we have the less reason to regret this loss, since it has preserved to us Cicero's treatises upon this subject; which we may well suppose to have been chiefly owing to their own excellency, and the great esteem they have always had in the world. Besides his *Two Books of Invention*, which Quintilian here calls his *Books of Rhetoric*, there are extant of his, *Three Books of an Orator*; one of *famous Orators*; and another, which is called *The Orator*; as also his *Topics*, a preface *Concerning the best sort of Orators*, and a treatise *Of the parts of Oratory*. Each of which treatises, whether we regard the justness and delicacy of the thoughts, the usefulness of the rules, or the elegance and beauty of the style, deserves to be frequently perused by all who are lovers of eloquence. For who can be thought so well qualified to give the rules of any art, as he who excelled all mankind in the practice of them? But those *Four books to Herennius*, which are published among Cicero's works, seem with good reason to be attributed to Cornificius, whom

Quin-

Quintilian here mentions. And Celsus is by some affirmed to have taught oratory, whom he also places among the rhetoricians, and whose *Eight books of Medicine* are yet extant, written in so beautiful a style as plainly shows him to be a master of eloquence. But Quintilian himself outdid all who went before him in diligence and accuracy as a writer. His *Institutions* are so comprehensive, and written with such great exactness and judgment, that they are generally allowed to be the most perfect work of the kind. With this excellent author we shall finish the account of the Latin rhetoricians.

There were indeed some others in the following ages, whose works are yet extant; but as they contain nothing of moment which is not to be found in those already mentioned, we shall forbear to name them. Much less shall we descend to that numerous body of writers, who since the revival of learning have treated upon this subject, for the same reason. And a very good judge\* has not long since given it as his opinion, that the method of forming the best system of oratory, is to collect it from the finest precepts of Aristotle, Cicero, Quintilian, Longinus, and other celebrated authors: with proper examples taken from the choicest parts of the purest antiquity. And this is the method attempted to be pursued in the following treatise.

## § 2. Of the Nature of Oratory.

THE terms *rhetoric* and *oratory*, having no other difference but that one is taken from the Greek language and the other from the Latin, may be used promiscuously; but the case is not the same with respect to the words *rhetorician* and *orator*. For although the Grecians used the former, both to express those who taught the art, and those who practised it, yet the Romans afterward, when they took that word into their language, confined it to the teachers of the art, and called the rest orators. And there seems to have been a sufficient reason for this distinction, since the art was the same in both, and might therefore go by either name: but the different province of rhetoricians and orators made it not improper that they should be called by different names. Besides, anciently, before rhetoric was made a separate and distinct art from philosophy, the same persons taught both. And then they were called not only *rhetoricians* but *sophists*. But because they often employed their art rather to vindicate what was false and unjust, than to support truth and virtue; this dissingenuous conduct, by which they frequently imposed upon weak minds, brought a discredit both upon themselves and their profession. And therefore the name *sophist* or *sophister*, has been more generally used in an ill sense, to signify one skilled rather in the arts of caviling, than qualified to speak well and accurately upon any subject.

It is not necessary to use many words, to prove that oratory is an art. For it is comprised under certain rules, agreeable to reason, delivered in a regular method, and suited to attain the end it proposes; which are characters sufficient to denominate it an art. Indeed the case is the same here as in most other things, that a good genius is of itself more serviceable than the most exact acquaintance with all the rules of art where that is wanting. But it is sufficient that art

help nature, and carry it farther than it can otherwise advance without it. And he who is desirous to gain the reputation of a good orator, will find the assistance of art very necessary. Some persons have thought, that many of the common systems written upon the subject of oratory have been attended with this inconvenience, that, by burdening the mind with too great a number of rules about things of less importance, they have oftentimes rather discouraged than promoted the study of eloquence. This undoubtedly is an extreme which should be always carefully avoided. But, however, an indifferent guide in a strange road is better than none at all. It may be worth while to hear Quintilian's opinion upon this head. "I would not (says he) have young persons think they are sufficiently instructed, if they have learned one of those compends which are commonly handed about, and fancy themselves safe in the decrees, as it were, of these technical writers. The art of speaking requires much labour, constant study, a variety of exercise, many trials, the greatest prudence, and readiness of thought. However, these treatises are useful, when they set you in a plain and open way, and do not confine you to one narrow tract, from which he who thinks it a crime to depart must move as slowly as one that walks upon a rope." We see he is not for having us confine ourselves too closely to systems, though he thinks they are of service at first, till use and experience render them less necessary.

The business of oratory is to teach us to speak well; which, as Cicero explains it, is to speak *justly, methodically, floridly, and copiously*. <sup>4. The object of it.</sup>

Now, in order to speak *justly*, or pertinently, a person must be master of his subject, that he may be able to say all that is proper, and avoid whatever appears foreign and trifling. And he must clothe his thoughts with such words and expressions as are most suited to the nature of the argument, and will give it the greatest force and evidence.

And as it teaches to speak *justly*, so likewise *methodically*. This requires, that all the parts of a discourse be placed in their proper order, and with such just connection, as to reflect a light upon each other, and thereby to render the whole both clear in itself, and easy to be retained. But the same method is not proper for all discourses. And very frequently a different manner is convenient in handling the same subject. For it is plain, that art, as well as nature, loves variety; and it discovers the speaker's judgment, when the disposition of his discourse is so framed, as to appear easy and natural, rather than the effect of industry and labour.

To speak *floridly*, is so peculiar a property of this art, that some have wholly confined it to the pomp and ornaments of language. But that it extends farther, and respects things as well as words, we shall have occasion to show hereafter. It contains indeed the whole subject of eloquence, but does not wholly consist in it. True and solid eloquence requires not only the beauties and flowers of language, but likewise the best sense and clearest reasoning. Besides, rhetoric give rules for the several sorts of style, and directs the use of them agreeably to the nature of the subject.

But the force of oratory appears in nothing more than

\* Archb.  
Cambray.  
Lett. p.  
213.

<sup>4</sup>  
Oratory an  
art.

than a *copiousness* of expression, or a proper manner of enlargement, suited to the nature of the subject which is of great use in persuasion, and forms the last property required by Cicero, of speaking well. A short and concise account of things is often attended with obscurity, from an omission of some necessary circumstances relating to them. Or, however, where that is not the case, yet for want of proper embellishments to enliven the discourse, and thereby to excite and fix the hearers attention, it is apt to slip through their minds without leaving any impression. But where the images of things are drawn in their full proportion; painted in their proper colours, set in a clear light, and represented in different views, with all the strength and beauties of eloquence, they captivate the minds of the audience with the highest pleasure, engage their attention, and by an irresistible force move and bend them to the design of the speaker.

The principal end and design of oratory is to persuade: for which reason it is frequently called the *art of persuasion*. Indeed the orator has often other subordinate views; as when he endeavours either to delight his hearers with what is pleasant and agreeable, or to conciliate their good opinion by a smooth and artful address; but still both these are in order to persuade and excite them to action.

An objection, may, perhaps hence be formed against eloquence as an art which may be employed for persuading to ill as well as good. There is no doubt that it may; and so reasoning may also be, and too often is, employed for leading men into error. But who would think of forming an argument from this against the cultivation of our reasoning powers? Reason, eloquence, and every art which ever has been studied among mankind, may be abused, and may prove dangerous in the hands of bad men: but it were perfectly childish to contend, that upon this account they ought to be abolished.

While the orator employs his art in pursuing only these ends for which it was at first designed, the persuading men to good and virtuous actions, and dis-

suading them from every think that is ill and vicious nothing can be more commendable in itself, or useful to human societies.

§ 3. *Of the Division of Oratory.*

ORATORY consists of four parts; *invention, disposition, elocution, and pronounciation*. This will appear by considering the nature of each of them and what it contributes in forming an orator. Every one who aims to speak well and accurately upon any subject, does naturally in the first place inquire after and pursue such thoughts as may seem most proper to explain and illustrate the thing upon which he designs to discourse. And if the nature of it requires that he should bring reasons to confirm what he says, he not only seeks the strongest, and such as are like to be best received; but also prepares to answer any thing which may be offered to the contrary. This is *invention*.—After this he deliberates with himself in what method to dispose of those things which have occurred to his mind, that they may appear in the plainest light, and not lose their force by disorder and confusion. This is the business of *disposition*.—His next concern is to give his thoughts an agreeable dress; by making choice of the fittest words, clearest expressions, smooth and harmonious periods, with other ornaments of style, as may best suit the nature of his subject, brighten his discourse, and render it most entertaining to his hearers. And this is called *elocution*.—The last thing he attends to, is to deliver what he has thus composed, with a just and agreeable *pronounciation*. And daily experience convinces us, how much this contributes both to engage the attention and impress what is spoken upon the mind. This then is the method to which nature directs, in order to qualify ourselves for discoursing to the best advantage: Though by custom and habit these things become so familiar to us, that we do not always attend to them separately in their natural order. However, it is the business of art to follow nature, and to treat of things in that manner which she dictates.

6  
Oratory consists of four parts.

PART I. OF INVENTION.

CHAP. I. *Of Invention in general; and particularly of Common Places, and State of a Cause.*

7  
Invention the discoveries of such things as are fitted to persuade

INVENTION, considered in general, is the discovery of such things as are proper to persuade. And in order to attain this end, the orator proposes to himself three things: To prove or illustrate the subject upon which he treats; to conciliate the minds of his hearers; and to engage their passions in his favour. And as these require different kinds of arguments or motives, invention furnishes him with a supply for each of them, as will be shown in their order.

An argument, as defined, by Cicero, is a reason which induces us to believe what before we doubted of.

And as different kinds of discourses require different arguments, rhetoricians have considered them two ways; in general, under certain heads, as a common fund for all subjects; and in a more particular manner, as they are suited to *demonstrative, deliberative, or judicial* discourses. At present we shall treat only upon

the former of these. And now, that one thing may receive proof and confirmation from another, it is necessary that there be some relation between them; for all things are not equally adapted to prove one another. Thus, in measuring the quantity of two things which we would show to be either equal or unequal, if they are of such a nature that one cannot be applied to the other, then we take a third thing, which may be applied to them both; and that must be equal at least to one of the two, which if applied to the other, and found equal to that also, we presently conclude that these two things are equal; but if it be unequal to the other, we say that these two things are unequal. Because it is the certain any known property of all quantities, that whatsoever two things are equal to a third, are equal to one another; and where one of any two things is equal to a third, and the other unequal, those two things are unequal to one another. What has been said of quantities, will hold true in all other cases, that so far as any two things or ideas agree

**Invention.** agree to a third, so far they agree to one another. So Likewise, on the contrary, as far as one of any two things or ideas does agree to a third, and the other does not, so far they disagree with one another; in which respect, one of them cannot be truly affirmed of the other. Since, therefore in every proposition, one thing is spoken of another, if we would find out whether the two ideas agree to each other or not, where this is not evident of itself, we must find out some third thing, the idea of which agrees to one of them: and then that being applied to the other, as it does agree or disagree with it, so we may conclude, that the two things proposed do agree or disagree with one another. This will be made more clear by an example or two. Should it be inquired, *Whether virtue is to be loved*; the agreement between virtue and love might be found by comparing them separately with happiness, as a common measure to both. For since the idea of happiness agrees to that of love, and the idea of virtue to that of happiness; it follows, that the ideas of virtue and love agree to one another; and therefore it may be affirmed, *That virtue is to be loved*. But on the contrary, because the idea of misery disagrees with that of love, but the idea of vice agrees to that of misery, the two ideas of vice and love must consequently disagree with one another; and therefore it would be false to assert, *That vice is to be loved*. Now, this third thing logicians call the *medium*, or *middle term*, because it does as it were connect two extremes; that is both parts of a proposition. But rhetoricians call it an *argument*, because it is so applied to what was before proposed, as to become the instrument of procuring our assent to it. Thus far as is the nature and use of arguments. We shall next explain by what methods they are to be sought.

8  
These called arguments.

A lively imagination, and readiness of thought, are undoubtedly a very great help to invention. Some persons are naturally endued with that quickness of fancy, and penetration of mind, that they are seldom at a loss for arguments either to defend their own opinions, or to attack their adversaries. However, these things being the gift of nature, and not to be gained by art, do not properly fall under our present consideration.

9  
Learning necessary to an orator.

It will be readily granted, that great learning and extensive knowledge are a noble fund for invention. An orator therefore should be furnished with a stock of important truths, solid maxims of reason, and a variety of knowledge, collected and treasured up both from observation and a large acquaintance with the liberal arts; that he may not only be qualified to express himself in the most agreeable manner, but likewise to support what he says with the strongest and clearest arguments.

But because all are not born with a like happy genius, and have not the same opportunity to cultivate their minds with learning and knowledge; and because nothing is more difficult than to dwell long upon the consideration of one thing, in order to find out the strongest arguments, which may be offered for and against it; upon these accounts, art has prescribed a method to lessen, in some measure, these difficulties, and help every one to a supply of arguments upon any

subject. And this is done by the contrivance of *common places*, which Cicero calls the *seats* or *heads of arguments*, and by a Greek name *topics*. They are of two sorts, *internal* and *external*.

I. *Internal topics*. Though things, with regard to their nature and properties, are exceedingly various, yet they have certain common relations, by means whereof the truth of what is either affirmed or denied concerning them in any respect may be evinced. The ancient Greek rhetoricians therefore reduced these relations to some general heads, which are termed *loci* or *common places*; because the reasons or arguments suited to prove any proposition are reposit in them, as a common fund or receptacle. And they are called *internal heads*, because they arise from the subject upon which the orator treats; and are therefore distinguished from others named *external*, which he fetches from without, and applies to his present purpose, as will be shown hereafter. Cicero and Quintilian make them 16; three of which comprehend the whole thing they are brought to prove, namely, *definition*, *enumeration*, and *notation*: of the remaining 13, some contain a part of it, and the rest its various properties and circumstances, with other considerations relating to it; and these are, *genus species*, *antecedents*, *consequents*, *adjuncts*, *conjugates*, *cause*, *effect*, *contraries*, *opposites*, *similitude*, and *dissimilitude*, *comparison*.

10  
Rules of art to supply the place of extensive learning or acute genius.

*Definition* explains the nature of the thing defined, and shows what it is. And to whatsoever the definition agrees, the thing defined does so likewise. If therefore Socrates be a rational creature, he is a man; because it is the definition of a man, that he is a rational creature.

*Enumeration* takes in all the parts of a thing. And from this we prove, that what agrees to all the parts agrees to the whole; and what does not agree to any one or more parts, does not agree to the whole: As when Cicero proves to Piso that all the Romans hate him, by enumerating the several ranks and orders of Roman citizens who all did so.

*Notation*, or etymology, explains the meaning or signification of a word. From which we reason thus: "If he cannot pay his debts, he is insolvent;" for that is the meaning of the word *insolvent*.

*Genus* is what contains under it two or more sorts of things, differing in nature. From this head logicians reason thus: "Because every animal is mortal, and man is an animal, therefore man is mortal." But orators make a further use of this argument, which they call *ascending from the hypothesis to the thesis*; that is, from a particular, to a general: As should a person, when speaking in praise of justice, take occasion from thence to commend and show the excellency of virtue in general, with a view to render that particular virtue more amiable. For since every species contains in it the whole nature of the genus to which it relates besides what is peculiar to itself, whereby it is distinguished from it; what is affirmed of the genus, must of necessity be applicable to the species.

*Species* is that which comprehends under it all the individuals of the same nature. From hence we may argue, "He is a man, therefore he has a rational soul." And orators sometimes take occasion from this head to descend from the thesis to the hypothesis; that

Invention.

that is, in treating upon what is more general, to introduce some particular contained under it, for the greater illustration of the general.

*Antecedents* are such things, as, being once allowed, others necessarily, or very probably, follow. From this head an inseparable property is proved from its subject; as, It is material, and therefore corruptible.

*Consequents* are such things as, being allowed necessarily or very probably infer their antecedents. Hence the subject is proved from an inseparable property, in this manner: It is corruptible and therefore material.

*Adjuncts* are separable properties of things, or circumstances that attend them. These are very numerous, and afford a great variety of arguments, some of which usually occur in every discourse. They do not necessarily infer their subject; but, if fitly chosen, render a thing credible, and are a sufficient ground for assent. The way of reasoning from them we shall show presently.

*Conjugates* are words deduced from the same origin with that of our subject. By these the habit is proved from its acts; He who does justly is just. He does not act wisely, therefore he is not wise. But this inference will not hold, unless the actions appear continued and constant.

A *cause* is that, by the force of which a thing does exist. There are four kinds of causes, matter, form, efficient and end, which afford a great variety of arguments. The way of reasoning from them is to infer the effect from the cause: as, Man is endued with reason therefore he is capable of knowledge.

An *effect* is that which arises from a cause: therefore the cause is proved by it: as, He is endued with knowledge, therefore with reason.

*Contraries* are things, which under the same genus, are at the utmost distance from each other; so that what we grant to the one, we utterly deny the other: as, Virtue ought to be embraced, therefore vice should be avoided.

*Opposites* are such things, which, though repugnant to each other; yet are not directly contradictory: as To love and to injure, to hate and to commend. They differ from contraries in this, that they do not absolutely exclude one another. An argument is drawn from things repugnant, thus: He will do a man a mischief, therefore he does not love him. He loves a man therefore he will not reproach him.

*Similitude* is an agreement of things in quality. Thus Cicero proves, that pernicious citizens ought to be taken out of the state; by the likeness they bear to corrupted members, which are cut off to prevent further damage to the body.

*Dissimilitude* is a disagreement of things in quality. Cicero From this head shows the preference of his own exile to Piso's government of Macedonia; by the difference between their conduct, and the people's esteem of them.

*Comparison* is made three ways: for either a thing is compared with a greater, with a less, or with its equal. This place, therefore, differs from that of similitude on this account, that the quality was considered in that, but here the quantity. An argument from the greater is thus drawn: If five legions could not conquer the enemy, much less will two.

We shall just give one example of the manner of

reasoning from these heads, whereby the use of them may further appear. If any one, therefore, should have endeavoured to persuade Cicero not to accept of his life upon the condition offered him by Antony. That he would burn his Philippic orations which had been spoken against him, he might be supposed to use such arguments as these; partly taken from the adjuncts of Cicero, partly from those of Antony, and partly from the thing itself. And first with regard to Cicero, it might be said, That so great a man ought not to purchase his life at so dear a price as the loss of that immortal honour which by so great pains and labour he had acquired. And this might be confirmed by another argument, That now he was grown old, and could not expect to live much longer. And from the character of Antony might argue thus: That he was very crafty and deceitful; and only designed, by giving him hopes of life, to have the Philipics first burnt, which otherwise he knew would transmit to posterity an eternal brand of infamy upon him; and then he would take off the author. And this might be shown by comparison. For since he would not spare others, who had not so highly exasperated him, and from whom he had not so much to fear; certainly he would not forgive Cicero, since he knew well enough, that so long as he lived, he himself could never be in safety. And, lastly, an argument might also be fetched from the nature of the thing itself, in the following manner: That Cicero by this action would shamefully betray the state, and the cause of liberty, which he had through his whole life most courageously defended, with so great honour to himself, and advantage to the public. Upon such an account, a person might have used these or the like arguments with Cicero, which arise from the forementioned heads.

From this account of common places, it is easy to conceive what a large field of discourse they open to the mind upon every subject. At the same time, though we have mentioned them from our respect for the orators of Greece and Rome, we heartily subscribe to the opinion of a celebrated modern, who gives of them the following account.

"The Grecian sophists were the first inventors of this artificial system of Oratory; and they showed a prodigious subtilty and fertility in the contrivance of these loci. Succeeding rhetoricians, dazzled by the plan, wrought them into so regular a system, that one would think they meant to teach how a person might mechanically become an orator, without any genius at all. They gave him receipts for making speeches on all manner of subjects. At the same time, it is evident, that though this study of common places might produce very showy academical declamations, it could never produce useful discourses on real business. The loci indeed supplied a most exuberant fecundity of matter. One who had no other aim, but to talk copiously and plausibly, by consulting them on every subject, and laying hold of all that, they suggested, might discourse without end; and that, too, though he had none but the most superficial knowledge of his subject. But such discourse could be no other than trivial. What is truly solid and persuasive, must be drawn *ex visceribus cause*, from a thorough knowledge of the subject, and profound meditation on it. They who

**Invention:** who would direct students of oratory to any other sources of argumentation, only delude them; and by attempting to render rhetoric too perfect an art, they render it, in truth, a trifling and childish study."

**13**  
**Of external topics, generally called testimonies.** II. *Of external topics.* When the orator reasons from such topics as do not arise from his subject, but from things of a different nature, these are called *external*. They are all taken from authorities, and are by one general name called *Testimonies*.

Now a testimony may be expressed by writing, speech, or any other sign proper to declare a person's mind. And all testimonies may be distinguished into two sorts, divine and human. A divine testimony, when certainly known to be such, is incontestable, and admits of no debate, but should be acquiesced in without hesitation. Indeed the ancient Greeks and Romans esteemed the pretended oracles of their deities, the answers of their augurs, and the like fallacies, divine testimonies: but with us no one can be ignorant of their true notion, though they do not so directly come under our present consideration. Human testimonies, considered as furnishing the orator with arguments, may be reduced to three heads; *writings*, *witnesses*, and *contracts*.

**14**  
**Reduced to three heads and separately explained.** 1. By *writings*, here, are to be understood written laws, wills, or other legal instruments, expressed and conveyed in that manner. And it is not so much the force and validity of such testimonies, considered in themselves, that is here intended, as the occasion of dispute which may at any time arise concerning their true design and import, when produced in proof upon either side of a controversy. And these are five; *Ambiguity*. Disagreement between the words and intention, *Contrariety*, *Reasoning*, and *Interpretation*.

A writing is then said to be ambiguous, when it is capable of two or more senses, which makes the writer's design uncertain. Now ambiguity may arise either from single words, or the construction of sentences. From single words; as when either the sense of a word, or the application of it, is doubtful. As, should it be questioned, whether ready money ought to be included under the appellation of chattels left by a will; or, if a testator bequeath a certain legacy to his nephew Thomas, and he has two nephews of that name. But ambiguity is also sometimes occasioned from the construction of a sentence; as when several things or persons having been already mentioned, it is doubtful to which of them that which follows ought to be referred. For example, a person writes thus in his will: 'Let my heir give as a legacy to Titius an horse out of my stable, which he pleases.' Here it may be questioned, whether the word *he* refers to the heir or to Titius: and consequently, whether the heir be allowed to give Titius which horse he pleases, or Titius may choose which he likes best. Now as to controversies of this kind, in the first case abovementioned, the party who claims the chattels may plead, that all moveable goods come under that name, and therefore that he has a right to the money. This he will endeavour to prove from some instances where the word has been so used. The business of the opposite party is to refute this by showing that money is not there included. And if either side produce precedents in his favour, the other may endeavour to show that the cases are parallel. As to the second case,

arising from an ambiguity in the name, if any other **Invention.** words or expressions in the will seem to countenance either of the claimants, he will not fail to interpret them to his advantage. So likewise, if any thing said by the testator, in his lifetime, or any regard shown to either of these nephews more than the other, may help to determine which of them was intended, a proper use may be made of it. And the same may be said with regard to the third case. In which the legatee may reason likewise from the common use of language and show that in such expressions it is usual to make the reference to the last or next antecedent; and from thence plead that it was the design of the testator to give him the option. But in answer to this it may be said, that allowing it to be very often so, yet in this instance it seems more easy and natural to repeat the verb *give* after *pleases*, and so to supply the sentence, *which he pleases to give him*, referring it to the heir, than to bring in the verb *choose*, which was not in the sentence before; and so, by supplying the sense, *which he pleases to choose*, to give the option to Titius. But where controversies of this kind arise from a law, recourse may be had to the laws where the same thing has been expressed with greater clearness; which may help to determine the sense of the passage in dispute.

A second controversy from writings is, when one party adheres to the words, and the other to what he asserts was the writer's intention. Now he who opposes the literal sense, either contends, that what he himself offers is the simple and plain meaning of the writing, or that it must be so understood in the particular case in dispute. An instance of the former is this, as we find it in Cicero. A person who died without children, but left a widow, had made this provision in his will: "If I have a son born to me, he shall be my heir." And a little after: "If my son die before he comes of age, let Curius be my heir." There is no son born: Curius therefore sues for the estate, and pleads the intention of the testator, who designed him for his heir, if he should have no son who arrived at age; and says, there can be no reason to suppose he did not intend the same person for his heir if he had no son, as if he should have one who afterwards died in his minority. But the heir at law insists upon the words of the will: which, as he says, require, that first a son should be born, and afterwards die under age, before Curius can succeed to the inheritance; and there being no son, a substituted heir, as Curius was, can have no claim where the first heir, does not exist, from whom he derives his pretension and was to succeed by the appointment of the will.—Of the latter case, rhetoricians give this example: "It was forbidden by a law to open the city-gates in the night. A certain person notwithstanding, in time of war, did open them in the night, and let in some auxiliary troops, to prevent their being cut off by the enemy, who was posted near the town." Afterwards, when the war was over, this person is arraigned, and tried for his life on account of this action. Now, in such a case, the prosecutor founds his charge upon the express words of the law; and pleads, that no sufficient reason can be assigned for going contrary to the letter of it, which would be to make a new law, and not to execute one already made. The defendant, on the other hand alleges, That the fact he is charged

Invention. with cannot, however, come within the intention of the law; since he either could not, or ought not, to have complied with the letter of it in that particular case, which must therefore necessarily be supposed to have been excepted in the design of that law when it was made. But to this the prosecutor may reply, That all such exceptions as are intended by any law, are usually expressed in it: and instances may be brought of particular exceptions expressed in some laws; and if there be any such exceptions in the law under debate, it should especially be mentioned. He may further add, That to admit of exceptions not expressed in the law itself, is to enervate the force of all laws, by explaining them away, and in effect to render them useless. And this he may further corroborate, by comparing the law under debate with others, and considering its nature and importance, and how far the public interest of the state is concerned in the due and regular execution of it; from whence he may infer, that should exceptions be admitted in other laws of less consequence, yet however, they ought not in this. Lastly, he may consider the reason alleged by the defendant, on which he founds his plea, and show there was not that necessity of violating the law in the present case, as is pretended. And this is often the more requisite, because the party who disputes against the words of the law, always endeavours to support his allegations from the equity of the case. If, therefore, this plea can be enervated, the main support of the defendant's cause is removed. For as the former arguments are designed to prevail with the judge, to determine the matter on this side the question from the nature of the case; so the intention of this argument is to induce him to it, from the weakness of the defence made by the opposite party. But the defendant will on the contrary, use such arguments as may best demonstrate the equity of his cause, and endeavour to vindicate the fact from his good design and intention in doing it. He will say, That the laws have allotted punishments for the commission of such facts as are evil in themselves, or prejudicial to others: neither of which can be charged upon the action for which he is accused: That no law can be rightly executed, if more regard be had to the words and syllables of the writing, than to the intention of the legislator. To which purpose, he may allege that direction of the law itself, which says, "The law ought not to be too rigorously interpreted, nor the words of it strained; but the true intention and design of each part of it duly considered." As also that saying of Cicero, "What law might not be weakened and destroyed, if we bend the sense to the words, and do not regard the design and view of the legislator?" Hence he may take occasion to complain of the hardship of such a procedure, that no difference should be made between an audacious and wilful crime, and an honest or necessary action, which might happen to disagree with the letter of the law, though not with the intent of it. And as it was observed before to be of considerable service to the accuser, if he could remove the defendant's plea of equity; so it will be of equal advantage to the defendant, if he can fix upon any words in the law, which may in the least seem to countenance his case since this will take off the main force of the charge.

The third controversy of this kind is, when two writings happen to clash with each other, or at least

seem to do so. Of this Hermogenes gives the following instance. One law enjoins: "He who continues alone in a ship during a tempest, shall have the property of the ship." Another law says, "A disinherited son shall enjoy no part of his father's estate." Now a son, who had been disinherited by his father, happens to be in his father's ship in a tempest, and continues there alone when every one else had deserted it. He claims the ship by the former of these laws and his brother tries his right with him by the latter. In such cases, therefore, it may first be considered, "Whether the two laws can be reconciled. And if that cannot be done, then, Which of them appears more equitable. Also, Whether one be positive and the other negative: because prohibitions are a sort of exceptions to positive injunctions. Or, If one be a general law, and the other more particular and come nearer to the matter in question. Likewise, Which was last made: since former laws are often abrogated either wholly or in part, by subsequent laws; or at least were designed to be so. Lastly, it may be observed, Whether one of the laws be not plain and express; and the other more dubious, or has any ambiguity in it. All or any of which things, that party will not omit to improve for his advantage whose interest is concerned in it."

The fourth controversy is *reasoning*. As when something, not expressly provided for by a law, is inferred by a similitude, or parity of reason, from what is contained in it. Quintilian mentions this instance of it. "There was a law made at Tarentum, to prohibit the exportation of wool; but a certain person exports sheep." In this case, the prosecutor may first compare the thing which occasions the charge, with the words of the law, and show their agreement, and how unnecessary it was that particular thing, should have been expressly mentioned in the law since it is plainly contained in it, or at least an evident consequence from it. He may then plead that many things of a like nature are omitted in other laws for the same reason. And lastly, he may urge the reasonableness and equity of the procedure. The defendant, on the other hand, will endeavour to show the deficiency of the reasoning, and the difference between the two cases. He will insist upon the plain and express words of the law, and set forth the ill tendency of such inferences and conclusions drawn from similitudes and comparisons, since there is scarce any thing but in some respect may bear a resemblance to another.

The last controversy under this head is *interpretation*, in which the dispute turns upon the true meaning and explication of the law in reference to that particular case. We have the following instance of this in the Pandects; "A man who had two sons, both under age, substitutes Titius as heir to him who should die last, provided both of them died in their minority. They both perish together at sea before they came to age. Here arises a doubt whether the substitution can take place, or whether the inheritance devolves to the heir at law." The latter pleads, That as neither of them can be said to have died last, the substitution cannot take place: which was suspended, upon the condition that one died after the other. But to this it may be said, It was the intention of the testator, that if both died in their nonage, Titius should

vention, should succeed to the inheritance; and therefore it makes no difference whether they died together, or one after the other: and so the law determines it.

2. The *second* head of external arguments are *Witnesses*. These may either give their evidence, when absent, in writing subscribed with their name; or present, by word of mouth. And what both of them testify, may either be from hearsay; or what they saw themselves, and were present at the time it was done. As the weight of the evidence may be thought greater or less on each of these accounts, either party will make such use of it as he finds for his advantage. The characters of the witnesses are also to be considered; and if any thing be found in their lives or behaviour that is justly exceptionable, to invalidate their evidence it ought not to be omitted. And how they are affected to the contending parties, or either of them, may deserve consideration; for some allowances may be judged reasonable in case of friendship, or enmity, where there is no room for any other exception. But regard should chiefly be had to what they testify; and how far the cause is affected by it. Cicero is very large upon most of these heads in his defence of Marcus Fonteius, with a design to weaken the evidence of the Gauls against him. And where witnesses are produced on one side only, as orators sometimes attempt to lessen the credit of this kind of proof, by pleading that witnesses are liable to be corrupted, or biased by some prevailing interest or passion, to which arguments taken from the nature and circumstances of things are not subject; it may be answered on the other hand, that sophistical arguments and false colourings are not exposed to infamy or punishment, whereas witnesses are restrained by shame and penalties, nor would the law require them if they were not necessary.

3. The *third* and last head of external arguments are *Contracts*; which may be either public or private. By public are meant the transactions between different states, as leagues, alliances, and the like; which depend on the laws of nations, and come more properly under deliberative discourses, to which we shall refer them. Those are called *private*, which relate to lesser bodies or societies of men, and single persons; and may be either written or verbal. And it is not so much the true meaning and purport of them that is here considered, as their force and obligation. And, as the Roman law declares, "Nothing can be more agreeable to human faith, than that persons should stand to their agreements." Therefore, in controversies of this kind, the party whose interest it is that the contract should be maintained, will plead, that such covenants have the force of private laws, and ought religiously to be observed, since the common affairs of mankind are transacted in that manner: and therefore to violate them, is to destroy all commerce and society among men. On the other side it may be said, that justice and equity are chiefly to be regarded, which are immutable; and besides, that the public laws are the common rule to determine such differences, which are designed to redress those who are aggrieved. And, indeed, where a compact has been obtained by force or fraud, it is in itself void, and has no effect either in law or reason. But on the other hand, the Roman lawyers seem to have very rightly determined, that all such obligations as are founded on natural equity,

though not binding by national laws, and are therefore called *nuda pacta*, ought, however, in honour and confidence to be performed.

III. *Of the State of a Controversy.* The ancients, observing that the principal question or point of dispute in all controversies might be referred to some particular head, reduced those heads to a certain number, that both the nature of the question might by that means be better known, and the argument suited to it be discovered with greater ease. And these heads they call *issues*.

By the state of a controversy, then we are to understand the principal point in dispute between contending parties, upon the proof of which the whole cause or controversy depends. We find it expressed by several other names in ancient writers: as, the *constitution of the cause*, the *general head*, and the *chief question*. And as this is the principal thing to be attended to in every such discourse; so it is what first requires the consideration of the speaker, and should be well fixed and digested in his mind, before he proceeds to look for arguments proper to support it. Thus Anthony, the Roman orator, speaking of his own method in his pleading, says: "When I understand the nature of the cause, and begin to consider it, the first thing I endeavour to do is, to settle with myself what that is to which all my discourse relating to the matter in dispute ought to be referred: then I diligently attend to these other two things, How to recommend myself, or those for whom I plead, to the good esteem of my hearers; and how to influence their minds, as may best suit my design." This way of proceeding appears very agreeable to reason and prudence. For what can be more absurd, than for a person to attempt the proof of any thing, before he has well settled in his own mind a clear and distinct notion what the thing is which he would endeavour to prove? Quintilian describes it to be, "That kind of question which arises from the first conflict of causes." In judicial cases, it immediately follows upon the charge of the plaintiff, and plea of the defendant. Our common law expresses it by one word, namely the *issue*. Which interpreters explain, by describing it to be, "That point of matter depending in suit, whereupon the parties join, and put their cause to the trial." Examples will further help to illustrate this, and render it more evident. In the cause of Milo, the charge of the Clodian party is, *Milo killed Clodius*. Milo's plea or defence, *I killed him, but justly*. From hence arises this grand question, or state of the cause, *Whether it was lawful for Milo to kill Clodius?* And that Clodius was lawfully killed by Milo, is what Cicero in his defence of Milo principally endeavours to prove. This is the main subject of that fine and beautiful oration. The whole of his discourse is to be considered as centering at last in this one point. Whatever different matters are occasionally mentioned, will, if closely attended to, be found to have been introduced some way or other the better to support and carry on this design. Now in such cases, where the fact is not denied, but something is offered in its defence, the state of the cause is taken from the defendant's plea, who is obliged to make it good: As in the instance here given, the chief point in dispute was the lawfulness of Milo's action, which it was Cicero's business to demonstrate.

Invention.

But when the defendant denies the fact, the state of the cause arises from the accusation; the proof of which then lies upon the plaintiff, and not, as in the former case, upon the defendant. So in the cause of Roscius the charge made against him is, *That he killed his father*. But he denies the fact. The grand question therefore to be argued is, *Whether or not he killed his father?* The proof of this lay upon his accusers. And Cicero's design in his defence of him is to show, that they had not made good their charge. But it sometimes happens that the defendant neither absolutely denies the fact, nor attempts to justify it; but only endeavours to qualify it, by denying that it is a crime of that nature, or deserves that name, by which it is expressed in the charge. We have an example of this proposed by Cicero: "A person is accused of sacrilege, for taking a thing, that was sacred, out of a private house. He owns the fact, but denies it to be sacrilege: since it was committed in a private house, and not in a temple." Hence this question arises, *Whether to take a sacred thing out of a private house, is to be deemed sacrilege or, only simple theft?* It lies upon the accuser to prove what the other denies; and therefore the state of the cause is here also as well as in the preceding case taken from the indictment.

But besides the principal question, there are other subordinate questions which follow upon it in the course of a dispute, and should be carefully distinguished from it. Particularly that which arises from the reason, or argument, which is brought in proof of the principal question. For the principal question itself proves nothing, but is the thing to be proved, and becomes at last the conclusion of the discourse. Thus, in the cause of Milo his argument is, *I killed Clodius justly, because he assassinated me*. Unless the Clodian party be supposed to deny this, they give up their cause. From hence therefore this subordinate question follows, *Whether Clodius assassinated Milo?* Now Cicero spends much time in the proof of this, as the hinge on which the first question, and consequently the whole cause, depended. For if this was once made to appear, the lawfulness of Milo's killing Clodius, which was the grand question or thing to be proved, might be inferred as an allowed consequence from it. This will be evident, by throwing Milo's argument, as used by Cicero, into the form of a syllogism.

*An assassin is lawfully killed:*

*Clodius was an assassin:*

*Therefore he was lawfully killed by Milo, whom he assassinated.*

If the minor proposition of this syllogism was granted, no one would deny the conclusion: for the Roman law allowed of self-defence. But as Cicero was very sensible this would not be admitted so he takes much pains to bring the court into the belief of it. Now where the argument brought in defence of the second question is contested, or the orator supposes that it may be so, and therefore supports that with another argument, this occasions a third question consequent upon the former; and in like manner he may proceed to a fourth. But be they more or fewer, they are to be considered but as one chain of subordinate questions

Invention.

dependent upon the first. And though each of them has its particular state, yet none of these is what rhetoricians call *The state of the Cause*, which is to be understood only of the principal question. And if, as it frequently happens, the first or principal question is itself directly proved from more than one argument; this makes no other difference, but that each of these arguments, so far as they are followed by others to support them, become a distinct series of subordinate questions, all dependent upon the first. As when Cicero endeavours to prove, that Roscius did not kill his father from two reasons or arguments: *Because he had neither any cause to move him to such a barbarous action nor any opportunity for it*.

Moreover, besides these subordinate questions, there are also incidental ones often introduced, which have some reference to the principal question, and contribute towards the proof of it, though they are not necessarily connected with it, or dependent upon it. And each of these also has its state though different from that of the cause. For every question or point of controversy, must be stated, before it can be made the subject of disputation. And it is for this reason, that every new argument advanced by an orator is called a *question*; because it is considered as a fresh matter of controversy. In Cicero's defence of Milo, we meet with several of this sort of questions, occasioned by some aspersions which had been thrown out by the Clodian party to the prejudice of Milo. As, "That he was unworthy to see the light, who owned he had killed a man:" For Milo before his trial had openly confessed he killed Clodius. So likewise, "That the senate had declared the killing of Clodius was an illegal action." "And further, "That Pompey, by making a new law to settle the manner of Milo's trial, had given his judgment against Milo." Now to each of these Cicero replies before he proceeds to the principal question. And therefore though the question, in which the state of a controversy consists, it is said by Quintillian to arise from "the first conflict of causes," yet we find by this instance of Cicero that is not always the first question in order, upon which the orator treats.

But it sometimes happens, that the same cause or controversy contains in it more than one state. Thus in judicial causes, every distinct charge occasions a new state. All Cicero's orations against Verres relate to one cause, founded upon a law of the Romans against unjust exactions made by their governors of provinces upon the inhabitants: but as that prosecution is made up of as many charges as there are orations, every charge or indictment has its different state. So likewise his oration in defence of Caelius has two states, in answer to a double charge, made against him by his adversaries: one, "for borrowing money of Clodia, in order to bribe certain slaves to kill a foreign ambassador;" and the other, "for an attempt afterward to poison Clodia herself." Besides which, there were several other matters of a less heinous nature, which had been thrown upon him by his accusers, with a design very likely, to render the two principal charges more credible; to which Cicero first replies, in the same manner as in his defence of Milo.

Though all the examples we have hitherto brought to illustrate this subject have been taken from judicial cases;

## Invention

cases; yet not only these, but very frequently discourses of the deliberative kind, and sometimes those of the demonstrative, are managed in a controversial way. And all controversies have their state. And therefore Quintilian very justly observes, that "states belong both to general and particular questions; and to all sorts of causes, demonstrative, deliberative, and judicial." In Cicero's oration for the Manilian law, this is the main point in dispute between him and those who opposed that law: "Whether Pompey was the fittest person to be intrusted with the management of the war against Mithridates?" This is a subject of the deliberative kind. And of the same nature was that debate in the senate concerning the demolition of Carthage. For the matter in dispute between Cato, who argued for it, and those who were of the contrary opinion seems to have been this: "Whether it was for the interest of the Romans to demolish Carthage?" And so likewise in those two fine orations of Cato and Caesar, given us by Sallust, relating to the conspirators with Cataline, who were then in custody, the controversy turns upon this: "Whether those prisoners should be punished with death, or perpetual imprisonment?" Examples of the demonstrative kind are not so common; but Cicero's oration concerning the 'Answers of the soothsayers,' may afford us an instance of it. Several prodigies had lately happened at Rome; upon which the soothsayers being consulted, assigned this as the reason of them, Because some places consecrated to the gods had been afterwards converted to civil uses. Clodius charged this upon Cicero; whose house was rebuilt at the public expence, after it had been demolished by Clodius, and the ground consecrated to the goddess Liberty. Cicero in this oration retorts the charge; and shows that the prodigies did not respect him but Clodius. So that the question in dispute was, "To which of the two those prodigies related?" This oration does not appear to have been spoken in a judicial way, and must therefore belong to the demonstrative kind. His invective against Piso is likewise much of the same nature, wherein he compares his own behaviour and conduct with that of Piso.

As to the number of these states, both Cicero and Quintilian reduce them to three. "We must (says Quintilian) agree with those, whose authority Cicero follows, who tells us, that three things may be inquired into in all disputes: Whether a thing is; what it is; and how it is. And this is the method which nature prescribes. For in the first place, it is necessary the thing should exist about which the dispute is: because no judgment can be made either of its nature or quality till its existence be manifest; which is therefore the first question. But though it be manifest that a thing is, it does not presently appear what it is: and when this is known, the quality yet remains: and after these three are settled, no further inquiry is necessary." Now the first of these three states is called the *conjunctural state*; as if it be inquired, "Whether one person killed another?" This always follows upon the denial of a fact, by one of the parties; as was the case of Roscius. And it receives its name from hence, that the judge is left, as it were, to conjecture, whether the fact was really committed or not, from the evidence produced on the other side. The second is called

the *definitive state*, when the fact is not denied: but the dispute turns upon the nature of it, and what name it is proper to give it: as in that example of Cicero, "Whether to take a sacred thing out of a private house be theft or sacrilege?" For in this case it is necessary to settle the distinct notion of those two crimes, and show their difference. The third is called the *state of quality*; when the contending parties are agreed both as to the fact, and the nature of it; but the dispute is, "Whether it be just or unjust, profitable or unprofitable, and the like;" as in the cause of Milo.

From what has been said upon this subject, the use of it may in a good measure appear. For whoever engages in a controversy, ought in the first place to consider with himself the main question in dispute, to fix it well in his mind, and keep it constantly in his view; without which he will be very liable to ramble from the point, and bewilder both himself and his hearers. And it is no less the business of the hearers principally to attend to this; by which means they will be helped to distinguish and separate from the principal question what is only incidental, and to observe how far the principal question is affected by it; to perceive what is offered in proof, and what is only brought in for illustration; not to be misled by digressions, but to discern when the speaker goes off from his subject, and when he returns to it again; and, in a word, to accompany him through the whole discourse, and carry with them the principal chain of reasoning upon which the cause depends, so as to judge upon the whole, whether he has made out his point, and the conclusion follows from the premises.

#### CHAP. II. Of Arguments suited to Demonstrative Discourses.

THESE consist either in praise or dispraise; and, agreeably to the nature of all contraries, one of them will serve to illustrate the other.

Now we either praise *persons* or *things*.

I. In praising or dispraising *persons*, rhetoricians prescribe two methods. One is, to follow the order in which every thing happened that is mentioned in the discourse; the other is, to reduce what is said under certain general heads, without a strict regard to the order of time.

1. In pursuing the former method, the discourse may be very conveniently divided into three periods. The first of which will contain what preceded the person's birth; the second, the whole course of his life; and the third what followed upon his death.

Under the first of these may be comprehended what is proper to be said concerning his country or family. And therefore, if these were honourable, it may be said to his advantage, that he no wise disgraced them, but acted suitably to such a descent. But if they were not so, they may be either wholly omitted; or it may be said, that instead of deriving thence any advantage to his character, he has conferred a lasting honour upon them; and that it is not of so much moment where, or from whom, a person derives, his birth as how he lives.

In the second period, which is that of his life, the qualities both of his mind and body, with his circumstances in the world, may be separately considered.

Though,

discourses.

Invention. Though, as Quintilian rightly observes, "All external advantages are not praises for themselves, but according to the use that is made of them. For riches, and power, and interest, as they have great influence, and may be applied either to good or bad purposes, are a proof of the temper of our minds; and therefore we are either made better or worse by them." But these things are a just ground for commendation, when they are the reward of virtue or industry. Bodily endowments are health, strength, beauty, activity, and the like; which are more or less commendable, according as they are employed. And where these, or any of them, are wanting, it may be shown, that they are abundantly compensated by the more valuable endowments of the mind. Nay, sometimes a defect in these may give an advantageous turn to a person's character; for any virtue appears greater, in proportion to the disadvantages the person laboured under in exerting it. But the chief topics of praise are taken from the virtues, and qualifications of the mind. And here the orator may consider the disposition, education, learning, and several virtues, which shone through the whole course of the person's life. In doing which, the preference should always be given to virtue above knowledge or any other accomplishment. And in actions, those are most considerable, and will be heard with greatest approbation, which a person either did alone, or first, or wherein he had fewest associates; as likewise those which exceeded expectation, or were done for the advantage of others rather than his own. And further, as the last scene of a man's life generally commands the greatest regard, if any thing remarkable at that time was either said or done, it ought particularly to be mentioned. Nor should the manner of his death, or cause of it, if accompanied with any commendable circumstances, be omitted; as if he died in the service of his country, or in the pursuit of any other laudable design.

The third and last period relates to what followed after the death of the person. And here the public loss, and public honours conferred upon the deceased, are proper to be mentioned. Sepulchres, statues, and other monuments to perpetuate the memory of the dead, at the expence of the public, were in common use both among the Greeks and Romans. But in the earliest times, as these honours were more rare, so they were less costly. For as in one age it was thought a sufficient reward for him who died in the defence of his country, to have his name cut in a marble inscription, with the cause of his death; so in others it was very common to see the statues of gladiators, and persons of the meanest rank, erected in public places. And therefore a judgment is to be formed of these things from the time, custom, and circumstances, of different nations: since the frequency of them renders them less honourable, and takes off from their evidence as the rewards of virtue. But, as Quintilian says, "Children are an honour to their parents, cities to their founders, laws to those who compiled them, arts to their inventors, and useful customs to the authors of them."

And this may suffice for the method of praising persons, when we propose to follow the order of time, as Isocrates has done in his funeral oration upon Evagoras king of Samis, and Pliny in his panegyric

upon the emperor Trajan. But as this method is very plain and obvious, so it requires the more agreeable dress to render it delightful; lest otherwise it seem rather like an history than an oration: For which reason, we find, that epic poets, as Homer, Virgil, and others, begin with the middle of their story, and afterwards take a proper occasion to introduce what preceded, to diversify the subject, and give the greater pleasure and entertainment to their readers.

2. The other method above hinted was, to reduce the discourse to certain general heads without regarding the order of time. As if any one, in praising the elder Cato, should propose to do it, by showing that he was a most prudent senator, an excellent orator, and most valiant general; all which commendations are given him by Pliny. In like manner, the character of a good general may be comprised under four heads; skill in military affairs, courage, authority, and success: from all which Cicero commends Pompey, And agreeably to this method Suetonius has written the lives of the first twelve Cæsars.

But in the praising of persons, care should always be taken to say nothing that may seem fictitious or out of character, which may call the orator's judgment or integrity in question. It was not without cause, therefore, that Lyfippus the statuary, as Plutarch tells us, blamed Appelles for painting Alexander the Great with thunder in his hand; which could never suit his character as a man, however he might boast of his divine descent; for which reason Lyfippus himself made an image of him holding a spear, as the sign of a warrior. Light and trivial things in commendations are likewise to be avoided, and nothing mentioned but what may carry in it the idea of something truly valuable, and which the hearers may be supposed to wish for, and is proper to excite their emulation. These are the principal heads of praise with relation to men. In dispraise, the heads contrary to these are requisite; which being sufficiently clear from what has been said, need not particularly be insisted on.

II. We proceed therefore to the other part of the division, which respects *things*, as distinguished from persons. By which we are to understand all beings inferior to man, whether animate or inanimate; as likewise the habits and dispositions of men, either good or bad, when considered separately, and apart from their subjects, as arts and sciences, virtues and vices, with whatever else may be a proper subject for praise or dispraise. Some writers, indeed, have, for their own amusement and the diversion of others, displayed their eloquence in a jocular manner upon subjects of this kind. So Lucian has written in praise of a fly, and Syneusis an elegant encomium upon baldness. Others, on the contrary, have done the like in a satirical way. Such is Seneca's apotheosis or consecration of the emperor Claudius; and Mysopogon or beard-hater, written by Julian the emperor. Not to mention several modern authors, who have imitated them in such ludicrous compositions. But as to these things, and all of the like nature, the observation of Antony in Cicero seems very just: "That it is not necessary to reduce every subject we discourse upon to rules of art." For many are so trivial, as not to deserve it: and others so plain and evident of themselves,

Invention. as not to require it. But since it frequently comes in the way both of orators and historians to describe countries, cities, and facts, we shall briefly mention the principal heads of invention proper to illustrate each of these.

Countries, then, may be celebrated from the pleasantness of their situation, the clemency and wholesomeness of the air, and goodness of the soil; to which last may be referred the springs, rivers, woods, plains, mountains and minerals. And to all these may be added their extent, cities, the number and antiquity of the inhabitants; their policy, laws, custom, wealth, character for cultivating the arts both of peace and war; their princes, and other eminent men they have produced. Thus Pacatus has given us a very elegant description of Spain, in his panegyric upon the emperor Theodosius, who was born there.

Cities are praised from much the same topics as countries. And here, whatever contributes either to their defence or ornament ought particularly to be mentioned; as the strength of the walls and fortifications, the beauty and splendor of the buildings, whether sacred or civil, public or private. We have in Herodotus a very fine description of Babylon, which was once the strongest, largest, and most regular city in the world. And Cicero has accurately described the city of Syracuse, in the island Sicily in one of his orations against Verres.

But facts come much oftener under the cognizance of an orator. And these receive their commendation from their honour, justice, or advantage. But in describing them, all the circumstances should be related in their proper order; and that in the most lively and affecting manner, suited to their different nature. Livy has represented the demolition of Alba by the Roman army, which was sent thither to destroy it, thro' the whole course of that melancholy scene, in a style so moving and pathetic, that one can hardly forbear condoling with the inhabitants upon reading his account.

But in discourses of this kind, whether of praise or dispraise, the orator should (as he ought indeed upon all occasions) well consider where, and to whom, he speaks. For wise men often think very indifferently both of persons and things from the common people. And we find that learned and judicious men are frequently divided in their sentiments, from the several ways of thinking to which they have been accustomed. Besides, different opinions prevail, and gain the ascendant, at different times. While the Romans continued a free nation, love of their country, liberty, and public spirit, were principles in the highest esteem among them. And therefore, when Cato killed himself, that he might not fall into the hands of Cæsar, and survive the liberty of his country, it was thought an instance of the greatest heroic virtue; but afterwards, when they had been accustomed to an arbitrary government, and spirit of liberty was now lost, the poet Martial could venture to say,

*Death to avoid 'tis madness sure to die.*

A prudent orator therefore will be cautious of opposing any settled and prevailing notions of those to whom he addresses; unless it be necessary, and then he will do it the softest and most gentle manner.

### CHAP. III. *Of Arguments suited to Deliberative Discourses.*

THIS kind of discourses must certainly have been very ancient; since, doubtless, from the first beginning of mens conversing together, they deliberated upon their common interest, and offered their advice to each other. But neither those of the laudatory nor judicial kind could have been introduced, till mankind were settled in communities, and found it necessary to encourage virtue by public rewards, and bring vice under the restraint of laws. The early practice of suavity discourses appears from sacred writ, where we find, that when Moses was ordered upon an embassy into Egypt, he would have excused himself for want of eloquence. And Homer represents the Greeks at the siege of Troy, as flocking like a swarm of bees to hear their generals harangue them. Nor is this part of oratory less conspicuous for its usefulness to mankind, than for its antiquity; being highly beneficial either in councils, camps, or any societies of men. How many instances have we upon record, where the fury of an enraged multitude has been checked and appeased by the prudent and artful persuasion of some particular person? The story of Agrippa Menenius, when the commons of Rome withdrew from the senators, and retired out of the city, is too well known to need reciting. And how often have armies been animated and fired to the most dangerous exploits, or recalled to their duty, when ready to mutiny, by a moving speech of their general? many instances of which we find in history.

All deliberation respects something future, for it is in vain to consult about what is already past. The subject matter of it is, either things public or private, sacred or civil; indeed all the valuable concerns of mankind, both present and future, come under its regard. And the end proposed by this kind of discourses is chiefly profit or interest. But since nothing is truly profitable, but what is in some respect good; and every thing which is good in itself may not in all circumstances be for our advantage; properly speaking, what is both good and profitable, or beneficial good, is the end here designed. And therefore, as it sometimes happens, that what appears profitable may seem to interfere with that which is strictly just and honourable; in such cases it is certainly most advisable to determine on the safer side of honour and justice, notwithstanding some plausible things may be offered to the contrary. But where the dispute lies apparently between what is truly honest, and some external advantage proposed in opposition to it, all good men cannot but agree in favour of honesty. Such was the case of Regulus, who, being taken prisoner by the Carthaginians, was permitted to go to Rome upon giving his oath, that unless he could persuade the senate to set at liberty some young Carthaginian noblemen, then prisoners at Rome, in exchange for him, he should return again to Carthage. But Regulus, when he came to Rome, was so far from endeavouring to prevail with the senate to comply with the desire of the Carthaginians, that he used all his interest to dissuade them from hearkening to the proposal. Nor could the most earnest intreaties of his earnest relations and friends, nor any arguments they were able to offer, engage him to continue at Rome, and not return again

Invention.  
17  
Of deliberative discourses, and the arguments suited to them,

Invention.

to Carthage. He had then plainly in his view, on the one side, ease, security, affluence, honours, and the enjoyment of his friends; and on the other, certain death, attended with cruel torments. However, thinking the former not consistent with truth and justice, he chose the latter. And he certainly acted as became an honest and brave man, in choosing death, rather than to violate his oath. Though whether he did prudently in persuading the senate not to make the exchange, or they in complying with him, we shall leave others to determine. Now, when it proves to be a matter of debate, whether a thing upon the whole be really beneficial or not; as here arise two parts, advice and dissuasion, they will each require proper heads of argument. But as they are contrary to each other, he who is acquainted with one, cannot well be ignorant of the other. We shall therefore chiefly mention those proper for advice, from whence such as are suited to dissuade will easily be perceived. Now the principal heads of this kind are these following, which are taken from the nature and properties of the thing itself under consideration.

1. *Pleasure* often affords a very cogent argument in discourses of this nature. Every one knows what an influence this has upon the generality of mankind. Though, as Quintilian remarks, pleasure ought not of itself to be proposed as a fit motive for action in serious discourses, but when it is designed to recommend something useful, which is the case here. So would any one advise another to the pursuit of polite literature, Cicero has furnished him with a very strong inducement to it from the pleasure which attends that study, when he says, "If pleasure only was proposed by these studies, you would think them an entertainment becoming a man of sense and a gentleman. For other pursuits neither agree with all times, all ages, nor all places; but these studies improve youth, delight old age, adorn prosperity, afford a refuge and comfort in adversity, divert us at home, are no hindrance abroad, sleep, travel, and retire with us into the country."

2. *Profit*, or advantage. This has no less influence upon many persons than the former; and when it respects things truly valuable, it is a very just and laudable motive. Thus Cicero, when he sends his *books of offices* to his son, which he wrote in Latin for his use, advises him to make the best advantage both of his tutor's instructions, and the conversation at Athens, where he then was; but withal to peruse his philosophical treatises, which would be doubly useful to him, not only upon account of the subjects, but likewise of the language, as they would enable him to express himself upon those arguments in Latin, which before had only been treated of in Greek.

3. *Honour*; than which no argument will sooner prevail with generous minds, or inspire them with greater ardour. Virgil has very beautifully described Hector's ghost appearing to Æneas the night Troy was taken, and advising him to depart, from this motive of honour;

O goddess-born, escape by timely flight  
The flames and horrors of this fatal night.  
The fates already have possess'd the wall;  
Troy nods from, high, and totters to her fall.

Enough is paid to Priam's royal name;  
More than enough to duty and to fame.  
If by a mortal hand my father's throne  
Cou'd be defended, 'twas by mine alone.

Invention.

The argument here made use of to persuade Æneas to leave Troy immediately, is, that he had done all that could be expected from him, either as a good subject or brave soldier, both for his king and country; which were sufficient to secure his honour; and now there was nothing more to be expected from him when the city was falling, and impossible to be saved; which could it have been preserved by human power, he himself had done it.

But although a thing considered in itself appear beneficial if it could be attained, yet the expediency of undertaking it may still be questionable; in which case the following heads, taken from the circumstances which attend it, will afford proper arguments to engage in it.

(1.) The *possibility* of succeeding may sometimes be argued, as one motive to this end. So Hannibal endeavoured to convince king Antiochus that it was possible for him to conquer the Romans if he made Italy the seat of the war; by observing to him, not only that the Gauls had formerly destroyed their city, but that he had himself defeated them in every battle he fought with them in that country.

(2.) But an argument founded upon *probability* will be much more likely to prevail. For in many affairs of human life, men are determined either to prosecute them or not, as the prospect of success appears more or less probable. Hence Cicero, after the fatal battle at Pharsalia, dissuades those of Pompey's party, with whom he was engaged, from continuing the war any longer against Cæsar; because it was highly improbable, after such a defeat, by which their main strength was broken, that they should be able to stand their ground, or meet with better success than they had before.

(3.) But further, since probability is not a motive strong enough with many persons to engage in the prosecution of a thing which is attended with considerable difficulties, it is often necessary to represent the facility of doing it, as a further reason to induce them to it. And therefore Cicero makes use of this argument to encourage the Roman citizens in opposing Mark Anthony (who upon the death of Cæsar had assumed an arbitrary power), by representing to them, that his circumstances were then desperate, and that he might easily be vanquished.

(3.) Again, if the thing he advised can be shown to be in any respect necessary, this will render the motive still much stronger for undertaking it. And therefore Cicero joins this argument with the former, to prevail with the Roman citizens to oppose Anthony, by telling them, that "The consideration before them was, not in what circumstances they should live, but whether they should live at all, or die with ignominy and disgrace." This way of reasoning will sometimes prevail when all others prove ineffectual. For some persons are not to be moved, till things are brought to an extremity, and they find themselves reduced to the utmost danger.

(5.) To these heads may be added the consideration

**Invention.** tion of the *event*, which in some cases carries great weight with it. As when we advise to the doing of a thing from this motive, That whether it succeed or not, it will yet be of service to undertake it. So after the great victory gained by Themistocles over the Persian fleet at the straits of Salamis, Mardonius advised Xerxes to return into Asia himself, lest the report of his defeat should occasion an insurrection in his absence: but to leave behind him an army of 300,000 men under his command; with which, if he should conquer Greece, the chief glory of the conquest would redound to Xerxes; but if the design miscarried, the disgrace would fall upon his generals.

These are the principal heads which furnish the orator with proper arguments in giving advice. Cicero, in his oration for the Manilian law, where he endeavours to persuade the Roman people to choose Pompey for their general in the Mithridatic war, reasons from three of these topics, into which he divides his whole discourse; namely, the necessity of the war, the greatness of it, and the choice of a proper general. Under the first of these he shows, that the war was necessary, from four considerations; the honour of the Roman state, the safety of their allies, their own revenues, and the fortunes of many of their fellow-citizens, which were all highly concerned in it, and called upon them to put a stop to the growing power of king Mithridates, by which they were all greatly endangered. So that this argument is taken from the head of *necessity*. The second, in which he treats of the greatness of the war, is founded upon the topic of *possibility*. For though he shows the power of Mithridates to be very great, yet not so formidable, but that he might be subdued; as was evident from the many advantages Lucullus had gained over him and his associates. In the third head, he endeavours to prevail with them to intrust the management of the war in the hands of Pompey, whom he describes as a consummate general, for his skill in military affairs, courage, authority in success; in all which qualities he represents him as superior to any other of their generals whom they could at that time make choice of. The design of all which was, to persuade them, that they had very good reason to hope for success, and a happy event of the war, under his conduct. So that the whole force of his reasoning under this head is drawn from *probability*. These are the three general topics which make up that fine discourse. Each of which is indeed supported by divers other arguments and considerations, which will be obvious in perusing the oration itself, and therefore need not be here enumerated. On the contrary, in another oration he endeavours to dissuade the senate from consenting to a peace with Mark Antony, because it was base, dangerous, and impracticable.

But no small skill and address are required in giving advice. For since the tempers and sentiments of mankind, as well as their circumstances, are very different and various; it is often necessary to accommodate the discourse to their inclinations and opinions of things. And therefore the weightiest arguments are not always the most proper and fittest to be used on all occasions. Cicero, who was an admirable master of this art, and knew perfectly well how to suit what he said

to the taste and relish of his hearers, in treating upon this subject, distinguishes in unking into two sorts; the ignorant and unpolished, who always prefer profit to honour; and such as are more civilized and polite, who prefer honour and reputation to all other things. Wherefore they are to be moved by these different views: Praise, glory, and virtue, influence the one; while the other is only to be engaged by a prospect of gain and pleasure. Besides, it is plain, that the generality are much more inclined to avoid evils than to pursue what is good; and to keep clear of scandal and disgrace, than to practise what is truly generous and noble. Persons likewise of a different age act from different principles; young men for the most part view things in another light from those who are older and have had more experience, and consequently are not to be influenced by the same motives.

#### CHAP. IV. Of Arguments suited to Judicial Discourses.

In judicial controversies there are two parties; the plaintiff or prosecutor, and the defendant or person charged. The subjects of them is always something past. And the end proposed by them Cicero calls *equity*, or *right and equity*; the former of which arises from the laws of the country, and the latter from reason and the nature of things. For at Rome the praetors had a court of equity, and were empowered, in many cases relating to property, to relax the rigour of the written laws. But as this subject is very copious, and causes may arise from a great variety of things, writers have reduced them to three heads, which they call *states*, to some one of which all judicial proceedings may be referred; namely, *whether a thing is*, what *it is*, or *how it is*. By the *state* of a cause therefore is meant the principal question in dispute, upon which the whole affair depends. Which, if it stops in the first inquiry, and the defendant denies the fact, the state is called *conjectural*; but if the fact be acknowledged, and yet denied to be what the adversary calls it, it is termed *definitive*; but if there is no dispute either about the fact or its name, but only the justice of it, it is called the *state of quality*: as was shown more largely before (See n<sup>o</sup> 15). But we there considered these states only in a general view, and deferred the particular heads of argument proper for each of them to this *judicial* kind of discourses; where they most frequently occur, and from which examples may easily be accommodated to other subjects.

All judicial causes are either *private* or *public*. Those are called *private*, which relate to the right of particular persons; and they are likewise called *civil* causes, as they are conversant about matters of property. *Public* causes are those which relate to public justice and the government of the state; which are also called *criminal*, because by them crimes are prosecuted, whether capital, or those of a less heinous nature. We shall take the heads of the arguments only from this latter kind, because they are more copious, and easy to be illustrated by examples; from which such as agree to the former, namely, *civil* causes, will sufficiently appear.

1. The *conjectural* state. When the accused person denies

Invention.

denies the fact, there are three things which the prosecutor has to consider; whether he *would* have done it, whether he *could*, and whether he *did* it. And hence arise three topics; from the *will*, the *power*, and the *signs* or circumstances which attended the action. The affections of the mind discover the will; as, passion, an old grudge, a desire of revenge, a resentment of an injury, and the like. Therefore Cicero argues from Clodius's hatred of Milo, that he designed his death; and from thence infers, that he was the aggressor in the combat between them, wherein Clodius was killed. This is what he principally endeavours to prove, and comes properly under this state; for Milo owned that he killed him, but alleged that he did it in his own defence. So that in regard to this point, Which of them assaulted the other? the charge was mutual. The prospect of advantage may also be alleged to the same purpose. Hence it is said of L. Cassius, that whenever he sat as judge in a case of murder, he used to advise and move the court to examine to whom the advantage arose from the death of the deceased. And Cicero puts this to Anthony concerning the death of Cæsar. "If any one (says he) should bring you upon trial, and use that saying of Cassius, *Cui bona?* 'Who got by it? look to it, I beseech you, that you are not confounded.'" To these Arguments may be added, hope of impunity, taken either from the circumstances of the accused person, or of him who suffered the injury. For persons, who have the advantage of interest, friends, power, or money, are apt to think they may easily escape; as likewise such who have formerly committed other crimes with impunity. Thus Cicero represents Clodius as hardened in vice, and above all the restraint of laws, from having so often escaped punishment upon committing the highest crimes. On the contrary, such a confidence is sometimes raised from the condition of the injured party, if he is indigent, obscure, timorous, or destitute of friends; much more if he has an ill reputation, or is loaded with popular hatred and resentment. It was this presumption of the obscurity of Roscius, who lived in the country, and his want of interest at Rome, which encouraged his accusers to charge him with killing his father, as Cicero shows in his defence of him. Lastly, the temper of a person, his views, and manner of life, are considerations of great moment in this matter. For persons of bad morals, and such as are addicted to vice, are easily thought capable of committing any wickedness. Hence Sallust argues from the evil disposition and vicious life of Catiline, that he affected to raise himself upon the ruins of his country.—The second head is the *power* of doing a thing; and there are three things which relate to this, the *place*, the *time*, and *opportunity*. As if a crime is said to have been committed in a private place where no other person was present; or in the night; or when the injured person was unable to provide for his defence. Under this head may likewise be brought in the circumstances of the persons; as if the accused person was stronger, and so able to overpower the other; or more active, and so could easily make his escape. Cicero makes great use of this topic in the case of Milo, and shows, that Clodius had all the advantages of *place*, *time*, and *opportunity*, to execute his de-

sign of killing him. The third head comprehends Invention.

the *signs* and circumstances which either preceded, accompanied, or followed, the commission of the fact. So threats, or the accused person being seen at or near the place before the fact was committed, are circumstances that may probably precede murder; fighting, crying out, bloodshed, are such as accompany it; paleness, trembling, inconsistent answers, hesitation, or faltering of the speech, something found upon the person accused which belonged to the deceased, are such as follow it. Thus Cicero proves, that Clodius had threatened the death of Milo, and given out that he should not live above three days at the farthest.—These arguments, taken from conjectures, are called *presumptions*, which though they do not directly prove that the accused person committed the fact with which he is charged; yet when laid together, they appeared very strong, sentence by the Roman law might sometimes be given upon them, to convict him.

These are the topics from which the prosecutor takes his arguments. Now the business of the defendant is to invalidate these. Therefore such as are brought from the *will*, he either endeavours to show are not true, or so weak as to merit very little regard. And he refutes those taken from the *power*, by proving that he wanted either opportunity or ability; as, if he can show, that neither the place nor time insisted on was at all proper; or that he was then in another place. In like manner he will endeavour to confute the *circumstances*, if they cannot be directly denied, by showing that they are not such as do necessarily accompany the fact, but might have proceeded from other causes, though nothing of what is alleged had been committed; and it will be of great service to assign some other probable cause. But sometimes the defendant does not only deny that he did the fact, but charges it upon another. Thus Cicero, in his oration for Roscius, not only defends him from each of these three heads, but likewise charges the fact upon his accusers.

2. The *definitive* state, which is principally concerned in defining and fixing the name proper to the fact: though orators seldom make use of exact definitions, but commonly choose larger descriptions, taken from various properties of the subject or thing described.

The heads of argument in this state are much the same to both parties. For each of them defines the fact his own way, and endeavours to refute the other's definition. We may illustrate this by an example from Quintilian; "A person is accused of sacrilege, for stealing money out of a temple, which belonged to a private person." The fact is owned; but the question is, *Whether it be properly sacrilege?* The prosecutor calls it so, because it was taken out of a temple, but since the money belonged to a private person, the defendant denies it to be sacrilege, and says it is only simple theft. Now the reason why the defendant uses this plea, and insists upon the distinction, is, because by the Roman law the penalty of theft was only four times the value of what was stolen; whereas sacrilege was punished with death. The prosecutor then forms his definition agreeable to his charge, and says, "To steal any thing out of a sacred place is sacrilege." But the defendant excepts against this definition,

Invention.

definition, as defective; and urges, that it does not amount to sacrifice, unless the thing stolen was likewise sacred. And this case might once, perhaps, have been a matter of controversy, since we find it expressly determined in the Pandects, that "An action of sacrilege should not lie, but only of theft, against any one who should steal the goods of private persons deposited in a temple."

The second thing is the proof brought by each party to support his definition; as in the example given us by Cicero, of one "who carried his cause by bribery, and was afterwards prosecuted again upon an action of prevarication." Now, if the defendant was cast upon this action, he was, by the Roman law, subjected to the penalty of the former prosecution. Here the prosecutor defines prevarication to be, *Any bribery or corruption in the defendant, with a design to pervert justice.* The defendant, therefore, on the other hand, restrains it to *bribing only the prosecutor.*

And if this latter sense agrees better with the common acceptance of the word, the prosecutor in the third place pleads the intention of the law, which was to comprehend all bribery in judicial matters under the term of *prevarication*. In answer to which the defendant endeavours to show, either from the head or contraries, that a real prosecutor and a prevaricator are used as opposite terms in the law; or from the etymology of the word, that the prevaricator denotes one who pretends to appear in the prosecution of a cause, while in reality he favours the contrary side; and consequently, that money given for this end only can, in the sense of the law, be called *prevarication*.

Lastly, the prosecutor pleads, that it is unreasonable that he who does not deny the fact should escape by a cavil about a word. But the defendant insists upon his explication as agreeable to the law; and says, the fact is misrepresented and blackened, by affixing to it a wrong name.

3. The third state is that of *quality*, in which the dispute turns upon the justice of an action. And here the defendant does not deny he did the thing he is charged with; but asserts it to be right and equitable from the circumstances of the case, and the motives which induced him to it.

And, first, he sometimes alleges the reason of doing it was in order to prevent some other thing of worse consequence, which would otherwise have happened. We have an instance of this in the life of Epaminondas, who, with two other generals joined in the command with him, marched the Theban army into Peloponnesus against the Lacedemonians; but by the influence of a contrary faction at home, their commissions were superseded, and other generals sent to command the army. But Epaminondas, being sensible that, if he obeyed this order at that time, it would be attended with the loss of the whole army, and consequently the ruin of the state, refused to do it; and having persuaded the other generals to do the like, they happily finished the war in which they were engaged; and upon their return home Epaminondas taking the whole matter upon himself, on his trial was acquitted. The arguments proper in this case are taken from the justice, usefulness, or necessity, of

Invention.

the action. The accuser therefore will plead, that the fact was not just, profitable, nor necessary, considered either in itself or comparatively with that for the sake of which it is said to have been done: and he will endeavour to show, that what the defendant assigns for the reason of what he did might not have happened as he pretends. Besides, he will represent of what ill consequence it must be, if such crimes go unpunished. The defendant, on the other hand, will argue from the same heads, and endeavour to prove the fact was just, useful, or necessary. And he will further urge, that no just estimate can be made of any action, but from the circumstances which attend it; as the design, occasion, and motives for doing it: which he will represent in the most favourable light to his own cause, and endeavour to set them in such a view as to induce others to think they could not but have done the same in the like circumstances.

Again, the cause of an action is sometimes charged by the defendant upon the party who received the damage, or some other person, who either made it necessary, or induced him to do it. The first of these was Milo's plea for killing Clodius, because he assaulted him with a design to take away his life. Here the fact is not denied, as in the case of Roscius above mentioned, under the *conjectural* state; but justified from the reason of doing it. For that an assassin might be justly killed, Cicero shows both from law and reason. The accuser, therefore, in such a case, will, if there be room for it, deny the truth of this allegation. So the friends of Clodius affirmed that Milo was the aggressor, and not Clodius; which Cicero, in his defence of Milo, principally labours to refute. In the second case, the prosecutor will say, No one ought to offend because another has offended first; which defeats the course of public justice, renders the laws useless, and destroys the authority of the magistrate. The defendant on the other hand, will endeavour to represent the danger and necessity of the case, which required an immediate remedy, and in that manner; and urges, that it was vain and impracticable to wait for redress in the ordinary way, and therefore no ill consequence can arise to the public. Thus Cicero, in defending Sextius, who was prosecuted for a riot in bringing armed men into the forum, shows that his design was only to repel force with force; which was then necessary, there being no other means left for the people to assemble, who were excluded by a mob of the contrary party. Of the third case we have also an example in Cicero, who tells us, that, "in making a league between the Romans and Samnites, a certain young nobleman was ordered by the Roman general to hold the swine (designed for a sacrifice): but the senate afterwards disapproving the terms, and delivering up their general to the Samnites, it was moved, Whether this young man ought not likewise to be given up." Those who were for it might say, that to allege the command of another, is not a sufficient plea for doing an ill action; and this is what the Roman law now expressly declares. But in answer to that, it might be replied, that it was his duty to obey the command of his general, who was answerable for his now orders, and not those who were obliged to execute them; and therefore to

*Invention.* give up this young nobleman would be to punish one person for the fault of another.

Lastly, a fact is sometimes rather excused than defended, by pleading that it was not done designedly, or with any ill intent. This is called *concession*; and consists of two parts, *apology* and *intreaty*. The former represents the matter as the effect of inadvertency, chance, or necessity. Aristotle gives us an example of inadvertency or imprudence in a woman at Athens, who gave a young man a love-potion, which killed him; for which she was tried, but acquitted: though afterwards this was made criminal by the Roman law. The case of Adrastus, as related by Herodotus, is an instance of chance; who being intrusted by Cræsus with the care of his son, as they were hunting, killed him accidentally with a javelin which he threw at a boar. It is necessity, when a person excuses his making a default from stress of weather, sickness, or the like. Thus Cicero pleaded his illness contracted by the fatigue of a long journey, as an excuse for not appearing in the senate upon the summons of Mark Antony, who threatened to oblige him to it by pulling his house down. But what the defendant here attributes to inadvertency, chance, or necessity, the opposite party will attribute to design, negligence, or some other culpable reason; and represent it as a matter injurious to the public to introduce such precedents; and also produce instances, if that can be done, where the like excuses have not been admitted. On the other hand, the defendant will insist on his innocence, and show the hardship and severity of judging mens actions rather by the event, than from the intention: that such a procedure makes no difference between the innocent and the guilty; but must necessarily involve many honest men in ruin and destruction, discourage all virtuous and generous designs, and turn greatly to the prejudice of human society. He will also consider the instances alleged by the accuser, and show the difference between them and his own case. And, lastly, he will have recourse to intreaty, or a submissive address to the equity and clemency of the court, or party offended, for pardon; as Cicero has done in his oration to Cæsar, in favour of Ligarius.

#### CHAP. V. *Of the Character and address of an Orator.*

<sup>19</sup>  
*Propriety of manners necessary in an orator, both with respect to character and address.*

HAVING considered and explained the first part of invention, which furnishes the orator with such arguments as are necessary for the proof of his subject, we are next to show what are the proper means to conciliate the minds of his hearers; to gain their affection; and to recommend both himself and what he says, to their good opinion and esteem. For the parts of invention are commonly thus distinguished; that the first respects the *subject* of the discourse, the second the *speaker*, and the third the *hearers*. Now the second of these, which we have at present to explain, is by Quintilian called a *propriety of manners*. And in order to express this, it is necessary, as he tells us, "that every thing appear easy and natural, and the disposition of the speaker be discovered by his words." We may form an easy conception of this from the conduct of such persons as are most nearly concerned in each others welfare. As when relations or friends converse

*Invention.* together upon any affairs of importance, the temper and disposition of the speaker plainly shows itself by his words and manner of address. And what nature here directs to without colouring or disguise, the orator is to endeavour to perform by his art. Though indeed, if what a person says be inconsistent with his usual conduct and behaviour at other times, he cannot expect it should gain much credit, or make any deep impression upon his hearers: which may be one reason why the ancient rhetoricians make it so necessary a qualification in an orator, that he be a good man; since he should always be consistent with himself, and, as we say, talk in character. And therefore it is highly requisite, that he should not only gain the skill of assuming those qualities which the nature and circumstances of his discourse require him to express; but likewise that he should use his utmost endeavours to get the real habits implanted in his mind. For as by this means they will be always expressed with greater ease and facility; so by appearing constantly in the course of his life, they will have more weight and influence upon particular occasions.

Now there are four qualities, more especially suited to the character of an orator, which should always appear in his discourses, in order to render what he says acceptable to his hearers; and these are, *wisdom*, *integrity*, *benevolence*, and *modesty*.

1. *Wisdom* is necessary; because we easily give into those whom we esteem wiser and more knowing than ourselves. Knowledge is very agreeable and pleasant to all, but few make very great improvements in it; either by reason they are employed in other necessary affairs, and the mind of man cannot attend to many things at once; or because the way to knowledge at first is hard and difficult, so that persons either do not care to enter upon the pursuit of it, or, if they do, they are many times soon discouraged, and drop it, for want of sufficient resolution to surmount its difficulties. Such, therefore as either cannot, or do not care to give themselves the trouble of examining into things themselves, must take up with the representation of others; and it is an ease to them to hear the opinion of persons whom they esteem wiser than themselves. No one loves to be deceived; and those who are fearful of being misled, are pleased to meet with a person, in whose wisdom, as they think they can safely trust. The character of wisdom therefore is of great service to an orator, since the greater part of mankind are swayed by authority rather than arguments.

2. But this of itself is not sufficient, unless the opinion of *integrity* be joined with it. Nay, so far from it, that the greater knowledge and understanding a man is supposed to have, unless he likewise have the character of an honest man, he is often the more suspected. For knowledge without honesty, is generally thought to dispose a person, as well as qualify him, to deceive.

3. And to both these qualities the appearance of kindness and *benevolence* should likewise be added. For though a person have the reputation of wisdom and honesty, yet if we apprehend he is either not well affected to us, or at least regardless of our interest, we are in many cases apt to be jealous of him. Mankind are naturally swayed by their affections, and much influenced

Invention.

fluenced through love or friendship; and therefore nothing has a greater tendency to induce persons to credit what is said, than intimations of affection and kindness. The best orators have been always sensible what great influence the expression of kindness and benevolence have upon the mind of others to induce them to believe the truth of what they say; and therefore they frequently endeavour to impress them with the opinion of it. Thus Demosthenes begins his celebrated oration for Ctesiphon. "It is my hearty prayer (says he) to all the deities, that this my defence may be received by you with the same affection which I have always expressed for you and your city." And it is a very fine image of it which we have in Cicero, where in order to influence the judges in favour of Milo he introduces him speaking thus, as became a brave man, and a patriot, even upon the supposition he should be condemned by them: "I bid my fellow citizens adieu: may they continue flourishing and prosperous; may this famous city be preserved, my most dear country, however it has treated me: may my fellow citizens enjoy peace and tranquillity without me, since I am not to enjoy it with them, though I have procured it for them: I will withdraw, I will be gone."

§. *Modesty.* It is certain, that what is modestly spoken is generally better received than what carries in it an air of boldness and confidence. Most persons, though ignorant of a thing, do not care to be thought so; and would have some deference paid to their understanding. But he who delivers himself in an arrogant and assuming way seems to upbraid his hearers with ignorance, while he does not leave them to judge for themselves, but dictates to them, and as it were, demands their assent to what he says: which is certainly a very improper method to win upon them. For not a few, when convinced of an error in such a way, will not own it; but will rather adhere to their former opinion, than seem forced to think right, when it gives another the opportunity of a triumph. A prudent orator therefore will behave himself with modesty that he may not seem to insult his hearers; and will set things before them in such an engaging manner as may remove all prejudice either from his person or what he asserts. This is particularly necessary in the exordium of a discourse. If the orator set out with an air of arrogance and ostentation, the self-love and pride of the hearers will be presently awakened, and will follow him with a very suspicious eye throughout all his progress. His modesty should discover itself not only in his expressions at the beginning, but in his whole manner; in his looks, in his gestures, in the tone of his voice. Every auditory take in good part these marks of respect and awe, which are paid to them by one who addresses them. Indeed the modesty of an introduction should never betray any thing mean or abject. It is always of great use to an orator, that together with modesty and deference to his hearer, he should show a certain sense of dignity, arising from a persuasion of the justice or importance of the subject on which he is to speak. For to speak timorously, and with hesitation, destroys the credit of what is offered; and so far as the speaker seems to distrust what he says himself, he often induces others to do the like.

Invention.

But, as has been said already, great care is to be taken that these characters do not appear feigned and counterfeit. For what is fictitious can seldom be long concealed. And if this be once discovered, it makes all that is said suspected, how specious soever it may otherwise appear.

It is further necessary, that the orator should know the world, and be well acquainted with the different tempers and dispositions of mankind. Not indeed can any one reasonably hope to succeed in this province, without well considering the circumstances of time and place, with the sentiments and dispositions of those to whom he speaks: which, according to Aristotle, may be distinguished four ways, as they discover themselves by the several *affections, habits, ages, and fortunes* of mankind. And each of these require a different conduct and manner of address.

The *affections* denote certain emotions of the mind, which, during their continuance, give a great turn to the disposition. For love prompts to one thing, and hatred to another. The like may be said of anger, lenity, and the rest of them.

Persons differ likewise according to the various *habits* of their minds. So a just man is inclined one way, and an unjust man another; a temperate man to this, and an intemperate man to the contrary.

And as to the several *ages* of men, Aristotle has described them very accurately; and how persons are differently affected in each of them. He divides the lives of men, considered as hearers, into three stages; youth, middle age, and old age.—Young men, he says, have generally strong passions, and are very eager to obtain what they desire; but are likewise very mutable, so that the same thing does not please them long. They are ambitious of praise, and quick in their resentments: lavish of their money, as not having experienced the want of it: frank and open, because they have not often been deceived: and credulous for the same reason. They readily hope the best, because they have not suffered much, and are therefore not so sensible of the uncertainty of human affairs; for which reason they are likewise more easily deceived. They are modest, from their little acquaintance with the world. They love company and cheerfulness, from the briskness of their spirits. In a word, they generally exceed in what they do; love violent, hate violently, and act in the same manner through the rest of their conduct.—The disposition of old men is generally contrary to the former. They are cautious, and enter upon nothing hastily; having in the course of many years been often imposed upon: having often erred, and experienced the prevailing corruption of human affairs; for which reason they are likewise suspicious, and moderate in their affections either of love or hatred. They pursue nothing great or noble, and regard only the necessities of life. They love money; having learned by experience the difficulty of getting it, and how easily it is lost. They are fearful, which makes them provident. Commonly full of complaints, from bodily infirmities, and a deficiency of spirits. They please themselves rather with the memory of what is past, than with any further prospect; having so short a view of life before them, in comparison of what is already gone: for which reason, also, they love to talk of things past; and prefer them.

Invention

them to what is present, of which they have but little relish, and know they must shortly leave them. They are soon angry, but not to excess. Lastly, they are compassionate, from a sense of their own infirmities, which makes them think themselves of all persons most exposed.—Persons of a middle age, betwixt these two extremes, as they are freed from the rashness and temerity of youth, so they have not yet suffered the decays of old age. Hence in every thing they generally observe a better conduct. They are neither so hasty in their assent as the one, nor so minutely scrupulous as the other, but weigh their reasons of things. They regard a decency in their actions; are careful and industrious; and as they undertake what appears just and laudable upon better and more deliberate consideration than young persons, so they pursue them with more vigour and resolution than those who are older.

As to the different *fortunes* of mankind, they may be considered as noble, rich, or powerful: and the contrary to these.—Those of high birth, and noble extraction, are generally very tender of their honour, and ambitious to increase it: it being natural for all persons to desire an addition to those advantages of which they find themselves already possessed. And they are apt to consider all others as much their inferiors, and therefore expect great regard and deference should be shown them.—Riches, when accompanied with a generous temper, command respect from the opportunities they give of being useful to others; but they usually elate the mind, and occasion pride. For as money is commonly said to command all things, those who are possessed of a large share of it, expect others should be at their beck; since they enjoy that which all desire, and which most persons make the main pursuit of their lives to obtain.—But nothing is more apt to swell the mind than power. This is what all men naturally covet, even when perhaps they would not use it. But the views of such persons are generally more noble and generous than of those who only pursue riches and the heaping up of money. A state contrary to these gives a contrary turn of mind; and in lower life, persons' dispositions usually differ according to their station and circumstances. A citizen and a courtier, a merchant and a soldier, a scholar and a peasant, as their pursuits are different, so is generally their turn and disposition of mind.

It is the orator's business, therefore, to consider these several characters and circumstances of life, with the different bias and way of thinking they give to the mind; that he may so conduct himself in his behaviour and manner of speaking, as will render him most acceptable, and gain him the good esteem of these whom he addresses.

#### CHAP. VI. *Of the Passions.*

20  
It is necessary though difficult, to engage the interest of the passions.

As it is often highly necessary for the orator, so it requires his greatest skill, to engage the passions in his interest. Quintilian calls this *the soul and spirit of his art*. And, doubtless, nothing more discovers its empire over the minds of men, than this power to excite, appease, and sway their passions, agreeably to the design of the speaker. Hence we meet with the charac-

ters of *admirable, divine*, and other splendid titles, ascribed to eloquence by ancient writers. It has indeed been objected by some, that whatever high encomiums may be given of this art by the admirers of it, it is however dissingenuous to deceive and impose upon mankind, as those seem to do, who, by engaging their passions, give a bias to their minds, and take them off from the consideration of the truth; whereas every thing should be judged of from the reasons brought to support it, by the evidence of which it ought to stand or fall. But in answer to this, it may be considered that all fallacy is not culpable. We often deceive children for their good; and physicians sometimes impose on their patients, to come at a cure. And why, therefore, when persons will not be prevailed with by reason and argument, may not an orator endeavour, by engaging their passions, to persuade them to that which is for their advantage? Besides, Quintilian makes it a necessary qualification of an orator, that he be an honest man, and one who will not abuse his art. But since those of a contrary character will leave no methods untried in order to carry their point, it is requisite for those who design well to be acquainted with all their arts, without which they will not be a match for them; as in military affairs it is highly advantageous for the general of an army to get himself informed of all the designs and stratagems of the enemy, in order to counteract them. Indeed this part of oratory is not necessary at all times, nor in all places. The better prepared persons are to consider truth, and act upon the evidence of it, the less occasion there appears for it. But the greater part of mankind, either do not duly weigh the force of arguments, or refuse to act agreeably to their evidence. And where this is the case, the persons will neither be convinced by reason, nor moved by the authority of the speaker, the only way left to put them upon action, is to engage their passions. For the passions are to the mind, what the wind is to a ship: they move, and carry it forward; he who is without them, is in a manner without action, dull and lifeless. There is nothing great or noble to be performed in life, wherein the passions are not concerned. The Stoics, therefore, who were for eradicating the passions, both maintained a thing in itself impossible, and which, if it was possible, would be of the greatest prejudice to mankind. For while they appeared such zealous assertors of the government of reason, they scarce left it any thing to govern: for the authority of reason is principally exercised in ruling and moderating the passions, which, when kept in a due regulation, are the springs and motives to virtue. Thus hope produces patience, and fear industry; and the like might be shown of the rest. The passions therefore are not to be extirpated, as the Stoics asserted, but put under the direction and conduct of reason. Indeed where they are ungovernable and resist the controul of reason, they are, as some have fitly called them, *diseases of the mind*; and frequently hurry men into vice, and the greatest misfortunes of life: just as the wind, when it blows moderately, carries on the ship; but if it be too boisterous and violent may overset her. The charge therefore brought against this art, for giving rules to influence the passions appears groundless and unjust; since the proper use of the passions is, not to hinder the exercise

Invention.

**Invention.** exercise of reason, but to engage men to act agreeably to reason. And if an ill use be sometimes made of this, it is not the fault of the art, but of the artist.

We shall here consider the passions, as they may be separately referred, either to *demonstrative*, *deliberative*, or *judicial* discourses; though they are not wholly confined to any of them.

21  
Of the pas-  
sions which  
may be re-  
ferred to  
demonstra-  
tive dis-  
courses.

1. To the *demonstrative* kind, we may refer *joy* and *sorrow*, *love* and *hated*, *emulation* and *contempt*.

*Joy* is an elation of the mind, arising from a sense of some present good. Such a reflection naturally creates a pleasant and agreeable sensation, which ends in a delightful calm and serenity. This is heightened by a description of former evils, and a comparison between them and the present felicity. Thus Cicero endeavours to excite in the minds of his fellow-citizens the highest sense of joy and delight at Catiline's departure from Rome, by representing to them the imminent danger which threatened both them and the city while he continued among them.

*Sorrow*, on the contrary, is an uneasiness of mind arising from a sense of some present evil. This passion has generally a place in funeral discourses. And it may be heightened, like the former, by comparison, when any past happiness is set, in opposition to a present calamity. Hence Cicero aggravates the sorrow at Rome occasioned by the death of Metellus, from his character, and great services to the public, while living.

*Love* excites us to esteem any person for some excellency, and to do him all the good in our power. It is distinguished from *friendship*, which is mutual; and therefore love may continue where friendship is lost; that is, the affection may remain on one side. And when we assist a person from no other motive but to do him a kindness, Aristotle calls this *good-will*. Love takes its rise from a variety of causes. Generosity, benevolence, integrity, gratitude, courtesy, and other social virtues, are great incitements to love any one endued with such qualities. And persons generally love those who are of a like disposition with themselves and pursue the same views. It is therefore the chief art of a flatterer to suit himself in every thing to the inclination of the person whose good graces he courts. When the orator would excite this affection towards any person, it is proper to show, that he is possessed of at least some, if not all, of these agreeable qualities. When the conspirators with Catiline were to be brought to justice, Cicero was very sensible of the envy he should contract on that account, and how necessary it was for him to secure the love of the Roman senate for his support and protection in that critical juncture. And this he endeavours to do in his fourth oration against Catiline, by representing to them in the most pathetic manner, that all the labours he underwent, the difficulties he consisted with, and the dangers to which he was exposed on that account, were not for his own sake, but for their safety, quiet, and happiness.

*Hated* is opposed to love, and produced by the contrary dispositions. And therefore persons hate those who never did them any injury, from the ill opinion they have of their base and vicious inclinations. So that the way to excite this passion is, by showing that any one has committed some heinous

act with an ill intent. And the more nearly affected persons are by such actions, in what they account of the greatest concern, the higher in proportion their hatred rises. Since life therefore is esteemed the most valuable good, Cicero endeavours to render Mark Antony odious to the citizens of Rome, by describing his cruelty.

*Emulation*, is a disquiet, occasioned by the felicity of another, not because he enjoys it, but because we desire the like for ourselves. So that this passion is in itself good and laudable, as it engages men to pursue those things which are so. For the proper objects of emulation are any advantages of mind, body, or fortune, acquired by study or labour.

Emulation therefore is excited by a lively representation of any desirable advantages which appear to be attainable, from the example of others who are or have been possessed of them. But where the felicity of another occasions an uneasiness, not from the want of it, but because he enjoys it, this passion is called *envy*, which the ancients describe as an hideous monster, feeding upon itself, and being its own tormentor. Aristotle justly observes, that it most usually affects such persons as were once upon a level with those they envy. For most men naturally think so well of themselves, that they are uneasy to see those who were formerly their equals advanced above them. But, as this is a base and vicious passion, the orator is not to be informed how to excite it, but how to lessen or remove it. And the method prescribed by Cicero for this purpose is, to show that the things which occasioned it have not happened to the envied person undeservedly, but are the just reward of his industry or virtue; that he does not so much convert them to his own profit or pleasure, as to the benefit of others; and that the same pains and difficulties are necessary to preserve them with which they were at first acquired.

*Contempt* is opposed to emulation, and arises from misconduct in things not of themselves vicious: As where a person either acts below his station and character, or affects to do that for which he is not qualified. Thus Cicero endeavours to expose Cæcilius, and bring him into contempt of the court, for pretending to rival him in the accusation of Verres, for which he was altogether unfit.

2. To *deliberative* discourses may be referred *fear*, *hope*, and *shame*.

*Fear* arises from the apprehension of some great and impending evil. For the greatest evils, while they appear at a distance, do not much affect us. Such persons occasion fear, who are possessed of power, especially if they have been injured, or apprehend so; likewise those who are addicted to do injuries, or who bear us an ill will. And the examples of others, who have suffered in a like case, or from the same persons, help to excite fear. From the circumstances therefore either of the thing or person, it will not be difficult for the orator to offer such arguments as may be proper to awaken this passion. So Demosthenes when he would persuade the Athenians to put themselves in a condition of defence against king Philip, enumerates the several acts of hostility already committed by him against the neighbouring states. And because mens private concerns generally more affect them than what relates to the public, it is proper sometimes

22  
Of the pas-  
sions which  
may be re-  
ferred to  
delibera-  
tive dis-  
courses.

Invention. to show the necessary connection these have with each other, and how the ruin of one draws the other after it.

The contrary passion to *fear*, is *hope*; which arises either from a prospect of some future good, or the apprehension of safety from those things which occasion our fear. Young persons are easily induced to hope the best, from the vigour of their spirits. And those who have escaped former dangers are encouraged to hope for the like success for the future. The examples of others also, especially of wise and considerate men, have often the same good effect. To find them calm and sedate when exposed to the like dangers, naturally creates confidence and the hopes of safety. But nothing gives persons such firmness and steadiness of mind, under the apprehension of any difficulties, as a consciousness of their own integrity and innocence. Let dangers come from what quarter they will, they are best prepared to receive them. They can calmly view an impending tempest, observe the way of its approach, and prepare themselves in the best manner to avoid it. In Cicero's oration for the Manilian law, he encourages the Roman citizens to hope for success against Mithridates, if they chose Pompey for their general, from the many instances of his former successes, which he there enumerates.

*Shame* arises from the apprehension of those things that hurt a person's character. *Modesty* has been wisely implanted in mankind by the great Author of nature, as a guardian of virtue, which ought for this reason to be cherished with the greatest care; because, as Seneca has well observed, "if it be once lost, it is scarce ever to be recovered." Therefore the true cause or foundation of shame is any thing base or vicious; for this wounds the character, and will not bear reflection. And he must arrive at no small degree of insensibility, who can stand against such a charge, if he be conscious to himself that it is just. Therefore, to deter persons from vicious actions, or to expose them for the commission of them, the orator endeavours to set them in such a light as may most awaken this passion, and give them the greatest uneasiness by the reflection. And because the bare representation of the thing itself is not always sufficient for this purpose, he sometimes enforces it by enlarging the view, and introducing those persons as witnesses to the fact for whom they are supposed to have the greatest regard. Thus, when some of the Athenians, in an arbitration about certain lands which had been referred to them by the contending parties, proposed it as the shortest way of deciding the controversy, to take the possession of them into their own hands; Cydias, a member of the assembly, to dissuade them from such an unjust action, desired them to imagine themselves at that time in the general assembly of the states of Greece (who would all hear of it shortly), and then consider how it was proper to act. But where persons labour under an excess of modesty which prevents them from exerting themselves in things fit and laudable, it may sometimes be necessary to show that it is faulty and ill grounded. On the other hand, *immodesty*, or impudence, which consists in a contempt of such things as affect the reputation, can never be too much discouraged and exposed. And the way of doing this is to make use of such arguments as are most proper to

excite shame. We have a very remarkable instance of it in Cicero's second Philippic, wherein he affixes this character upon Mark Antony through every scene of his life.

3. To *judicial discourses*, may be referred *anger* and *lenity*, *pity*, and *indignation*.

*Anger* is a resentment, occasioned by some affront, or injury, done without any just reason. Now men are more inclined to resent such a conduct, as they think they less deserve it. Therefore persons of distinction and figure, who expect a regard should be paid to their character, can the less bear any indications of contempt. And those who are eminent in any profession or faculty, are apt to be offended if reflections are cast either upon their reputation or art. Magistrates also, and persons in public stations, sometimes think it incumbent on them to resent indignities, for the support of their office. But nothing sooner inflames this passion, than if good services are rewarded with slights and neglect. The instance of Narses, the Roman general, is remarkable in this kind; who, after he had been successful in his wars with the Goths, falling under the displeasure of the emperor Justin, was removed from the government of Italy, and received by the empress with this taunt, *That he must be sent to weave among the girls*; which so provoked him, that he said he would weave such a web as they never should be able to unravel. And accordingly, he soon after brought down the Longobards, a people of Germany, into Italy; where they settled themselves in that part of the country, which from them is now called *Lombardy*. (See NARSSES). The time and place in which an injury was done, and other circumstances that attended it, may likewise contribute very much to heighten the fact. Hence Demosthenes, in his oration against Midias, endeavours to aggravate the injury of being struck by him, both as he was then a magistrate, and because it was done at a public festival. From hence it appears, that the persons who most usually occasion this passion are such as neglect the rules of decency, contemn and insult others, or oppose their inclinations; as likewise the ungrateful, and those who violate the ties of friendship, or requite favours with injuries. But when the orator endeavours to excite anger, he should be careful not to exceed due bounds in aggravating the charge, lest what he says appear rather to proceed from prejudice, than a strict regard to the demerit of the action.

*Lenity* is the remission of anger. The designs of mens actions are principally to be regarded; and therefore what is done ignorantly, or through inadvertency; is sooner forgiven. Also to acknowledge a fault, submit, and ask pardon, are the ready means to take off resentment. For a generous mind is soon cooled by submission. Besides, he who repents of his fault, does really give the injured party some satisfaction, by punishing himself: as all repentance is attended with grief and uneasiness of mind, and this is apt very much to abate the desire of revenge. As, on the contrary, nothing is more provoking, than when the offender either audaciously justifies the fact, or confidently denies it. Men are likewise wont to lay aside their resentment, when their adversaries happen by some other means to suffer what they think a sufficient satisfaction. Lastly, easy circumstances, a lucky inci-

23

discourses,  
and the ar-  
guments  
suited to  
them.

Invention.

dent or any thing which gives the mind a turn to mirth and pleasure, has a natural tendency to remove anger. For anger is accompanied with pain and uneasiness, which very ill suit joy and cheerfulness. The orator, therefore, in order to assuage and pacify the minds of his auditors, will endeavour to lessen their opinion of the fault, and by that means to take off the edge of their resentment. And to this purpose, it will be proper either to represent that the thing was not designed, or that the party is sorry for it; or to mention his former services; as also to show the credit and reputation which will be gained by a generous forgiveness. And this last topic is very artfully wrought up by Cicero, in his address to Cæsar, in favour of Ligarius.

*Pity* arises from the calamities of others, by reflecting, that we ourselves are liable to the like misfortunes. So that evils, considered as the common lot of human nature, are principally the cause of pity. And this makes the difference between *pity* and *good-will*, which arises merely from a regard to the circumstances of those who want our assistance. But considering the uncertainty of every thing about us, he must seem in a manner divested of humanity, who has no compassion for the calamities of others; since there is no affliction which happens to any man, but either that, or some other as great, may fall upon himself. But those persons are generally soonest touched with this passion, who have met with misfortunes themselves. And by how much greater the distress is, or by how much the person appears less deserving it, the higher pity does it excite: for which reason, persons are generally most moved at the misfortunes of their relations and friends, or those of the best figure and character. The orator, therefore, in order to excite the greater pity, will endeavour to heighten the idea of the calamity, from the several circumstances both of the thing itself and the person who labours under it. A fine example of this may be seen in Cicero's defence of Muræna, *cap. 40. &c.*

*Indignation*, as opposed to *pity*, is an uneasiness at the felicity of another who does not seem to deserve it. But this respects only external advantages, such as riches, honours, and the like; for virtues cannot be the object of this passion. Aristotle therefore says, "that pity and indignation are generally to be found in the same persons, and are both evidences of a good disposition." Now the orator excites this passion, by

showing the person to be unworthy of that felicity which he enjoys. And as, in order to move compassion, it is sometimes of use to compare the former happy state of the person with his present calamity; so here, the greater indignation is raised, by comparing his former mean circumstances with his present advancement: as Cicero does in the case of Vatinius.

These are the passions with which an orator is principally concerned. In addressing which, not only the greatest warmth and force of expression is often necessary; but he must likewise first endeavour to impress his own mind with the same passion he would excite in others.

A man may convince, and even persuade others to act, by mere reason and argument. But that degree of eloquence which gains the admiration of mankind, and properly denominates one an orator, is never found without warmth or passion. Passion, when in such a degree as to rouse and kindle the mind, without throwing it out of the possession of itself, is universally found to exalt all the human powers. It renders the mind infinitely more enlightened, more penetrating, more vigorous and masterly, than it is in its calm moments. A man, actuated by a strong passion, becomes much greater than he is at other times. He is conscious of more strength and force; he utters greater sentiments, conceives higher designs, and executes them with a boldness and a felicity of which on other occasions he could not think himself capable. But chiefly with respect to persuasion, is the power of passion felt. Almost every man in passion is eloquent. Then he is at no loss for words and arguments. He transmits to others, by a sort of contagious sympathy, the warm sentiments which he feels; his looks and gestures are all persuasive; and nature here shows herself infinitely more powerful than art. This is the foundation of that just and noted rule, *Si vis me flere, dolendum est primum ipsi tibi.*

The warmth, however, which we express, must be suited to the occasion and the subject; for nothing can be more preposterous than an attempt to introduce great vehemence into a subject, which is either of slight importance, or which, by its nature, requires to be treated of calmly. A temperate tone of speech is that for which there is most frequent occasion; and he who is on every subject passionate and vehement, will be considered as a blusterer, and meet with little regard.

## PART II. OF DISPOSITION.

**A**S *Invention* supplies the orator with necessary materials, so *Disposition* directs him how to place them in the most proper and suitable order. Disposition therefore, considered as a part of oratory, naturally follows invention. And what is here chiefly intended by it is, the placing the several parts of a discourse in a just method and dependence upon one another.

Writers are not all agreed in determining the parts of an oration: though the difference is rather in the manner of considering them, than in the things themselves. But Cicero, whom we shall here follow, men-

tions six, namely, *Introduction*, *Narration*, *Proposition*, *Confirmation*, *Confutation*, and *Conclusion*.

### CHAP. I. Of the Introduction.

THE design of this is to prepare the minds of the hearers for a suitable reception of the remaining parts that are to follow. And for this end, three things are requisite; that the orator gain the *good opinion* of his hearers, that he secure their *attention*, and give them some *general notion* of his subject.

1. *Good opinion.* When the orator introduces his discourse, and gives a general notion of the subject.

**Disposition.** discourse with his own person, he will be careful to do it with modesty, and seem rather to extenuate his virtues and abilities, than to magnify them. And where the nature of the subject may seem to require it, he will endeavour to show, that some just and good reason induced him to engage in it. We have a very fine example of this in Cicero's oration for the poet Aulus Licinius Archias, which beginning thus: "If I have any natural genius, which I am sensible is very small, or any ability in speaking wherein I own I have been very conversant; or any skill acquired from the study and precepts of the best arts, to which my whole life has been devoted; this Aulus Licinius has, in a particular manner, a right to demand of me the fruit of all these things. For as far back as I can remember and call to mind what passed in my youth to the present time, he has been my adviser and encourager: both to undertake and pursue this course of studies." When the orator sets out with the persons of those to whom the discourse is made, it is not unusual to commend them for their virtues, and those especially which have a more immediate relation to the present subject. Thus Cicero begins his oration of thanks for the pardon of Marc'cellus, with an encomium upon the mildness, clemency, and wisdom of Cæsar, to whom it was addressed. But sometimes the orator expresses his gratitude for past favours; as Cicero has done in his orations, both to the people and senate of Rome, after his return from banishment.—And at other times he declares his concern for them and their interest; in which manner Cicero begins his fourth oration against Catiline, which was made in the senate. "I perceive (says he) that all your countenances and eyes are turned on me; I perceive that you are solicitous, not only for your own danger, and that of the state but for mine likewise, if that should be removed. Your affection for me is pleasant in misfortunes, and grateful in sorrow; but I adjure you to lay it aside, and forgetting my safety consider yourselves and your children." But in judicial cases, both the character of the person whose cause he espouses, and that of the adverse party likewise, furnish the orator with arguments for exciting the good-will of his hearers; The former, by commemorating his virtues, dignity, or merits, and sometimes his misfortunes and calamities. So Cicero, in his defence of Flaccus, begins his oration in commending him on the account of his services done to the public, the dignity of his family, and his love to his country. And Demosthenes, in his oration against Midias, sets out with a recital of his vices in order to recommend his own cause to the favourable opinion of the court.

2. **Attention.** On this head, Cicero says, "We shall be heard attentively on one of these three things; if we propose what is great, necessary, or for the interest of those to whom the discourse is addressed." So that, according to him, the topics of attention are much the same with those of good opinion, when taken from the subject. And indeed, people are naturally led to attend either to those things or persons of which they have entertained a favourable opinion. But in order to gain this point, the orator sometimes thinks it proper to request the attention of his audience. Thus Cicero, in his defence of Cluentius, after having shown the heinousness of the charge against

him concludes his introduction in the following manner, speaking to the judges; "Wherefore I intreat, that while I briefly and clearly reply to a charge of many years standing, you will, according to your usual custom, give me a kind and attentive hearing." And again, in his second Philippic, addressing himself to the senate: "But as I must say something for myself and many things against Mark Antony; one of these I beg of you, that you will hear me kindly, while I speak for myself; and the other I will undertake for, that when I speak against him, you shall hear me with attention." But though the introduction be the most usual and proper place for gaining attention, yet the orator finds it convenient sometimes to quicken and excite his hearers in other parts of his discourse, when he observes they flag, or has something of moment to offer.

3. Some *general account* of the subject of the discourse. This is always necessary, which the two others are not. And therefore it must be left to the prudence of the orator when to use or omit them as he shall judge proper, from the nature of his discourse, the circumstance of his hearers, and how he stands with them. But some account of the subject is what cannot be neglected. For every one expects to be soon informed of the design of the speaker, and what he proposes to treat of. Nor when they are all made use of, it is necessary they should always stand in the order we have here placed them. Cicero sometimes enters immediately upon his subject, and introduces the other heads afterwards. As in his third oration against Catiline, made to the body of the Roman people, which begins thus: "You see that the state, all your lives, estates, fortunes, wives and children, and this seat of the greatest empire, the most flourishing and beautiful city, having by the favour of heaven towards you, and my labours, counsels, and dangers, been this day rescued from fire and sword and the very jaws of destruction, are preserved and restored to you." And then he proceeds to recommend himself to their esteem and benevolence, from the consideration of these benefits.

These are the heads which commonly furnish matter for this part of a discourse. But orators often take occasion from the time, place largeness of the assembly or some other proper circumstance, to compliment their hearers, recommend themselves, or introduce the subject upon which they are about to treat. Instances of each of these may be met with in several of Cicero's orations. And sometimes they set out with some comparison, similitude or other ornament, which they accommodate to the occasion of their discourse. Thus Isocrates enters upon his celebrated panegyric in praise of his countrymen the Athenians with the following comparison: "I have often wondered what could be their design who brought together these assemblies, and instituted the gymnastic sports, to propose so great rewards for bodily strength; and to vouchsafe no honour to those who applied their private labours to serve the public, and so cultivated their minds as to be serviceable to others, to whom they ought to have shown greater regard. For although the strength of a champion was doubled, no benefit would from thence accrue to others: but all enjoy the prudence of one man, who will hearken to his advice." In some cases, orators

25  
Introduction is not confined to these heads, but can admit of other matter, if furnished by the circumstances of the case,

Disposition. orators have recourse to a more covert and artful way of opening their subject, endeavour to remove jealousies, apologize for what they are about to say, and seem to refer it to the candour of the hearers to judge of it as they please. Cicero appears to have been a perfect master of this art, and used it with great success. Thus in his seventh Philippic, where he seems to express the greatest concern, lest what he was about to say should give any offence to the senate to whom he was speaking: "I (says he) who always declared for peace, and to whom peace among ourselves, as it is wished for by all good men, was in a particular manner desirable; who have employed all my industry in the forum, in the senate, and in the defence of my friends, whence I have arrived to the highest honours, a moderate fortune, and what reputation I enjoy: I therefore who owe what I am to peace, and without it could not have been the person I am, be that what it will, for I would arrogate nothing to myself; I speak with concern and fear, how you will receive what I am going to say: but I beg and intreat you, from the great regard I have always expressed for the support and advancement of your honour, that if any thing said by me should at first appear harsh or unfit to be received, you will notwithstanding please to hear it without offence, and not reject it till I have explained myself: I then, for I must repeat it again, who have always approved of peace, and promoted it, am against a peace with Mark Antony." This is called *insinuation*; and may be necessary, where a cause is in itself doubtful, or may be thought so from the received notions of the hearers, or the impressions already made upon them by the contrary side. An honest man would not knowingly engage in a bad cause; and yet through the prevailing prejudice, that may be so esteemed which is not so in itself. In these cases, therefore, great caution and prudence are necessary to give such a turn to things, and place them in that view as may be least liable to offence. And because it sometimes happens that the hearers are not so much displeased at the subject as the person, Quintilian's rule seems very proper, when he says, "it the subject displeases, the character of the person, should support it; and when the person gives offence, he should be helped by the cause."

#### CHAP. II. *Of Narration.*

THE orator having prepared his hearers to receive his discourses with candour and attention, and acquainted them with his general design in the introduction, before he proceeds directly to his subject, often finds it necessary to give some account of what preceded, accompanied, or followed upon it. And this he does in order to enlarge the view of the particular point in dispute, and place it in a clearer light. This is called *narration*; which is a recital of something done, in the order and manner in which it was done. Hence it is easy to perceive what those things are which properly enter into a narration. And such are the cause, manner, time, place, and consequences of an action; with the temper, fortune, views, ability, associates, and other circumstances of those concerned in it. Not that each of these particulars is necessary in every narration; but so many of them at least as are requisite to set the matter in a just light,

and make it appear credible. Besides in relating a Disposition, fact, the orator does not content himself with such an account of it as is barely sufficient to render what he says intelligible to his hearers; but describes it in so strong and lively a manner as may give the greatest evidence to his relation, and make the deepest impression upon their minds. And if any part of it appears at present less probable, he promises to clear up and remove any remaining doubts in the progress of his discourse. For the foundation of his reasoning afterwards is laid in the narration, from whence he takes his arguments for the conformation. And therefore it is a matter of no small importance that this part be well managed, since the success of the whole discourse so much depends upon it. See NARRATION.

There are four properties required in a good narration; that it be short, clear, probable and pleasant.

1. The *brevis* of a narration is not to be judged of barely from its length: for that may be too long, which contains but a little; and that too short, which comprehends a great deal. Wherefore he depends upon the nature of the subject, since some things require more words to give a just representation of them, and others fewer. That may properly therefore be called a *short narration*, which contains nothing that could well have been omitted, nor omits any thing which was necessary to be said. Now in order to avoid both these extremes, care should be taken not to go farther back in the account of things, nor to trace them down lower, than the subject requires; to say that only in general, which does not need a more particular explication; not to assign the causes of things, when it is enough to show they were done; and to omit such things as are sufficiently understood, from what either preceded, or was consequent upon them. But the orator should be careful, lest, while he endeavours to avoid prolixity, he run into obscurity. Horace was very sensible of this danger, when he said:

By striving to be short, I grow obscure.

2. *Perspicuity.* This may justly be esteemed the chief excellency of language. For as the design of speech is to communicate our thoughts to others, that must be its greatest excellence which contributes most to this end; and that, doubtless, is perspicuity. As perspicuity therefore is requisite in all discourse, so it is particularly serviceable in a narration which contains the substance of all that is to be said afterwards. Wherefore, if this be not sufficiently understood, much less can those things which receive their light from it. Now the following things render a narration clear and plain: Proper and significant words, whose meaning is well known and determined; short sentences, though full and explicit, whose parts are not perplexed but placed in their just order; proper particles to join the sentences, and show their connection and dependence on each other; a due regard to the order of time, and other circumstances necessary to be expressed; and, lastly, suitable transitions.

3. *Probability.* Things appear probable when the causes assigned for them appear natural; the manner in which they are described is easy to be conceived; the consequences are such as might be expected; the character of the persons are justly represented;

Disposition.

and the whole account is well attested, consistent with itself, and agreeable to the general opinion. Simplicity likewise in the manner of relating a fact, as well as in the style, without any reserve or appearance of art, contributes very much to its credibility. For truth loves to appear naked and open, stript of all colouring or disguise. The conspiracy of Catiline was so daring and extravagant, that no one but such a desperado could ever have undertaken it with any hopes of success. However, Cicero's account of it to the senate was so full and exact, and so well suited to the character of the person, that it presently gained credit. And therefore, when, upon the conclusion of Cicero's speech, Catiline, who was present, immediately stood up, and desired they would not entertain such hard thoughts of him, but consider how much his family had always been attached to the public interest, and the great services they had done the state; their resentments rose to high, that he could not be heard: upon which he immediately left the city, and went to his associates.

4. The last thing required in a narration is, that it be *pleasant* and *entertaining*. And this is more difficult, because it does not admit of that accurate composition and pompous dress which delight the ear, and recommend some other parts of a discourse. For it certainly requires no small skill in the speaker, while he endeavours to express every thing in the most natural, plain, and easy manner, not to grow flat and tiresome. For Quintilian's remark is very just, that "the most experienced orators find nothing in eloquence more difficult, than what all who hear it fancy they could have said themselves." And the reason of this seems very obvious. For as all art is an imitation of nature, the nearer it resembles that, the more perfect it is in its kind. Hence unexperienced persons often imagine that to be easiest which suits best with those natural ideas to which they have been accustomed; till, upon trial, they are convinced of their mistake. Wherefore, to render this part of a discourse pleasant and agreeable, recourse must be had to variety both in the choice of words and turns of the expression. And therefore questions, admirations, interjections, imagery, and other familiar figures, help very much to diversify and enliven a narration, and prevent it from becoming dull and tedious, especially when it is carried on to any considerable length.

27  
The uses of  
narration.

Having given a brief account of the nature and properties of a narration, we shall now proceed to consider the uses of it.

Laudatory orations are usually as it were a sort of continued narration, set off and adorned with florid language and fine images proper to grace the subject, which is naturally so well fitted to afford pleasure and entertainment. Wherefore a separate narration is more suited to *deliberative* and *judicial* discourses. In Cicero's oration for the Manilian law (which is of the former kind), the design of the narration is to show the Roman people the necessity of giving Pompey the command of the army against king Mithridates, by representing the nature of that war, which is done in the following manner; "A great and dangerous war (says he) threatens your revenues and allies from two very powerful kings, Mithridates and Tigranes; one of whom not being pursued after his defeat, and the

Disposition.

other provoked, they think they have an opportunity to seize Asia. Letters are daily brought from those parts to worthy gentlemen of the equestrian order, who have large concerns there in farming your revenues; they acquaint me, as friends, with the state of the public affairs, and danger of their own; that many villages in Bithynia, which is now your province, are burnt down, that the kingdom of Ariobarzanes, which borders upon your revenues, is entirely in the enemy's power; that Lucullus, after several great victories, is withdrawn from the war; that he who succeeds him is not able to manage it: that all the allies and Roman citizens wish and desire the command of that war may be given to one particular person; and that he alone, and no other, is dreaded by the enemies. You see the state of the case; now consider what ought to be done." Here is an unhappy scene of affairs, which seemed to call for immediate redress. The causes and reasons of it are assigned in a very probable manner, and the account well attested by persons of character and figure. And what the consequences would be, if not timely prevented, no one could well be ignorant. The only probable remedy suggested in general is, the committing that affair to one certain person, which he afterwards shows at large could be no other than Pompey. But in Cicero's defence of Milo (which is of the *judicial* kind), the design of the narration, which is greatly commended by Quintilian, is to prove that, in the combat between Clodius and Milo, the former was the aggressor. And in order to make this appear he gives a summary account of the conduct of Clodius the preceding year; and from the course of his actions and behaviour, shows the inveterate hatred he bore to Milo, who obstructed him in his wicked designs. For which cause he had often threatened to kill him, and given out that he should not live beyond such a time; and accordingly he went from Rome without any other apparent reason, but that he might have an opportunity to attack him in a convenient place near his own house, by which he knew Milo was then obliged to pass. Milo was in the senate that day, where he staid till they broke up, then went home, and afterwards set forward on his journey. When he came to the place in which he was to be assaulted, Clodius appeared every way prepared for such a design, being on horseback, and attended with a company of desperate ruffians ready to execute his commands: whereas Milo was with his wife in a chariot, wrapped up in his cloak, and attended with servants of both sexes. These were all circumstances which preceded the fact. And as to the action itself, with the event of it, the attack, as Cicero says, was begun by the attendants of Clodius from an higher ground, who killed Milo's coachman: upon which Milo, throwing of his cloak, leaped out, and made a brave defence against Clodius's men, who were got about the chariot. But Clodius, in the heat of the skirmish, giving out that Milo was killed, was himself slain by the servants of Milo, to avenge, as they thought, the death of their master. Here seems to be all the requisites proper to make this account credible. Clodius's open and avowed hatred of Milo, which proceeded so far as to threaten his life; the time of his leaving Rome; the convenience of the place; his habit and company so different from those

of

Disposition. of Milo; joined with his known character of a most profligate and audacious wretch, could not but render it very probable that he had formed that design to kill Milo. And which of them began the attack might very reasonably be credited from the advanced ground on which Clodius and his men were placed; the death of Milo's coachman at the beginning of the combat; the skirmish afterwards at the chariot; and the reason of Clodius's own death at last, which does not appear to have been intended, till he had given out that Milo was killed.

But a distinct and separate narration is not always necessary in any kind of discourse. For if the matter be well known before, a set and formal narrative will be tedious to the hearers. Or if one party has done it already, it is needless for the other to repeat it. But there are three occasions especially, in which it may seem very requisite: when it will bring light to the subject; when different accounts have already been given out concerning it; or when it has been misrepresented by the adverse party. If the point in controversy be of a dubious nature, or not sufficiently known to the hearers, a distinct account of the matter, with the particular circumstances attending it, must be very serviceable, in order to let them into a true state of the case, and enable them to judge of it with greater certainty.

Moreover, where the opposite party has set the matter in a false light by some artful and invidious turns, or loaded it with any odious circumstances, it seems no less necessary that endeavours should be used to remove any ill impressions, which otherwise might remain upon the minds of the hearers, by a different and more favourable representation. And if any thing can be fixed upon to make the contrary account appear absurd or incredible, it ought particularly to be remarked. Thus Cicero, in his defence of Sextus Roscius, shows that he was many miles distant from Rome at the time he was charged with having killed his father there. "Now (says he), while Sextus Roscius was at Ameria, and this Titus Roscius [*his accuser*] at Rome, Sextus Roscius [*the father*] was killed at the baths on Mount Palatine, returning from supper. From whence I hope there can be no doubt who ought to be suspected of the murder. And, were not the thing plain of itself, there is this farther suspicion to fix it upon the prosecutor; that, after the fact was committed, one Manlius Glaucia, an obscure fellow, the freedman, client, and familiar, of this Titus Roscius, first carried the account of it to Ameria, not to the son of the deceased, but to the house of Titus Capito his enemy;" with more to the same purpose. But what we bring it for is, to show the use which Cicero makes of this narration for retorting the crime upon the prosecutors.

But the orator should be very careful, in conducting this part, to avoid every thing which may prejudice the cause he espouses. Falseness, and a misrepresentation of facts, are not to be justified; but no one is obliged to say those things which may hurt himself. We shall just mention one instance of this from Cicero, where he has shown great skill in this respect, in pleading before Cæsar for the pardon of Ligarius, who had joined with Pompey in the civil war. For Ligarius, having been represented by the adverse party as an

enemy to Cæsar, and so esteemed by Cæsar himself; Cicero very artfully endeavours in his narration to take off the force of this charge, by showing, that, when the war first broke out, he refused to engage in it: which he would not have done, had he borne any personal hatred to Cæsar. "Quintus Ligarius (says he), before there was any suspicion of a war, went into Africa as a legate to the proconsul Caius Confidius; in which he so approved himself, both to the Roman citizens and allies, that, when Confidius left the province, the inhabitants would not be satisfied he should leave the government in the hands of any other person. Therefore Quintus Ligarius having excused himself in vain for some time, accepted of the government against his will; which he so managed during the peace, that both the citizens and allies were greatly pleased with his integrity and justice. The war broke out on a sudden, which those in Africa did not hear of till it was begun; but upon the news of it, partly through inconsiderate haste, and partly from blind fear, they looked out for a leader, first for their own safety, and then as they were affected; when Ligarius, thinking of home, and desirous to return to his friends, would not be prevailed on to engage in any affairs. In the mean time, Publius Accius Varus, the prætor, who was formerly governor of Africa, coming to Utica, recourse was immediately had to him, who very eagerly took upon himself the government; if that can be called a *government*, which was conferred on a private man by the clamour of the ignorant multitude, without any public authority. Ligarius, therefore, who endeavoured to avoid every thing of that kind, ceased to act soon after the arrival of Varus." Here Cicero ends his narrative. For though Ligarius afterwards joined with Pompey's party, yet to have mentioned that, which was nothing more than what many others had done, whom Cæsar had already pardoned, could have served only to increase his displeasure against him. And therefore he doubtless showed great skill in so managing his account, as to take off the main force of the accusation, and by that means make way for his pardon, which he accordingly obtained.

### CHAP. III. Of the Proposition.

In every just and regular discourse, the speaker's intention is to prove or illustrate something. And when he lays down the subject upon which he designs to treat, in a distinct and express manner, this is called the *proposition*.

Orators use several ways in laying down the subject of their discourses. Sometimes they do it in one general proposition. We have an instance of this in Cicero's speech to the senate, the day after Cæsar was killed (as it is given us by Dion Cassius), in which his design was to persuade them to peace and unanimity. "This (says he) being the state of our affairs, I think it necessary that we lay aside all the discord and enmity which have been among us, and return again to our former peace and agreement." And then he proceeds to offer his reasons for this advice.

At other times, to give a clearer and more distinct view of their discourse, they subjoin to the proposition

28  
The proposition is a distinct and express manner of laying down the subject on which an orator means to treat.

**Disposition.** the general heads of argument by which they endeavour to support it. This method Cicero uses in his seventh Philippic, where he says, "I who have always commended and advised to peace, am against a peace with Mark Antony. But why am I averse to peace? Because it is base, because it is dangerous, and because it is impracticable. And I beseech you to hear me with your usual candour, while I make out these three things."

29  
When the subject refers to several different things, and requires to be laid down in distinct propositions, it is called a partition.

But when the subject relates to several different things, which require each of them to be separately laid down in a distinct proposition; it is called a *partition*; though some have made two kinds of *partition*, one of which they call *separation*, and the other *enumeration*. By the former of these, the orator shows in what he agrees with his adversary, and wherein he differs from him. So in the case formerly mentioned, of a person accused of sacrilege for stealing private money out of a temple, he who pleads for the defendant says, "He owns the fact; but it being private money the point in question is, Whether this be sacrilege!" And in the cause of Milo, Cicero speaking of Clodius, says, "The point which now comes before the court, is not, Whether he was killed or not; that we confess: but, Whether justly or unjustly." Now in reality here is no partition, since the former branch of the proposition is what is agreed upon, and given up; and consequently it is only the latter that remains to be disputed. It is called *enumeration*, when the orator acquaints his hearers with the several parts of his discourse upon which he designs to treat. And this alone properly speaking, is a *partition*. Thus Cicero states his plea in his defence of Muræna: "I perceive the accusation consists of three parts: the first respects the conduct of his life; the second his dignity and the third contains a charge of bribery."

There are three things requisite in a good partition: that it be *short*, *complete*, and consist but of a *few members*.

A partition is said to be *short*, when each proposition contains in it nothing more than what is necessary. So that the brevity here required is different from that of a narration; for that consists chiefly in things, this in words. And, as Quintilian justly observes, brevity seems very proper here, where the orator does not show what he is then speaking of, but what he designs to discourse upon.

Again it ought to be *complete* and perfect. And for this end, care must be taken to omit no necessary part in the enumeration.

But, however there should be as *few heads* as is consistent with the nature of the subject. The ancient rhetoricians prescribe three or four at the most. And we do not remember that Cicero ever exceeds that number. But it is certain, the fewer they are, the better, provided nothing necessary be omitted. For too large a number is both difficult of retention, and apt to introduce that confusion which partition is designed to prevent.

Hitherto we have been speaking only of these heads into which the subject or general arguments of the discourse is at first divided. For it is sometimes convenient to divide these again, or at least some of them, into several parts or members. And when this happens, it is best done, as the speaker comes to each of

them in the order at first laid down; by which means the memory of the hearers will be less burdened than by a multitude of particulars at one and the same time. Thus Cicero, in his oration for the Manilian law, comprises what he designs to say under three general heads. "First (says he) I shall speak of the nature of the war, then of its greatness, and lastly about the choice of a general." And when he comes to the first of these, he divides it again into four branches; and shows, "how much the glory of the Romans, the safety of their allies; their greatest revenues, and the fortunes of many of their citizens, were all concerned in that war." The second head, in which he considers the greatness of the war, has no division. But when he comes to the third head, concerning the choice of a general, he divides that likewise into four parts; and shows, that so many virtues are necessary in a consummate general, such as one as was proper to have the management of that war, namely, *skill in military affairs, courage, authority, and success*: all which he attributes to Pompey. And this is the scheme of that celebrated oration.

This subdividing, however, should never have place but when it is absolutely necessary. To split a subject into a great many minute parts by divisions and subdivisions without end, has always a bad effect in speaking. It may be proper in a logical treatise; but it makes an oration appear hard and dry, and unnecessarily fatigues the memory. In a sermon, there may be from three to five, or six heads, including subdivisions: seldom should there be more.

Further, some divide their subject into two parts, and propose to treat upon it *negatively* and *positively*; by showing first what it is not, and then what it is. But while they are employed to prove what it is not, they are not properly treating upon that, but something else; which seems as irregular as it is unnecessary. For he who proves what a thing is, does at the same time show what it is not. However in fact, there is a sort of division by affirmation and negation, which may sometimes be conveniently used. As if a person, charged with killing another, should thus state his defence: *I had done right if I had killed him, but I did not kill him*. Here indeed, if the latter can be plainly made to appear, it may seem needless to insist upon the former. But if that cannot be so fully proved but there may be room left for suspicion, it may be proper to make use of both: for all persons do not see things in the same light, and he who believes the fact, may likewise think it just; while he who thinks it unjust, may not believe it, but rather suppose, had it really been committed by the party, he would not have denied it, since he looked upon it as defensible. And this method of proceeding, Quintilian compares to a custom often used in traffic, when persons make a large demand at first, in order to gain a reasonable price. Cicero uses this way of reasoning in his defence of Milo; but in the contrary order: that is, he first answers the charge; and then justifies the fact, upon the supposition that the charge was true. For he proves, first, that Clodius was the aggressor; and not Milo, as the contrary party had asserted: and then to give the greater advantage to his cause, he proceeds to show, that if Milo had been the aggressor, it would however have been a glorious action

35  
Negative, and positive divisions of a subject.

Disposition tion to take off such an abandoned wretch, who was not only a common enemy to mankind, but had like wife often threatened his life.

A good and just partition is attended with considerable advantages. For it gives both light and ornament to a discourse. And it is also a great relief to the hearers, who, by means of these stops and rests, are much better enabled to keep pace with the speaker without confusion, and by casting their thoughts either way, from what has been said, both know and are prepared for what is to follow. And as persons, in travelling a road with which they are acquainted, go on with greater pleasure and less fatigue, because they know how far it is to their journey's end; so to be apprised of the speaker's design, and the several parts of his discourse which he proposes to treat on, contributes very much to relieve the hearer, and keep up his attention. This must appear very evident to all who consider how difficult it is to attend long and closely to one thing, especially when we do not know how long it may be before we are like to be released. Whereas, when we are before-hand acquainted with the scheme, and the speaker proceeds regularly from one thing to another, opportunity is given to ease the mind, by relaxing the attention, and recalling it again when necessary. In a sermon, or in pleading at the bar, few things are of greater consequence than a proper or happy division. It should be studied with much accuracy and care; for if one take a wrong method at first setting out, it will lead them astray in all that follows. It will render the whole discourse either perplexed or languid; and though the hearers may not be able to tell where the fault or disorder lies, they will be sensible there is a disorder some where, and find themselves little affected by what is spoken. The French writers of sermons study neatness and elegance in the division of their subjects much more than the English do; whose distributions, though sensible and just, yet are often inartificial and verbose.

#### CHAP. IV. Of Confirmation.

<sup>31</sup>  
Confirmation is used for the arguments brought in defence of a subject.

THE orator having acquainted his hearers in the proposition with the subject on which he designs to discourse, usually proceeds either to prove or illustrate what he has there laid down. For some discourses require nothing more than an enlargement or illustration, to set them in a proper light, and recommend them to the hearers; for which reason, likewise, they have often no distinct proposition. But where arguments are brought in defence of the subject, this is properly *confirmation*. For, as Cicero defines it "confirmation is that which gives proof, authority, and support to a cause, by reasoning." And for this end, if any thing in the proposition seems obscure, or liable to be misunderstood, the orator first takes care to explain it, and then goes on to offer such arguments for the proof of it, and represent them in such a light, as may be most proper to gain the assent of his hearers.

But here it is proper to observe, that there are different ways of reasoning suited to different arts. The mathematician treats his subject after another manner than the logician, and the orator in a me-

thod different from them both. Two methods of reasoning are employed by orators, the *synthetic* and *analytic*.

1. Every piece of synthetic reasoning may be resolved into a syllogism or series of syllogisms, (see Logic) Thus we may reduce Cicero's argument, by which he endeavours to prove that Clodius assaulted Milo, and not Milo Clodius, to a syllogism in this manner:

*He was the aggressor, whose advantage it was to kill the other.*

*But it was the advantage of Clodius to kill Milo, and not Milo to kill him.*

*Therefore Clodius was the aggressor, or he assaulted Milo.*

The thing to be proved was, that Clodius assaulted Milo, which therefore comes in the conclusion: and the argument, by which it is proved, is taken from the head of profit or advantage. Thus the logician would treat this argument; and if either of the premises were questioned, he would support it with another syllogism. But this short and dry way of reasoning does not at all suit the orator: who not only for variety changes the order of the parts, beginning sometimes with the minor, and at other times with the conclusion, and ending with the major; but likewise clothes each part with such ornaments of expression as are proper to enliven the subject, and render it more agreeable and entertaining. And he frequently joins, either to the major proposition, or minor, and sometimes to both, one or more arguments to support them; and perhaps others to confirm or illustrate them as he thinks it requisite. Therefore, as a logical syllogism consists of three parts or propositions, a rhetorical syllogism frequently contains four, and many times five parts. And Cicero reckons this last the most complete. But all that is said in confirmation of either of the premises is accounted but as one part. This will appear more evident by examples. By a short syllogism Cicero thus proves, that the Carthaginians were not to be trusted: "Those who have often deceived us, by violating their engagements, ought not to be trusted. For if we receive any damage by their treachery, we can blame no body but ourselves. But the Carthaginians have often so deceived us. Therefore it is madness to trust them." Here the major proposition is supported by a reason. The minor needed none; because the treachery of the Carthaginians was well known. So that this syllogism consists of four parts. But by a syllogism of five parts he proves somewhat more largely and elegantly, that the world is under the direction of a wise governor. The major is this: "Those things are better governed which are under the direction of wisdom, than those which are not." This he proves by several instances: "A house managed with prudence has every thing in better order, and more convenient than that which is under no regulation. An army commanded by a wise and skilful general is in all respects better governed than one which has a fool or madman at the head of it. And the like is to be said of a ship, which performs her course best under the direction of a skilful pilot." Then he proceeds to the minor thus: "But nothing is better governed than the universe."

Which

<sup>32</sup>  
Synthetic reasoning may always be resolved into a syllogism or series of syllogisms.

Disposition. Which he proves in this manner: "The rising and setting of the heavenly bodies keep a certain determined order; and the several seasons of the year do not only necessarily return in the same manner, but are suited to the advantage of the whole; nor did the vicissitudes of night and day ever yet become prejudicial, by altering their course." From all which he concludes, "That the world must be under the direction of a wise governor." In both these examples, the regular order of the parts is observed. We shall therefore produce another, in which the order is directly contrary; for beginning with the conclusion, he proceeds next to the minor proposition, and so ends with the major. In his defence of Cælius, his design is to prove that Cælius had not led a loose and vicious life, with which his enemies had charged him. And this he does, by showing he had closely followed his studies, and was a good orator. This may probably at first sight appear but a weak argument, though to him who considers what Cicero everywhere declares necessary to gain that character, it may perhaps be thought otherwise. The sense of what he says here may be reduced to this syllogism.

*Those who have pursued the study of oratory, so as to excel in it, cannot have led a loose and vicious life.*

*But Cælius has done this.*

*Therefore his enemies charge him wrongfully.*

But let us hear Cicero himself. He begins with the conclusion, thus: "Cælius is not chargeable with profuseness, extravagancy, contracting of debts, or intemperance, a vice which age is so far from abating that it rather increases it. Nay, he never engaged in amours, and those pleasures of youth, as they are called, which are soon thrown off, as reason prevails." Then he proceeds to the minor, and shows from the effects, that Cælius had closely applied himself to the best arts, by which he means those necessary for an orator: "You have now heard him make his own defence, and you formerly heard him engaged in a prosecution (I speak this to vindicate, not to applaud him), you could not but perceive his manner of speaking, his ability, his good sense and command of language. Nor did he only discover a good genius, which will oftentimes do much of itself when it is not improved by industry; but what he said (if my affection for him did not bias my judgment) appeared to be the effect of learning, application, and study." And then he comes to the major: "But be assured, that those vices charged upon Cælius, and the studies upon which I am now discoursing, cannot meet in the same person. For it is not possible that a mind, disturbed by such irregular passions, should be able to go through what we orators do, I do not mean only in speaking, but even in thinking." And this he proves by an argument taken from the scarcity of good orators, "Can any other reason be imagined, why so few, both now, and at all times have engaged in this province, when the reward of eloquence are so magnificent, and it is attended with so great delight, applause, glory and honour? All pleasures must be neglected; diversions, recreations, and entertainments omitted; and even the conversation of all our friends must in a manner be laid aside. This it is which de-

ters persons from the labour and study of oratory; not their want of genius or education."

2. By *Enthymem*. But orators do not often use complete syllogisms, but most commonly enthymems. An *enthymem*, as is shown elsewhere, is an imperfect syllogism, consisting of two parts; the conclusion, and one of the premises. And in this kind of syllogism, that proposition is omitted, whether it be the major or minor, which is sufficiently manifest of itself, and may easily be supplied by the hearers. But the proposition that is expressed is usually called the *antecedent* and the conclusion the *consequent*. So if the major of that syllogism be omitted, by which Cicero endeavours to prove that Clodius assaulted Milo, it will make this enthymem;

*The death of Milo would have been an advantage to Clodius.*

*Therefore Clodius was the aggressor; or, therefore he assaulted Milo.*

In like manner that other syllogism above-mentioned by which he shows that the Carthaginians ought not to be trusted, by omitting the minor, may be reduced to the following enthymem.

*Those who have often broken their faith ought not to be trusted*

*For which reason the Carthaginians ought not to be trusted.*

Every one would readily supply the minor, since the perfidiousness of the Carthaginians was known by a proverb. But it is reckoned a beauty in enthymems when they consist of contrary parts: because the turn of them is most acute, and pungent. Such is that of Micipsa in Sallust: "What stranger will be faithful to you who are an enemy to your friends?" And so likewise that of Cicero for Milo, speaking of Clodius: "You sit as avengers of his death; whose life you would not restore, did you think it in your power." Orators manage enthymems in the same manner they do syllogisms; that is, they invert the order of the parts, and confirm the proposition by one or more reasons: and therefore a rhetorical enthymem frequently consists of three parts, as a syllogism does of five. Though, strictly speaking, a syllogism can consist of no more than three parts, and an enthymem but of two: and the arguments brought to support either of the propositions constitute so many new enthymems, of which the part they are designed to prove is the conclusion. To illustrate this by an example:

*An honest man thinks himself under the highest obligation to his country.*

*Therefore he should shun no danger to serve it.*

In this *enthymem* the major is wanting, which would run thus: "He who is under the highest obligations to another, should shun no danger in order to serve him." This last proposition is founded upon the common principle of gratitude; which requires that, to the utmost of our power, a return should be made in proportion to the kindness received. And this being a maxim generally allowed, it is omitted by the orator. But now this enthymem, consisting of the minor and conclusion, might be managed in some such manner

Disposition as this, beginning with the conclusion: "An honest man ought to shun no danger, but readily expose his life for the safety and preservation of his country." Then the reason of this conduct might be added, which is the antecedent of the enthymem, or minor of the syllogism: "For he is sensible, that his obligations to his country are so many, and so great, that he can never fully requite them." And this again might be confirmed by an enumeration of particulars: "He looks upon himself as indebted to his country for every thing he enjoys; for his friends, relations, all the pleasures of life, and even for life itself." Now the orator calls this *one enthymem*, though in reality there are two: For the second reason, or argument, added to the first, becomes the antecedent of a new enthymem, of which the first reason is the consequent. And if these two enthymems were expressed separately in the natural order of the parts, the former would stand thus: "An honest man thinks himself under the highest obligations to his country; therefore he ought to shun no danger for its preservation." The latter thus: "An honest man esteems himself indebted to his country for every thing he enjoys; therefore he thinks he is under the highest obligations to it." The same thing might be proved in the like way of reasoning, by arguments of a different kind. From comparison, thus: "As it would be thought base and ungrateful in a son not to hazard himself for the preservation of his father; an honest man must certainly esteem it so when his country is in danger." Or from an example, in this manner: "An honest man in like circumstances would propose to himself the example of Decius, who freely gave up his life for the service of his country. He gave up his life indeed, but did not loose it; for he cannot be said to have lost his life who lives in immortal honour." Orators frequently intermix such arguments to adorn and illustrate their subject with others taken from the nature and circumstances of things. And now, if we consider a little this method of reasoning, we shall find it the most plain and easy imaginable. For when any proposition is laid down, and one or more reasons subjoined to prove it, each reason joined with the proposition makes a distinct enthymem, of which the proposition is the conclusion. Thus Cicero, in his seventh Philippic, lays down this as the foundation of his discourse, "That he is against a peace with Mark Antony;" for which he gives three reasons: "Because it is base, because it is dangerous, and because it is impracticable." These severally joined with the proposition, form three enthymems; and upon each of these he discourses separately, which make up that oration. And this method is what persons for the most part naturally fall into, who know nothing of the terms *syllogism* or *enthymem*. They advance something, and think of a reason to prove it, and another perhaps to support that; and, so far as their invention will assist them, or they are masters of language, they endeavour to set what they say in the plainest light, give it the best dress, embellish it with proper figures and different turns of expression; and, as they think convenient, illustrate it with similitudes, comparisons, and the like ornaments, to render it most agreeable, till they think what they have advanced sufficiently proved. As this method of arguing therefore is the

Vol. XIII.

most plain, easy, and natural; so it is what is most commonly used in oratory. Whereas a strict syllogistical way of discoursing is dry and jejune, cramps the mind, and does not admit of those embellishments of language which are a great advantage to the orator: for which reason he seldom uses complete syllogisms; and when he does, it is with great latitude. In every discourse care should be taken not to blend arguments confusedly together that are of a separate nature. "All arguments (says the elegant Dr Blair) are directed to prove one or other of these three things; that something is true; that it is morally right or fit; or that it is profitable and good. These make the three great subjects of discussion among mankind; truth, duty, and interest. But the arguments directed towards any one of them are generically distinct, and he who blends them all under one topic, which he calls his argument, as, in sermons especially, is too often done, will render his reasoning indistinct and inelegant. Suppose, for instance, that I am recommending to an audience benevolence, or the love of our neighbour; and that I take my first argument from the inward satisfaction which a benevolent temper affords; my second, from the obligation which the example of Christ lays upon us to this duty; and my third, from its tendency to procure us the good-will of all around us; my arguments are good, but I have arranged them wrong: for my first and third arguments are taken from considerations of interest, internal peace and external advantages; and between these, I have introduced one, which rests wholly upon duty. I should have kept those classes of arguments, which are addressed to different principles in human nature, separate and distinct."

II The other method of reasoning is the analytic, in which the orator conceals his intention concerning the point he is to prove, till he has gradually brought his hearers to the designed conclusion. They are led on, step by step, from one known truth to another, till the conclusion be stolen upon them, as the natural consequence of a chain of propositions. As, for instance, when one intending to prove the being of a God, sets out with observing that every thing which we see in the world has had a beginning; that whatever has had a beginning, must have had a prior cause; that in human productions, art shown in the effect, necessarily infers design in the cause; and proceeds leading you on from one cause to another, till you arrive at one supreme first cause, from whom is derived all the order and design visible in his works. This is much the same with the Socratic method, by which that philosopher silenced the sophists of his age.

He proceeded by several questions, which being separately granted, the thing designed to be inferred was afterwards put, which by reason of its similitude with several cases allowed before, could not be denied. But this is a captious way of reasoning; for while the respondent is not aware of what is designed to be inferred, he is easily induced to make those concessions, which otherwise he would not. Besides, it is not so well suited to continued discourses, as to those which are interlocutory; and therefore we meet with it ofteneft in the Socratic dialogues both of Plato and Xenophon. However, it may be made use in oratory by a figure called *subjection*, when the same per-

**Disposition** son first puts the question, and then makes the answer.

So in the famous cause of Epaminondas, general of the Thebans, who was accused for refusing to surrender his command to his successor appointed by the state, till after he had engaged the enemy, and given them a total defeat, Cicero thus represents his accuser pleading for the words of the law against Epaminondas, who alleged the intention of it in his defence: "Should Epaminondas add that exception to the law, which, he says, was the intention of the writer, namely, *Except any one refuse to give up his command when it is for the interest of the public he should not*; would you admit of it? I believe not. Should you yourselves, which is a thing most remote from your justice and wisdom, in order to screen him, order this exception to be added to the law, without the command of the people; would the Thebans suffer it to be done? No certainly. Can it be right then to come into that, as if it was written, which it would be a crime to write? I know it cannot be agreeable to your wisdom to think so."

35  
May comprehend  
reasoning  
by example

Under the analytic method may be comprehended reasoning by *example*. Rhetoricians use this word in a different sense from the common acceptance. For that is usually called an *example*, which is brought either to prove or illustrate some general assertion: As if any one should say, that *human bodies may be brought to sustain the greatest labours by use and exercise*; and in order to prove this should relate what is said of Milo of Croton, that "by the constant practice of carrying a calf several furlongs every day, he could carry it as far after it has grown to its full size." But in oratory the word *example*, is used for any kind of similitude; or, as Vossius defines it, "When one thing is inferred from another, by reason of the likeness which appears between them." Hence it is called an *imperfect induction*, which infers something from several others of a like nature, and has always the greatest force when the examples are taken from facts. Now facts may be compared with respect to some agreement or similitude between them, which in themselves are either equal or unequal. Of the former kind this is an instance: "Cato acted as became a patriot and a lover of his country's liberty, in opposing the arms of Cæsar; and therefore so did Cicero." The reason of the inference is founded in the parity of the case, which equally concerned all good subjects of the Roman government at that time. For all were alike obliged to oppose a common enemy, who endeavoured to subvert the constitution, and subject them to his own arbitrary power. But though an example consists in the comparison of two single facts, yet several persons may be concerned in each fact. Of this kind is that which follows: "As Pompey, Cæsar, and Crassus, acted illegally in the first triumvirate, by engrossing the sole power into their own hands, and by that means violating the public liberty; so likewise did Augustus, Mark Antony, and Lepidus, in the second triumvirate by pursuing the same measures." But when Cicero defends Milo for killing Clodius, from the like instances of Ahala Servilius, Scipio Nafica, Lucius Opimius, and others; that is not an example, but an induction: because one thing is there inferred from its similitude to several others. But when a comparison is

made between two facts that are unequal, the inference may be either from the greater to the less, or from the less to the greater. From the greater to the less in this manner: "Cæsar had no just pretensions to the Roman government, and therefore much less had Antony." The reason lies in the difference between the two persons. Cæsar had very much enlarged the bounds of the Roman empire by his conquests, and greatly obliged the populace by his generosity; but as he had always acted by an authority from the senate and people of Rome, these things gave him no claim to a power over them. Much less then had Antony any such pretence who always acted under Cæsar, and had never performed any signal services himself. Cicero has described the difference between them in a very beautiful manner, in his second Philippic, thus speaking to Antony: "Are you in any thing to be compared to him? He had a genius, sagacity, memory, learning, care, thought, diligence; he had performed great things in war, though detrimental to the state; he had for many years designed to get the government into his hands, and obtained his end by much labour and many dangers; he gained over the ignorant multitude by public shows, buildings, congiaries, and feasts; obliged his friends by rewards, and his enemies by a show of clemency. In a word, he subjected a free state to slavery, partly through fear, and partly compliance. I can liken you to him for ambition of power; but in other things you are in no respect to be compared with him." By a comparison from the less to the greater, Cicero thus argues against Catiline: "Did the brave Scipio, when a private man, kill Tiberius Gracchus, for attempting to weaken the state; and shall we consuls bear with Catiline endeavouring to destroy the world by fire and sword?" The circumstances of these two cases were very different; and the comparison runs between a private man, and a consul entrusted with the highest authority; between a design only to raise a tumult, and a plot to destroy the government: whence the orator justly infers, that what was esteemed lawful in one case, was much more so in the other. The like way of reasoning is sometimes used from other similitudes, which may be taken from things of all kinds, whether animate or inanimate. Of the former sort is that of Cicero speaking of Muræna, when candidate for the consulship, after he had himself gone through that office: "If it is usual (says he) for such persons as are safely arrived in port, to give those who are going out the best account they can with relation to the weather, pirates, and coasts; because thus nature directs us to assist those who are entering upon the same dangers which we ourselves have escaped: how ought I, who now after a great storm am brought within a near prospect of land, to be affected towards him, who, I perceive, must be exposed to the greatest tempests of the state?" He alludes to the late disturbances and tumults occasioned by the conspiracy of Catiline, which had been so happily suppressed by him in the time of his consulship. Of the latter kind is that of Quintilian: "As the ground is made better and more fruitful by culture, so is the mind by instruction." There is both a beauty and justness in this simile.

But comparisons are sometimes made between facts and

Disposition and other things, in order to infer some difference or opposition between them. In comparing two facts, on account of some disagreement and unlikeness, the inference is made from the difference between one and the other in that particular respect only. As thus: "Though it was not esteemed cruelty in Brutus to put his two sons to death, for endeavouring to betray their country; it might be so in Manlius, who put his son to death, only for engaging the enemy without orders, though he gained the victory." The difference between the two facts lies in the different nature of the crime. The sons of Brutus entered into a conspiracy to betray their country; and though they miscarried in it, yet the intention and endeavours they used to accomplish it were criminal in the highest degree. But young Manlius could only be charged with rashness. His design was honourable, and intended for the interest of his country; only it was irregular, and might have proved of ill consequence to military discipline. Now in all such cases, the force of the argument is the stronger the greater the difference appears. But the same facts which differ in one respect may agree in many others; as in the example here mentioned. Brutus and Manlius were both magistrates as well as fathers; they both killed their sons, and that for a capital crime by the Roman law. In any of which respects they may be compared in a way of similitude: as, "If Brutus might lawfully put his son to death for a capital crime, so might Manlius." But now contrary facts do not only differ in some certain respect, but are wholly opposite to each other; so that what is affirmed of the one must be denied of the other; and if one be a virtue, the other is a vice. Thus Cicero compares the conduct of Marcellus and Verres in a way of opposition. "Marcellus (says he), who had engaged, if he took Syracuse, to erect two temples at Rome, would not beautify them with the spoils he had taken: Verres, who had made no vows no Honour and Virtue, but to Venus and Cupid, endeavoured to plunder the temple of Minerva. The former would not adorn the gods with the spoils of other deities: the latter carried the ornaments of Minerva, a virgin, into the house of a strumpet." If therefore the conduct of Marcellus was laudable and virtuous, that of Verres must bear the contrary character. But this way of reasoning has likewise place in other respects. Thus Cicero, in the quarrel between Cæsar and Pompey, advised to peace from the difference between a foreign and domestic war: "That the former might prove beneficial to the state; but in the latter, whichever side conquered, the public must suffer." And thus the ill effects of intemperance may be shown in a way of opposition: "That as temperance preserves the health of the body, keeps up the vigour of the mind, and prolongs life; so excess must necessarily have the contrary effects."

Thus we have given a brief account of the principal ways of reasoning commonly made use of by orators. As to the disposition of arguments, or the order of placing them, some advise to put the weaker, which cannot wholly be omitted, in the middle: and such as are stronger, partly in the beginning, to gain the esteem of the hearers and render them more attentive; and partly at the end, because what is last heard is likely

to be retained longest; But if there are but two arguments, to place the stronger first, and then the weaker; and after that to return again to the former, and insist principally upon that. But this must be left to the prudence of the speaker, and the nature of the subject. Though to begin with the strongest, and so gradually descend to the weakest, can never be proper, for the reason last mentioned. Nor ought arguments to be crowded too close upon one another; for that takes off from their force, as it breaks in upon the attention of the hearers, and does not leave them sufficient time duly to consider them. Nor indeed should more be used than are necessary; because the fewer they are, the more easily they are remembered. And the observation of a great master of eloquence upon this subject is certainly very just, that arguments ought rather to be weighed than numbered.

#### CHAP. V. Of Confutation.

THE forms of reasoning here are the same as have been already explained under *Confirmation*. *Confutation*, however, is often the more difficult task; because he who is to prove a thing comes usually prepared; but he who is to confute it is frequently left, to a sudden answer. For which reason, in *judicial* cases, Quintilian says, "It is as much easier to accuse than defend, as it is to make a wound than to heal it." Therefore, not only a good judgment, but a readiness of thought also, seems necessary for this province. But, in all disputes, it is of the greatest consequence to observe where the stress of the controversy lies. For without attending to this, persons may cavil about different matters without understanding each other, or deciding any thing. And in confutation, what the adversary has advanced ought carefully to be considered, and in what manner he has expressed himself. As to the things themselves, whether they immediately relate to the matter in dispute, or are foreign to it. Those things that are foreign to the subject may either be past over in silence, or in a very few words shown to be insignificant. And there ought likewise to be a distinction made between such things as relate to the subject, according to their importance. Those that appear to have no great weight should be slightly remarked. For to insist largely upon such matters is both tiresome to the hearers, and apt to bring the judgment of the speaker into question. And therefore things of that nature are generally better turned off with an air of neglect, a pungent question, or an agreeable jest, than confuted by a serious and laboured answer. But those things, which relate to the merits of the cause, may be confuted either by *contradicting* them, or by showing some *mistake* in the reasoning, or their *invalidity* when granted.

Things may be *contradicted* several ways. What is apparently false may be expressly *denied*. Thus Cicero in his defence of Cluentius: "When the accuser had said, that the man fell down dead after he had drunk off his cup, denies that he died that day." And things which the adversary cannot prove, may likewise be denied. Of which we have also an instance in Cicero, who first upbraids Mark Anthony as guilty of a breach not only of good breeding, but likewise of friendship, for reading publicly a private letter he had sent him.

Disposition

And then adds, "But what will you say now, If I should deny that ever I sent you that letter? How will you prove it? By the hand-writing? In which I confess you have a peculiar skill, and have found the benefit of it. But how can you make it out? For it is in my secretary's hand. I cannot but envy your master who had so great a reward for teaching you to understand just nothing. For what can be more unbecoming not only an orator, but even a man, than for any one to offer such things, which if the adversary denies, he has nothing more to say?" It is an handsome way of contradicting a thing, by showing that the adversary himself maintained the contrary. So when Oppius was charged with defrauding the soldiers of their provisions, Cicero refutes it, by proving, that the same persons charged Oppius with a design to corrupt the army by his liberality. An adversary is never more effectually silenced than when you can fasten contradictions upon him; for this is stabbing him with his own weapon. Sometimes a thing is not in express terms denied, but represented to be utterly incredible. And this method exposes the adversary more than a bare denial. So when some persons reproached Cicero with cowardice, and a shameful fear of death, he recites their reasons in such a manner, that any one would be inclined to think the charge entirely false. "Was it becoming me (says he) to expect death with that composedness of mind as some have imagined? Well, and did I then avoid it? Nay, was there any thing in the world that I could apprehend more desirable? Or when I had done the greatest things in such a crowd of ill-minded persons about me, do you think banishment and death were not always in my view, and continually sounding in my ears as my certain fate, while I was so employed? Was life desirable when all my friends were in such sorrow, and myself in so great distress, deprived of all the gifts both of nature and fortune? Was I so unexperienced, so ignorant, so void of reason and prudence? Had I never seen nor heard any thing in my whole life? Did all I had read and studied avail nothing? What! did not I know that life is short, but the glory of generous actions permanent? When death is appointed for all, does it not seem eligible, that life, which must be wrested from us, should rather be freely devoted to the service of our country, than reserved to be worn out by the decays of nature? Was not I sensible, there has been this controversy among the wisest men, that some say, the minds of men and their consciences utterly perish at death; and others, that the minds of wise and brave men are then in their greatest strength and vigour, when they are set free from the body? The first state is not greatly to be dreaded, to be void of sense: but the other, of enjoying larger capacities, is greatly to be desired. Therefore, since I always aimed at dignity, and thought nothing was worth living for without it; how should I, who am past the consulship, and did so great things in it, be afraid to die?" Thus far Cicero. There is likewise an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the adverse party. Thus Cicero, in his oration against Vatinius, says: "You have objected to me, that I defended Cornelius, my old friend, and your acquaintance. But pray why should I not have defended him? Has Cornelius car-

ried any law contrary to the omens? Has he violated any law? Has he assaulted the consul? Did he take possession of a temple by force of arms? Did he drive away the tribune, who opposed the passing a law? Has he thrown contempt upon religion? Has he plundered the treasury? Has he pillaged the state? No, these, all these, are your doings." Such an unexpected return is sometimes of great service to abate the confidence of an adversary.

A second way of confutation is, by observing some *flaw* in the reasoning of the adverse party. We shall endeavour to illustrate this from the several kinds of reasoning treated of before under *confirmation*. And first, as to syllogisms; they may be refuted, either by showing some mistake in the premises, or that the conclusion is not justly deduced from them. So when the Clodian party contended, that Milo ought to suffer death for this reason, Because he had confessed that he had killed Clodius; that argument, reduced to a syllogism, would stand thus:

*He who confesses he has killed another, ought not to be allowed to see the light.*

*But Milo confesses this.*

*Therefore he ought not to live.*

Now the force of this argument lies in the major or first proposition; which Cicero refutes, by proving, that the Roman people had already determined contrary to what is there asserted: "In what city (says he) do these men dispute after this weak manner? In that wherein the first capital trial was in the case of the brave Horatius, who, before the city enjoyed perfect freedom, was saved by the suffrages of the Roman people, though he confessed that he killed his sister with his own hand." But when Cicero accused Verres for mal-administration in his government of Sicily, Hortensius, who defended him, being sensible the allegations brought against him could not be denied, had no other way left to bring him off, but by pleading his military virtues in abatement, which at the time were much wanted, and very serviceable to the state. The form of the argument was this:

*That the Romans then wanted good generals.*

*That Verres was such.*

*And consequently, that it was for the interest of the public that he should not be condemned.*

But Cicero, who knew his design, states the argument for him in his charge; and then answers it by denying the consequence, since the crimes of Verres were of so heinous a nature, that he ought by no means to be pardoned on the account of any other qualifications: Though indeed he afterwards refutes the minor or second proposition, and shows that he had not merited the character of a good general. Enthymems may be refuted, either by showing that the antecedent is false, or the consequent not justly inferred from it. As thus, with respect to the former case:

*A strict adherence to virtue has often proved detrimental.*

*Therefore virtue ought not constantly to be embraced.*

Here the antecedent may be denied. For virtue is always beneficial to those who strictly adhere to it, both in the present satisfaction it affords them, and the future

*Disposition* ture rewards they may certainly expect from it. And as to the latter case, in this manner :

*She is a mother.*

*Therefore she loves her children.*

Now as the certainty of that inference depends upon this general assertion, That all mothers love their children, which is not true, the mistake of the reasoning may be shown from the instance of Media and others, who destroyed their own children. As to *induction* and *example*, by which the truth or equity of a thing is proved from its likeness to one or more other things; the reasoning in either is invalid, if the things so compared can be shown not to have that similitude or agreement on which the inference is founded. One instance therefore may serve for both. As when Cicero, after the death of Cæsar, pleaded for the continuance of his laws, but not of those which were made afterwards by Mark Antony; Because, though both were in themselves invalid, and impositions upon the public liberty; yet some of Cæsar's were useful, and others could not be set aside without disturbance to the state, and injuring particular persons; but those of Antony were all detrimental to the public.

The last method of *confutation* before-mentioned was, when the orator does in some sense *grant* the adversary his argument, and at the same time shows its *invalidity*. And this is done by a variety of ways, according to the different nature of the subject. Sometimes he allows what was said may be true; but pleads, that what he contends for is necessary. This was the method by which Hortensius proposed to bring off Verres, as we have already shown from Cicero, whose words are these, addressing himself to the judges: "What shall I do? which way shall I bring in my accusation? where shall I turn myself? for the character of a brave general is placed like a wall against all the attacks I can make. I know the place, I perceive where Hortensius intends to display himself. He will recount the hazards of war, the necessities of the state, the scarcity of commanders; and then he will intreat you, and do his utmost to persuade you, not to suffer the Roman people to be deprived of such a commander upon the testimony of the Sicilians, nor the glory of his arms to be sullied by a charge of avarice." At other times the orator pleads, that although the contrary opinion may seem to be attended with advantage, yet that his own is more just or honourable. Such was the case of Regulus, when his friends endeavoured to prevail with him to continue at Rome, and not return to Carthage, where he knew he must undergo a cruel death. But as this could not be done without violating his oath, he refused to hearken to their persuasions. Another way of confutation is, by retorting upon the adversary his own argument. Thus Cicero, in his defence of Ligarius, says: "You have, Tubero, that which is most desirable to an accuser, the confession of the accused party; but yet such a confession, that he was on the same side that you, Tubero, chose yourself, and your father too, a man worthy of the highest praise. Wherefore, if there was any crime in this, you ought first to confess your own before you attempt to fasten any upon Ligarius." The orator takes this advantage where an argument proves

*Disposition* too much, that is, more than the person designed it for, who made use of it. Not much unlike this is what they call *inversion*, by which the orator shows, that the reasons offered by the opposite party make for him. So when Cæcilius urged, that the province of accusing Verres ought to be granted to him, and not to Cicero, because he had been his treasurer in Sicily at the time those crimes were committed with which he was charged, and consequently knew most of that affair; Cicero turns the argument upon him, and shows, for that very reason he was the most unfit of any man to be intrusted with his prosecution; since having been concerned with him in his crimes, he would certainly do all in his power to conceal or lessen them. Again, sometimes the charge, is acknowledged, but the crime shifted off to another. Thus, when Sextius was accused of sedition, because he had got together a body of gladiators, and brought them into the forum, where a warm engagement happened between them and Clodius's faction; Cicero owns the fact, but charges the crime of sedition upon Clodius's party in being the aggressors. Another method made use of for the same purpose is, to alleviate the charge, and take off the force of it, by showing, that the thing was not done with that intention which the adversary insinuates. Thus Cicero, in his defence of king Deiotarus, owns he had raised some forces, though not to invade the Roman territories, as had been alleged, but only to defend his own borders, and send aid to the Roman generals.

We have hitherto been speaking of the methods of confutation used by orators, in answering those arguments which are brought by the contrary party. But sometimes they raise such objections themselves to what they have said, as they imagine may be made by others; which they afterwards answer, the better to induce their hearers to think, that nothing considerable can be offered against what they have advanced, but what will admit of an easy reply. Thus, when Cicero, at the request of the Sicilians, had undertaken the accusation of Verres, it came under debate, whether he, or Cæcilius, who had been Verres's quaestor in Sicily, should be admitted to that province. Cicero, therefore, in order to set him aside, among other arguments, shows his incapacity for such an undertaking, and for that end recounts at large the qualifications necessary for an orator. Which he represents to be so many and great, that he thought it necessary to start the following objection to what he had himself said upon that subject. "But you will say perhaps, Have you all these qualifications?" To which he thus replies: "I wish I had; but it has been my constant study from my youth to gain them. And if, from their greatness and difficulty, I have not been able to attain them, who have done nothing else through my whole life; how far, do you imagine, you must be from it, who never thought of them before; and even now, when you are entering upon them, have no apprehension, what, and how great, they are?" This is an effectual way of defeating an adversary, when the objection is well founded, and clearly answered. But we shall have occasion to consider this matter more largely hereafter, under the figure *prolepsis*, to which it properly relates.

CHAP. VI. *Of the Conclusion.*

37  
The conclusion is a recapitulation and address to the passions:

RHETORICIANS make the *conclusion* of a discourse to consist of two parts; *recapitulation*, and an *address to the passions*.

1. *Recapitulation* is a summary account of what the speaker has before offered in maintenance of his subject; and is designed both to refresh the memory of the hearers, and to bring the principal arguments together into a narrow compass, that they may appear in a stronger light. Now there are several things necessary to a good repetition.

And first, it must be short and concise; since it is designed to refresh the memory, and not to burden it. For this end, therefore, the chief things only are to be touched upon; those on which the cause principally depends, and which the orator is most desirous should be regarded by his hearers. Now these are, The general heads of the discourse, with the main arguments brought to support them. But either to insist particularly upon every minute circumstance, or to enlarge upon those heads which it may be thought proper to mention, carries in it so much the appearance of a repetition, as of a new discourse.

Again, it is convenient in a repetition to excite things in the same order in which they were at first laid down. By this means the hearers will be enabled much better to keep pace with the speaker as he goes along; and if they happen to have forgot any thing, they will the more readily recal it. And besides, this method appears most simple and open, when the speaker reviews what he has said in the same manner it was before delivered, and sets it in the clearest light for others to judge of it. But though a repetition contains only the same things which had been more largely treated of before; yet it is not necessary they should be expressed in the same words. Nay, this would many times be tiresome and unpleasant to the hearers; whereas a variety of expression is grateful, provided the sense be the same. Besides, every thing ought now to be represented in the strongest terms, and in so lively a manner, as may at the same-time both entertain the audience, and make the deepest impression upon their minds. We have a very exact and accurate example of repetition in Cicero's oration for Quintus. Cicero then was a young man, and seems to have kept more closely to the rules of art, than afterwards, when by use and practice he had gained a greater freedom of speaking. We formerly cited the partition of this speech, upon another occasion, which runs thus: "We deny, Sextus Nevius, that you were put into the possession of the estate of P. Quintus, by the prætor's edict. This is the dispute between us. I will therefore show, first, that you had no just cause to apply to the prætor for the possession of the estate of P. Quintus; then, that you could not possess it by the edict; and lastly, that you did not possess it. When I have proved these three things, I will conclude." Now Cicero begins his conclusion with a repetition of those three heads, and a summary account of the several arguments he made use of under each of them. But they are too long to be here exhibited. In his oration for the Manilian law, his repetition is very short. He proposed in the partition to speak to three

things: the nature of the war against king Mithridates, the greatness of it, and what sort of general was proper to be intrusted with it. And when he has gone through each of these heads, and treated upon them very largely, he reduces the substance of what he has said to this general and short account; "Since therefore the war is so necessary, that it cannot be neglected; and so great, that it requires a very careful management; and you can intrust it with a general of admirable skill in military affairs, of singular courage, the greatest authority, and eminent success: do you doubt to make use of this so great a blessing, conferred and bestowed upon you by heaven, for the preservation and enlargement of the Roman state?" Indeed this repetition is made by Cicero, before he proceeds to the confutation; and not at the end of his discourse, where it is usually longer and more particular: however, this may serve to show the nature of such a recital.

But sometimes a repetition is made, by running a comparison between the speaker's own arguments and those of the adverse party; and placing them in opposition to each other. And this method Cicero takes in the conclusion of his third oration upon the Agrarian law. And here sometimes the orator takes occasion to find fault with his adversary's management, in these and such like expressions: "This part he has entirely dropt. To that he has given an invidious turn, or a false colouring. He leaves arguments, and flies to intreaties; and not without good reason, if we consider the weakness of his cause."

But when the discourse is very long, and the arguments insisted on have been many, to prevent the hearers growing out of patience by a more particular recital, the orator sometimes only just mentions such things, which he thinks of least consequence, by saying, that he omits or passes over them, till he comes to what is of greater moment, which he represents more fully. This method Cicero has taken in his defence of Cluentius; where, having run over several lesser heads in the manner now described, he then alters his expression, and introduces what was of more importance, by saying, "What I first complain of, is that wickedness, which is now discovered." And so he proceeds more particularly to recite those things which immediately related to Cluentius. And this is what the writers upon this art call *preterition*. But this much may serve for repetition or recapitulation.

2. We now proceed to the other part of the conclusion, which consists in an *address to the passions*. Indeed the orator sometimes endeavours occasionally to work upon the passions of his hearers in other parts of his discourse, but more especially in the conclusion, where he is warmest himself, and labours to make them so. For the main design of the introduction is to conciliate the hearers, and gain their attention; of the narration, proposition, and confirmation, to inform them; and of the conclusion, to move them. And therefore, to use Quintilian's words, "Here all the spring's of eloquence are to be opened. It is here we secure the minds of the hearers, if what went before was well managed. Now we are past the rocks and shallows, all the sails may be hoisted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place

Disposition place here." Now the passions, to which the orator more particularly addresses, differ according to the nature of the discourse. In demonstrative orations, when laudatory,—love, admiration, and emulation, are usually excited; but in invectives,—hatred, envy, and contempt. In deliberative subjects, either the hope of gratifying some desire is set in view, or the fear of some impending evil. And in judicial discourses, almost all the passions have place, but more especially resentment and pity; inasmuch that most of the ancient rhetoricians mention only these two. But having treated upon the nature of the passions, and the methods suited both to excite and allay them, in a former chapter, we shall at present only add a few general observations, which may not be improper in this place, where the skill of the orator in addressing to them is more especially required.

The orator will observe what circumstances either of things, or persons, or both, will furnish him with motives proper to apply to those passions he desires to excite in the minds of his hearers. Thus Cicero, in his orations for Plancus and Sylla, moves his hearers from the circumstances of the men; but in his accusation of Verres, very frequently from the barbarity and horrid nature of his crimes; and from both, in his defence of Quintus.

But the same passion may be excited by very different methods. This is plain from the writings of those Roman satyrists which are yet extant; for they have all the same design, and that is to engage men to a love of virtue, and hatred of vice: but their manner is very different, suited to the genius of each writer. Horace, endeavours to recommend virtue, by laughing vice out of countenance; Persius moves us to an abhorrence and detestation of vice, with the gravity and severity of a philosopher; and Juvenal, by open and vehement invectives. So orators make use of all these methods in exciting the passions; as may be seen by their discourses, and particularly those of Cicero. But it is not convenient to dwell long upon the same passion. For the image thus wrought up in the minds of the hearers does not last a great while, but they soon return to reflection. When the emotion, therefore, is once carried as high as it well can be, they should be left under its influence, and the speaker proceed to some new matter, before it declines again.

Moreover, orators, sometimes endeavour to raise contrary passions to each other, as they are concerned for opposite parties. So the accuser excites anger and resentment, but the defendant pity and compassion. At other times, one thinks it sufficient to allay and take off that passion which the other has raised, and bring the hearers to a calm and sedate consideration of the matter before them.

But this especially is to be regarded, that the orator express the same passion himself with which he endeavours to affect others; and that not only in his action and voice, but likewise in his language: and therefore his words, and manner of expression, should be suited to that perturbation and disorder of mind which he designs to represent. However, a decency and propriety of character is always carefully to be observed; for, as Cicero very well remarks, "A ne-

glect of this is not only very culpable in life, but likewise in discourse. Nor do the same things equally become every speaker, or every audience; nor every time, and every place." And therefore he greatly commends that painter, who, designing to represent in a picture the sacrifice of Iphigenia, Agamemnon's daughter, drew Chalcas the priest with a sad countenance; Ulysses, her father's great friend, more dejected; and her uncle Menelaus, most disconsolate; but threw a veil over the face of Agamemnon himself, as being unable to express that excess of sorrow which he thought was proper to appear in his countenance. And this justness of character is admirably well observed by Cicero himself, in his defence of Milo; for as Milo was always known to be a man of the greatest resolution, and most undaunted courage, it was very improper to introduce him (as the usual method then was in capital cases) moving pity, and begging for mercy. Cicero therefore takes this part upon himself; and what he could not do with any propriety in the person of Milo, he performs in his own, and thus addresses the judges: "What remains but that I intreat and beseech you, that you would show that compassion to this brave man, for which he himself does not solicit, but I, against his inclination, earnestly implore and request. Do not be less inclined to acquit him, if in this our common sorrow, you see no tear fall from Milo's eyes; but perceive in him the same countenance, voice, and language, as at other times, steady and unmoved. Nay, I know not whether for this reason you ought not much sooner to favour him: For if, in the contests of gladiators (persons of the lowest condition and fortune in life), we are wont to be displeased with the timorous and suppliant, and those who beg for their life; but interpose in favour of the brave and courageous, and such as expose themselves to death; and we show more compassion to those who do not sue for it, than to those who do: with how much greater reason ought we to act in the same manner towards the bravest of our fellow-citizens?" And as these words were agreeable to his own character, while soliciting in behalf of another; so, immediately after, he introduces Milo speaking like himself, with a generous and undaunted air: "These words of Milo (says he) quite sink and dispirit me, which I daily hear from him. Farewel, farewell, my fellow citizens, farewell! may you be happy, flourish, and prosper; may this renowned city be preserved, my most dear country, however it has treated me; may it continue in peace, though I cannot continue in it, to whom it owes its peace. I will retire; I will be gone."

But as persons are commonly more affected with what they see than with what they hear, orators sometimes call in the assistance of that sense in moving the passions. For this reason it was usual among the Romans, in judicial cases, for accused persons to appear with a dejected air and a sordid garb, attended by their parents, children, or other relations and friends, with the like dress and aspect; as likewise to shew their scars, wounds, bloody garments, and other things of the like nature, in open court. So when, upon the death of Cæsar, Mark Antony harangued the populace, he at the same time exposed to their view the garment

Disposition. garment in which he was stabbed, fixed upon a pole; at which sight they were so enraged, that immediately they ran with lighted torches to set fire to the houses of the conspirators. But this custom at last became so common, and was sometimes so ill conducted, that the force of it was greatly abated, as we learn from Quintilian. However, if the Romans proceeded to an excess on the one hand, the strictness of the Areopagites at Athens may perhaps be thought too rigid on the other; for in that court, if the orator began to say any thing which was moving, an officer immediately stood up, and bade him be silent. There is certainly a medium between these two extremes, which is sometimes not only useful, but even necessary: for, as Quintilian very justly says, "It is necessary to apply to the passions, when those things which are true, just, and of common benefit, cannot be come at any other way."

#### CHAP. VII. *Of Digression, Transition, and Amplification.*

38  
Digression,  
transition,  
and ampli-  
fication,  
defined and  
explained.

THE number, order, and nature of the parts which constitute a complete and regular oration, we have endeavoured to explain in several preceding chapters. But there are two or three things yet remaining, very necessary to be known by an orator, which seem most properly to come under the second branch of his art.—And these are, *Digression*, *Transition*, and *Amplification*.

I. *Digression*, as defined by Quintilian, is, "A going off from the subject we are upon to some different thing, which may however be of service to it." We have a very beautiful instance of this in Cicero's defence of Cælius, who was accused of having first borrowed money of Clodia, and then engaging her servants to poison her. Now, as the proof of the fact depended upon several circumstances, the orator examines them separately; and shows them to be all highly improbable. "How (says he) was the design of this poison laid? Whence came it? how did they get it? by whose assistance, to whom, or where, was it delivered?" Now to the first of these queries he makes the accuser give this answer: "They say Cælius had it at home, and tried the force of it upon a slave provided on purpose, whose sudden death proved the strength of the poison." Now as Cicero represents the whole charge against Cælius as a fiction of Clodia, invented out of revenge for some slights he had put upon her; to make this the more probable, he insinuates that she had poisoned her husband, and takes this opportunity to hint it, that he might show how easy it was for her to charge another with poisoning a servant, who had done the same to her own husband. But not contented with this, he steps out of his way, and introduces some of the last words of her husband Metellus, to render the fact more barbarous and shocking, from the admirable character of the man. "O immortal gods! why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity? For I saw, I myself saw (and it was the most doleful scene of my whole life) when Q. Metellus was taken from the bosom of his country; and when he, who thought himself born to be serviceable to this state, within three days after he had appeared with such advantage

Disposition. in the senate, in the forum, and everywhere in public, was snatched from us in the flower of his age, and prime of his strength and vigour. At which time, when he was about to expire, and his mind had lost the sense of other things, still retaining a concern for the public, he looked upon me, as I was all in tears, and intimated in broken and dying words, how great a storm hung over the city and threatened the whole state; often striking the wall which separated his house from that of Quintus Catulus, and frequently calling both upon him and me, and seeming to grieve not so much at the approach of his own death, as that both his country and I should be deprived of his assistance. Had he not been wickedly taken off on a sudden, how would he after his consulship have withstood the fury of his kinsman Publius Clodius, who, while in that office, threatened in the hearing of the senate, to kill him with his own hand, when he first began to break out? And will this woman dare to come out of those doors, and talk of the force of poison? will not she fear lest the house itself should speak the villainy? will not she dread the conscious walls, nor that sad and mournful night? But I return to the accusation." And then he proceeds to consider and refute the several circumstances of the accusation. All this was no part of his argument; but having mentioned the charge of poison, he immediately takes occasion to introduce it, in order to excite the indignation of the hearers against Clodia, and invalidate the prosecution as coming from a person of her character. Digression cannot properly be said to be a necessary part of a discourse; but it may sometimes be very convenient, and that upon several accounts.

As first, where a subject is of itself flat and dry, or requires close attention, it is of use to relieve and unbend the mind by something agreeable and entertaining. For which reason Quintilian observes, that the orators of his time generally made an excursion in their harangues upon some pleasing topic, between the narration and the proof. But he condemns the practice, as too general; for while they seemed to think it necessary, it obliged them sometimes to bring in things trifling and foreign to the purpose. Besides, a digression is confined to no one part of a discourse, but may come in anywhere, as occasion offers; provided it fall in naturally with the subject, and be made some way subservient to it. We never meet with it in Cicero, without some evident and good reason. So in his prosecution of Verres for his barbarous and inhuman outrages against the Sicilians, he takes an occasion to launch out in a beautiful description of the island, and to recount the advantages which accrued from it to the Romans. His subject did not necessarily lead him to this, but his view in it was to heighten and aggravate the charge against Verres.

Again, as a *digression* ought not to be made without sufficient reason, so neither should it be too frequent. And he who never does it but where it is proper and useful, will not often see occasion for it. Frequently to leave the subject, and go off to other things, breaks the thread of the discourse, and is apt to introduce confusion. Indeed some kinds of writing admit of a more frequent use of digressions than others. In history they are often very serviceable. For as that

Disposition that consists of a series of facts, and a long continued narrative without variety, is apt to grow dull and tedious; it is necessary at proper distances to throw in something entertaining, in order to enliven it, and keep up the attention. And accordingly we find the best historians often embellish their writings with descriptions of cities, rivers, and countries, as likewise with the speeches of eminent persons upon important occasions, and other ornaments, to render them the more pleasing and delightful. Poets take a still greater liberty in this respect: for as their principal view is most commonly to please, they do not attend so closely to connection; but as an image offers itself, which may be agreeably wrought up, they bring it in, and go off more frequently to different things, than other writers.

Another property of a *digression* is, that it ought not to be too long, lest the hearers forget what preceded, before the speaker returns again to his subject.

For a digression being no principal part of a discourse, nor of any further use than as it serves some way or other to enforce or illustrate the main subject; it cannot answer this end, if it be carried to such a length, as to cause that either to be forgotten or neglected. And every one's memory will not serve him to connect together two parts of a discourse, which lie at a wide distance from each other. The better therefore to guard against this, it is not unusual with orators, before they enter upon a digression of any considerable length, to prepare their hearers, by giving them notice of it, and sometimes desiring leave to divert a little from the subject. And so likewise at the conclusion they introduce the subject again by a short transition. Thus Cicero in the example cited above, when he has finished his digression concerning the death of Metellus, proceeds to his subject again with these words: "But I return to the accusation."

Indeed we find orators sometimes, when fore pressed, and the cause will not bear a close scrutiny, artfully run into digressions with a design to divert the attention of the hearers from the subject, and turn them to a different view. And in such cases, as they endeavour to be unobserved, so they do it tacitly without any transition or intimation of their design; their business being only to get clear of a difficulty, till they have an opportunity of entering upon some fresh topic.

39  
Transitions  
often used  
on various  
occasions.

II. *Transitions* are often used not only after a digression, but likewise upon other occasions. A transition is, "A form of speech, by which the speaker in a few words tells his hearers both what he has said already, and what he next designs to say." Where a discourse consists of several parts, this is often very proper in passing from one to another, especially when the parts are of a considerable length; for it assists the hearers to carry on the series of the discourse in their mind, which is a great advantage to the memory. It is likewise a great relief to the attention, to be told when an argument is finished, and what is to be expected next. And therefore we meet with it very frequently in history. But we consider it at present only as made use of by orators. Cicero, in his second oration against Catiline, who had then left Rome, having at large described his conduct and designs, he adds: "But why do I talk so long concern-

ing one enemy, and such an one; who owns himself an enemy, and whom I do not fear, since, what I always desired, there is now a wall between us; and say nothing of those, who conceal themselves, who remain at Rome, and among us." And then he proceeds to give an account of the other conspirators.

But sometimes, in passing from one thing to another, a general hint of it is thought sufficient to prepare the hearers, without particularly specifying what has been said, or is next to follow. Thus Cicero in his second Philippic says, "But those things are old, this is yet fresh." And again: "But I have insisted too long upon trifles, let us come to things of greater moment." And at other times, for greater brevity, the transition is imperfect, and mention made only of the following lead, without any intimation of what has been said already. As in Cicero's defence of Muræna, where he says: "I must now proceed to the third part of my oration concerning the charge of bribery." And soon after: "I come now to Cato, who is the support and strength of this charge."

40  
Amplification

III. The third and last head is, *Amplification*. Now Amplification by amplification is meant, not barely a method of enlarging upon a thing; but so to represent it in the fullest and most comprehensive view, as that it may in the liveliest manner strike the mind, and influence the passions. Cicero, speaking of this, calls it *the greatest commendation of eloquence*; and observes, "that it consists not only in magnifying and heightening a thing, but likewise in extenuating and lessening it." But though it consists of these two parts, and may be applied either way; yet to amplify, is not to set things in a false light, but to paint them in their just proportion and proper colours, suitable to their nature and qualities. Rhetoricians have observed several ways of doing this.

One is to ascend from a particular thing to a general. Thus Cicero, in his defence of Archias, having commended him as an excellent poet, and likewise observed, that all the liberal arts have a connection with each other, and a mutual relation between them, in order to raise a just esteem of him in the minds of his hearers, takes occasion to say many things in praise of polite literature in general, and the great advantages that may be received from it. "You will ask me, (says he), why we are so delighted with this man? Because he supplies us with those things, which both refresh our minds after the noise of the forum, and delight our ears when wearied with contention. Do you think we could either be furnished with matter for such a variety of subjects, if we did not cultivate our minds with learning; or bear such a constant fatigue, without affording them that refreshment? I own I have always pursued these studies; let those be ashamed, who have so given up themselves to learning, as neither to be able to convert it to any common benefit, nor discover it in public. But why should it shame me, who have so lived for many years, that no advantage or ease has ever diverted me, no pleasure allured me, nor sleep retarded me, from this pursuit. Who then can blame me, or who can justly be displeased with me, if I have employed that time in reviewing these studies, which has been spent by others in managing their affairs, in the celebration of festivals, or other diversions, in refreshments of mind and body,

Disposition body, in unseasonable banquets, in dice, or tennis? And this ought the rather to be allowed me, because my ability as an orator has been improved by those pursuits, which, such as it is, was never wanting to assist my friends. And if it be esteemed but small, yet I am sensible from what spring I must draw those things which are of the greatest importance." With more to the same purpose; from which he draws this inference: "Shall I not therefore love this man? shall I not admire him? shall I not by all means defend him?"

A contrary method to the former is, to descend from a general to a particular. As if any one, while speaking in commendation of eloquence, should illustrate what he says from the example of Cicero, and show the great services he did his country, and the honours he gained to himself, by his admirable skill in oratory. Our common way of judging of the nature of things is from what we observe in particular instances, by which we form general notions concerning them. When therefore we consider the character of Cicero, and the figure he made in the world, it leads us to conclude, there must be something very admirable in that art by which he became so celebrated. And this method he has taken himself in his oration for the Manilian law, where having first intimated the scarcity of good generals at that time among the Romans, he then describes the virtues of a complete commander as a proof of it, and shows how many and great qualifications are necessary to form such a character, as courage, prudence, experience, and success: all which he afterwards applies to Pompey.

A third method is by an enumeration of parts. So when Cicero, upon the defeat of Mark Antony before Mutina, proposed that a funeral monument should be erected in honour of the soldiers who were killed in that battle, as a comfort to their surviving relations; he does it in this way, to give it the greater weight: "Since (says he) the tribute of glory is paid to the best and most valiant citizens by the honour of a monument, let us thus comfort their relations, who will receive the greatest consolation in this manner: their parents, who produced such brave defenders of the state; their children, who will enjoy these domestic examples, of fortitude; their wives, for the loss of such husbands, whom it will be more fitting to extol than lament; their brethren, who will hope to resemble them no less in their virtues than their aspect. And I wish we may be able to remove the grief of all these by our resolutions." Such representations greatly enlarge the image of a thing, and afford the mind a much clearer view of it than if it were contracted into one single proposition.

Again, another method not much unlike the former is, when any thing is illustrated from a variety of causes. Thus Cicero justifies his behaviour in retiring, and not opposing his enemies, when they spirited up the mob in order to banish him, from the following reasons, which at that time determined him to such a conduct: "When (says he) unless I was given up, so many armed fleets seemed ready to attack this single ship of the state, tossed with the tempests of seditions and discords, and the senate was now removed from the helm; when banishment, murder, and outrage, were threatened; when some, from an apprehension of

their own danger, would not defend me; others were incited by an inveterate hatred to all good men, others thought I stood in the way, others took this opportunity to express their resentment, others envied the peace and tranquillity of the state; and upon all these accounts I was particularly struck at: should I have chosen rather to oppose them (I will not say to my own certain destruction, but to the greatest danger both of you and your children), than alone to submit to and undergo what threatened us all in common?" Such a number of reasons brought together, must set a thing in a very strong and clear light.

The like may be said of a number and variety of effects. Thus Cicero describes the force and excellence of oratory from its great and surprising effects, when he says, "Nothing seems to be more excellent, than by discourse to draw the attention of a whole assembly, delight them, and sway their inclinations different ways at pleasure. This, in every free state, and especially in times of peace and tranquillity, has been always in the highest esteem and reputation. For what is either so admirable, as for one only, or a very few, out of a vast multitude, to be able to do that which all have a natural power of doing; or so delightful to hear, as a judicious and solid discourse in florid and polite language? or so powerful and grand, as to influence the populace, the judges, the senate, by the charms of eloquence? Nay, what is so noble, so generous, so munificent, as to afford aid to supplicants, to support the afflicted, give safety, deliver from dangers, and preserve from exile? Or what is so necessary as to be always furnished with arms to guard yourself, assert your right, or repel injuries? And not to confine our thoughts wholly to the courts of justice or the senate, what is there in the arts of peace more agreeable and entertaining than good language and a fine way of speaking? For it is this especially wherein we excel other animals, that we can discourse together, and convey our thoughts to each other by words. Who therefore would not esteem, and in a particular manner endeavour to surpass others in that wherein mankind principally excels brute beasts? But to proceed to its chief advantages: What else would have drawn men into societies, or taken them off from a wild and savage life, and soften them into a polite and civilized behaviour; or, when settled in communities, have restrained them by laws?" Who but, after such a description, must conceive the strongest passion for an art attended with so many great and good effects?

A thing may likewise be illustrated by its opposite. So the blessings and advantages of peace may be recommended from the miseries and calamities of war; and thus Cicero endeavours to throw contempt upon Catiline and his party, by comparing them with the contrary side: "But if, omitting all these things with which we abound, and they want, the senate, the knights, the populace, the city, treasury, revenues, all Italy, the provinces, and foreign nations; if, I say, omitting these things, we compare the causes themselves in which each side is engaged, we may learn from thence how despicable they are.—For on this side modesty is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that fraud; on this piety, on that profaneness; on this con-

**Elocution:** constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion: In a word, equity, temperance, fortitude, prudence, and all virtues, contend with injustice, luxury, cowardice, rashness, and all vices; plenty with want; reason with folly; sobriety with madness; and, lastly, good hope with despair. In such a contest, did men desert us, would not heaven ordain that so many and so great vices should be defeated by these most excellent virtues?"

Gradation is another beautiful way of doing this. So when Cicero would aggravate the cruelty and barbarity of Verres for crucifying a Roman citizen, which was a sort of punishment only inflicted upon slaves, he chooses this way of doing it. "It is a crime (says he) to bind a Roman citizen, wickedness to whip him, and a sort of parricide to kill him; what then must I call it to crucify him? No name can sufficiently express such a villany." And the images of things may be thus heightened, either by ascending, as in this instance; or descending, as in that which follows, re-

lating to the same action of Verres: "Was I not to complain of or bewail these things to Roman citizens, nor the friends of our state, nor those who had heard of the Roman name; nay, if not to men, but beasts; or, to go yet further, if in the most desert wilderness, to stones and rocks; even all mute and inanimate creatures would be moved by so great and heinous cruelty."

And, to name no more, facts may be amplified from their circumstances; as time, place, manner, event, and the like. But instances of this would carry us too far; and therefore we shall only add, that, as the design of *amplification* is not barely to prove or evince the truth of things, but also to adorn and illustrate them, it requires a florid and beautiful style, consisting of strong and emphatical words, flowing periods, harmonious numbers, lively tropes, and bright figures. But the consideration of these things come under the third part of oratory, upon which we are now to enter.

### PART III. OF ELOCUTION.

**E**LOCUTION directs us to suit both the words and expressions of a discourse to the nature of the subject, or to speak with propriety and decency. This faculty is in one word called *eloquence*; and those persons who are possessed of it are therefore styled *eloquent*.

*Elocution* is twofold, general and particular. The former treats of the several properties and ornaments of language in common; the latter considers them as they are made use of to form different sorts of style.

#### I. GENERAL ELOCUTION.

41  
General  
Elocution  
defined.

THIS, according to rhetoricians, consists of three parts; *Elegance*, *Composition*, and *Dignity*. A discourse which has all these properties suitably adjusted, must, with respect to the language, be perfect in its kind, and delightful to the hearers.

##### CHAP. I. Of Elegance.

ELEGANCE consists in two things, *Purity* and *Per-spiciuity*: And both these, as well with respect to single words, as their construction in sentences. These properties in language give it the name of *elegant*, for a like reason that we call other things so which are clean and neat in their kind. But in the common use of our tongue, we are apt to confound *elegance* with *eloquence*; and say, *a discourse is elegant*, when we mean by the expression, that it has all the properties of fine language.

##### § 1. Purity.

42  
Purity ex-  
plained and  
illustrated.

By this we are to understand the choice of such words and phrases as are suited and agreeable to the use of the language in which we speak: and so grammarians reduce the faults they oppose to it to two sorts, which they call *barbarism* and *solecism*; the former of which respects single words, and the latter their construction. But we shall consider them jointly, and

in a manner different from grammarians; for with them all words are esteemed pure which are once adopted into a language, and authorized by use. And as to phrases, or forms of expression, they allow them all the same claim, which are agreeable to the analogy of the tongue. But in oratory, neither all words nor all expressions are so called which occur in language; but such only as come recommended by the authority of those who speak or write with accuracy and politeness. Indeed it is a common saying, *that we should think with the learned, and speak with the vulgar*. But the meaning of that expression is no more than that we should speak agreeably to the common usage of the tongue, that every one may understand us; and not choose such words or expressions as are either difficult to be understood, or may carry in them an appearance of affectation and singularity. But in order to set this matter in a clearer light, we shall here recount the principal things which vitiate the purity of language.

And first, it often happens, that such words and forms of speaking as were introduced by the learned are afterwards dropped by them as mean and sordid, from a seeming baseness contracted by vulgar use. For polite and elegant speakers distinguish themselves by their discourse, as persons of figure do by their garb; one being the dress of the mind, as the other is of the body. And hence it comes to pass, that both have their different fashions, which are often changed; and as the vulgar affect to imitate those above them in both, this frequently occasions an alteration when either becomes too trite and common. But beside these sordid words and expressions, which are rendered so by the use of the vulgar, there is another sort first introduced by them, which is carefully to be avoided by all those who are desirous to speak well. For the vulgar have their peculiar words and phrases, suited to their circumstances, and taken from such things as usually occur in their way of life. Thus in the old comedians, many things are spoken by servants, agreeable to their character, which would be

Elocution. very unbecoming from the mouth of a gentleman. And we cannot but daily observe the like instances among ourselves.

Again, this is common to language with all other human productions, that it is in its own nature liable to a constant change and alteration. For, as Horace has justly observed,

All human works shall waste;  
Then how can feeble words pretend to last.

Nothing could ever please all persons, or at least for any length of time. And there is nothing from which this can less be expected than language. For as the thoughts of men are exceedingly various, and words are the signs of their thoughts, they will be constantly inventing new signs to express them by, in order to convey their ideas with more clearness or greater beauty. If we look into the different ages of the Latin writers, what great alterations and changes do we find in their language? How few now understand the remaining fragments of the *twelve tables*? Nay, how many words do we meet with even in Plautus, the meaning of which has not yet been fixed with certainty by the skill of the best critics? And if we consider our own language, it will appear to have been in a manner entirely changed from what it was a few ages since. To mention no others, the celebrated Chaucer is to most persons now almost unintelligible, and wants an expofitor. And even since our own memory, we cannot but have observed, that many words and expressions, which a few years ago were in common use, are now in a manner laid aside and antiquated; and that others have constantly succeeded, and daily do succeed, in their room. So true is that observation of the same poet:

Some words that have or else will feel decay  
Shall be restor'd, and come again in play;  
And words now fam'd shall not be fancied long;  
They shall not please the ear, nor move the tongue:  
As use shall these approve, and those condemn;  
Use, the sole rule of speech, and judge supreme.

We must therefore no less abstain from antiquated or obsolete words and phrases, than from fordid ones. Though all old words are not to be thought antiquated. By the former we mean such as, though of an ancient standing, are not yet entirely disused nor their signification lost. And from the use of these we are not to be wholly debarred, especially when they appear more significant than any others we can fix upon. But as to phrases or expressions, greater caution seems still necessary: and such as are old should doubtless, if at all, be used more sparingly. The Latin tongue was brought to its greatest perfection in the reign of Augustus, or somewhat sooner; and he himself studied it very carefully. For, as Suetonius tells us, "He applied himself to eloquence, and the study of the liberal arts, from his childhood, with great diligence and labour. He chose a manner of speaking which was smooth and elegant: he avoided the ill savour, as he used to call it, of antiquated words; and he was wont to blame Tiberius for his affectation of them." In our own language, such words are to be esteemed antiquated, which the most polite persons have dropped, both in their discourse and writings; whose example

Elocution. we should follow, unless we would be thought to converse rather with the dead than the living.

But further: As on the one hand we must avoid obsolete words and phrases; so, on the other, we should refrain from new ones, or such whose use has not yet been sufficiently established, at least among those of the best taste. Words may be considered as new in two respects; either when they are first brought into a language, or when they are used in a new sense. As the former of these may sometimes leave us in the dark by not being understood, so the latter are most apt to mislead us; for when we hear a word that has been familiar to us, we are presently led to fix that idea to it with which it has usually been attended. And therefore, in both cases, some previous intimation may be necessary. Cicero, who perhaps enlarged the furniture of the Roman tongue more than any one person besides, appears always very cautious how he introduces any thing new, and generally gives notice of it when he attempts it, as appears in many instances scattered through his works. What bounds we are now to fix to the purity of the Latin tongue in the use of it, the learned are not well agreed. It is certain, our furniture is much less than when it was a living language, and therefore the greater liberty must of necessity be sometimes taken. So that their opinion seems not unadvisable, who direct us to make choice principally of what we are furnished with from the writers of the Augustan age; and, where we cannot be supplied from them, to make use of such authors as lived nearest to them, either before or since. And as to our own tongue, it is certainly prudent to be as careful how we admit any thing into it that is uncouth or disagreeable to its genius, as the ancient Romans were into theirs; for the perfection of a language does in a great measure consist in a certain analogy and harmony running through the whole, by which it may be capable of being brought to a standard.

But besides those things already mentioned, any mistake in the sense of words, or their construction, is opposed to purity. For to speak purely, is to speak correctly. And such is the nature of these faults in elocution, that they are often not so easy to be observed by hearing as by reading. Whence it is, that many persons are thought to speak better than they write; for while they are speaking, many slips and inaccuracies escape disregarded, which in reading would presently appear. And this is more especially the case of persons unacquainted with arts and literature; who, by the assistance of a lively fancy and flow of words, often speak with great ease and freedom, and by that means please the ear; when, at the same time, what they say, would not so well bear reading.

We shall only add, that a distinction ought likewise to be made between a poetic diction and that of prose writers. For poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words; so that what is a beauty in them would often appear unnatural and affected in prose.

#### § 2. Of Perspicuity.

PERSPICUITY, as well as *purity*, consists partly in *single words*, and partly in their *construction*.

43  
Perspicuity  
explained  
and illustrated.

I. As

Elocution.

44  
As to single  
words.

I. As to *single words*, those are generally clearest and best understood which are used in their proper sense. But it requires no small attention and skill to be well acquainted with the force and propriety of words; which ought to be duly regarded, since the perspicuity of a discourse depends so much upon it. Cæsar seems plainly to have been of this mind, when he tells us, "The foundation of eloquence consists in the choice of words." It may not be amiss, therefore, to lay down some few observations, by which the distinct notions of words and their peculiar force may more easily be perceived. All words may be divided into *proper words* and *tropes*. Those are called *proper words*, which are expressed in their proper and usual sense. And *tropes* are such words as are applied to some other thing than what they properly denote, by reason of some similitude, relation, or contrariety between the two things. So, when a subtle artful man is called a *fox*, the reason of the name is founded in a similitude of qualities. If we say, *Cicero will always live*, meaning *his works*, the cause is transferred to the effect. And when we are told, *Cæsar conquered the Gauls*, we understand that he did it with the assistance of his army; where a part is put for the whole, from the relation between them. And when Cicero calls Antony a *fine guardian of the state*, every one perceives he means the contrary. But the nature and use of tropes will be explained more fully hereafter in their proper place. All words must at first have had one original and primary signification, which, strictly speaking, may be called their *proper sense*. But it sometimes happens through length of time, that words lose their original signification, and assume a new one, which then becomes their proper sense. So *hostis* in the Latin tongue at first signified a *stranger*; but afterwards that sense of the word was entirely laid aside, and it was used to denote a *public enemy*. And in our language, it is well known, that the word *knave* anciently signified a *servant*. The reason of the change seems to be much the same, as in that of the Latin word *latro*; which first signified a *soldier*, but afterwards a *robber*. Besides, in all languages it has frequently happened, that many words have gradually varied from their first sense to others somewhat different; which may, notwithstanding, all of them, when rightly applied, be looked upon as proper. Nay, in process of time, it is often difficult to say which is the original, or most proper sense. Again, sometimes two or more words may appear to have the same signification with each other, and may therefore be used indifferently; unless the beauty of the period, or some other particular reason, determine to the choice of one rather than another. Of this kind are the words *ensis* and *gladius* in the Latin tongue; and in ours, *pity* and *compassion*. And there are other words of so near an affinity to each other, or at least appear so from vulgar use, that they are commonly thought to be synonymous. Such are the words *mercy* and *pity*; though mercy in its strict sense is exercised towards an offender, and pity respects one in distress. As this peculiar force and distinction of words is carefully to be attended to, so it may be known several ways. Thus the proper signification of substantives may be seen by their application to other substantives. As in the instance just now given, a person is said to show *mercy*

to a criminal, and *pity* to one in distress. And in the like manner, verbs are distinguished, by being joined to some certain nouns, and not to others. So a person is said to *command an inferior*, to *intreat a superior*, and to *desire an equal*. Adjectives also, which denote the properties of things, have their signification determined by those subjects to which they most properly relate. Thus we say, *an honest mind*, and *a healthful body*; *a wise man*, and *a fine house*. Another way of distinguishing the propriety of words, is by their use in gradations. As if one should say, *Hatreds, grudges, quarrels, tumults, seditions, wars, spring from unbridled passions*. The proper sense of words may likewise be known by observing to what other words they are either opposed, or used as equivalent. So in that passage of Cicero, where he says, "I cannot perceive why you should be angry with me: If it be because I defend him whom you accuse, why may not I be displeased with you for accusing him whom I defend? You say, I accuse my enemy; and I say, I defend my friend." Here the words *accuse* and *defend*, *friend* and *enemy*, are opposed; and *to be angry* and *displeased*, are used as terms equivalent. Lastly, the derivation of words contributes very much to determine their true meaning. Thus because the word *manners* comes from the word *man*, it may properly be applied either to that or any other put for it. And therefore we say, *the manners of men*, and *the manners of the age*, because the word *age* is there used for *the men of the age*. But if we apply the word *manners* to any other animal, it is a trope. By these and such like observations we may perceive the proper sense and peculiar force of words, either by their connection with other words, distinction from them, opposition to them, equivalency with them, or derivation. And by thus fixing their true and genuine signification, we shall easily see when they become tropes. But though words, when taken in their proper signification, generally convey the plainest and clearest sense; yet some are more forcible, sonorous, or beautiful, than others. And by these considerations we must often be determined in our choice of them. So whether we say, *he got*, or *he obtained*, *the victory*, the sense is the same; but the latter is more full and sonorous. In Latin, *timeo* signifies *I fear*; *pertimeo* is more full and significant; and *pertimesco* more sonorous than either of the former. The Latin and Greek languages have much the advantage of ours in this respect, by reason of their compositions; by the help of which they can often express that in one word for which we are obliged to put two words, and sometimes more. So *pertimeo* cannot be fully expressed in our language by one word; but we are forced to join one or two particles to the verb, to convey its just idea, and say, *I greatly*, or *very much fear*: and yet even then we scarce seem to reach its full force. As to tropes, though generally speaking they are not to be chosen where plainness and perspicuity of expression is only designed, and proper words may be found; yet through the penury of all languages, the use of them is often made necessary. And some of them, especially metaphors, which are taken from the similitude of things, may, when custom has rendered them familiar, be considered as proper words, and used in their stead. Thus, whether we say, *I see your meaning*, or, *I understand your meaning*, the sense is equally clear, though the

Elocution.

the latter expression is proper, and the former metaphorical, by which the action of seeing is transferred from the eyes to the mind.

45  
As to the  
construction  
of sentences.

II. But *perspicuity* arises not only from a choice of *single words*, but likewise from the *construction* of them in sentences. For the meaning of all the words in a sentence, considered by themselves, may be very plain and evident; and yet by reason of a disorderly placing them, or confusion of the parts the sense of the whole may be very dark and obscure. Now it is certain, that the most natural order is the plainest; that is, when both the words and parts of a sentence are so disposed, as best agrees with their mutual relation and dependence upon each other. And where this is changed, as is usually done, especially in the ancient languages, for the greater beauty and harmony of the periods; yet due regard is had by the best writers to the evidence and perspicuity of the expression.

But to set this subject in a clearer light, on which the perfection of language so much depends, we shall mention some few things which chiefly occasion obscurity; and this either with respect to single words, or their construction.

And first, all ambiguity of expression is one cause of obscurity. This sometimes arises from the different senses in which a word is capable of being taken. So we are told, that upon Cicero's addressing himself to Octavius Cæsar, when he thought himself in danger from his resentment, and reminding him of the many services he had done him, Octavius replied, *He came the last of his friends*. But there was a designed ambiguity in the word *last*, as it might either respect the time of his coming, or the opinion he had of his friendship. And this use of ambiguous words we sometimes meet with, not only in poetry, where the turn and wit of an epigram often rests upon it; but likewise in prose, either for pleasantry or ridicule. Thus Cicero calls Sextus Clodius *the light of the senate*; which is a compliment he pays to several great men, who had distinguished themselves by their public services to their country. But Sextus, who had a contrary character, was a relation of P. Clodius, whose dead body, after he had been killed by Milo, he carried in a tumultuous manner into the senate-house, and there burnt it with the senators benches, in order to inflame the populace against Milo. And it is in allusion to that riotous action, that Cicero, using this ambiguous expression, calls him *the light of the senate*. In such instances, therefore, it is a beauty, and not the fault we are cautioning against: as the same thing may be either good or bad as it is differently applied.— Though even in such designed ambiguities, where one sense is aimed at, it ought to be sufficiently plain, otherwise they lose their intention. And in all serious discourses they ought carefully to be avoided. But obscurity more frequently arises from the ambiguous construction of words, which renders it difficult to determine in what sense they are to be taken. Quintilian gives us this example of it: “A certain man ordered in his will, that his heir should erect for him a statue holding a spear made of gold.” A question arises here, of great consequence to the heir from the ambiguity of the expression, whether the words *made of gold* are to be applied to the *statue* or the *spear*; that is, whe-

ther it was the design of the testator by this appointment, that the whole statue, or only the spear, should be made of gold. A small note of distinction, differently placed between the parts of this sentence, would clear up the doubt, and determine the sense either way. For if one comma be put after the word *statue*, and another after *spear*, the words *made of gold* must be referred to the statue, as if it had been said, *a statue made of gold, holding a spear*. But if there be only the first comma placed after *statue*, it will limit the words *made of gold* to the *spear* only; in the same sense as if it had been said, *A statue holding a golden spear*. And either of these ways of expression would in this case have been preferable, for avoiding the ambiguity, according to the intention of the testator. The ancient heathen oracles were generally delivered in such ambiguous terms. Which, without doubt, were so contrived on purpose, that those who gave out the answers might have room left for an evasion. See ORACLE.

Again, obscurity is occasioned either by too short and concise a manner of speaking, or by sentences too long and prolix; either of these extremes have sometimes this bad consequence. We find an instance of the former in Pliny the elder, where speaking of hellebore, he says, “They forbid it to be given to aged persons and children, and less to women than men.” The verb is wanting in the latter part of the sentence, *and less to women than men*: which in such cases being usually supplied from what went before, would here stand thus; *and they forbid it to be given less to women than men*. But this is directly contrary to the sense of the writer, whose meaning is, either that it is ordered to be given in a less quantity to women than men, or not so frequently to women as men. And therefore the word *order* is here to be supplied, which being of a contrary signification to *forbid*, expressed in the former part of the sentence, occasions the obscurity. That long periods are often attended with the same ill effect, must be so obvious to every one's experience, that it would be entirely needless to produce any examples in order to evince the truth of it. And therefore we shall only observe, that the best way of preventing this seems to be by dividing such sentences as exceed a proper length into two or more; which may generally be done without much trouble.

Another cause of obscurity, not inferior to any yet mentioned, is *parenthesis*, when it is either too long or too frequent. This of Cicero, in his oration for Sylla, is longer than we usually find in him: “O immortal gods! (for I must attribute to you what is your own; nor indeed can I claim so much to my own abilities as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state), you inflamed my mind with a desire to save my country.” But where any obscurity arises from such sentences, they may frequently be remedied by much the same means as was just now hinted concerning long and prolix periods; that is by separating the parenthesis from the rest of the sentence, and placing it either before or after. So in this sentence of Cicero, the parenthesis may stand last, in the following manner:— “O immortal gods! you inflamed my mind with a desire to save my country: for I must attribute to you what is your own; nor indeed can I claim so much to my

Elocution.

**Elocution.** my own abilities, as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state." This order of the sentence is very plain, and less involved than the former.

## CHAP. II. Of Composition.

46  
Composition defined and divided.

COMPOSITION, in the sense it is here used, gives rules for the structure of sentences, with the several members, words, and syllables, of which they consist, in such a manner as may best contribute to the force, beauty, and evidence of the whole.

Composition consists of four parts, which rhetoricians call *period, order, juncture, and number*. The first of these treats of the structure of sentences; the second, of the parts of sentences, which are words and members; and the two last, of the parts of words, which are letters and syllables. For all articulate sounds, and even the most minute parts of language, come under the cognizance of oratory.

### § 1. Of Period.

47  
Period defined and explained.

In every sentence or proposition, something is said of something. That of which something is said, logicians call the *subject*, and that which is said of it, the *predicate*: but in grammatical terms, the former is a *noun substantive of the nominative case*, and the latter a *finite verb*, denoting affirmation, and some state of being, acting, or suffering. These two parts may of themselves constitute a sentence: As when we say, *The sun shines*, or *The clock strikes*, the word *sun* and *clock* are the subject in these expressions, *shines* and *strikes* imply each the copula and predicate. Most commonly, however, the noun and the verb are accompanied with other words, which in grammatical construction are said either to be connected with or to depend upon them; but in a logical consideration they denote some property or circumstance relating to them. As in the following sentence: *A good man loves virtue for itself*. The subject of this sentence is *a good man*; and the predicate, or thing affirmed of him, that he *loves virtue for itself*. But the two principal or necessary words, on which all the rest depend, are *man* and *loves*. Now a simple sentence consists of one such noun and verb, with whatever else is joined to either or both of them. And a compound sentence contains two or more of them; and may be divided into so many distinct propositions, as there are such nouns and verbs, either expressed or understood. So in the following sentence, *Compliance gains friends, but truth procures hatred*, there are two members, each of which contains in it an entire proposition. For, *Compliance gains friends* is one complete sentence, and *Truth procures hatred* is another; which are connected into one compound sentence by the particle *but*. Moreover, it frequently happens, that compound sentences are made up of such parts or members, some if not all of which are themselves compounded, and contain in them two or more simple members. Such is that of Sallust: "*Ambition has betrayed many persons into deceit; to say one thing, and to mean another; to found friendship and enmity, not upon reason, but interest; and to be more careful to appear honest, than really to be so.*" This sentence consists of four members; the last of which

**Elocution.** three, consisting of opposite parts, are all compounded, as will appear by expressing them at length in the following manner: *Ambition has betrayed many persons into deceit; [that is, ambition] has betrayed them to say one thing, and to mean another; it has betrayed them to found friendship and enmity, not upon reason, but interest; and it has betrayed them to be more careful to appear honest, than really to be so.* The three last of these members, beginning with the words *it betrays*, are all of them compounded, and consist of two opposite members; which might each of them be expressed at length in the same manner, by supplying the ellipsis. As, *Ambition has betrayed many persons to say one thing, and it has betrayed them to mean another.* And so of the rest. From this instance we see how much is left to be supplied by the mind in all discourse, which if expressed would both destroy its harmony and render it exceedingly tedious. But still regard must be had to that which is omitted, so as to render what is said consistent with it; otherwise there can be no propriety in what is spoken. Nor can the members of a sentence be distinguished and duly ranged in their proper order, without this. But to proceed: Some sentences consist either wholly, or in part, of such members as contain in them two or more compound ones, which may therefore for distinction's sake, be called *decompound members*.—Of this kind is that of Cicero, in his defence of Milo: "Great is the force of conscience, great either way: that those persons are not afraid who have committed no offence; and those who have offended always think punishment present before their eyes." The latter member of this sentence, which begins with the word *that*, contains in it two compound members, which represent the different state of mind between innocent and guilty persons. And it is in the proper distinction and separation of the members in such complex sentences, that the art of pointing chiefly consists. For the principal use of a comma is to divide the simple members, a semicolon the compound ones, a colon such as are decompounded, and a period the whole from the following sentence. We mention this the rather, to show the different acceptation of these terms by grammarians, from that of the ancient writers upon oratory. For these latter apply them to the sense, and not to any points of distinction. A very short member, whether simple or compound, with them is a comma, and a longer a colon; for they have no such term as a semicolon. Besides, they call a very short sentence, whether simple or compound, a *comma*, and one of somewhat a greater length, a *col.n.* And therefore, if a person expressed himself either of these ways in any considerable number of sentences together, he was said to speak by commas or colons. But a sentence containing more words than will consist with either of these terms, they call a simple period; the least compound period with them requiring the length of two colons. However, this way of denominating sentences, and the parts of them, rather from their length than the nature of them, appearing not so suitable, we have chosen rather to make use of the terms *simple and compound members*; and to call all those *compound periods*, which contain two or more members, whether simple or compound.

But to proceed: Sentences, with respect to their form or composition, are distinguished into two sorts, called

Elocution.

called by Cicero *tracta*, "straight or direct;" and *contorta*, "bent or winding." By the former are meant those whose members follow each other in a direct order, without any inflection; and by the latter, those which strictly speaking are called *periods*. For *περίοδος* in Greek signifies a *circuit* or *circle*. And so the Latins call it *circuitus* and *ambitus*. By which both of them mean a sentence consisting of correspondent parts, so framed, that the voice in pronouncing them may have a proper elevation and cadency, and distinguish them by its inflection; and as the latter part returns back, and unites with the former, the period, like a circle, surrounds and incloses the whole sense. This elevation of the voice in the former part of the period, is by the Greeks called *πρότασις*, and by the Latins *propositio*; and the depression of it in the latter part, by the one *ἀποδοσις*, and by the other *reditio*.

Now as simple sentences have not these correspondent parts, which require any inflection of the voice; nor a circular form, by reason of their brevity; they are not properly periods, in the strict sense of the word: though in common speech, the words *sentence* and *period* are often used as equivalent terms. Thus, if we say, *Generous minds are incited to the performance of noble exploits from motives of glory*; here is no distinction of parts, nor inflection of the voice in this sentence. And indeed there is not any thing which relates to the structure of these sentences, but what will more properly be taken notice of in the second part of *composition*, which is *order*.

And as to those compound sentences, whose members follow each other in a direct order, without any inflection, there is little art required in their composition. We shall produce one example of this kind from Cicero: "Natural reason inclines men to mutual converse and society; and implants in them a strong affection for those who spring from them; and excites them to form communities, and join in public assemblies; and, for these ends, to endeavour to procure both the necessities and conveniences of life; and that not for themselves only, but likewise for their wives, children, and others who are dear to them, and have a right to their assistance." Here are five short members in this sentence, placed in a series, without any inflection of the parts, or orbit of the whole. And as such sentences have no other boundary but the conclusion of the sense, suited to the breath of the speaker, he may either contract or lengthen them at pleasure, without offending the ear. So, should the sentence last mentioned conclude with the first member in this manner, *Natural reason inclines men to mutual converse and society*; the sense would be perfect, and the ear satisfied. The case would be the same at the end of the second member, thus: *Natural reason inclines men to mutual converse and society, and implants in them a strong affection for those who spring from them*. And the like may be said of the rest. Since such sentences therefore may be thus limited at pleasure, it seems more convenient both for the speaker and hearers to confine them to a moderate length.

But because the principal art relating to this part of composition lies in the frame and structure of such compound sentences as are properly called *periods*, we shall treat upon these somewhat more largely. In the

Elocution.

formation of these periods, two things are chiefly to be regarded; their *length*, and *cadency*. As the length ought to be suited to the breadth of the speaker, the ancient rhetoricians scarce admit of more than four colons; by which we may here understand compound members of a moderate size, which will be generally found a suitable and proportionate length. For to extend them farther than the voice can well manage must be painful to the speaker, and of consequence unpleasant to the hearers. As to the cadency, what Cicero has observed, is found true by experience, that the ears judge what is full and what is deficient; and direct us to fill up our periods, that nothing be wanting of what they expect. When the voice is raised at the beginning of a sentence, they are in suspense till it be finished; and are pleased with a full and just cadency, but are sensible of any defect, and are displeased with redundancy. Therefore care must be taken that periods be neither deficient, and as it were maimed, that is, that they do not drop before their time, and defraud the ears of what seemed to be promised them; nor, on the other hand, offend them by too long and immoderate excursions. This rise and cadency of the voice in pronunciation, depend on the nature and situation of the members, as we shall endeavour to show by particular instances; in the explanation of which, by the word *members*, are to be understood such as are uncompounded. In a period of two members, the turn of the voice begins with the latter member. Of this kind is the following sentence of Cicero: "If impudence prevailed as much in the forum and courts of justice, as insolence does in the country and places of less resort; Aulus Cæcina would submit as much to the impudence of Sextus Ebutius in this cause, as he did before to his insolence when assaulted by him." Here the cadency begins at the words *Aulus Cæcina*. If a sentence consist of three members, the inflection is best made at the end of the second member: for if it begin immediately after the first, the voice will be either apt to sink too low, and not to be heard, before it reach the end; or else be precipitated, in order to prevent it. Cicero begins his oration for Milo with a sentence of this form: "Although I fear, it may be a shame to be dismayed at the entrance of my discourse in defence of a most valiant man; and that it nowise becomes me, while Milo is more concerned for the safety of the state than for himself, not to show the same greatness of mind in his behalf: yet this new form of prosecution terrifies my eyes, which, whatever way they turn, want the ancient custom of the forum, and former manner of trials." Here the cadency beginning at the third member with the word *yet*, makes a proper division of the sentence, and easy for the speaker. But a period of four members is reckoned the most complete and perfect, where the inflection begins at the middle, that is, with the third member. Nor is it the same case here, as if, in a sentence of three members, the cadency be made at the second. For in proportion to the time of raising the voice may the space be allowed for its sinking. The following sentence of Cicero gives us an instance of this, where he speaks to his son: "Although, son Mark, having now been an hearer of Cratippus for a year, and this at Athens, you ought to abound in the precepts and doctrines of philosophy,

Elocution

Elocution

philosophy, by reason of the great character both of your instructor and the city; one of which can furnish you with knowledge, and the other with examples: yet, as I always to my advantage joined the Latin tongue with the Greek, and have done it not only in oratory, but likewise in philosophy; I think you ought to do the same, that you may be equally conversant in both languages." The turn in this period begins at the word *yet*; which standing near the middle, the voice is raised to that pitch in pronouncing the former part, as to admit of a gradual cadency, without being lost before the conclusion of the sentence. But where the sense does not suit with this division at the entrance upon the third member, it is best made at the fourth. Such is the following sentence of Cicero: "If I have any genius, which I am sensible is very small: or any readiness in speaking, wherein I do not deny but I have been much conversant; or any skill in oratory, from an acquaintance with the best arts, to which I confess I have been always inclined: *no one* has a better right to demand of me the fruit of all these things, than this Aulus Læcinius." The cadency of this sentence does not begin till the words *no one*; yet it ends handsomely, and without disappointing the ear. Though indeed the three first members having each of them an inflection, check the elevation of the voice, and by that variety in the pronunciation add to the harmony of the sentence. An equality of the members should likewise be attended to in the composition of a period, the better to adjust their rise and cadency. And for this reason, in sentences of three members, where the cadency begins with the third; or in those of four members, where it begins at the fourth; it promotes the harmony to make the last member longest. This is properly the nature of rhetorical periods, which when rightly formed have both an equal beauty and dignity in their composition.

But as all discourse is made up of distinct sentences, and whenever we express our thoughts it is in some of the forms abovementioned; so the use of them is not promiscuous, but suited to answer different designs in speaking. And in this view they are considered and made use of by the orator, as will be shown hereafter.

### § 2. Of Order.

48  
Order defined and illustrated.

By *order*, rhetoricians mean the placing each word and member of a sentence in such a manner as will most contribute to the force, beauty, or evidence of the whole,

Order is of two kinds, *natural* and *artificial*. And each of these may be considered with respect to the parts either of simple or compound sentences.

As to simple sentences, we may call that order *natural*, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction. And it may properly enough admit of this name, as it is founded in the nature of a proposition, and the relation of the several words of which it consists to each other. This we explained in the last chapter; and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon. And it is this: *The fame of Isocrates excited Aristotle to the profession of oratory.* Here these words, *the fame*

*of Isocrates*, contain the subject of this sentence, with what relates to it; and all those which follow, *excited Aristotle to the profession of oratory*, make up the predicate and its dependants. And in both parts each word grammatically considered stands in its proper order of construction. And this seems agreeable to the natural way of conveying our thoughts, which leads us first to express the subject or thing of which some other thing is said, before the predicate or that which is said concerning it; and with respect to both, as every idea succeeds another in the order of our conceptions, to range it in the same order when we communicate them to others. Our language in the general keeps pretty much to this method. But in one thing particularly it recedes from it; and that is, in placing adjectives, which denote the properties of things, before their substantives or subjects, whose properties they are: As when it is said, *Evil communication corrupts good manners.* And this we always do, except something follows which depends upon the adjective. So we say, *He was a man eminent for his virtue*: not *an eminent man*.

*Artificial* order, as it respects simple sentences, has little or no regard to the natural construction of words; but disposes them in such a manner as will be most agreeable to the ear, and best answer the design of the speaker. The Latins take a much greater liberty in this respect than we do, or than the nature of our language will permit. Quintilian says, it is best for the verb to stand last, when there is no particular reason to the contrary. And he gives this reason for it, *because the force of the sentence lies in the verb*. So that, according to him, they seem to have had this view in putting the verb at the end; that as the whole sentence is imperfect without the verb, the mind being thus held in suspense might receive the deeper impression from it at last. They likewise separate such words as have an immediate relation between them or dependence one upon another, and place any of them first or last as they please. In short, their order seems in a manner arbitrary, if it does not break in upon perspicuity, to which they usually attend. But most of these things are unsuitable to the genius of our language. One might say indeed, *Convince him you cannot*; instead of saying, *You cannot convince him*: Or, *With my own eyes I saw it*; for, *I saw it with my own eyes*. And again: *In proportion to the increase of luxury the Roman state declined*; for, *The Roman state declined in proportion to the increase of luxury*. But this inversion of words is proper in English composition only when it gives force to the expression; as in the higher style it often does. It serves to impress known truths upon the mind, but is unfit for communicating the first principles of knowledge.

As to compound sentences, that is, such as consist of two or more members, either simple or compound; what relates to the words in each member separately is the same as in simple sentences. But with regard to the disposition of the several members, that may be called the *natural order*, which so places them as they mutually depend on each other. Thus the antecedent member naturally precedes the relative; as in this expression, *Men are apt to forgive themselves what they blame in others*. In hypothetical sentences the conditional member naturally stands first. Thus: *If Socrates be a rational creature, he is a man.* That

Elocution.

member which expresses the effect of an action naturally comes last; as, *Though you offer ever so good reasons, you will not prevail with him.* The like may be said of time, with regard to things done in it; as *The Roman eloquence soon declined, when Cicero was dead.* And to name no more, the reason of a thing naturally follows that of which it is the reason; as thus: *All the pleasures of life must be uncertain, since life itself is not secure.*

When this order is inverted, it may be styled *artificial*. So to keep to the instances already given, the two members in the first sentence may be thus inverted: *What they blame in others men are apt to forgive themselves.* In the second, in this manner: *Socrates is a man, if he be a rational creature.* In the third, thus: *You will not prevail with him, though you offer ever so good reasons.* And so in the rest: As, *When Cicero was dead, the Roman eloquence soon declined;* and, *Since life itself is not secure, all the pleasures of life must be uncertain.* The variety of inversions in a sentence may generally be greater or less in proportion to the number of its members. In the following sentence of Cicero, the natural order seems to be this: *If that greatness of mind be void of justice, which shows itself in dangers and labours, it is blameable.* Which may be varied by changing the place of the first and third member, in the following manner: *That greatness of mind is blameable which shows itself in dangers and labours, if it want justice.* Or by altering the place of all the three members thus: *That greatness of mind is blameable, if it be void of justice, which shows itself in dangers and labours.* But oftentimes one member may be included in another, as in the instance here given: *If that greatness of mind which shows itself in dangers and labours, be void of justice, it is blameable.* Here the relative member is included in the conditional, which is placed first, and the antecedent member follows both. But in Cicero it stands thus: *That greatness of mind, which shows itself in dangers and labours, if it want justice, is blameable;* where the relative and conditional members are both included in the antecedent member. The Latin tongue commonly admits of a much greater variety in the transposition of members, as well as in that of single words, than suits with our idiom. In the following sentence the natural order is much preferable, as it best suits with the proper elevation and cadency of the voice in its pronunciation: *I am willing to remit all that is past, provided it may be done with safety.* But should we invert the members, and say, *Provided it may be done with safety, I am willing to remit all that is past;* the harmony of the cadency would be lost. And if the latter member be included in the former, the alteration will still be worse; as, *I am willing, provided it may be done with safety, to forgive all that is past.* Here the inflection of the voice falls upon the same member as before, and destroys the beauty of the period by its elevation afterwards. Some sentences admit of no involution of their members. Such are those whose members are connected by conjunctive or disjunctive particles. As, *Virtue furnishes the mind with the truest pleasure in prosperity, and affords it the greatest comfort in adversity.* And, *A wise man is neither elated by prosperity, nor distressed by adversity.* And the like may be said of those where the latter mem-

Elocution.

ber begins with some illative or redditive particle. As in these instances: *The chief thing to be regarded in life is virtue, for all other things are vain and uncertain.* And, *Though fortune is always inconstant, yet she has many votaries.* Neither of the members in any of these ways of expression, and some others which might be named, can be included one in the other. In all the examples hitherto given, the sentences consist only of simple members; and indeed compound members are not so often inverted, nor included one in another, by reason of their length. However, we shall here produce one instance of each: *Whoever considers the uncertainty of human affairs, and how frequently the greatest hopes are frustrated; he will see just reason to be always on his guard, and not place too much dependence upon things so precarious.* This sentence consists of two compound members, which here stand in their natural order, but may be thus inverted: *He will see just reason to be always on his guard, and not place too much dependence on things so precarious; whoever considers the uncertainty of human affairs and how often the greatest hopes are frustrated.* In the following sentence one compound member is included in another: *Let us not conclude while dangers are at a distance, and do not immediately approach us, that we are secure; unless we use all necessary precaution to prevent them.* Here the natural order would be: *While dangers are at a distance, and do not immediately approach us; let us not conclude, that we are secure, unless we use all necessary precaution to prevent them.*

But there are some other considerations relating to order, which, being taken from the nature of things, equally suit all languages. So, in amplifying, there should be a constant gradation from a less to a greater; as when Cicero says, *Ambition creates hatred, shyness, discords, seditions, and wars.* On the contrary, in extenuating we should descend from a greater to a less; as if, speaking of the ancient laws of Rome, one should say, *They were so far from suffering a Roman citizen to be put to death, that they would not allow him to be whipt, or even to be bound.* In constituting any whole, we put the parts first; as, *Invention, disposition, elocution, and pronunciation, make up the art of oratory.* But in separating any whole, the parts follow: as, *The art of oratory may be divided into these four parts; invention, disposition, elocution, and pronunciation.* In every enumeration care must be taken not to mix the whole with the parts; but if it be mentioned at all, it must either be put first or last. So it would be wrong to say, *He was a man of the greatest prudence, virtue, justice, and modesty:* for the word *virtue* here contains in it the other three, and therefore should not be inserted among them. See LANGUAGE, n° 17.

### § 3. Of Juncture and Number.

QUINTILIAN, speaking of composition, represents a discourse as very happy in that respect, when the order, *juncture*, and *number*, are all just and proper. The first of these which gives rules for the due placing of the words and members of a sentence, has been already explained. We now proceed to the other two, which relate to letters and syllables; the former treating of their connection, and the latter of their quantity.

I. As

Elocution.

49  
The nature and use of juncture explained and illustrated.

I. As to *juncture*. A due attention is to be paid to the nature of the vowels, consonants, and syllables in the connection of words, with regard to the sound.

As to the *first*, when a word ends with a vowel, and the next begins either with a different vowel, or the same repeated, it usually renders the pronunciation hollow and unpleasant. For, as Quintilian has justly observed, "This makes a chasm in the sentence, and stops the course of it." For there must be some pause, in order to pronounce them both, or otherwise the sound of one will be lost. So, for instance, in pronouncing these words, *the other day*, unless you stop a little after the word *the*, the sound of *e* will not be heard; and if it is dropt, it will occasion a rougher sound, from the aspiration of *th* twice repeated so near together, as *th' other day*. Therefore to prevent both these inconveniences, we usually say, *t' other day*. But the different consonants, which together with the vowels make up those syllables, often cause a considerable difference in the pronunciation, so as to render it more or less agreeable. As, if we say, *he overdid it*, the words *he over* have not so harsh a sound, as *the other*; though still they require some pause to keep them distinct. Besides, some vowels meet more amicably, and admit of a softer pronunciation, than others. Those which have the weakest and smallest sound, follow best; because they occasion the least alteration of the organ in forming the two sounds. Such are *e* and *i*; and therefore, without any chasm in the sound, or hesitation of the voice, we say, *he is*. But where the action of the organs is greater, and the sound stronger, the pronunciation is more difficult: as when we say, *thro' all*. For here is a contrary motion of the lips, which are first put forward in sounding the *o*, and then drawn backward to pronounce the *a*; and therefore the sound is much softer to say, *tho' every*, where their action is less. And the like ill effect commonly happens from the repetition of the same vowel: as if we say, *go on*; or, *you usually act thus*. There is a considerable difference between these two expressions, in repeating the sound of the vowel, and where either of them is doubled in a single word. For then the same sound only is protracted by one continued motion of the organ; as in the words *good*, and *deem*. But here the sound is repeated again by a new action of the organ; which, if precipitated, obscures the sound of one of the vowels; and, if too much retarded, makes a chasm in the pronunciation; either of which is unpleasant to the ear.

But as the coalition of two vowels occasions an hollow and obscure sound, so the meeting of some consonants renders it very harsh and rough. Thus the words *king Xerxes*, and *public good*, when so placed have not only a roughness, but likewise a difficulty in their pronunciation, from the contrary action of the lips; which in the former are first drawn back and then forward, but in the latter the contrary way, and in both of them with some considerable force. But this may very easily be avoided, by saying, with a little alteration in the words, *Xerxes the king*, and *the good of the public*. So likewise the words *ill company*, have a softer sound than *bad company*, for the same reason. To multiply instances of this kind seems unnecessary, which so frequently occur in all discourses.

The repetition of the same syllable, at the end and beginning of words, is the last thing to be considered. And a little observation will convince us, that where this happens, it generally renders the sound either confused or unpleasant. Cicero was often rallied on account of this verse:

*O fortunatam natam me consule Romam.*

Every one will easily perceive a disagreeable sound in the following expression: "A man many times does that unadvisedly, of which he afterwards repents." The chime of the words *man many* both seems affected, and displeases the ear. But this will soon be remedied, if we separate those two words, and say, "A man does that many times unadvisedly."

From the short account here given of this part of composition, it is easy to perceive what things are necessary to render it most complete and accurate; which are these following. If a word end with a vowel, the next ought to begin with a consonant, or such a vowel whose sound may agree well with the former. But if a word conclude with a consonant, either a vowel should follow, or such a consonant whose pronunciation will suit with it. And lastly, the same syllable ought not to be repeated at the end of one word, and the beginning of the next. It has been observed by some critics, that the following verse at the beginning of Virgil's *Æneid* has all these properties:

*Arma virumque cano, Trojæ qui primus ab oris.*

Where any word in this verse ends with a vowel, the next begins with a consonant; and where any one ends with a consonant, the next begins with a vowel; and there is no repetition of the same sound throughout the whole. But this is what rarely happens, especially in our language, which abounds with consonants. And what Quintilian says of the coalition of vowels, in treating upon this subject, seems applicable to the whole. "This (says he) is a thing not much to be dreaded; and I know not whether the neglect of it, or too great a concern about it, be worse. It necessarily checks the vigour of the mind, and diverts it from matters of greater importance. And therefore, as it shows negligence to permit it, so to be in constant fear of it discovers a low genius." This was the opinion of that judicious writer. And as these things cannot always be attended to, it may be sufficient to avoid them, where they prove very offensive to the ear, and it may be done without some greater inconvenience. So in this sentence, *Honesty is the best policy*, the coalition of *t* and *p* in the two last words *best policy* produces a roughness in their pronunciation; but as the expression is strong, and cannot perhaps be well altered for the better, the sound here ought to give way to the sense.

II. *Number*. This respects the quantity of syllables, as *Juncture* does their quality. In the Greek and Roman languages every syllable has its distinct quantity; and is either long, short, or common: two or more of which joined together in a certain order make a foot, and a determinate number of these in a different order constitute their several sorts of metre. This variety of sounds gives a much greater harmony to their poetry, than what can arise only from the

Elocution.

50  
The nature and use of number.

Elocution.

feat of the accent, and the similitude of sound at the end of two verses, which chiefly regulate our metre. And although their prose was not so confined with regard to the feet, either as to the kind or place of them, as their metrical compositions; yet it had a sort of measure, more especially in the rise and cadency of their periods. This they call *rhetorical number*. And accordingly the ancient writers upon this art acquaint us what feet are best suited to the beginning, middle, or conclusion of a sentence. Such rules are not applicable to our language, which has not that accurate distinction of quantity in its syllables. For we are apt to confound accent with quantity, and pronounce those syllables longest on which we lay the accent, though in their nature they are not so. As in the word *admirable*, where none but the first syllable *ad* is pronounced long; though that is only rendered so by position, and the two following are so by nature. And again, in the word *avarice*, we found the first a long for the same reason, and the second short; contrary to the nature of both these vowels. However, we shall offer a few things that may be of some use to modulate our periods and adjust their cadency.

A great number of monosyllables do not stand well together. For as there ought to be a greater distance in the pronunciation between one word and another, than between the syllables of the same word; such pauses, though short, yet, when too frequent, make the sound rough and uneven, and by that means spoil its harmony. And this may seem more necessary to be attended to, because the English language abounds so much with monosyllables. On the contrary, a continuation of many long words makes a sentence move too slow and heavily. And therefore such periods generally run best, which have a proper mixture of words of a different length. Besides, as every word has its accent, which with us stands for quantity, a number either of monosyllables, or long words, coming together, so far abates the harmony, as it lessens the variety.

Again several words of the same ending do not stand well together, especially where the accent falls upon the same syllable in each of them. For this creates too great a jingle by the similitude of sound; and is apt to displease, from an appearance of affectation. Of this kind is the following sentence: *Nothing is more welcome, delightful, or wholesome, than rest to a wearied man*. In such expressions therefore, if the order of the words cannot well be altered, some other word should be substituted in the room of one of them at least to diversify the sound. So in the example here given, the sound might be varied by saying, *Nothing is more welcome, pleasant, or wholesome*.

But to add no more, if a sentence end with a monosyllable, it is apt to hurt the cadency, and disappoint the ear; whereas words of a moderate length carry a greater force with them, by the fulness of their sound, and afford the ear what it expected. And there is one sort of monosyllables more especially, which never stand well at the conclusion of a period, though we frequently find them there; and these are the signs of cases. Thus we say, *Avarice is a crime, which wise men are too often guilty of*. But the cadency

would doubtless be more agreeable if it was altered thus: *Avarice is a crime, of which wise men are too often guilty*. Every one must perceive, when the accent falls upon the last syllable in the sentence, as it does if it end with *of*, the sound is not so pleasant as when it rests upon the preceding syllable in the word *guilty*. Nor are very long words well suited either to the beginning or conclusion of a period; for they retard the pronunciation at first, and fall too heavy at the end.

### CHAP. III. Of Dignity.

DIGNITY consists in the right use of tropes and figures. It is not sufficient for an orator to express himself with propriety and clearness, or in smooth and harmonious periods; but his language must likewise be suited to the nature and importance of the subject. And therefore, as *elegance* gives rules for the first of these, and *composition* for the second; so does *dignity* for the last of them. It is very evident, that different subjects require a different style and manner of expression; since, as Quintilian says, "What is magnificent in one discourse would be turgid in another; and those expressions which appear low upon a sublime subject, would suit lesser matters: and as in a florid harangue a mean word is remarkable, and like a blemish; so any thing lofty and bright upon a trivial argument is disproportionate, and like a tumour upon an even surface." Now this variety in the manner of expression arises in a great measure from tropes and figures, which not only enliven and beautify a discourse, but give it likewise force and grandeur; for which reason this part of elocution seems to have been called *dignity*.

Tropes and figures are distinguished from each other in several respects. Tropes mostly affect single words, but figures whole sentences. A trope conveys two ideas to the mind by means of one word; but a figure throws the sentence into a different form from the common and usual manner of expression. Besides, tropes are chiefly designed to represent our thoughts, but figures our passions.

#### § I. Tropes.

A trope, which is a figure of words, has been usually defined to be the change of a word from its proper signification to some other with advantage, either as to beauty or strength. The words, *with advantage*, are added in the definition, because a trope ought not to be chosen, unless there is some good reason for using it rather than the proper word. But in what manner, or how far, it can be said of all tropes in general, that they change the proper signification of words, will best appear by considering the nature of each kind of them separately. Now in every trope a reference is had to two things, which occasions two ideas; one of the thing expressed, and another of that thing to which it has a respect, and is supplied by the mind. For all tropes are taken either from things internally related, as the whole and a part; or externally, as cause and effect, subject and adjunct; or from some similitude that is found between them; or from a contrariety. The first of these is called *synecdoche*, the second *metonymy*, the

Elocution.

51  
The necessity of dignity in an oration.

52  
Tropes, what.

**Elocution.** the third *metaphor*, and the last *irony*. We shall endeavour to illustrate this by examples. When we say, *Hannibal beat the Romans*; the meaning is, that Hannibal and his army did this. So that although in some sense a part may here be said to stand for the whole, which makes it a *synecdoche*; yet, strictly speaking, the word *Hannibal* does not alter its sense, but there is an ellipsis in the expression, Hannibal being put for himself and his army. But if we say, *Cicero should be read by all lovers of eloquence*; here indeed the word *Cicero* appears to be changed from its proper sense, and to signify the books of Cicero; which is a *metonymy*, the author being put for his works; and therefore such expressions need not be deemed elliptical. Again, if any one speaking of a subtle and crafty man, should say *he is a fox*; the meaning is, he is like a fox; which is a *metaphor*; where the word *fox* retains its proper sense, and denotes that animal, to which the man is compared on account of his craft. Lastly, if a person say to another, *Well done*; meaning that the thing was ill done, the word *well* keeps its own sense; but from the manner of its pronunciation, or some other circumstance attending the expression it will be evident that the contrary is intended: which is called an *irony*. From these instances it may appear in what latitude we must understand the common definition of a trope, which makes it to consist in the change of a word from its proper sense into some other. But though in reality there are but four kinds of tropes, which are distinguished by so many different respects which things bear one to another; yet as these several respects are found in a variety of subjects, and attended with different circumstances, the names of *tropes* have from hence been greatly multiplied; which, however, may all be referred to some or other of those already mentioned, as will be shown when we come to treat of them in their order. And for distinction sake we shall call the former *primary*, and the latter *secondary*, *tropes*.

We now proceed to consider the reasons which have occasioned the introduction of tropes. And these, as Quintilian observes, are three; *necessity*, *emphasis*, and *beauty*.

53  
Why introduced.

1. Tropes were first introduced from *necessity*, deriving their origin unquestionably in a considerable degree from the barrenness of language, because no language which we know contains a sufficient number of proper words to express all the different conceptions of our minds: but the principal cause of their introduction seems to be that extensive influence which imagination possesses over every kind of speech. The mind considers the same thing various ways; views it in different lights; compares it with other things; and observes their several relations and affections; wherein they agree, and in what they differ. From all which reflections, it is furnished with almost an infinite number of ideas; which cannot all of them be distinguished and expressed by proper words, since new ones occur daily. And were this possible, yet would it be impracticable; because the multitude of words must be so vastly great, that the memory could not retain them, nor be able to recal them as occasion required. Tropes have in a good measure redressed both these inconveniences; for by means of them

the mind is not burdened with a numberless stock of different words, and yet nothing seems to want a name. Thus sometimes, where a word is wanting to express any particular thing, it is clearly enough represented by the name of some other thing, by reason of the similitude between them. At other times, the cause is signified by the effect; the subject by the adjunct; or the contrary. And the whole is often understood by a part, or a part by the whole. And thus by the use of tropes, the mind is helped to conceive of something not expressed, from that which is expressed. It is much the same case, as when we have occasion to speak of a person, whose name we are either unacquainted with, or have forgot; for by describing his person, abode, or some other circumstances relating to him, those we converse with as well understand whom we mean, as if we mentioned his name. So the shepherd in Virgil, when he could not think of the name of Archimedes, describes him by his works:

And what's his name who form'd the sphere,  
And show'd the seasons of the sliding year?

Besides, it sometimes happens in a discourse, that those things are necessary to be said, which, if expressed in their proper terms, would be offensive; but being clothed with metaphors, may be conveyed to the mind with decency. Thus then the imagination never contemplates any one idea single and alone, but always along with other ideas, which may be called its *accessories*, and which often operate more forcibly upon the mind than the principal idea itself does. In their nature, they are often more agreeable, and frequently also more familiar, to our conceptions; or perhaps they remind us of a greater variety of important circumstances. Hence the name of the accessory is often preferred, as, *e. g.* when we want to point out the time in which a state enjoyed its chief reputation, &c. the proper words might do, but the imagination suggests the flourishing period of a plant or tree; and we say "the Roman empire flourished most under Augustus;" Catiline, we say, was the *head* instead of the *leader* of his party, because the head is the principal part of the human figure.

2. A second reason abovementioned for the use of tropes was, *emphasis*. Tropes do many times express things with greater force and evidence than can be done by proper words. We receive much the greater part of our knowledge by our senses. And similitudes taken from sensible things, as in metaphors, very much assist the mind in its reflections upon those things which do not come under the cognizance of the senses. For it is certain, that we are sooner and more strongly affected with sensible objects, than with things of which we can have no ideas but from the internal operations of our own minds. Nay, sometimes one bright and lively trope shall convey a fuller and more just idea of a thing than a large periphrasis. So when Virgil calls the Scipios *two thunderbolts of war*, he gives a more lively image of the rapid force and speedy success of their arms, than could have been conveyed by a long description in plain words. And in many cases the tropical use of words is so emphatical, and suited to the idea we design to excite, that in this respect it may

Elocution:

may be justly esteemed the most proper. So, *incensed with anger, inflamed with desire, fallen into an error*, are all metaphorical expressions, used in a way of similitude; and yet perhaps no proper words can be made use of, which will convey a more lively image of the thing we design to represent by them.

But *beauty* and ornament, as was observed before, have been another cause of the use of tropes. Some subjects require a more florid and elegant dress than others. When we describe or applaud, ornaments of speech and a gaiety of expression are requisite. And it is the business of an orator to entertain his hearers at the same time that he instructs them. Now Cicero, who was an admirable judge of the force and power of eloquence, has observed, that tropical expressions give the mind the greatest delight and entertainment. "I have often wondered (says he) why tropes should give greater pleasure than proper words. I imagine the reason must be, either that there is an appearance of wit in neglecting what is at hand, and making choice of something at a distance; or that the hearer is furnished with a different thought, without being led into a mistake, which affords a very agreeable pleasure; or that a whole similitude is conveyed to the mind by a single word; or that, particularly in the best and most lively metaphor, the image is presented to our sight, which is the quickest of our senses." And therefore he supposes, that "as garments were first invented from necessity, to secure us from the injuries of the weather, but improved afterwards for ornament and distinction; so the poverty of language first introduced tropes, which were afterwards increased for delight." Besides, a variety of expression is pleasing in a discourse. It is many times necessary that the same thing should be repeated; and if this be done in the same words, it will grow tiresome to the hearers, and sink their esteem of the speaker's ability. Therefore, to prevent this, it is proper the expression should be varied, that although the sense be the same, it may give the mind a new pleasure by its different dreis.

We come now, in the last place, to lay down some directions proper to be observed in the choice of tropes.

And first, as every trope gives us two ideas; one, of the word expressed; and another, which, by means of that, the mind connects with it; it is necessary, that the relation between these two appear very plain and evident. For an obscure trope is always faulty, unless where some particular reason makes it necessary. And therefore tropes ought not to be too far-fetched, lest that should render them dark. For which reason Cicero says, he should not choose to call any thing destructive to a person's fortune, *the Syrtis of his patrimony*, but rather the *rock of it*; nor the *Charybdis of his state*, but the *gulph of it*. For those who either did not know that the Syrtis were two quicksands upon the coast of Africa, or that Charybdis was a gulph in the strait of Sicily, both of them very destructive to mariners, would be at a loss to understand the meaning of the metaphor. Besides, metaphors taken from things we have seen, affect the mind more forcibly than those which are taken from such things as we have only heard of. Now there is scarce any one who has not seen a rock or a gulph; but there are very few persons, comparatively, who have been either at

Charybdis or the Syrtis. It is necessary therefore in a good trope, not only that there be a near affinity between the two ideas, but likewise that this affinity be very obvious and generally known, so that the word be no sooner pronounced but both images do immediately present themselves to the mind.

Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, so as neither to heighten nor diminish the just idea of it. Indeed, sometimes when we speak of things indefinitely, we say too much, lest we should seem to say too little. And this manner of speaking is called an *hyperbole*; which is not uncommon in the sacred writings. So, for instance, Saul and Jonathan are said to be *swifter than eagles, and stronger than lions*. But even in this way of expression a proportion is to be observed. For some very considerable and unusual excess of the thing in its kind is at least designed by it; which, perhaps, cannot, or however is not necessary to be defined. And therefore Quintilian blames Cato for calling the top of an hill a *wart*; because the proportion between the two ideas is nowise adequate. And so, on the contrary, Aristotle censures Euripides for calling rowing *the empire of the oar*. Poets indeed are allowed a greater liberty in this respect; but an orator should be modest in his expressions, and take care that he neither so heighten nor diminish the natural ideas of things by tropes, as to lead his hearers into mistakes.

But further: As a moderate use of tropes, justly applied, beautifies and enlivens a discourse; so an excess of them causes obscurity, by running it into abstruse allegories and riddles. Tropes are not the common and ordinary dress of our thoughts, but a foreign habit: and therefore he who fills his discourse with a continued series of them, seems to act like one who appears in public in a strange dress; which no man of character would choose to do.

Moreover, as one use of tropes is pleasure and entertainment, we should endeavour to make choice of such as are smooth and easy. But if at any time we think it necessary to use a harsh trope, it is proper to soften it by some precaution. For, as Cicero very handsomely says, *a trope shou'd be modest, since it stands in a place which does not belong to it; for which reason it shou'd seem to come thither by permission, and not by force*. And therefore, when he thought it harsh to say, *The death of Cato made the senate an orphan*; he guards the expression by saying, *The death of Cato has (If I may be allowed to say so) rendered the senate an orphan*.

And, to add no more, care should be taken how we transfer tropes from one language into another. For as they are frequently taken not only from natural things, or such notions as are common to the generality of mankind, but likewise from the manners, customs, and occurrences of particular nations; so they may be very plain and obvious to those among whom they took their rise, but altogether unintelligible to others who are unacquainted with the reason of them. It was customary for the Roman soldiers to carry their money in their girdles; hence it was the same thing with them to say, *a person had lost his girdle*, as that *he had lost his money*. And because the Romans wore the  *toga*, which was a long gown, in time of peace, and a different garb when engaged in war, their writers

**Elocution.** ters sometimes use the word *toga* to signify peace. But as neither of these customs is in use among us, so neither would the tropes suit our language, or be generally understood by us. And even in such tropes as are taken from the common nature of things, languages very much differ. There is a very beautiful trope in the account of St Paul's shipwreck, where it is said, *The ship was caught and could not bear up into the wind.* The original word, that we translate *bear up*, is *αποφθαλμιν*; and properly signifies, *to look or keep its eyes against it*; which is a very strong and lively image, taken from animate beings and when applied to men often signifies *to withstand or resist*: as, *αποφθαλμιν πολεμω*, *to resist an enemy*; and Plutarch says of Demosthenes, that he could not *αποφθαλμιν το αργυριον*, *look against or resist the power of money*. Nothing is more common with Latin writers, than to call men of a public spirit and true patriots, *lumina et ornamenta reipublicæ*, that is, *the lights and ornaments of the state*. And we have borrowed from them the use of both these metaphors. But because tropes and figures illustrate and heighten the style, they call them also *lumina orationis*, or *the lights of a discourse*. It sometimes happens that only the tropical sense of a word is taken from one language into another, and not the proper signification of the same word. So *scrupulus* in Latin properly signifies *a little stone, which getting into the shoe hurts a person as he walks*; hence it is applied to the mind, and used to express *a doubt, or uneasy thought that gives it pain*. We have borrowed this latter sense of the word, but not the former.

## ART. I. PRIMARY TROPES.

54  
Metaphor,  
what.

I. *Metaphor.* A metaphor, as usually defined, is, *A trope, which changes words from their proper signification to another different from it, by reason of some similitude between them.* But that a word, when used metaphorically, does not alter its signification, but retains its proper sense, was shewn above. However, it may not be amiss to explain this matter more fully, and set it in a clearer light. Every metaphor, then, is nothing else but a short similitude. Cicero calls it *a similitudo reduced to a single word.* And Quintilian to the same purpose says, that "a metaphor is a short similitude, and differs from it only in this, that the former is compared to the thing we design to express, and the latter is put for it. It is a similitude, when I say of a man, he has acted like a lion; and a metaphor, when I say, he is a lion." Thus far Quintilian. Now in every similitude three things are requisite; two things that are compared together; and a third, in which the similitude or likeness between them consists. And therefore, to keep to this example, when Horace calls a Roman foldier *a lion*, if the word *lion* did not retain its proper sense, there could be no similitude; because there would not be two things to be compared together with respect to a third, which is necessary in every similitude, and was designed by this expression. The sense of which is plainly this: *That as a lion seizes his prey with the greatest fierceness, so a Roman foldier with like rage and fury attacked his enemies.* In the same manner, when Cicero calls *Piso the vulture of the province*, his meaning is, that he was like a vulture, or acted in such a manner as a vulture acts, that is, rapaciously. So that the real difference between a meta-

phor and a similitude consists in this; that a metaphor has not those signs of comparison which are expressed in a similitude. But some persons have run into mistakes in reasoning from tropes of this kind. For they have so argued from metaphorical words, as if all the affections and properties of the things expressed by them might be attributed to those other things to which they are applied, and by that means have strained the comparison (which has usually but one particular view), in order to make it tally in other respects, where there is not that similitude of ideas. We will endeavour to make this evident by another example from Cicero, where he calls M. Antony *the torch of the state*. The similitude between Antony and a torch lay in this: *That as a torch burns and destroys every thing within its reach, so Antony brought desolation and ruin wherever he came.* Now a torch has not only a property to burn, but also to give light; but the similitude would not hold in this respect, nor was it at all designed. For Cicero never calls a wicked profligate man, as Antony was, *the light of the state*; though he often gives that character to good and virtuous men, who by their examples do as it were enlighten others, and show them the way to be happy themselves and useful to others. But though metaphors are usually taken from a similitude between two things, as in the instances here mentioned; yet sometimes they are founded in the similitude which two things bear to two others in some particular respect, by means whereof what properly belongs to one of them is transferred to the other: the former of which are called *simple metaphors*, and the latter *analogous*. Hence the rudder of a ship may be called its *reins*; for what the reins are to a horse, that the rudder is to a ship in guiding and directing it. So that here is a double similitude, one between a ship and a horse, and another between the rudder of the former and the reins of the latter; and from the analogy between the use of the rudder to the one and reins to the other, the reins, which belong properly to the horse, are applied to the ship. Again, some metaphors are reciprocal, in which the similitude holds either way. Thus to steer and to govern are used reciprocally both of a ship and a state: the proper expressions being, *to steer a ship*, and *govern a state*; and the contrary metaphorical. But though we say, *the foot of a mountain*, borrowing the similitude from animals; yet we do not say, on the contrary, *the bottom of an animal*, meaning his feet; and therefore that metaphor is not reciprocal. From this account therefore of the nature of a metaphor, it may be said to be, *The application of a word by way of similitude to some other thing than what it properly signifies.* And the plainer this similitude appears, the greater beauty there is in the trope.

The use of metaphors is very extensive, as large as universal nature. For there are scarce any two things which have not some similitude between them. However, they may all be reduced to four kinds; which was the second thing proposed to be considered.

The first kind of metaphors therefore may be taken from similitudes between animate beings. As where those things which properly relate to brutes, are accommodated to men; or those which belong to men are applied to brutes. Of the former sort is that joke of Cicero: *My brother being asked by Philip, why he barked*

1. locution.

*barked so?* answered, *Because he saw a thief.* Here *barking*, the property of a dog is applied to a man: And the reply does not seem to carry more severity or harshness with it than the question. By the latter sort we say, *a crafty fox*, and *a generous horse*; which are affections that properly relate to men. And to this kind of metaphors may those likewise be referred, when that which properly belongs to the senses is applied to the mind. Thus we often say *that we see a thing*, when we mean *that we understand or apprehend it*. And in the same sense we say, *that we hear such a thing*, or *person*. And by the like manner of expression, a person is said *to smell out a thing*. And those who have a genius or disposition for any art or science, are said *to have a taste for it*; and such as have entered upon the study of it, are said *to have a touch of it*. These are common ways of speaking in most languages, and very expressive of what is intended by them. And we may also bring those metaphors under this head, by which the properties and affections of men are attributed to the Deity: as, when God is said *to hear, see, be angry, repent*, and the like; which are forms of expressions very frequent in the sacred writings.

A second kind of metaphors lies between inanimate things, whether natural or artificial, which bear some similitude to each other. And this head is very extensive. Thus we say, *floods of fire*, and *clouds of smoke*, for large quantities. And so likewise, *to inflame an account*, that is, to heighten or increase it; with innumerable others of the like sort. In the two first of these instances, the terms proper to one element are applied to another; and as those elements of fire and water are opposite to each other, they show the extensiveness of this trope, that there are no things in nature so contrary, but may come within the limits of it, and be accommodated to each other in a way of similitude. In the last example, a natural action is applied to what is artificial.

A third sort of metaphors is, when inanimate things are applied to animals, on account of some like properties between them. Thus Homer calls Ajax, *the bulwark of the Greeks*, on account of his valour, which like a wall defended them from the Trojans. And nothing is more common with Cicero, than to brand ill men with the character of being *the pest of the state*, by reason of the mischief which they bring to the public. So likewise he calls Zeno the philosopher *an acute man*, for his great discernment and quick perception of things; fetching the allusion from metals when brought to an edge or a point. As, on the contrary, old Chremes in Terence calls himself *a stone*, for want of apprehension. And we say, *a gay person*, and *a bright genius*, by this kind of metaphor.

The fourth and last kind of metaphors is that by which the actions and other attributes of animals are accommodated to inanimate things. Thus Cicero, speaking of Clodius, says: "The very altars, when they saw that monster fall, seemed to move themselves and assist their right against him." Here the words *saw, move*, and *assist*, are all metaphors taken from the properties of animals. And Virgil, when he would represent the impetuous force and rapidity of the river Araxes, says, *it disdain'd a bridge*. And it is a very usual epithet, which Homer gives to words, to call

them *πτερόντα*, or *winged*, to intimate the swiftness of Elocution.

Lastly, as to the choice of metaphors, those are esteemed the finest and strongest, which *give life and action to inanimate things*. The reason of which is, because they do as it were invigorate all nature, introduce new forms of beings, and represent their images to the sight, which of all the senses is the quickest, most active, and yet most unwearied. What can be more moving, or in stronger terms express the villany of Clodius, than when Cicero says, "The very altars of the gods seemed to exult at his death." And the same great orator particularly commends those metaphors, for their sprightliness and vivacity, which are taken from the sense of seeing; as when we say *a bright thought* or *a gay expression*.

However, care must be taken not to venture upon too bold and daring metaphors. Poets indeed claim greater liberty in this respect, whose view is often to amuse, terrify, or delight, by heightening the just and natural images of things. But it is expected the orator should reason coolly, though strongly and forcibly; and not by theatrical representations so transport the mind, as to take it off from reflection, unless perhaps on some particular occasion. And yet, on the other hand, metaphors ought not to sink below the dignity of what they are designed to express; but the idea they convey should at least be equal to the proper word in the place of which they are substituted.

But there is a very great difference in the choice of metaphors, as they are designed either to praise or dispraise. One thing may be compared to another in a great variety of respects. And the same thing may be made to appear either noble or base, virtuous or vicious, by considering it in a different light. Such metaphors, therefore, as are chosen to commend, must be taken from great and laudable things; and on the contrary, those which are designed to discommend, from things vile and contemptible. Aristotle gives us a very pleasant example of this in the poet Simonides. A certain person, who had carried the prize at a race of mules, offered him a reward to write a poem in honour of that action. Simonides thought he did not bid high enough; and therefore put him off with saying, the subject was too mean to write in praise of mules, which were the offspring of asses. But upon his being offered a larger sum, he undertook the task; and, as Aristotle observes, when he has occasion to speak of the mules in that poem, he does not mention them by that name, but calls them *the daughters of fleet and generous horses*, though he might with as much propriety have called them *the daughters of dull asses*. But it was the poet's business, in praising, to take the most advantageous part of the character. Where things are capable of such different turns, metaphorical expressions are generally most beautiful. And sometimes the same metaphor may be applied contrary ways, both in praise and dispraise, as it will suit different properties of the thing to which it refers. So a *dove*, in a metaphorical sense, may represent either *innocence or fear*; and an *iron heart* may denote either *courage or cruelty*; as an *hard head*, *strength or weakness of thought*. And this ambiguity in the application of metaphorical words often affords occasion for jests

Elocution.

jefts and concise wit. We observed before, that Cicero never calls ill men, *lights of the state*. But he once in this manner calls Sextius Clodius *the light of the Senate*. For when his kinsman Publius Clodius had been killed by Milo, and his corpse was brought to Rome, Sextius raised the mob, and in a tumultuous manner carried it into the senate-house, where they burnt it, and by that means set the building on fire: For which seditious action Cicero passes that joke upon him, under the metaphor of light, which elsewhere he always uses in a good sense.

But to proceed: All forced and harsh metaphors should be avoided; the one being no less disagreeable to the mind than the other to the ear. Nor should they come too thick in a discourse. In a word, they ought not to be used, but either where a proper word is wanting, or where they are more significant or beautiful than the proper word.

55  
Metonymy  
defined and  
explained.

II. *Metonymy*. This, as defined by Quintilian, is, *the putting one word for another*. But Vossius describes it more fully, when he calls it, "A trope, which changes the name of things that are naturally united, but in such a manner as that one is not of the essence of the other." That a metonymy is thus distinguished from the other tropes, has been sufficiently shown already in the two last chapters. When it is said, *to put one word for another, or, to change the names of things*, the meaning is, that the word so used changes its sense, and denotes something different from its proper signification. Thus, when *Mars* is put for *war*, and *Ceres* for *corn*, they lose their personal sense, and stand for the effects of which those deities were said to be the cause. So likewise, when Virgil says,

He drank the frothing bowl,

the word *bowl* must necessarily signify the liquor in the bowl. And when in another place, describing the temple of Juno at Carthage, in which the actions of the Trojan war were represented, and the images of the heroes, he makes Æneas, upon discovering that of Priam among the rest, cry out,

Lo here is Priam;

it is plain the word *Priam* there must stand not for his person, but his *image* or *figure*. And this property of changing the sense of the word appears peculiar to metonymy. In treating upon a metaphor, we observed the mistake of those who teach, that a word used metaphorically loses its proper signification; whereas it only changes its place, but not its sense; being applied to a thing to which it does not naturally belong, by way of similitude. And as the not attending to this has run some persons into very great absurdities, in treating upon metaphorical expressions, and reasoning from them in the tropical sense; so the like has happened to others in some instances of a metonymy, where, by misapprehending their true nature, they have reasoned from them in the literal sense, as we shall show presently. A metonymy is not so extensive as a metaphor, nor altogether so necessary: because nothing is said by a metonymy, which cannot be expressed in proper words; whereas metaphors are often used for want of proper words to express some ideas. However, metonymies are very useful in language; for they enrich a discourse with an agreeable variety, and

VOL. XIII.

Elocution.

give both force and beauty to an expression. And what we observed with relation to a metaphor, is true also of this trope; that some metonymies, even in common discourse, are more frequently made use of than the proper words in whose room they are put. So, *pale death*, *a blind way*, and *a happy state*, are very common expressions with us. And it is more usual to say, *This is such a person's hand*, or *I know his hand*, than his writing, when we intend this latter sense of the word.

We now proceed to the division of metonymies; which are commonly distinguished into four kinds, from the different manner in which things are naturally, but externally, united to one another. Now things are thus united, or one thing depends upon another, either with respect to its productions, or in the manner of its existence when produced. In the former way the effect depends upon its cause, and in the latter the adjunct upon its subjects. And hence arise four sorts of metonymies, which receive their names from the *cause* and *effect*, the *subject* and the *adjunct*.

It is called a *metonymy of the cause*, when the external cause is put for the effect. The external cause is twofold, the agent and end, which are usually called the *efficient* and *final cause*. Of the former kind are such metonymies, where the inventor or author is put for what was invented or effected by him. Thus, as we said before, *Ceres* is sometimes put for *corn*, the use of which she was said first to have introduced; and *Mars* for *war*, over which she was thought to preside. And by this way of speaking, any artist or writer is put for his work. So Juvenal, blaming the luxury and profuseness of the Romans, says, *There are few tables without Mentor*; that is, which were not made by him, or after his manner. And our Saviour says, in the parable of the rich man and Lazarus, *They have Moses and the prophets*, Meaning the books of Moses and the prophets. But under this sort of metonymy is included not only the agent, strictly so called, but also any means or instruments made use of in the doing of a thing, when put for the thing done. Thus, *polite literature* is called *humanity*, because it cultivates and improves the human mind. And in that expression of Cicero, *Words move nobody but him who understands the tongue*; the word *tongue*, which is the instrument of speech, is put for *speech* or *language*. And in the like sense, *arms* are sometimes put for *war*, and the *sword* for *slaughter*. By the same kind of metonymy likewise any affection or quality is put for its effect. As when it is said, *the end of government is to maintain justice*; that is, *such mutual offices among men as are the effects of justice*. And so likewise in that of Cicero, *It is the business of magistrates to check the levity of the multitude*, by which he means tumults occasioned by their levity. Moreover, as human affections are attributed to the Deity in a metaphorical sense, so several parts of the human body are likewise ascribed to him by this kind of metonymy. Thus, his *hand* and his *arm* are used to express his power, as his *ear* and his *eye*, his *care* and *providence*, these being the instruments of such effects in mankind. Metonymies of the final cause are those by which the end in doing a thing is put for the thing done. As when we say, *The watch is set*, meaning the *watchmen*, who are appointed for that purpose. And so likewise

3 H

that

Elocution. that expression, *to make an example*, as it signifies to *punish*, in order to deter others from the like crimes by such an example. As also that of Virgil,

Phyllis should garlands crop;

by which are meant *flowers* to make garlands.

The second kind of metonymy puts the effect for the efficient cause, whether the agent, or only the means and instrument. So Virgil calls the two Scipios *the destruction of Lybia*, because they were the agents who effected it. And Horace compliments his patron Mæcenas with the titles of being *his guard and honour*; that is, his guardian, and the author of his honour. But when Cicero tells the citizens of Rome, that *the death of Clodius was their safety*, he means the occasion only of their safety. And elsewhere he calls that *a dark hope and blind expectation*, the effect of which was dubious and uncertain to those who entertained it. And in like manner, the sons of the prophets, when they were eating the pottage which Elisha had ordered to be set before them, cried out, *There is death in the pot*: that is, *some deadly thing*, as is presently after explained. And thus sweat, which is the effect of labour, is sometimes put for labour. As in the threat denounced against Adam, *In the sweat of thy face shalt thou eat bread*, that is, by labour in cultivating the ground. And in allusion to this way of speaking, Antony the orator tells Crassus, "the improvement of the style by constant exercise, as he prescribed, was a thing of much sweat." And *virtue is said to be gained by sweat*, that is, continued care and exercise in subduing the passions, and bringing them to a proper regulation. But in these two expressions there is likewise a metaphor, the effect of bodily labour being applied to that of the mind. In all these instances, the effect is put for the efficient cause.

The third kind of metonymy is, when the subject is put for the adjunct. By subject here, in a large sense of the word, may be understood that wherein some other thing is contained, or about which it is conversant; as likewise the possessor with respect to the thing he possesses; and the thing signified, when put for the sign of it. Now, by the first of these ways of speaking, the seat of any faculty or affection is used for the faculty or affection itself. So it is usual to say, *a man of a clear head*, when we mean a clear mind or understanding; the seat of the mind being supposed to be in the head. And a person is said *to have a warm heart*, because the heart has been thought the seat of the affections. In like manner, the place where any actions are performed is put for the actions done in it. As when Cicero says, "Do not always think of the forum, the benches, the rostra, and the senate;" meaning the discourses which were usually made in those places. So likewise the country, or place of residence, is put for the inhabitants, as in that passage of Cicero: "And to omit Greece, which always claimed the pre-eminence for eloquence, and Athens, the inventress of all sciences, where the art of speaking was invented and perfected; in this city of ours, (meaning Rome), no studies have prevailed more than that of eloquence:" where the words Greece and Athens stand to denote the inhabitants of those places. And hither may also be referred those expressions in which the time is put for the persons living in it; as,

*the degeneracy of the present age, the virtue of former times.* Elocution.

In the second way abovementioned, the object is used for the person or thing employed about it: As when Cicero says, "In time of battle the laws are silent;" where by *laws* he intends the *judges*, who pronounce sentence according to law. By the third of these ways, in which the possessor is put for the thing he possesses, we say, *to devour, destroy, or ruin a man*, meaning not his *person* but his *estate*. And mythologists explain the fable of Actæon by this trope, who is said to have been devoured by his dogs: for by dogs they understand flatterers and parasites, who consumed his estate, and brought him to beggary. By the last way before recited, which puts the thing signified for the sign, statutes and pictures are called by the names of the persons which they represent; as in that jest of Cicero upon his brother Quintus, when, as Macrobius relates, "being in the province which his brother had governed; and seeing a large portrait of part of his body, holding a shield, though Quintus was but a little man, he said, My half brother is bigger than my whole brother." The Popish doctrine of transubstantiation is founded upon an abuse of this trope. For when our Saviour, speaking of the bread and wine at that time before him, says, "This is my body, and this is my blood," his plain meaning is, they were the signs of his body and blood, the thing signified being put for the sign by this sort of metonymy. But the Papists take the expression literally, which must doubtless be very absurd; since the words relate to the time then present, while Christ was yet living, and spoke them; when it was impossible for the bread and wine to be converted into his body and blood, it being evident to all who were present, that those elements, and his body, existed separately at the same time. But if the words are explained by this trope, the sense is plain and easy, and the way of speaking familiar to all writers. Whereas they who plead for the literal sense might with equal reason assert, that those expressions abovementioned are to be taken literally, in which several parts of the human body, as the hand, the arm, the ear, and the eye, are ascribed to the Deity; or that, when our Saviour in a metaphorical sense calls himself *a vine*, and *a door*, these words were designed to be applied to him strictly and properly, and not by way of similitude only, as is the case of all metaphors.

The fourth kind of metonymy is that wherein the adjunct is put for the subject, which is done in the same variety of ways as the former. It is therefore a metonymy of the adjunct, when the thing contained is put for that which contains it. As when Virgil says, "They lie down upon purple;" that is, upon couches dyed with purple. And again, "They crown the wine;" meaning the bowl which contained the wine, it being the custom of the ancients to deck their bowls with garlands at their entertainments. By these tropes likewise virtues and vices are put for the persons in whom they are found. As in that beautiful passage of Cicero, where, comparing the profligate army of Catiline with the forces of the state, he says, "On this side modesty is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that deceit; on this piety, on that profaneness; on this constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion;

in

**Elocution.** in a word, equity, temperance, fortitude, prudence, and all virtues, engage with injustice, luxury, cowardice, rashness, and all vices." And to this trope those expressions are to be referred, in which any thing is put for the object about which it is conversant. As in that saying of the wise man, "Hope deferred makes the heart sick;" where hope is put for the thing hoped for. And thus Suetonius calls the emperor Titus *the love and delight of mankind*, whose mild and obliging temper rendered him the object of those agreeable affections to all persons under his government. A third use of this trope is by putting a thing for the time in which it was done. Thus we say of a person, *he has served so many campaigns*, meaning so many summers, that being the usual time in which armies are drawn out into the field. Lastly, by this metonymy, the sign is put for the thing it signifies: as, *the sceptre for the regal dignity*, and *the sword for the authority of the magistrate*.

56 **Synecdoche explained.** III. *Synecdoche*. This is a trope by which either the whole of a thing is put for a part of it, or a part for the whole; so that the two things, whose ideas are presented to the mind in this trope, are internally related to each other: by which, as has been shown already, it is distinguished from all the other tropes. In a *synecdoche* the word retains its proper sense, and the expression is elliptical, as will appear by the several species of it, wherein the ellipsis in most of the examples is very obvious, and may with no great difficulty be supplied. Now a thing may be considered as a whole in three different respects, which logicians call an *universal*, *essential*, and *integral whole*. An universal whole is any genus with regard to its several species; as, an *animal* with respect to *mankind* and *brutes*, or *philosophy* with respect to the several *arts* and *sciences* comprised under it. An essential whole consists of matter and form; as, a *man* of *body* and *soul*. And an integral whole is any body or quantity, with respect to the several parts of which the matter of it is composed, and into which it may be divided: as, an *human body* with respect to its *several members*; or a *year*, as divisible into *months*, *weeks*, and *days*. And thus rhetoric is an integral whole in respect to the four parts that compose it; namely, invention, disposition, elocution, and pronunciation. So likewise any aggregate body, as a civil community, which is divisible into those who govern and are governed; or any army, consisting of the general and his soldiers. As a whole therefore, in each of these acceptations of the word, is frequently put for a part, and a part for the whole; hence arise six species or sorts of *synecdoche*.

The first of these puts the genus for the species.—Thus, virtue in general is sometimes used to denote some particular sort of virtue. As when Cicero mentions virtue as one of the four qualifications necessary in a general, he means greatness of mind. And so persons are often commended for instances of virtue shown in their conduct, which respect only some single virtue, as justice, temperance, or the like: And in this sense Cicero calls Clodius *a deadly animal*. So when our Saviour commissions his apostles to *preach the gospel to every creature*, the meaning is, *every rational creature*. And thus likewise, *to talk to a person* some-

times denotes the same thing as to *blame* him, which is **Elocution.** one way of talking.

The second kind of *synecdoche* he puts the species for the genus. Thus *bread* denotes any kind of food: as when a person is said to *get his bread by his labour*. In the same way of speaking, *money* is put for any kind of wealth in general. And it is an usual expression to say, that *wine destroys more than the sword*; that is, than any *hostile arms*. And the legal form of banishment among the Romans was, to prohibit persons *the use of fire and water*; that is, *the most common and ordinary necessities of life*, in which all others were included.

The third species of this trope is, when the essential whole is put for one of its parts; that is, either for the matter or form. Thus, in the Evangelist, Mary Magdalen says, *they have taken away my Lord, and I know not where they have laid him*, meaning his *body*. So it is usual to say of a deceased person, *He was buried at such a time*. And in the inscriptions of sepulchral monuments we frequently meet with this expression, *Here lies such an one*; that is, his *corpse*. Nor are instances uncommon in which the whole being is put for the form. Thus when Cicero says, *Those persons live, who have fled from the confinement of the body, as from a prison*; by *persons* must necessarily be understood their *souls*, which are here distinguished from and set in opposition to their *bodies*. And so Virgil represents Æneas as meeting with Dido and some of his Trojan friends in the infernal regions; by which are meant their *ghosts*.

The fourth kind of *synecdoche* is, when either the matter or form is put for the whole being. Thus *silver* and *gold* are used to signify money made of those metals; as when we say, *I have so much silver* or *so much gold*. And the word *soul*, both in our own and other languages, is put for the *whole person*. So with us, a *merry soul*, and a *dull soul*; in Cicero, *dear souls*; and in Horace, *candid souls*, are all used in this tropical sense. But this way of speaking occurs nowhere more frequently than in the sacred writings. Thus, for instance, it is said, *All the souls which came with Jacob into Egypt*, meaning the *persons*. And again, *The soul that sinneth it shall die*; from which expression, and others of the like import, some persons, by not attending to the nature of this trope, have been erroneously led to infer that the soul is naturally mortal. But sometimes only part of the matter stands to express the whole essence or being. So we imitate the Latins in using the word *caput* or *head* to denote either a *person* or *thing*. For, as with them *lapidum caput*, so with us a *witty head*, signifies the same as a *man of wit*. And in the same sense, *so many head of cattle* means *so many entire cattle*.

By the fifth sort of *synecdoche*, the whole of any material thing or quantity, whether continued or discrete, is put for a part of it. So when Cicero says, *A war is kindled through the whole world*, in compliment to his country, he calls the Roman empire *the world*. And this expression is also used by historians. Thus Cornelius Nepos, speaking of the quarrel between Mark Antony and Augustus, tells us, that *each of them desired to be lord of the world*. And in like manner St Luke says, *There went out a decree from Cæsar Augustus*,

*Elocution.* *Augustus, that all the world should be taxed.* So in St Paul's shipwreck, is said, *They ran the ship a-ground, that is, the head of her,* for it is plain by what follows, that the stern was loose. And as to discrete quantity, our Saviour, using this trope, said he should be *three days and three nights in the heart of the earth.* Though he did not continue three whole days and nights in the grave, but only part of the first and third day, and the whole second day, with the two whole nights between the first and third day, according to our way of reckoning. For he was buried on Friday in the afternoon, and rested in the grave that night, with the following day, which was the Jewish Sabbath, and was risen on the morning of the next day. So that we must necessarily have recourse to this synecdoche, which puts the whole for the part, to clear up that event.

By this kind of synecdoche, also; the plural number is sometimes put for the singular. Thus St Matthew says, *The thieves who were crucified with our Saviour reviled him:* though it is plain from St Luke, that only one of them did so. It may also be referred to this trope, when a certain number is put for an uncertain one. So it is an usual way of expression to say, *I have seen or done such a thing an hundred or a thousand times;* when perhaps so many are not really intended, but only in general some considerable number.

The sixth and last kind of synecdoche puts a part of any material thing or quantity for the whole of it. So we say of a man, *He shelters himself under such an one's roof;* that is, *in his house.* And of a fleet, that it *consists of so many sail;* meaning, *so many ships.* And by this trope, that is ascribed to a single person which was done by the assistance of others, and in conjunction with them: as when it is said, that *Hannibal killed forty thousand Romans at the battle of Cannæ:* For an army is an aggregate body, of which the general is the head, and consequently the chief part of it. And to this kind of synecdoche may also be referred such expressions in which the singular number is put for the plural: as if one should say, *A man is liable to be misled by the influence of irregular passions;* meaning *all men,* or *mankind in general.* Or when less than the real number is put for any round number: Thus some ancient writers, when they speak of the Grecian armada that came against Troy, call it a fleet of *a thousand ships;* though, according to Homer's list, it contained 1186. And so likewise the Greek interpreters of the Old Testament are usually called the *Seventy;* whereas, in reality, they were seventy-two.

57  
*Irony defined and illustrated.* IV. *Irony.* This is a trope in which one contrary is signified by another: As if any one should say, *Well done;* when at the same time his design is to intimate that the thing was *ill done.* So that, by this manner of expression, the speaker appears to mean something contrary to the sense of the word he makes use of. Not that the word is changed from its usual signification; but by the circumstances attending the expression, we perceive the contrary to what is spoken is intended. Quintilian observes, that an irony may be known one of these three ways: "by the manner of pronunciation, or from the nature of the person or the thing. For (as he adds) where any of these do

*Elocution.* not suit with the words, it is plain the speaker intends the contrary." The irony is very plain from the manner of pronunciation in that passage of Terence, where Simo, speaking to his servant by way of reproof, says, "You have taken great care indeed." From the circumstances of the person, when Cicero, addressing to Catiline, says, "He went to your companion, that excellent man, Marcus Marcellus." When he calls him an *excellent man*, it is evident he means the contrary; because no good man would be a companion of Catiline. And when he begins his oration for Ligarius with saying, "Cæsar, this is a new crime, and never heard of till now," the thing he is speaking of shows it to be an irony; for it was not new, as all who were present very well understood.

The subjects of irony are vices and follies of all kinds. And this way of exposing them is often more effectual than serious reasoning: For many persons, who, either from temper or want of reflection, cannot be moved by the force of an argument, are not proof against the poignancy of wit and raillery. And therefore we find the most grave and serious persons have not declined the use of this trope upon proper occasions. Socrates, whom the oracle pronounced the wisest man of his age, gave so much into it, that he got the name of *ωπαις*, that is, the *droll.* In the sacred writings we have a remarkable instance of it in the prophet Elijah, where he challenges the priests of Baal to prove the truth of their deity: For it is said expressly, "He mocked them, and said, Cry aloud, for he is a god; either he is talking, or he is purifying, or he is on a journey, or peradventure he sleepeth, and must be awaked." And Solomon takes the like method to expose the follies of youth by this ironical apostrophe, "Rejoice, O young man, in thy youth," with what follows, which is all ironical. Nay, our Saviour himself thought fit thus to reprove the Jewish doctors, when he says, "Full well ye reject the commandment of God, that ye may keep your own tradition:" Where, by the words *full well*, or, as it is in the original, *καλως*, it is very evident that a severe reprimand was intended.

An irony is used on a variety of occasions, as we shall show from some instances in Cicero. Sometimes he applies it in a way of jest and banter: As when he says, "We have much reason to believe the modest man would not ask him for his debt, when he pursues his life." At other times by way of insult and derision: Thus when he would represent the forces of Catiline as mean and contemptible, "O terrible war, (says he), in which this band of rakes are to march under Catiline! Draw out all your garriçons against this formidable body." Again, at other times, to give the greater force to his argument, he would seem as it were by this trope to recal and correct what he had said before; as in his oration for Milo: "But it is foolish in us to compare Drusus, Africanus, Pompey, and ourselves, with Clodius; all our calamities were tolerable, but no one can patiently bear the death of Clodius." Now the character of Clodius was so well known, that all who were present must be sensible he meant the contrary. And, to name no more, an irony is never used to greater advantage, than when it is followed immediately by something very stinging.

Thus,

**Elocution.** Thus, speaking of Piso, he says, "You have heard this philosopher: he denies that he was ever desirous of a triumph." And then addressing himself to him, he immediately adds, "O wretch! when you destroyed the senate, sold its authority, subjected your consulate to the tribune, overturned the state, betrayed my life and safety for the reward of a province; if you did not desire a triumph, what can you pretend you did not desire?" This must effectually confound the false gravity at that time assumed by Piso.

## Art. II. SECONDARY TROPES.

58  
Secondary Tropes similar in nature, tho not in name, to the former ones.

SECONDARY TROPES are so called, because they are all of the same nature with the former, and may be referred to some or other of them, though they have received different names.

They are chiefly eight in number; *Antonomasia*, *Communication*, *Litotes*, *Euphemism*, *Catachresis*, *Hyperbole*, *Metalepsis*, and *Allegory*. The three first of these are simple tropes, and may all be referred to a *Synecdoche*. But the five last are of a mixed or complex nature, and not confined to any one of the primary tropes; as will appear in treating upon them in order.

59  
A common word often used by way of eminence for any thing remarkable.

I. A common or general word is sometimes used for the proper name of some particular thing or person which upon any account is eminent and remarkable. So we say, *He is gone to the city*, or *he came from the city*, that is, *London*. And by the *Scriptures* we mean the *Bible*. So likewise, in speaking of persons, *the orator* is used for Cicero, *the poet* for Homer or Virgil, and *the philosopher* for Aristotle: and it is not unusual to say *the apostle*, when we mean St Paul. On the contrary; the proper names of things or persons are sometimes applied to any other of the same character. Thus we use the word *gospel* for any certain and undoubted truth. And *Carthaginian* *fith* proverbially stood for the greatest falsehood and deceit among the Romans. With the Greeks, *Hercules* signified a *strong man*, *Nestor* a *wise man*, and *Irus* a *beggar*; and the names of *Samson*, *Solomon*, and *Job*, now answer the like characters. Both these ways of expression are often very emphatical, and heighten the idea more than where things are expressed by their own name. To call a good orator *Cicero*, or an excellent poet a *second Virgil*, includes not only an encomium upon the arts themselves, but leads the mind to what is most perfect in them, and was peculiar to those persons. These forms of speech are called *antonomasia*, and come properly under a *synecdoche*; for in the former the whole is put for a part, and in the latter a part for the whole.

60  
A change of persons common in oratory.

II. Nothing is more common with orators, than a change of persons. Sometimes, to avoid envy, and prevent the imputation of pride, in assuming to themselves the praise of any laudable action, they ascribe it to their hearers, and do not say, *we*, but *ye did so and so*. At other times, when it is necessary to remind them of something which they have done amiss, or to caution them against some wrong step for the future; to prevent giving offence, they take it upon themselves, or at least join themselves with them, and do not say, *you have done this*, or *do not you do this*; but,

*we have done it, let us not do it*. And again, at other times, in compliment to their hearers, they join them as partners in the commendable actions or virtues of other persons; as when the whole body of the people is brought in to share the praise arising from the success of wise counsels or victorious arms. Such ways of speaking often occur both in Demosthenes and Cicero. They are called *communication*, and come properly under a *synecdoche* of the whole.

III. On the contrary, there is a mode of speech, in which, by denying the contrary, more is intended than the words express. This way of speaking is called *litotes*; and is often used for sake of modesty where a person is led to say any thing in his own praise, or to soften an expression which in direct terms might found harsh or give offence. As if one should say, *I do not commend you for that*; meaning, *I greatly discommend or blame you for it*: where more being understood than the words expressly denote, it is properly a *synecdoche* of the part. Not that this manner of speaking is always to be so interpreted; but where it is not, there is no trope; which must be judged of by the circumstances of the discourse. But that it frequently is so used, might be easily shown from many instances; though it will be sufficient to mention two or three. Cicero speaking of Cotta, calls him *no mean orator*, whom he had just called a *very great orator*. And he says of Varro, that, "he pursued his studies not without industry; and afterwards gives him the character "of a man of the greatest application." Which passages, compared together, plainly show the import of those negative expressions. And a friend of Cicero, writing to him, begins his letter thus: "Although I am sensible the news I send you will not be very pleasant." This news was concerning the death of another friend of Cicero's; and thereby the words *not very pleasant*, must, surely, be meant *very unpleasant and melancholy*; but he chose that expression in the beginning of his letter, as the softest and least shocking, the better to prepare him for the following account of what the news was. And in this way interpreters explain that passage in St Matthew: *And thou Bethlehem in the land of Judah art not the least among the princes of Judah*; where, by *not the least*, they understand the *greatest*, or *very great*, upon account of the honour it received by the birth of our Saviour, as the words immediately following plainly intimate.

IV. When any displeasing or ungrateful thing is expressed by a more soft and agreeable word, it is called *euphemism*. And as the word made use of is either contrary to the proper word, or only different from it, it may be referred to different tropes. The Latins have a soft way of expressing their disregard to a person, by saying *valeat*; which we have borrowed from them, and say, *fare him well*. When the contrary being intended to what is expressed, it comes properly under an *irony*. And as the word *death* carries in it an idea that is disagreeable to human nature, instead of saying a person is dead, we often say *he is deceased*, or *departed*; which we have also taken from the Latins, who use the words *decessit* and *obiit* in the same sense. So that in both languages it comes under a *synecdoche* of the whole; to depart out of life being one sort of departure. But when the evangelist speaking of Stephen, who was stoned to death, expresses it

**Elocution.**

61  
Litotes, where, by denying the contrary, more is meant than is expressed.

62  
Ungrateful things softened by agreeable words.

by

**Elocution.** by saying that *he fell asleep*; this is a beautiful metaphor, taken from the similitude between the death of a good man and sleep.

63 **Catachresis, or harsh tropes.** V. *Catachresis* signifies in general any harsh trope, though it is most commonly found in metaphors. It is principally used by poets, who make choice of it for novelty, or to enforce an expression, where the proper word does not seem strong enough. As when Milton, in describing the angel Raphael's descent from heaven, says, he

*Sails between worlds and worlds;*

where the novelty of the word enlivens the image more than if he had said *flies*. But it is sometimes found in the gravest authors, and even in the sacred writings. So we read of the *blood of the grape*. And Solomon says, *the horse-leech hath two daughters*. In all these instances the trope is a metaphor. But when St John says in the Revelations, *I turned to see the voice that spake to me*, it is here a metonymy of the adjunct; the word *voice* being put for the person who uttered it. In St Matthew we read of *Simon the leper*; not that he was then a leper, but had been so, and was cured; which is a *synecdoche* of the part. And when a criminal is said to *have had his reward*, that is, his punishment, it is an *irony*.

64 **Hyperbole** the boldest of all tropes.

VI. *Hyperbole* is the boldest of all tropes; for it exceeds the strict bounds of truth, and represents things either greater or less, better or worse, than they really are. But the representation is made in such a manner as not to impose on the hearers. For an *hyperbole* is not used to define or describe any thing accurately, but only to magnify or depress it in a considerable degree, when we either cannot or do not choose to represent it exactly. The excess in this trope is called *auxesis*; as when we say of any thing that is very high, *it reaches to the skies*. The defect, or contrary extreme, is termed *meiosis*: So we say of a very lean person, *he is nothing but skin and bones*, or *a mere skeleton*. It is principally metaphorical, but sometimes taken from other tropes. When Saul and Jonathan are said to have been *swifter than eagles*, and *stronger than lions*, the expression is founded in similitude, and is therefore a metaphor. When, instead of saying Cato was a very virtuous man, the historian calls him *the image of virtue*; it is an hyperbolical metonymy of the adjunct for the subject. And when we read in the Mosaic history of *cities fenced up to heaven*, there is a *synecdoche*. But if a man of weak sight be said to be *eagle-eyed*, it is an *irony*. Those hyperboles which are expressed comparatively, are commonly most emphatical, because they show a peculiarity in the excess. To say a thing is *as light as a feather*, carries the idea very far; but to say *it is lighter*, not only carries it still farther, but also heightens it, by leaving the mind at an uncertainty where to fix the limits.

65 **Metalepsis**, where two or more tropes are meant under one word.

VII. Sometimes two or more tropes, and those of a different kind, are contained under one word; so that several gradations, or intervening senses, come between the word that is expressed, and the thing designed by it. And this is called a *metalepsis*. The contests between Sylla and Marius proved very fatal to the Roman state. Julius Cæsar was then a young man. But Sylla observing his aspiring genius, said of him, "In one Cæsar there are many Marius's." Now

in this expression there is a *metalepsis*. For the word *Marius*, by a *synecdoche*, or *antonomasia*, is put for any ambitious and turbulent person; and this again, by a *metonymy* of the cause, for the ill effects of such a temper to the public. So that Sylla's meaning, divested of these tropes, was, that Cæsar would prove the most dangerous person to the Roman state that ever was bred in it: which afterwards proved true in the event. So when Virgil, describing that part of the African coast where Æneas arrived with his ships, says, *A dark wood hung over it*; the word *dark*, by a metonymy of the effect, is put for *shady*, and that again by the same trope for *thick*; for his meaning is, *a thick wood*. But the words of Dido, in the same poet, contain a larger gradation, when she says,

*Happy, ah truly happy, had I been,  
If Trojan ships our coasts had never seen.*

In which expression, first by a metonymy of the adjunct, the ships are put for the Trojans in the ships: and these, by a *synecdoche* of the whole, for Æneas, who was one of them; and again his arriving on the coast, by a metonymy of the cause, for her seeing him; and lastly, her seeing him, by the same trope, for the passion she had for him. So that her meaning is, she had been happy, if she had never entertained a passion for Æneas. This trope is more frequently to be met with in poets than in orators, as they take greater liberty in using distant allusions than is suited to that peripatetic of expression which is required in oratory. But as Quintilian has well observed, all the intermediate links of the chain in this trope are of no further use than to lead the mind gradually from the first to the last, the better to perceive their connection. As in the example last mentioned, relating to Dido, if we drop all the intervening steps, and connect the words expressed with what is directly intended, they will be found to contain a very remote cause put for the effect, which comes under a metonymy. On the contrary, in the second example, where *dark* stands for *thick*, the effect is put for a remote cause. And the first, which is founded in a similitude of temper between Cæsar and Marius, belongs to a *metaphor*.

66 **Allegory**, a continuation of tropes in one or more sentences. Thus Cicero says, "Fortune provided you no field, in which your virtue could run and display itself:" where the words *field* and *run* are metaphors taken from corporeal things, and applied to the mind. And in another passage, speaking of himself, he says, "Nor was I so timorous, that after I had steered the ship of the state through the greatest storms and waves, and brought her safe into port, I should fear the cloud of your forehead, or your colleague's pestilent breath. I saw other winds, I perceived other storms, I did not withdraw from other impending tempests, but exposed myself singly to them for the common safety." Here the state is compared to a ship, and all the things said of it under that image are expressed in metaphors made use of to signify the dangers with which it had been threatened. And indeed allegories generally consist of metaphors; which being the most beautiful tropes, a number of them well chosen and put together is one of the finest and brightest ornaments in language, and exceeds

Allegory, a continuation of tropes in one or more sentences.

**Elocution.** exceeds a single metaphor in lustre, as a constellation does a separate star. It is true, that allegories are sometimes found in other tropes; but this is very rare. In that known expression of Terence, the tropes are all metonymies: *Without Ceres and Bacchus, Venus grows cold*; that is, divested of the tropes, *Without meat and drink, love dies*. And Samion's riddle is made up of synecdoches: "Out of the eater came forth meat, and out of the strong came forth sweetness." But there is no small skill requir'd in the right management of allegories. For care should be taken, that the same kind of trope be carried through the whole, so as to compose one uniform and consistent set of ideas: otherwise they dress up a chimera, a thing that has no existence, and of which the mind can form no perception. And, as Quintilian says very justly, "to begin with a tempest and end with a fire, would be very ridiculous and unnatural." It is likewise very necessary that the allusions be all plain and evident, especially where the name of the thing alluded to is not expressed. These are called *pure allegories*. As that of Cicero: "So it happens, that I, whose business it is to repel the darts, and heal the wounds, am obliged to appear before the adversaries have thrown any dart; and they are allowed a time to attack us, when it will not be in our power to avoid the assault; and if they throw a poisonous dart, which they seem prepared to do, we shall have no opportunity to apply a remedy." The tropes here are all taken from military affairs, without any intimation what they are applied to. But that is plain from the context of the discourse. For he is speaking of the disadvantages he laboured under in defending his client against those of the opposite side, and so applies to the bar those terms which were proper to the field. But where the reference is not evident, it becomes a riddle: which is nothing else but an obscure allegory. To avoid this, therefore, the best writers generally use what they call *mixed allegories*; that is, such wherein the proper name of the thing is expressed, which the whole similitude respects. Of this kind is that in the speech of king Philip of Macedon, given us by Justin, where he says, "I perceive that cloud of a dreadful and bloody war arising in Italy, and a thunder-storm from the west, which will fill all places with a large shower of blood, wherever the tempest of victory shall carry it." The proper words *war*, *blood*, and *victory*, being joined to the tropes *cloud*, *shower*, and *tempest*, in this sentence, render the several parts of the similitude plain and evident. Quintilian thinks those allegories most beautiful, where the whole similitude is expressed, and those words, which in their proper sense relate to one of the two things between which the comparison is made, are allegorically applied to the other: As when Cornelius Nepos says of Atticus, "If that pilot gains the greatest reputation who preserves his ship in a boisterous and rocky sea; ought not he to be thought a man of singular prudence, who arrived in safety through so rainy and so great civil tempests?" These are the allegories with which orators are chiefly concerned.

#### § 2. Of Figures.

THIS term seems to have been borrowed from the stage, where the different habits and gestures of the

actors suitable to the several characters they sustained, were by the Greeks called *σχημα*, and by the Latins *figura*: And it is not unusual with us to say of a person, both with respect to his dress and action, that he makes a *very bad* or a *very graceful figure*. And a language is the dress, as it were, of our thoughts, in which they appear and are represented to others; so any particular manner of speaking, may, in a large sense of the word, be called its *figure*, in which latitude writers sometimes use it. But rhetoricians have retrained the sense of the word to such forms of speech as differ from the more common and ordinary ways of expression; as the theatrical habits of actors, and their deportment on the stage, are different from their usual garb and behaviour at other times. A *figure* therefore, in the sense it is used by rhetoricians, is, *A mode of speaking different from, and more beautiful and emphatical than, the ordinary and usual way of expressing the same sense*; or in other words, *That language which is suggested either by the imagination or the passions*. Now as the habits and gestures of our bodies are in a manner infinitely variable, so it is plain that the different forms of speech are almost innumerable. But every alteration from the common manner ought not to be esteemed a figure, nor deserves that character. It must contain some beauty, or express some passion, to merit a place among rhetorical figures, and be marked out for imitation.

The subject of *figures* seems to have been one of the last things which was brought into the art of oratory, in order to complete it. Aristotle, who treats so accurately upon other parts, says very little of this. But the Greek writers who came after him have abundantly supplied that deficiency. It is to them we owe the chief observations that have been made on this subject. They took notice of the several modes and turns of expression, observed their force and beauty, and gave them particular names by which they might be known and distinguished from each other. And indeed they have treated the matter with such minuteness and subtilty, that Quintilian seems, not without reason, to think they have multiplied figures to an excess. But though it was so late before they were taken notice of, and introduced into the art of speaking, yet the use of them in discourse was doubtless very ancient. The author of Homer's life, which some have ascribed to Plutarch, has shown, by examples taken out of him, that there is scarce a figure mentioned by rhetoricians, but is to be met with in the most ancient poet. And, if we consider the nature of speech, we shall easily perceive that mankind must have been under a necessity very early to introduce the use of *tropes* for supplying the want of proper words to express their simple ideas: so the like necessity must have put them upon the use of figures to represent their different passions. Though both of them were afterwards increased, and improved in such a manner as to become the chief ornaments of language. The passions of men have been always the same; they are implanted in us by nature, and we are all taught to discover them by the same ways. When the mind is disturbed, we show it by our countenance, by our actions, and by our words. Fear, joy, anger, alter the countenance, and occasion different emotions and gestures of the whole body. And we know with

**Elocution.**  
67  
The term figure appears to be borrowed from the stage.

Elocution.

what passion a man is affected, by hearing his words, though we do not see him. He does not express himself as he usually does at other times when cool and sedate. Objects appear to him in a different view, and therefore he cannot but speak of them in a different way. He interrogates, he exclaims, he admires, he appeals, he invokes, he threatens, he recalls his words, repeats them, and by many other different turns of expression varies his speech no less than his countenance, from his common and ordinary manner. Now as nature seems to teach us by these figurative expressions how to represent the different commotions of our minds, hence some have thought fit to call figures *the language of the passions*. And as these are given us, among other wise ends, to excite us the better to provide for our preservation and safety, this is done sometimes by force of arms, and at other times by discourse. And therefore Cicero very handsomely compares the conduct of an orator to the exercises of the palæstra: in which, as each combatant endeavours not only to defend himself, and attack his adversary, but likewise to do both with decency; so the principal weapons of an orator, as he represents them, are figures, which being no less the ornaments of language than images of our passions, answer all these purposes. Besides, figures chiefly distinguish the different kinds of style, furnish it with an agreeable variety, and often serve to represent things in a clear and forcible manner.

From this short account of the nature of figures, the advantage of them to an orator is very evident. They are a sort of natural eloquence, which every one falls into without attending to it, suitably to that temper of mind with which he is affected himself, and is desirous to affect others. In a cool and sedate discourse, such figures as convey our sentiments with the greatest strength and evidence are most proper. And there are others, which are suited to brighten and enliven more gay and sprightly subjects. Others again are more peculiarly adapted to express the disorders and perturbations of the mind. To repeat the same thing again would many times be deemed a tautology and impertinent: but to do this when the mind is ruffled, is not only allowable, but the repetition renders it more strong and affecting. So likewise to interrogate, exclaim, or admire, under the influence of a passion, impresses the hearers, and disposes them to attention: whereas at another time perhaps such ways of speaking would scarce be consistent with prudence. There is a natural sympathy in mens minds, which disposes them to receive impressions from those with whom they converse. Thus one gay and pleasant companion gives a cheerfulness and vivacity to a whole company; whereas, on the contrary, one who is dull and phlegmatic damps the spirits of all about him, and affects them with the same gloomy temper. Figures are peculiarly serviceable to an orator for answering these different intentions. And as he finds them in life, from thence he must copy them; as a painter does the features of the countenance, and the several parts of the body; figures being to the one what lines and colours are to the other. The design of Catiline to destroy the Roman state and burn the city, is a story well known. There was an army drawn together at a proper distance to favour the undertaking; and others were left in Rome, who had their parts

Elocution.

assigned them for burning the city, and destroying those who should escape the flames. And in a word, every thing was ready for putting in execution this horrid and barbarous scheme. So that nothing retarded it but the taking off Cicero, who was then consul, which was thought necessary to be done first. Cicero, upon information of the design against his life, finds means to prevent it, and the same day calls together the senate. And Catiline, who was a man of consummate boldness, had the confidence to appear in that assembly. Upon their meeting, Cicero opens to them the whole affair of the conspiracy, and the design against himself, in a most warm and pathetic harangue. In which he had two things in view; to raise the indignation of the senate against the conspirators, and particularly against Catiline; and, either by terrifying or exasperating him, to oblige him to leave the city. Now he does not begin this speech in his usual manner as at other times, by addressing his audience, bespeaking their favour and attention, or letting them gradually into the design of what he was about to say; but as Catiline was present, he immediately falls upon him with vehemence, in the following manner: "How far, Catiline, will you abuse our patience? How long will your fury insult us? What bounds will you set to your unbridled rage? Does neither the night guard of the palace, nor the city-watch, nor the peoples fear, nor the agreement of all good men, nor the meeting of this senate in this fortified place, nor the countenances and looks of this assembly, at all move you? Do not you perceive your designs are discovered, and that all who are present know of your conspiracy? Who of us, do you think, is ignorant of what you did the last night, and the night before, where you was, who were with you, and what you resolved on? O times, O manners! The senate knows this, the consul sees it; and yet this man lives!—lives? nay, comes into the senate, joins in the public counsels, observes and marks out each of us for destruction!" And in the same impetuous strain he proceeds through his whole speech, interpersing a great variety of the like strong and moving figures. And the discourse had its desired effect: for when Catiline stood up afterwards to make his defence, the whole senate was so inflamed, and their resentments against him rose so high, from what Cicero had said, that they had not patience to hear him speak; upon which he left both them and the city. Had Cicero, instead of venting his just indignation against the author of so barbarous and inhuman a design, in the manner he did, by figures suited to strike the passions of his hearers; had he, instead of this attempted to reason with him, and told the story in a cold and lifeless manner, he would have exposed himself to the contempt of Catiline; and by leaving the senate little or nothing moved at what he said, prevented perhaps their coming to those speedy and vigorous resolutions which were necessary at so critical a juncture. Let us suppose him to have expostulated with Catiline in much the same words as before, but thrown into a different form, and divested of those pathetic figures. As thus: "Catiline, you have really abused our patience to a great degree. You have insulted us with your furious proceedings a long while. You seem to have fixed no bounds to your

Elocution. your unbridled rage. Neither the night-guard of the palace, nor the city watch, nor the peoples fear, nor the agreement among good men, nor the calling together of the senate in this fortified place, nor the countenances and looks of this assembly, appear to move you in the least. I assure you we are all of us apprised of what you did the last night, and the night before, where you was, and who were with you, and what resolutions you came to. These are sad times, the age is very degenerate; that the senate should know all this, the consul see it; and yet that this man should live, come into the senate, hear all our debates, and mark us out to destroy us." You see the sense is entirely the same, and the words too in a great measure; so that there is little more than an alteration in the form of them. And yet who does not perceive how flat and languid such a way of talking must have appeared at that time? and how much it loses of that spirit and energy, which shows itself in Cicero's manner of expression? Had he delivered himself thus, it might indeed have made the senate look upon Catiline as an abandoned wretch, lost to all virtue and goodness, and perhaps have moved some to pity him on that account; as we are easily induced to compassionate persons in such circumstances, especially when descended from noble and virtuous ancestors, which was his case. But sure it would have been ill suited to fire their minds with that generous regard for their country, and the necessary precautions for its security, which the circumstances of the state then required. Nor would Catiline have been at all deterred by it, but rather encouraged in the prosecution of his designs, from the little effect a speech so managed must probably have had upon the minds of the senators. But Cicero knew very well that the passions of mankind are the springs of action: that it is many times not sufficient for an orator to convince their minds, by setting the truth in a clear light; but he must also raise their hopes, alarm their fears, inflame their anger, or excite some other suitable passion, before they will be brought to act with that zeal and fervour which the case may require. And as he was admirably well skilled in this art of touching the passions, he seldom fails to fix upon the proper methods of doing it, and makes choice of such figures and modes of speaking as in the strongest manner represent the emotions of his own mind. For every passion is not to be expressed by the same figures, any more than it is drawn by the same lines, or painted with the same colours. When Dido finds that Æneas is about to leave her, she uses all her arts to detain him. And as persons in great distress are seldom at a loss to express their condition in the most affecting way; she discovers her fear, anger, revenge, with the whole crowd of disorders which then possessed her mind, in a variety of moving figures, suited to raise the counter passions in his breast, as is finely represented by Virgil in that artful speech he has made for her, which we forbear to recite for no other reason but the length of it. But what particular figures are most accommodated to answer the several ends proposed by them, will best appear when we come to treat of them separately.

We shall therefore now proceed to lay down a few  
Vol. XIII.

Elocution. directions for the proper use of figures. And first they should always be accommodated to the sentiments, and rise in proportion to the images designed to be conveyed by them. So far as they are founded in reason, they are suited to impress the mind; but where the language outstrips the thought, though it may please the ear, and some weak persons may be carried away with a pomp of words, yet an intelligent hearer will soon see through the thin and airy dress. It is the sense which gives weight to the figure, as that by striking the imagination awakens the mind, and excites it to act in conformity to reason. Again, in the use of pathetic figures, it is generally better to be nervous than copious, that the images, by their closer union, may impress the mind with greater force and energy; though in such figures as are designed for ornament or illustration, a more diffusive way of painting is sometimes agreeable. But farther, the too frequent use of figures ought to be avoided. For what was observed in relation to tropes, is also true with respect to these; that a great number of them is apt to darken and obscure the style. And besides, Cicero's reflection in this case is very just, That "it is hard to say, what should be the reason, that those things, which most affect us with a sensible pleasure, and at first sight soonest move us, do likewise soonest cloy and satiate us." But that it is so, we find by common experience. Lastly, figures should be so interwoven in a discourse, as not to render the style rough and uneven, sometimes high and at other times low; now dry and jejune, then pompous and florid. In a word, they should rather seem to arise from nature than art; to offer themselves, than to be the effect of study; and to appear not like patches upon a face, but the agreeable beauty of a sound and healthful complexion. But of this we shall have occasion to speak more at large hereafter, in treating upon the different kinds or characters of style.

As to the division of figures, which is what remains to be considered, they are usually divided into two sorts, figures of words, and figures of sentences. The difference between them consists in this; that in the former, if you alter the words, or sometimes only the situation of them, you destroy the figure; but in the latter the figure remains, whatever words are made use of, or in what manner soever the order of them is changed. Thus when the name of a person or thing is repeated, to intimate some known property or quality belonging thereto, it is a verbal figure called *place*. Cicero was a true patriot and hearty lover of his country. And therefore we shall use this figure in saying, that *at the time of Catiline's conspiracy Cicero appeared like Cicero*. The sense would remain the same, but the figure would be lost, if we should alter the words, and say, *at that time Cicero appeared like himself*. So when two or more sentences, or members of a sentence, end with the same word, it is called *epitrophe*; as when we say, *To lose all relish of life, is in effect to lose life*. But if only the order of the words be changed in the latter clause thus, *To lose all relish of life, is to lose life in effect*; the figure vanishes. And this is the nature of the verbal figures. But it is not so in figures of sentences; they continue the same, whatever alterations are made in

**Elocution.** the words. An orator sometimes thinks it proper to change the form of his discourse, and address himself to his audience, or an absent person, or else perhaps to introduce some other person as speaking to them whose words may be supposed to carry greater weight and authority with them than his own. The former of these is called *apostrophe*, and the latter *prosopeia* or *imagery*; which require no certain words or order of expression.

#### ART. I. VERBAL FIGURES.

[67]  
Verbal  
figures distinguished  
into three  
sorts; with  
their various subdivisions.

THESE may be distinguished into three sorts, as they consist in a *deficiency* of words, a *redundancy*, or a *repetition*.

I. Of the first sort are *ellipsis* and *asyndeton*.

*Ellipsis*, is when one or more words are wanting in a sentence to complete the construction, and fully express the sense. This figure is often used in proverbial speeches: as when we say, *Many men, many minds*; that is, *have many minds*; and, *The more danger, the more honour*; that is, *gains more honour*. But where more is intended by such expressions than mere brevity, and especially when they are the effect of some passion, the figure receives another name, and is called *apostrophe*, which is placed among the figures of sentences, where we shall consider it.

*Asyndeton*, is when the particles that connect the members of a sentence one with another are left out, to represent either the celerity of an action, or the haste and eagerness of the speaker. Thus Cæsar expresses his speedy conquest of Pharnaces: *I came, I saw, I conquered*. If he had inserted the copulatives, and said, *I came, and I saw, and I conquered*, it would have retarded the expression, and not given so full and just an idea of the swiftness of the action. In the last article we took notice of the vehement and impetuous manner in which Cicero attacked Catiline in his first oration, where his design was to fire the minds of the senate against him, and oblige him to leave the city, both which points he gained by that speech. The next day, therefore, when Catiline was gone, he calls together the body of the citizens, and makes a speech to them, which in a sort of rapture or transport of mind he thus begins, by acquainting them with the departure of Catiline, *He is gone, departed, escaped, broken out*; intimating at the same time both the excessive rage in which Catiline left Rome, and the great pleasure with which he was himself affected on that account. This concise way of speaking adds likewise a considerable emphasis to an expression, and by bringing the several parts of a thing nearer together affects the mind with greater force. Thus Cicero sets Cato's character in a very strong and beautiful light by the use of this figure. "Nature itself (says he) has made you a great and excellent man for integrity, gravity, temperance, magnanimity, justice, in a word, for all virtues."

II. The second sort of verbal figures is contrary to these, and consists in a redundancy or multiplicity of words; which are likewise two, *pleonasmus* and *polyndeton*.

When we use more words than are necessary to express a thing, it is called *pleonasmus*. This is done sometimes for greater emphasis, as when we say, *Where in the world is he?* At other times it is designed to as-

certain the truth of what is said: So the servant in Terence, when the truth of what he had related was called in question, replies, *It is certainly so; I saw it with these very eyes*.

When the several parts of a sentence are united by proper particles, it is called *polyndeton*. This adds a weight and gravity to an expression, and makes what is said to appear with an air of solemnity; and by retarding the course of the sentence, gives the mind an opportunity to consider and reflect upon every part distinctly. We often meet with this figure in Demosthenes, which very well suits with the gravity of his style. So he encourages the Athenians to prosecute the war against king Philip of Macedon, from this consideration, that now "they had ships, and men, and money, and stores, and all other things which might contribute to the strength of the city, in greater number and plenty than in former times." Every article here has its weight, and carries in it a proper motive to animate them to the war. But if you remove the copulatives, the sentence will lose much of its force.

III. The third kind of verbal figures consists in a *repetition*. And either the same word in sound or sense, is repeated; or one of a like sound, or signification, or both.

Of the former sort there are ten, called *antanaclasis*, *plote*, *epizeuxis*, *climax*, *anaphora*, *epistrophe*, *symplote*, *epanalepsis*, *anadiplosis*, and *epanodos*. The two first of these agree in sound, but differ in sense; the eight following agree in both.

When the same word in sound but not in sense is repeated, it is called *antanaclasis*. This figure sometimes carries a poignancy in it; and when it appears natural and easy, discovers a ready turn of thought. As when a son, to clear himself of suspicion, assured his father *he did not wait for his death*; his father replied, *But I desire you would wait for it*. Here the word *wait* is taken in two different senses. It is likewise used on serious occasions, as in grave and moral precepts which are apt to affect the mind with greater pleasure when delivered in an agreeable dress. As this; *Care for those things in your youth, which in old age may free you from care*: Where the word *care* in the former place signifies to *provide*, and in the latter *anxiety of mind*. And even our Saviour himself once uses this figure, when he says to one of his disciples, who desired to be dismissed from attending him that he might go and bury his father; *Follow me, and let the dead bury their dead*: Where *dead* in one place denotes a *natural death*, and in the other a *moral or spiritual death*.

Sometimes the name of some person or thing is repeated again, to denote some particular character or property designed to be expressed by it; and then it is called *plote*. Thus Cicero says, *Young Cato wants experience, but yet he is Cato*; meaning he had the steady temper of the family. And so in the proverbial expression, *An ape is an ape, dress him ever so fine*.

When a word is repeated again with vehemence in the same sense, it is called *epizeuxis*. This figure shows the earnestness of the speaker, and his great concern of mind about what he says; and therefore has a natural tendency to excite the attention of the audience.

**Elocution.**

**Elocution.** It is suited to express anger, surprise, sorrow, and several other passions. As when Cicero would express his indignation against Anthony for having been the chief instrument in bringing on the civil war, he says to him: *You, you, Anthony, pushed Caesar upon the civil war.* And thus he tells Catiline in his first invective against him: *You live; and live, not to lay aside, but to pursue, your wicked design.* And when our Saviour would express his great concern and sorrow for the wickedness of the Jews, he does it in this pathetic manner: *O Jerusalem, Jerusalem, who killest the prophets!*

69 **Climax** is a beautiful kind of repetition, when the word, which ends the first member of a period, begins the second, and so through each member, till the whole is finished. There is a great deal of strength as well as beauty in this figure, where the several steps rise naturally, and are closely connected with each other. As in this example: *There is no enjoyment of property without government, no government without a magistrate, no magistrate without obedience, and no obedience where every one acts as he pleases.* But, as Quintilian observes, this figure lies so open, that it is apt to look too much like art; for which reason he advises not to use it often. To prevent this, therefore, orators sometimes disguise it, by not repeating the same word which stood in the former member, but some other equivalent to it. As in the following instance of Cicero for Milo: "Nor did he commit himself only to the people, but also to the senate; nor to the senate only, but likewise to the public forces; nor to these only, but also to his power with whom the senate had entrusted the whole commonwealth."

70 When several sentences, or members of a sentence, begin with the same word, it is called *anaphora*. This is a lively and elegant figure, and serves very much to engage the attention. For by the frequent return of the same word the mind of the hearer is held in an agreeable suspense, till the whole is finished. "You do nothing (says Cicero to Catiline), you attempt nothing, you think nothing, but what I not only hear, but also see, and plainly perceive." It is frequently used by way of question; which renders it not only beautiful, but likewise strong and nervous. As at the beginning of the same speech: "Does neither the night-guard of the palace, nor the city-watch, nor the peoples fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you?" And in another of his orations: "What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beasts as well as men seem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you and your ancestors have undergone the greatest labours?"

71 **Epistrophe** is contrary to the former, and makes the repetition at the end of each member or sentence. As thus: *Since concord was lost; friendship was lost, fidelity was lost, liberty was lost; all was lost.* And Cicero, in the charge which he brings against Mark Antony before the senate, makes use of this figure, when

he says, "Do you lament the destruction of three Roman armies? the author of that destruction was Antony. Do you bewail the loss of most eminent citizens? They have been taken from you by Antony. Is the authority of this order weakened? It is weakened by Antony."

**Symploce** takes in both these last figures. As in that of Cicero, "You would pardon and acquit him, whom the senate hath condemned, whom the people of Rome have condemned, whom all mankind have condemned." Here the several members both begin and end with the same word. We have a beautiful instance of it in St Paul, when he says, "Are they Hebrews? so am I. Are they Israelites? so am I. Are they the seed of Abraham! so am I."

When a sentence concludes with the word with which it began, it is called *epanalepsis*. As in that expression of Plautus, "Virtue contains all things, he wants no good thing who has virtue." The figure is the same, but the principle not so honest, in the advice which we find given by the miser in Horace, when he says, "Get money, if you can, honestly; but however, get money." This figure adds a force to an expression, when the principal thing designed to be conveyed is thus repeated, by leaving it last upon the mind. And it heightens the beauty of it, when the sentence has an agreeable turn arising from two opposite parts. As in Cicero's compliment to Cæsar: "We have seen your victory terminated by the war; your drawn sword in the city we have not seen." Hermogenes calls this a *circle*, because the sentence returns again to the same word, as that geometrical figure is formed by the orbicular motion of a line to the same point.

When the following sentence begins with the same word with which the former concluded, it is termed *anadiplosis*. As in the following instance: *Let us think no price too great for truth; truth cannot be bought too dear.* So in that passage of St John: *He came to his own, and his own received him not.* This figure generally suits best with grave and solemn discourses.

**Epanodos** is the inversion of a sentence, or repeating it backwards, so that it takes in the two last figures; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shows a readiness of thought. We have the following example of it in Minutius Felix, where he is exposing the folly of the Egyptian superstition. "Isis (says he), with Cynocephalus, and her priests, laments, bemoans, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother; in a little time the son is found, upon which they all rejoice. Nor do they cease every year to lose what they find, or to find what they lose. And is it not ridiculous to lament what you worship, or to worship what you lament?" It serves likewise to illustrate and enforce the sense, by setting it in two opposite views. As in that expression of the prophet: "Wo unto them who call good evil, and evil good; who put darkness for light, and light for darkness!"

Those figures which consist in a repetition of words of a like sound or signification, or both, are four;

Elocution.

Elocution.

*paronomasia*, *homoioputon*, *synonymia*, and *derivation*; the two first of which respect words that are similar in sound only, the third in sense, and the last in both.

76

When two words very near in sound, but different in sense, respect each other in the same sentence, it is called *paronomasia*. As when we say, *After a feast comes a fast*; and, *A friend in need is a friend indeed*. We usually call it a *pun*, which when new, and appositely used, passes for wit, and serves to enliven conversation. Nor is it wholly to be excluded from grave and serious discourses: for a witty jest has many times had a better effect than a solid argument, and prevailed with those who could not be moved by close reasoning. And therefore Cicero and the best speakers have sometimes recourse to it upon weighty and solemn occasions, as will be shewn hereafter in its proper place.

77

When the several parts of a sentence end with the same case, or a tense of a like sound, this also is considered as a figure, and named *homoioputon*. As thus: *No marvel though wisdom complain that she is either awfully despised, or carelessly neglected; either openly scorned, or secretly abhorred*. This figure is esteemed most beautiful when the parts are all of the same length, or pretty near it; as it adds to the harmony of the period, and renders the cadency of the several members more musical from the just proportion between them. The Greek rhetoricians were much addicted to this figure, and Isocrates is particularly celebrated for it. But some of the best orators seem to have industriously avoided it, as carrying in it too much the appearance of art. And it is remarkable, that this figure appears nowhere so much in all the works of Demosthenes, as in an oration which he did not speak himself, but wrote for his friend Diodorus, a man of that taste, who was to pronounce it as his own.

78

The next figure abovementioned is *synonymia*. Now strictly speaking, synonymous words are those which have exactly the same sense. But there being few such, the use of the term is so far extended as to comprehend words of a near affinity in their signification, which in discourse are frequently put for one another. So, *to desire*, and *intreat*, are sometimes used as equivalent terms; whereas *to desire* is no more than to wish for a thing, and *to intreat* is to express that inclination in words. In like manner, *esteem* and *honour* are often taken for synonymous words, though they have not precisely the same sense, but one is the usual consequence of the other; for esteem is the good opinion we entertain of a person in our mind, and honour the outward expression of that opinion. When two or more such words come together, they constitute this figure. As when Cicero, speaking of Piso, says, "His whole countenance, which is the tacit language of the mind, has drawn men into a mistake, and deceived, cheated, imposed on those who did not know him." This figure sometimes adds force to an expression, by enlivening the idea; and it often promotes the harmony and just cadency of a sentence, which otherwise would drop too soon, and disappoint the ear.

79

When such words as spring from the same root, as *justice*, *just*, *injustice*, *unjust*, and the like, come together in the same sentence, they make the figure called *derivatio*. Cicero observing the vanity of the philosophers who affected praise at the same time that they

decried it, uses this figure when he says of them, "The philosophers set their names to those very books which they write for the contempt of glory; and are desirous to be honoured and applauded even for what they say in contempt of honour and applause." This figure receives an additional beauty when repeated, especially in two opposite members; as, *He wished rather to die a present death, than to live a miserable life*.

#### Art. II. FIGURES of SENTENCES.

Of these, some are principally adapted for reasoning, and others to move the passions.

1. *Those suited for proof*. Which are six: *Prolepsis*, *hyperbole*, *anacoecosis*, *epitrope*, *parabole*, and *antithesis*.

*Prolepsis*, or *anticipation*, is so called, when the orator first starts an objection, which he foresees may be made either against his conduct or cause, and then answers it. Its use is to forestall an adversary, and prevent his exceptions, which cannot afterwards be introduced with so good a grace. Though it has likewise a farther advantage, as it serves to conciliate the audience, while the speaker appears desirous to represent matters fairly, and not to conceal any objection which may be made against him. The occasions of this figure are various; and the manner of introducing it very different. Sometimes the orator thinks it necessary to begin with it, in order to justify his conduct, and remove any exceptions which may be made against his design. Cicero, for several years together, after he first began to plead, had always been for the defendant in criminal cases. And therefore, when he was prevailed with to undertake the accusation of Verres, he begins his oration with this apology for himself: "If any one present should wonder, that when for several years past I have so conducted myself as to defend many and accuse none, I now on a sudden alter my custom, and undertake an accusation: when he shall have heard the occasion and reason of my design, he will both approve of it, and think no person so proper to manage this affair as myself." And then he proceeds to give an account of the reasons which moved him to engage in it. At other times the objection is admitted as an exception to what has been said, but not so as to affect it in general. Thus, when Cicero has represented the advantages of literature and the polite arts, he starts this objection to what himself had said. "But some one will ask, whether those great men, the memory of whose glorious actions is delivered down to posterity, were acquainted with that sort of learning I so applaud?" To which he replies, "Indeed this can scarce be said of them all. However, the answer is easy. I have known several persons of excellent abilities, who, without learning, by the force of an extraordinary genius have been men of great virtue and solidity. Nay I will add, that nature without learning, has oftener produced these qualifications, than learning without a genius. But yet it must still be owned, that where both these meet, they form something very excellent and singular." Again, at other times, the orator artfully represents the objection as something considerable and important, to give the greater weight to his answer when he has confuted it. Cicero, in his celebrated oration for the Manilian law, could not omit

80  
Of figures of sentences; some are for reasoning, and some for moving the passions

to

Elocution. to take notice, that Lucullus had already gained several very considerable advantages over Mithridates. And therefore, having before described the war as very great and dangerous, apprehending these two accounts might appear somewhat inconsistent, and be liable to an objection, he puts it thus artfully himself: "But now, after what I have said of Lucullus, it may probably be asked, How then can the war be so great? Be pleased to hear, for there seems to be very just reason for this question." And then he proceeds to show, from the power of king Mithridates at that time, his great abilities, long experience in military affairs, and fresh alliances, that the war was yet very great and dangerous. But sometimes, when the orator is sensible that what he has advanced lies open to an objection, he omits to make it in express terms; and yet proceeds to vindicate what he had said, as if it had been made. Thus, when Cicero had charged Verres with having plundered the inhabitants of Sicily of all their plate, jewels, and other valuable moveables, which he thought worth while to carry away; as the audience might imagine this to be scarce credible, he takes it for granted they thought so, and therefore immediately adds, "As strange as this is, I affirm it positively, without any intention to aggravate the crime." And so he goes on to the proof of his assertion. But this figure is likewise made use of to guard against some objection, which the speaker apprehends may be made against what he designs to say. And thus Cicero uses it in his oration for Sextius. "My province (says he), as I speak last, seems to call for affection to my friend, rather than his defence; complaint, rather than eloquence; expressions of grief, rather than art. And therefore, if I shall express myself with more warmth, or greater freedom, than those who have spoken before me, I hope you will grant me all that liberty of speech which you judge reasonable to be allowed to an affectionate sorrow and just resentment." This figure requires great prudence and discretion in the management of it. The speaker must consider well the temper, bias and other circumstances of his hearers, in order to form a right judgment what parts of his discourse may be most liable to exception. For to object such things, which the hearers would never have thought of themselves, is to give himself a needless trouble: and to start such difficulties, which he cannot afterwards fairly remove, will expose both himself and his cause. But as nothing gives an audience greater pleasure and satisfaction, than to have their scruples fully answered as they rise in their thoughts; so on the contrary, be a discourse otherwise ever so entertaining and agreeable, if there be any doubt left upon the minds of the hearers, it gives them a pain that continues with them till it be removed.

81 The figure *hypobole* or *subjection*, is not much unlike the former; and is, when several things are mentioned that seem to make for the contrary side, and each of them refuted in order. It consists of three parts, when complete; a proposition, an enumeration of particulars with their answers, and a conclusion.—Thus Cicero, upon his return from banishment, vindicates his conduct in withdrawing so quietly, and not opposing the faction that ejected him. "My departure (says he,) is objected to me, which charge I cannot answer without commending myself. For what

must I say? That I fled from a consciousness of guilt? But what was charged upon me as a crime, was so far from being a fault, that it is the most glorious action since the memory of man, (he means his punishing the associates of Catiline.) That I feared being called to an account by the people? That was never talked of; and if it had been done, I should have come off with double honour. That I wanted the support of good and honest men? That is false. That I was afraid of death? That is a calumny. I must therefore say, what I would not, unless compelled to it, that I withdrew to preserve the city." When the objections are put by way of question, as in the example here given, they add a briskness and poignancy to the figure. All the parts of it are not constantly expressed. For thus Cicero in his defence of P. Anicius introduces his adversary objecting, and himself answering, "The people judged ill, but they did judge; they should not have done it, but they had a power; I cannot submit to it, but many very great and wise men have."—Both the proposition and conclusion are here omitted.

The next figure in order is *anacoluthis*, or *communication*; by which the speaker deliberates either with the judges, the hearers, or the adversary himself. Thus Cicero addresses the judges in his accusation of Verres: "Now I desire your opinion what you think I ought to do. And I know your advice will be, though you do not declare it, what appears to me necessary to be done." In another place we find him reasoning in this manner with the adverse party: "What could you have done in such a case, and at such a time; when to have sat still, or withdrawn, would have been cowardice? When the wickedness and fury of Saturninus the tribune had called you into the capital; and the consuls, to defend the safety and liberty of your country; whose authority, whose voice, which party would you have followed, and whose command would you have chosen to obey?" The figure carries in it an air of modesty and condescension, when the speaker seems unwilling to determine in his own cause, but refers it to the opinion of others. It likewise shows a persuasion of the equity of his cause that he can leave it to their arbitration; and serves very much to conciliate their minds, while he joins them, as it were, with himself, and makes them of his party. And when the appeal is made to the adverse party, it is of considerable advantage, either to extort a confession, or at least to silence him. And therefore the sacred writers sometimes very beautifully introduce God himself thus expostulating with mankind; as the prophet Malachi, *A son honoureth his father, and a servant his master. If then I be a father, where is mine honour? and if I be a master, where is my fear?*

Another figure that comes under this head, is *epitrope* or *concession*; which grants one thing, to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or a part only, is granted. We shall consider each of these separately, and illustrate them with proper examples. Nothing more confounds an adversary, than to grant him his whole argument; and at the same time either to shew that it is nothing to the purpose, or to offer something else which may invalidate it. *I allow*, says the claimant by will against the heir at law, *that nobody was more nearly related to the deceased than you;* that

Elocution.

82

83

*Elocution.* *that he was under some obligations to you; that you were in the army together; but what is all this to the will?* And thus Cicero in his defence of Ligarius, who was accused by Tubero for having joined with Pompey in the civil war between him and Cæsar: "You have, Tubero, what an accuser would most desire, the accused person confessing the charge; but so as to affirm, that he was of the same party with you and your excellent father. Therefore own first that it was a crime in yourself, before you charge it as such upon Ligarius." Sometimes the orator gives up some particular point that would well admit of a dispute, to gain something more considerable, which he thinks cannot fairly be denied him. In the affair of Roscius, where the proof depended upon circumstances, Cicero, who defended him, inquires what reason could be alleged for his committing so black a crime, as to kill his father. And after he has shown there was no probable reason to be assigned for it, he adds, "Well, since you can offer no reason, although this might be sufficient for me, yet I will recede from my right; and upon the assurance I have of his innocence, I will grant you in this cause what I would not in another. I do not therefore insist on your telling me why he killed his father, but ask how he did it?" This appearance of candour and ingenuity in such concessions removes the suspicion of art, and gives greater credit to what is denied. We have an example of a feigned or ironical concession, in Cicero's defence of Flaccus; where, interceding for him on the account of his former good services in the time of Catiline's conspiracy, he says in the way of irony, If such things are to be overlooked, "let us appease the ghosts of Lentulus and Cethegus; let us recal those who are in exile; and let us be punished for our too great affection and love for our country." By this artful insinuation, the orator, after he has used all his arguments to persuade his hearers, does as it were set them at liberty, and leave them to their own election: it being the nature of man to adhere more steadfastly to what is not violently imposed, but referred to his own free and deliberative choice. And to these feigned concessions may be referred such ways of reasoning, by which the orator both justifies a charge brought against him upon the supposition of its being true, and also proves that the charge itself is false. Thus Cicero, in his defence of Milo, represents the taking off Clodius, with which Milo was accused, as a glorious action; after he has shewn that Milo's servants did it without the knowledge of their master.

84

*Parable* or *similitude*, illustrates a thing by comparing it with some other, to which it bears a resemblance. Similitudes are indeed generally but weak arguments, though often beautiful and fine ornaments. And where the design of them is not so much to prove what is doubtful, as to set things in a clear and agreeable light, they come properly under the notion of figures. They are of two sorts; simple and compound. Those are called *simple*, in which one thing only is likened or compared to another, in this manner: *As swallows appear in summer, but in winter retreat; so false friends show themselves in prosperity, but all fly away when adversity approaches.* Compound similitudes are such, wherein one thing is likened or compared to several others; as thus: *What light is to the world, phy-*

*sic to the sick, water to the thirsty, and rest to the weary; that is knowledge to the mind.* The more exact the agreement is between the things thus compared, they give the greater beauty and grace to the figure.

*Antithesis* or *opposition*, by which things contrary or different are compared to render them more evident. Thus Cicero says, "The Roman people hate private luxury, but love public grandeur." This is a very florid figure; and suited no less for amplification than proof. As in the following instance of Cicero, where, speaking of Pompey, he says, "He waged more wars than others had read; conquered more provinces than others had governed; and had been trained up from his youth to the art of war, not by the precepts of others, but by his own commands; not by miscarriages in the field but by victories; not by campaigns, but triumphs." It is esteemed a beauty in this figure when any of the members are inverted, which some call *antimetathesis*. As where Cicero, opposing the conduct of Verres when governor of Sicily, to that of Marcellus who took Syracuse the capital city of that island, says, "Compare this peace with that war, the arrival of this governor with the victory of that general, his profligate troops with the invincible army of the other, the luxury of the former with the temperance of the latter; you will say, that Syracuse was founded by him who took it, and taken by him who held it when founded." To this figure may also be referred *oxymoron*, or *seeming contradiction*; that is, when the parts of a sentence disagree in sound, but are consistent in sense. As when Ovid says of Althea, that *she was impiously pious*. And so Cato used to say of Scipio Africanus, that "he was never less at leisure, than when he was at leisure; nor less alone than when alone." By which he meant, as Cicero tells us, that "Scipio was wont to think of business in his retirement, and in his solitude to converse with himself." This is a strong and bold figure, which awakens the mind, and affords it an agreeable pleasure to find upon reflection, that what at first seemed contradictory, is not only consistent with good sense, but very beautiful.—The celebrated Dr Blair, whom we have more than once quoted in this article, has these observations on antithesis, or the contrast of two objects, "Contrast has always this effect, to make each of the contrasted objects appear in the stronger light. White, for instance, never appears so bright as when it is opposed to black, and when both are viewed together. Antithesis, therefore, may, on many occasions, be employed to advantage, in order to strengthen the impression which we intend that any object should make. In order to render an antithesis more complete, it is always of advantage, that the words and members of the sentence, expressing the contrasted objects, be similarly constructed, and made to correspond to each other. This leads us to remark the contrast more, by setting the things which we oppose more clearly over against each other; in the same manner as when we contrast a black, and a white object, in order to perceive the full difference of their colour, we should choose to have both objects of the same bulk and placed in the same light. Their resemblance to each other, in certain circumstances, makes their disagreement in others more palpable. At the same time, I must observe, that the frequent use of antithesis, especially where the opposition in the words is nice and quaint, is apt to render the

85

**Elocution.** the style disagreeable. A maxim, or moral saying, properly enough receives this form; both because it is supposed to be the fruit of meditation, and because it is designed to be engraven on the memory, which recalls it more easily by the help of such contrasted expressions. But where a string of such sentences succeed each other, where this becomes an author's favourite and prevailing manner of expressing himself, his style is faulty; and it is upon this account Seneca has been often and justly censured. Such a style appears too studied and laboured; it gives us the impression of an author attending more to his manner of saying things, than to the things themselves which he says." There is still another kind of antithesis, which consists in surprising us by the unexpected contrasts of things which it brings together; but it is such as is wholly beneath the dignity of an orator, or of grave compositions of any fort, and is fit only for pieces of professed wit and humour, calculated only to excite laughter or create ridicule.

86  
The second  
kind of  
figures of  
sentences.

II. *Those suited to move the passions.* Which are 13; namely, *epanorthosis*, *paralepsis*, *parabesia*, *aparethmesis*, *exergasia*, *hypotyposis*, *aporia*, *postopesis*, *erotesis*, *ecphonesis*, *epiphonema*, *apostrophe*, and *protopopæia*.

*Epanorthosis*, or *correction*, is a figure, by which the speaker either recalls or amends what he had said. It is used different ways. For sometimes one or more words are recalled by him, and others subjoined in their room; at other times, without recalling what has been said, something else is substituted as more suitable. This is a very extensive figure, and made use of in addressing different passions. We have an instance of it in Terence's *Self-tormentor*, where the old man, whose extraordinary concern for the absence of his son gave occasion to the name of the play, thus bewails his condition to his neighbour, "I have an only son, Chremes. Alas! did I say that I have; I had indeed; but it is now uncertain whether I have or not." Here, to aggravate his misfortune, he recalls a pleasing word, and substitutes another more affecting in its place. And Cicero, in his defence of Milo, speaking to the judges concerning Clodius, says, "Are you only ignorant what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?" Again, in his defence of Plancius, he says, "What greater blow could those judges, if they are to be called judges, and not parricides of their country, have given to the state, than when they banished him, who when prætor freed the republic from a neighbouring war, and when consul from a civil one?" He is speaking there of Opimius. But in commending the moderation of Lucius Mummius, who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recalls his whole expression, and by giving it a new turn heightens the compliment he designed him: "He chose rather (says he) to adorn Italy than his own house; though by adorning Italy his house seems to have received the greatest ornament." And sometimes the correction is made by substituting something contrary to what had been said before; as in the following passage of Cicero: "Cæsar (meaning Augustus), though but a youth, by an incredible and surprising resolution and courage, when Antony was most enraged,

and we dreaded his cruel and pernicious return from Brundisium, at a time when we neither asked, nor expected, nor desired it (because it was thought impossible), raised a very powerful army of invincible veterans; to effect which he threw away his whole estate: Though I have used an improper word; for he did not throw it away, but employed it for the safety of the government." At other times, as has been said, the correction is made by adding a more suitable word, without any repetition of the former. Thus Cicero, after he has inveighed against the crimes of Verres, breaks out into this pathetic exclamation: *O the clemency, or rather wonderful and singular patience, of the Roman people!* He did not think the word *clemency* strong enough, and therefore adds *patience*, as better answering his design. The sudden and unexpected turn of this figure gives a surprise to the mind, and by that means renders it the more pathetic.

*Paralepsis*, or omission, is another of these figures, when the speaker pretends to omit, or pass by, what at the same time he declares. It is used either in praise or dispraise. Thus Cicero, in his defence of Sextius, introduces his character in this manner, with a design to recommend him to the favour of the court: "I might say many things of his liberality, kindness to his domestics, his command in the army, and moderation during his office in the province: but the honour of the state presents itself to my view; and calling me to it, advises me to omit these lesser matters." But in his oration to the senate against Rullus the tribune, who had proposed a law to sell the public lands, he makes use of this figure to represent the pernicious effects of such a law, particularly with respect to the lands in Italy. "I do not complain (says he) of the diminution of our revenues, and the woful effects of this loss and damage. I omit what may give every one occasion for a very grievous and just complaint, that we could not preserve the principal estate of the public, the finest possession of the Roman people, the fund of our provisions, the granary of our wants, a revenue entrusted with the state; but that we must give up those land to Rullus, which, after the power of Sylla, and the largesses of the Gracchi, are yet left us. I do not say, this is now the only revenue of the state, which continues when others cease, is an ornament in peace, fails us not in war, supports the army, and does not fear an enemy. I pass over all these things, and reserve them for my discourse to the people, and only speak at present of the danger of our peace and liberties." His view here was to raise the indignation of the senate against Rullus, and excite them to oppose the law. There is a beautiful instance of this figure in St Paul's epistle to Philemon, where, after he has earnestly intreated him to receive again Onesimus his servant, who had run from him, and promised that if he had wronged him, or owed him any thing, he would repay it, he adds, *That I may not say, you owe even yourself to me.* Nothing could be a stronger motive to soften his displeasure against his servant, from a sense of gratitude to the apostle. Hermogenes has observed, that the design of this figure is to possess the minds of the audience with more than the words express, and that it is principally made use of on three occasions: either when things are small, but yet necessary to be mentioned;

87

Elocution.

tioned; or well known, and need not be enlarged on; or ungrateful, and therefore should be introduced with caution, and not set in too strong a light.

88

The next figure abovementioned was *Parrhesia*, or reprehension: Not that whenever a person admonishes or reproves another, it is to be esteemed a figure; but when it is done with art and address, and in such circumstances as render it difficult not to displease.—The orator therefore sometimes prepares his hearers for this, by commending them first, urging the necessity of it, representing his great concern for them as his motive, or joining himself with them. Thus Cicero charges the senate with the death of Servius Sulpicius, for sending him to Mark Antony under a very ill state of health. And his design in it was to bring them more readily into a motion he was about to make, that both a statue and a sepulchral monument might be erected to his memory at the public expence. “You, (says he) it is a very severe expression, but I cannot help saying it; you, I say, have deprived Servius Sulpicius of his life. It was not from cruelty indeed (for what is there with which this assembly is less chargeable?) but when his distemper pleaded his excuse more than his words, from the hopes you conceived that there was nothing which his authority and wisdom might not be able to effect, you vehemently opposed his excuse, and obliged him, who always had the greatest regard for your commands, to recede from his resolution.” Sometimes, indeed, the orator assumes an air of reproof, with a view only to pass a compliment with a better grace. As Cicero in his address to Cæsar, when he says, “I hear that excellent and wise saying from you with concern, That you have lived long enough either for the purposes of nature, or glory: for nature, perhaps, if you think so; and, if you please, for glory; but, what is principally to be regarded, not for your country.” It adds both a beauty and force to this figure, when it is expressed in a way of comparison. As in the following instance of Cicero; “But since my discourse leads me to this, consider how you ought to be affected for the dignity and glory of your empire. Your ancestors often engaged in war to redress the injuries of their merchants or sailors; how ought you then to resent it, when so many thousand Roman citizens were murdered by one message, and at one time? Your forefathers destroyed Corinth, the principal city of Greece, for the haughty treatment of their ambassadors; and will you suffer that king to go unpunished who has put to death a Roman legate, of consular dignity, in the most ignominious as well as most cruel manner? See, lest, as it was their honour to leave you the glory of so great an empire, it should prove your disgrace not to be able to maintain and defend what you have received from them.” By this figure, an address is made to the more tender passions, modesty, shame, and emulation, the attendants of an ingenuous temper, which is honestly touched, and most affected, by a just reproof.

89

Another of these pathetic figures is *Aprihensio*, or *enumeration*, when that which might be expressed in general by a few words, is branched out into several particulars, to enlarge the idea, and render it the more affecting. Cicero, in pleading for the Manilian law, where his design is to conciliate the love and esteem of the people to Pompey, thus enlarges upon

his character: “Now, what language can equal the virtue of Cneius Pompey? What can be said either worthy of him, or new to you, or which every one has not heard? For those are not the only virtues of a general which are commonly thought so; labour in affairs, courage in dangers, industry in acting, dispatch in performing, design in contriving; which are greater in him than in all other generals we have ever seen or heard of.” And so likewise, when he endeavours to dispossess Pompey of the apprehension that Milo designed to assassinate him: “If (says he) you fear Milo; if you imagine that either formerly, or at present, any ill design has been formed by him against your life; if the soldiers raised through Italy (as some of your officers give out), if these arms, if these cohorts in the Capitol, if the centries, if the watch, if the guards which defend your person and house, are armed to prevent any attempt of Milo, and all of them appointed, prepared, and stationed on his account; he must be thought a person of great power, and incredible resolution, above the reach and capacity of a single man, that the most consummate general and the whole republic are in arms against him only. But who does not perceive, that all the disordered and sinking parts of the state are committed to you, to rectify and support them by these forces?” This might have been said in a few words, that such vast preparations could never be intended for so low a purpose. But the orator’s view was to expose that groundless report, and shame it out of countenance. And soon after he endeavours to raise compassion for Milo under those prejudices by the same figure: “See how various and changeable is the state of human life. how unsteady and voluble is fortune, what infidelity in friends, what disguises suited to the times, what flights, what fears, even of the nearest acquaintance, at the approach of dangers.” Had no address to the passions been designed here, fewer of these reflections might have been sufficient. The use of this figure in amplification is very evident from the nature of it, which consists in unfolding of things, and by that means enlarging the conception of them.

*Exergisio*, or *expulsion*, has an affinity with the former figure: but it differs from it in this, that it consists of several equivalent expressions, or nearly such, in order to represent the same thing in a stronger manner; whereas the other enlarges the idea by an enumeration of different particulars. So that this figure has a near relation to synonymia, of which we have treated before under *Verbal figures*. We have an instance of it in Cicero’s defence of Sextius, where he says, “Those who at any time have incited the populace to sedition, or blinded the minds of the ignorant by corruption, or traduced brave and excellent men, and such as deserved well of the public, have with us always been esteemed vain, bold, bad, and pernicious citizens. But those who repressed the attempts and endeavours of such as, by their authority, integrity, constancy, resolution, and prudence, withstood their insolence, have been always accounted men of solidity, the chiefs, the leaders, and supporters of our dignity and government.” Nothing more is intended by this passage, but to set the opposite characters of factious persons and true patriots in the strongest light, with a view to recommend the one, and create a just hatred and detestation of the other.

90

So

**Elocution.** So elsewhere he represents the justice of self-defence in no less different times: "If reason (says he) prescribes this to the learned, and necessity to barbarians, custom to nations, and nature itself to brutes, always to ward off all manner of violence, by all possible ways, from their body, from their head, from their life; you cannot judge this to be a criminal and wicked action, without judging at the same time that all persons who fall among robbers and assassins must either perish by their weapons, or your sentence."—He is here addressing the judges in favour of Milo. The warmth and vehemence of the speaker often runs him into this figure, when he is affected with his subject, and thinks no words, no expressions, forcible enough to convey his sentiments; and therefore repeats one after another, as his fancy suggests them. This flow of expression, under the conduct of a good judgment, is often attended with advantage: as it warms the hearers, and impresses their minds, excites their passions, and helps them to see things in a stronger light.

**Hypotyposis, or imagery,** is a description of things painted in such strong and bright colours, as may help the imagination of the hearers to conceive of them rather as present to their view, than described in words. It is peculiarly suited for drawing characters; and often affords the finest ornaments in poetry and history, as well as oratory. Nor is it less moving, but suited to strike different passions, according to the nature of the subject, and artful management of the speaker. Cicero has thus drawn the picture of Catiline, consisting of an unaccountable mixture of contrary qualities. "He had (says he) the appearance of the greatest virtues: he made use of many ill men to carry on his designs, and pretended to be in the interest of the best men; he had a very engaging behaviour, and did not want industry nor application; he gave into the greatest looseness, but was a good soldier. Nor do I believe there was even the like monster in the world, made of such jarring and repugnant qualities and inclinations. Who at one time was more acceptable to the best men, and who more intimate with the worst? Who was once a better patriot, and who a greater enemy to this state? Who more devoted to pleasures, who more patient in labours? Who more rapacious, and yet more profuse? He suited himself to the humours of all he conversed with; was serious with the reserved, and pleasant with the jocular; grave with the aged, and facetious with the young; bold with the daring, and extravagant with the profligate." Such a character of a man, when accompanied with power and interest, must render him no less the object of fear than detestation, which was the design of Cicero in this description. And elsewhere, in order to prevail with the senate to direct the execution of those conspirators with Catiline who were then in prison, he paints the most dismal scene of that horrid design in the strongest colours. "Methinks (says he) I see this city, the light of the world, and citadel of all nations, suddenly falling into one fire; I perceive heaps of miserable citizens buried in their ruined country; the countenance and fury of Cethegus raging in your slaughter, presents itself to my view." This figure is very serviceable in amplification, as we have formerly shown in treating upon that subject. But no small judgment is required in the management of descriptions. Lesser circum-

stances should either be wholly omitted, or but slightly touched. and those which are more material drawn in their due proportion. Nature is as much the rule of the orator as of the painter, and what they both propose to imitate. And therefore, let a thought be ever so pleasing and beautiful in itself, it must not be introduced when foreign to the purpose, or out of its place, any more than a painter should attempt to alter nature, when he proposes to copy it. This figure requires likewise a vigorous and lively genius. For the images in description can rise no higher than the conception of the speaker, since the idea must first be formed in his own mind before he can convey it to others; and agreeably to the clearness with which he conceives it himself, he will be able to express it in words.

**Aporia, or doubt,** expresses the debate of the mind with itself upon a pressing difficulty. A person in such a state is apt to hesitate, or start several things successively, without coming to any fixed resolution. The uneasiness arising from such a disorder of thought is naturally very moving. Of this kind is that of Cicero for Cluentius, when he says, "I know not which way to turn myself. Shall I deny the scandal thrown upon him of bribing the judges? Can I say the people were not told of it? that it was not talked of in the court? mentioned in the senate? Can I remove an opinion so deeply and long rooted in the minds of men? It is not in my power. You, judges, must support his innocence, and rescue him from this calamity." Orators sometimes choose to begin their discourse with this figure. A diffidence of mind at first is not unbecoming, but graceful. It carries in it an air of modesty, and tends very much to conciliate the affections of the hearers. Livy gives us a very elegant example of this in a speech of Scipio Africanus to his soldiers, when, calling them together after a sedition, he thus bespeaks them: "I never thought I should have been at a loss in what manner to address my army. Not that I have applied myself more to words than things; but because I have been accustomed to the genius of soldiers, having been trained up in the camp almost from my childhood. But I am in doubt what or how to speak to you, not knowing what name to give you. Shall I call you *citizens*, who have revolted from your country? *Soldiers*, who have disowned the authority of your general, and broke your military oath? *Enemies*? I perceive the mien, the aspect, and habit of citizens; but discern the actions, words, designs, and dispositions of enemies."

Sometimes a passion has that effect, not so much to render a person doubtful what to say, as to stop him in the midst of a sentence, and prevent his expressing the whole of what he designed; and then it is called **Aposiopesis, or concealment.** It denotes different passions; as anger, which, by reason of its heat and vehemence, causes persons to break off abruptly in their discourse. So the old man in Terence, when he was jealous that his servant obstructed his designs, uses this imperfect, but threatening expression, *Whom, if I find.* And Neptune, when described by Virgil as very angry that the winds should presume to disturb the sea without his permission, after he has called them to him to know the reason of it, threatens them in this abrupt manner:

"Whom I—but first I'll lay the storm."

But Cicero, in writing to Atticus, applies it to ex-

Elocution.

prefers grief, where he says, "I know nothing of Pompey, and believe he must be taken, if he is not got on shipboard. O incredible swiftness! but of our friend—Though I cannot accuse him without grief, for whom I am in so much concern and trouble." And in a letter to Cassius he uses it to express fear, when he says to him, "Brutus could scarce support himself at Mutina; if he is safe, we have carried the day. But if—heaven avert the omen! all must have recourse to you." His meaning is, "If Brutus should be defeated."

94

The next figure is *erotesis*, or *interrogation*. But every interrogation or question is not figurative. When we inquire about a thing that is doubtful, in order to be informed, that is no figure, but the natural form of such expressions. As if I ask a person, *Where he is going?* or *What he is doing?* But then it becomes figurative when the same thing may be expressed in a direct manner; but the putting it by way of question gives it a much greater life and spirit. As when Cicero says, "Catiline, how long will you abuse our patience? do not you perceive your designs are discovered?" He might indeed have said, *You abuse our patience a long while. You must be sensible your designs are discovered.* But it is easy to perceive how much this latter way of expression falls short of the force and vehemence of the former. And so when Medea says, *I could save; and do you ask if I can destroy?* Had she said *I could save, and I can destroy*, the sentence had been flat, and very unfit to express the rage and fury in which the poet there represents her. This figure is suited to express most passions and emotions of the mind, as anger, disdain, fear, desire, and others. It serves also to press and bear down an adversary. Cicero frequently makes this use of it. As in his defence of Plancius: "I will make you this offer (says he), choose any tribe you please, and show, as you ought, by whom it was bribed; and if you cannot, as I believe you will not undertake it, I will prove how he gained it. Is this a fair contest? Will you engage on this foot? I cannot give you fairer play. Why are you silent? Why do you dissemble? Why do you hesitate? I insist upon it, urge you to it, press it, require, and even demand it of you." Such a way of pushing an antagonist shows the speaker has great confidence in his cause; otherwise he would never lay himself so open, if he was not assured the other party had nothing to reply. This figure likewise diversifies a discourse, and gives it a beautiful variety, by altering the form of expression, provided it be neither too frequent, nor continued too long at once. And besides, the warmth and eager manner in which it is expressed, enlivens the hearers, and quickens their attention.

95

*Ecphonesis*, or *exclamation*, is a vehement extension of the voice, occasioned by a commotion of mind, naturally venting itself by this figure, which is used by Cicero to express a variety of passions. It often denotes resentment or indignation. Thus, after his return from banishment, reflecting on those who had occasioned it, he breaks out into this moving exclamation: "O mournful day to the senate, and all good men, calamitous to the state, afflictive to me and my family, but glorious in the view of posterity!" His design was to excite an odium against the authors of his exile, when recalled in so honourable a manner.

Elocution.

And again, in his defence of Cælius: "O the great force of truth; which easily supports itself against the wit, craft, subtilty, and artful designs of men!" He had been just showing the absurdity of the charge against Cælius, and now endeavours to expose his accusers to the indignation of the court. At other times it is used to express disdain or contempt. As when speaking of Pompey's house, which was bought by Mark Antony, he says, "O consummate impudence! dare you go within that house! dare you enter that venerable threshold, and show your audacious countenance to the tutelary deities which reside there?" Nor is it less suited to indicate grief, as when he says of Milo, "O that happy country, which shall receive this man! ungrateful this, if it banish him! miserable, if it lose him!" And sometimes it serves to express admiration; as when, in compliment to Cæsar, he says, "O admirable clemency! worthy of the greatest praise, the highest encomiums, and most lasting monuments!" It has its use also in ridicule and irony. As in his oration for Balbus, where he derides his accuser, by saying, "O excellent interpreter of the law! master of antiquity! corrector and amender of our constitution!" The sacred writers sometimes use it by way of intreaty or wish. As the royal psalmist: "O that I had the wings of a dove, that I might flee away, and be at rest!" And at other times in triumph and exultation, as in that of St Paul: "O death, where is thy sting! O grave, where is thy victory!" It is frequently joined with the preceding figure *interrogation*; as appears in some of the instances here brought from Cicero. And it generally follows the representation of the thing which occasions it. Though sometimes it is made use of to introduce it, and then it serves to prepare the mind by exciting its attention. Thus Cicero, in his defence of Cælius, to render the character of Clodia more odious, at whose instigation he was accused, insinuates that she had before poisoned her husband; and to heighten the barbarity of the fact, and make it appear the more shocking, he introduces the account of it, with this moving exclamation: "O heavens, why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity?"

*Epiphonema*, or *acclamation*, has a great affinity with the former figure. And it is so called, when the speaker, at the conclusion of his argument, makes some lively and just remark upon what he has been saying, to give it the greater force, and render it the more affecting to his hearers. It is not so vehement and impetuous as exclamation, being usually expressive of the milder and more gentle passions. And the reflection ought not only to contain some plain and obvious truth, but likewise to arise naturally from the discourse which occasioned it, otherwise it loses its end. When Cicero has shown, that recourse is never to be had to force and violence, but in cases of the utmost necessity, he concludes with the following remark: "Thus to think, is prudence; to act, fortitude; both to think and act, perfect and consummate virtue." And elsewhere, after he has described a singular instance of cruelty and breach of friendship: "Hence (says he) we may learn, that no duties are so sacred and solemn, which covetousness will not violate." This figure is frequently expressed in a way of admiration. As when Cicero has observed, that all men are desirous to live

96

to

*Elocution.* to an advanced age, but uneasy under it when attained, he makes this just reflection upon such a conduct: "So great is their inconstancy, folly, and perverseness?"

97

The next figure in order is *apostrophe*, or *address*, when the speaker breaks off from the series of his discourse, and addresses himself to some particular person present or absent, living or dead; or to inanimate nature, as endowed with sense and reason. By this means he has an opportunity of saying many things with greater freedom than perhaps would be consistent with decency if immediately directed to the persons themselves. He can admonish, chide, or censure, without giving offence. Nor is there any passion, but may be very advantageously expressed by this figure. When an orator has been speaking of any particular person, on a sudden to turn upon him, and apply the discourse to that person himself, is very moving; it is like attacking an adversary by surprise, when he is off his guard, and where he least expects it. Thus Cicero: "I desire, senators, to be merciful, but not to appear negligent in so great dangers of the state; tho' at present I cannot but condemn myself of remissness. There is a camp formed in Italy, at the entrance of Etruria, against the state; our enemies increase daily; but we see the commander of the camp, and general of the enemies, within our walls, in the very senate, contriving some intestine ruin to the state. If now, Catiline, I should order you to be seized and put to death, I have reason to fear, that all good men would rather think I had deferred it too long, than charge me with cruelty. But I am prevailed with for a certain reason not to do that yet, which ought to have been done long since." This sudden turn of the discourse to Catiline himself, and the address to him in that unexpected manner, must have touched him very sensibly. So, in his defence of Milo, expressing his concern if he should not succeed in it, he says, "And how shall I answer it to you, my brother Quintus, the partner of my misfortunes, who art now absent." And elsewhere addressing to the soldiers of the Martian legion, who had been killed in an engagement with Mark Antony, he thus bespeaks them: "O happy death, which due to nature, was paid to your country! I may esteem you truly born for your country, who likewise received your name from Mars; so that the same deity seems to have produced this city for the world, and you for this city." And in his oration for Balbus he thus calls upon dumb nature to witness to Pompey's virtues: "I invoke you, mute regions; you, most distant countries; you seas, havens, islands, and shores. For what coast, what land, what place is there, in which the marks of his courage, humanity, wisdom, and prudence, are not extant? An appeal to heaven, or any part of inanimate nature, has something very sublime and solemn in it, which we often meet with in sacred writ. So the divine prophet: "Hear, O heavens! and give ear, O earth! for the Lord hath spoken." And in like manner, the prophet Jeremy: "Be astonished, O ye heavens, at this." See APOSTROPHE.

98

*Prosopopeia*, or the *fiction of a person*: by which, either an absent person is introduced speaking; or one who is dead, as if he was alive and present; or speech is attributed to some inanimate being. There is no

*Elocution.* figure, perhaps, which serves more or better purposes to an orator than this. For by this means he is enabled to call in all nature to his assistance, and can assign to every thing such parts as he thinks convenient. There is scarce any thing fit to be said, but may be introduced this way. When he thinks his own character is not of sufficient weight to affect his audience in the manner he desires, he substitutes a person of greater authority than himself to engage their attention. When he has severe things to say, and which may give offence as coming from himself; he avoids this, by putting them into the mouth of some other person from whom they will be better taken; or makes inanimate nature bring a charge, or express a resentment, to render it the more affecting. And by the same method he sometimes chooses to secure himself from a suspicion of flattery, in carrying a compliment too high. We meet with several very beautiful instances of this figure in Cicero; but an example of each sort may here suffice, beginning with that of an absent person, from his defence of Milo, whom he thus introduces as speaking to the citizens of Rome: "Should he, holding the bloody sword, cry out, Attend, I pray, hearken, O citizens, I have killed Publius Clodius; by this sword, and by this right hand, I have kept off his rage from your necks, which no laws, no courts of judicature, could restrain; it is by my means, that justice, equity, laws, liberty, shame, and modesty, remain in the city. Is it to be feared how the city would bear this action? Is there any one now, who would not approve and commend it." And in his oration for Balbus, he introduces Marius, who was then dead, to plead in his defence: "Can Balbus, (says he) be condemned, without condemning Marius for a like fact? Let him be present a little to your thoughts, since he cannot be so in person; that you may view him in your minds, though you cannot with your eyes. Let him tell you, he was not unacquainted with leagues, void of examples, or ignorant of war." And again, in his first invective against Catiline, he represents his country as thus expostulating with himself, and upbraiding him for suffering such a criminal as Catiline to live. "Should my country (says he), which is much dearer to me than my life, should all Italy, all the state, thus address me, Mark Tully what do you do? Do you suffer him, whom you have found to be an enemy, who you see is to be at the head of the war, whom you perceive your enemies wait for in their camp as their general, who has been the contriver of this wickedness, the chief of the conspiracy, the exciter of slaves and profligate citizens, to leave the city, which is rather to bring him in, than let him out? Will not you order him to be imprisoned, condemned, and executed? What prevents you? The custom of our ancestors? But private persons have often punished pernicious citizens in this state. The laws relating to the punishment of Roman citizens? But traitors never had the rights of citizens. Do you fear the censure of posterity? Truly you make a very handsome return to the people of Rome, who have advanced you from an obscure condition so early to the highest dignity; if you neglect their safety to avoid envy, or from the apprehension of any danger. And if you fear censure; which is most to be dreaded, that which may arise from justice and fortitude, or from

Elocution. cowardice and treachery? When Italy shall be wasted by a war, cities plundered, and houses burnt, do you think then to escape the severest censure?" In the management of this figure, care should be taken that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

In treating upon figures, we have hitherto considered them separately: but it may not be amiss to observe, that some expressions consist of a complication of them, and may come under the denomination of several figures, as well verbal as those of sentences, differently considered. Thus when Cicero says, "What, Tubero, did your drawn sword do in the Pharsalian battle? at whose side was its point directed? what was the intention of your arms?" As he speaks to Tubero, it is an apostrophe; as the expressions have much the same import, and are designed to heighten and aggravate the fact, it is *exergasia*; and as they are put by question, it is *interrogation*. So likewise, in his second Phil'ppic, where he says, "What can I think? that I am contemned? I see nothing in my life, interest, actions, or abilities, as moderate as they are, which Antony can despise. Did he think he could easily lessen me in the senate? But they, who have commended many famous citizens for their good government of the state, never thanked any but me for preserving it. Would he contend with me for eloquence? This would be a favour indeed. For what could be a larger and more copious subject, than for me to speak for myself against Antony? His design was really this: he thought he could not convince his associates, that he was truly an enemy to his country, unless he was so first to me." There are three figures in this passage; *doubt*, *interrogation*, and *subjection*. And again, when he introduces Sicily thus addressing Verres in a way of complaint: "Whatever gold, whatever silver, whatever ornaments in my cities, dwellings, temples, whatever right of any kind I possessed by the favour of the senate and people of Rome; you, Verres, have plundered and taken from me." Here is a *prosapopeia*, joined with the verbal figure *anaphora*, as several members of the sentence begin with the same word. The like instances of complex figures frequently occur, and therefore we need not multiply examples of them here.

### PARTICULAR ELOCUTION,

Or that part of Elocution which considers the several Properties and Ornaments of Language, as they are made use of to form different sorts of Style.

#### CHAP. IV. Of Style, and its different Characters.

99  
Particular  
elocution  
treats of  
style and  
its various  
characters.

The word *style*, properly signifies the instrument which the ancients used in writing. For as they commonly wrote upon thin boards covered over with wax, and sometime upon the barks of trees, they made use of a long instrument like a bodkin, pointed at one end, with which they cut their letters; and broad at the other, to erase any thing they chose to alter. And this the latins called *stylus*. But though this be the first sense of the word, yet afterwards it came

to denote the manner of expression. In which sense we likewise use it, by the same kind of trope that we call any one's writing his *hand*. Style, then, in the common acceptation of the word at present, is the peculiar manner in which a man expresses his conceptions by means of language. It is a picture of the ideas which rise in his mind, and of the order in which they are there produced. As to the reasons which occasion a variety of style, they are principally these.

Since both speech and writing are only sensible expressions of our thoughts, by which we communicate them to others; as all men think more or less differently, so consequently they in some measure differ in their style. No two persons, who were to write upon one subject, would make use of all the same words. And were this possible, yet they would as certainly differ in their order and connection, as two painters, who used the same colours in painting the same picture, would necessarily vary their mixtures and disposition of them, in the several gradations of lights and shades. As every painter therefore has something peculiar in his manner, so has every writer in his style. It is from these internal characters, in a good measure that critics undertake to discover the true authors of anonymous writings; and to show that others are spurious, and not the genuine productions of those whose names they bear; as they judge of the age of such writings from the words and manner of expression which have been in use at different times. And we may often observe in persons a fondness for some particular words or phrases; and a peculiarity in the turn or connection of their sentences, or in their transitions from one thing to another; by which their style may be known, even when they design to conceal it. For these things, through custom and habit, will sometimes drop from them, notwithstanding the greatest caution to prevent it.

There is likewise very often a considerable difference in the style of the same person, in several parts of his life. Young persons, whose invention is quick and lively, commonly run into a pompous and luxuriant style. Their fancy represents the images of things to their mind in a gay and and sprightly manner, clothed with a variety of circumstances; and while they endeavour to set off each of these in the brightest and most glittering colours, this renders their style verbose and florid, but weakens the force and strength of it. And therefore, as their imagination gradually cools, and comes under the conduct of a more mature judgment, they find it proper to cut off many superfluities; so that by omitting unnecessary words and circumstances, and by a closer connection of things placed in a stronger light, if their style becomes less swelling and pompous, it is, however, more correct and nervous. But as old age sinks the powers of the mind, chills the imagination, and weakens the judgment; the style, too, in proportion usually grows dry and languid. Critics have observed something of this difference in the writings even of Cicero himself. To be master of a good style, therefore, it seems necessary that a person should be endowed with a vigorous mind and lively fancy, a strong memory, and a good judgment. It is by the imagination that the mind conceives the images of things. If the impressions of those images be clear and distinct, the style will be so too.

Elocution. too; since language is nothing but a copy of those images first conceived by the mind. But if the images are faint and imperfect, the style will accordingly be flat and languid. This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can describe them in a more strong and lively manner. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disordered, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are warped and crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together with proper and suitable phrases to express them in their several connections and relations to each other. When the images of things offer themselves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and therefore, without a large furniture of words and phrases, the style will necessarily become insipid and jejune, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination will furnish the mind with plenty of ideas, and a good memory will help to clothe them in proper language; but unless they are both under the conduct of reason, they are apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, faster than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but void of sense. Many impertinencies, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So that such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly sallies of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of which best suit the ideas they are designed to convey; rather than the most gay and pompous. All things are not said which offer themselves to the mind, as fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly mentioned, and others discoursed on more largely and fully, according to their different importance. And every thing is placed in that order, and clothed in such a dress, as may represent it to the greatest advantage. So that, in a word, the foundation of a good style is chiefly good sense. Where these qualities all meet in a considerable degree, such persons have the happiness to excel, either in speaking or writing. But this is not generally the case. Many persons of a vigorous and sprightly imagination, have but a weak judgment; and others much more judicious can think but slowly. And it is this, in a great measure, which makes the difference between speaking and writing well, as one or the other of these qualities is predominant. A person of a lively fancy, ready wit, and valuable tongue, will deliver himself off hand much better and more acceptably, than one who is capable upon due premeditation, to discern farther into the subject, but cannot command his thoughts with the same ease and freedom. And this latter would have the same advantage of the other, were they both coolly to offer their sentiments in writing. Many things appear well in speaking, which will not bear a strict scrutiny. While the hearer's attention is obliged to keep pace with the speaker, he is not at leisure to observe every impropriety or incoherence, but many slips easily escape him, which in reading are presently discovered. Hence it is often found, that discourses, which were thought very fine when heard, appear to have much less beauty, as well as strength, when they come to be read. And therefore it is not without reason, that Cicero recommends to all those who are candidates for eloquence, and desirous to become masters of a good style, to write much. This affords them an opportunity to digest their thoughts, weigh their words and expressions, and give every thing its proper force and evidence; as likewise, by reviewing a discourse when composed, to correct its errors, or supply its defects; till by practice they gain a readiness both to think justly, and to speak with propriety and eloquence. But it is time to proceed to some other causes of the diversity of style.

Different countries have not only a different language, but likewise a peculiarity of style suited to their temper and genius. The eastern nations had a lofty and majestic way of speaking. Their words are full and sonorous, their expressions strong and forcible, and warmed with the most lively and moving figures. This is very evident from the Jewish writings in the Old Testament, in which we find a most agreeable mixture of simplicity and dignity. On the contrary, the style of the more northern languages generally partakes of the coldness of their climate. "There is <sup>Species</sup> (says Mr Addison\*) a certain coldness and indiffer- <sup>403.</sup> ence in the phrases of our European languages, when they are compared with the oriental forms of speech. And it happens very luckily, that the Hebrew idioms run into the English tongue with a peculiar grace and beauty. Our language has received innumerable elegancies and improvements from that infusion of Hebrewisms, which are derived to it out of the poetical passages in holy writ. They give a force and energy to our expressions, warm and animate our language, and convey our thoughts in more ardent and intense phrases than any that are to be met with in our own tongue. There is something so pathetic in this kind of diction, that it often sets the mind in a flame, and makes our hearts burn within us."

Again,

Elocution.

Again, people of different nations vary in their customs and manners which occasions a diversity in their style. This was very remarkable in the Attics, Asiatics and Rhodians, and is often taken notice of by ancient writers. The Athenians, while they continued a free state, where an active, industrious, and frugal people; very polite indeed, and cultivated arts and sciences beyond any other nation: but as they had powerful enemies, and were exceedingly jealous of their liberties, this preserved them from wantonness and luxury. And their way of speaking was agreeable to their conduct; accurate and close, but very full and expressive. The Asiatics, on the other hand, were more gay, and loose in their manners, devoted to luxury and pleasure; and accordingly they affected a florid and swelling style, filled with redundancies and superfluities of expression. Indeed, some of the ancients have attributed this looseness of style to their way of pursuing eloquence at first. For as they were put upon it by conversing with the Greek colonies who settled among them, they suppose, that, in imitating them, before they were masters of the language, they were often obliged to make use of circumlocutions, which afterwards became habitual, and very much weakened the force of their expressions, as it naturally would do. But one would think, if they were put to this necessity at first, when they found its ill effect, they might easily have amended it afterwards, as they grew better acquainted with the Greek language, had they been inclined so to do. The Rhodian style was a medium between the other two; not so concise and expressive as the Attic, nor yet so loose and redundant as the Asiatic. Quintilian says, it had a mixture of its author, and the humour of the people; and, like plants set in a foreign soil, degenerated from the Attic purity, but not so wholly as to lose it. They first received it from Æschines, who being worsted in his famous contest with Demosthenes, retired thither, and taught rhetoric, which put them upon the study of eloquence.

The style of the same country likewise very much alters in different ages. Cicero tells us, that the first Latin historians aimed at nothing more than barely to make themselves intelligible, and that with as much brevity as they could. Those who succeeded them advanced a step further; and gave somewhat a better turn and cadency to their sentences, though still without any dress or ornament. But afterwards, when the Greek language became fashionable at Rome, by copying after their writers, such as Herodotus, Thucydides, Xenophon, and others, they endeavoured to introduce all their beauties into their own tongue, which in Cicero's time was brought to its highest perfection. But it did not long continue in that state. A degeneracy of manners soon altered their taste, and corrupted their language, which Quintilian very much complains of in his time. The case was the same with respect to the Greek tongue; though that had the good fortune to continue its purity much longer than the Latin. Nor can any language be exempt from the common fate of all human productions; which have their beginning, perfection, and decay. Besides, there is a sort of fashion in language, as well as other things; and the generality of people are always fond

of running into the mode. Perhaps some one, or a few persons, fall into a manner which happens to please. This gives them a reputation; and others immediately copy after them, till it generally prevails. Cicero tells us, that the most ancient Greek orators whose writings were extant in his time, such as Pericles, Alcibiades, and others, were subtle, acute, concise, and abounded in sense rather than words. But another set that followed them, of which were Critias, Theramenes, and Lysias, retained the good sense of the former, and at the same time took more care of their style; not leaving it so bare as the former had done, but furnishing it with a better dress. After these came Isocrates, who added all the flowers and beauties of eloquence. And as he had abundance of followers, they applied these ornaments and decorations according to their different genius; some for pomp and splendor; and others to invigorate their style, and give it the greater force and energy. And in this latter way Demosthenes principally excelled. Now as each of these matters had its peculiar beauties, and generally prevailed in different ages, Cicero thinks this could not have happened otherwise than from imitation. And he attributes it to the same cause, that afterwards they sunk into a softer and smoother manner, not less exact and florid, but more cold and lifeless. If we take a view of our own tongue, Chaucer seems to have been the first who made any considerable attempts to cultivate it. And whoever looks into his writings, will perceive the difference to be so great from what it is at present, that it scarce appears to be the same language. The gradual improvements it has since received, are very evident in the writers almost of every succeeding age since that time: and how much farther it may still be carried, time only can discover. See *LANGUAGE passim*: For the English language in particular, see n<sup>o</sup> 38. for the other European languages, as well as the Greek and Latin, see n<sup>o</sup> 27, &c.

Another cause of the variety of style arises from the different nature and properties of language. A difference in the letters, the make of the words, and the order of them, do all affect the style. So Quintilian observes, that the Latin tongue cannot equal the Greek in pronunciation, because it is harsher. The Latins want two of the softest Greek letters, *ν* and *ξ*; and use others of a very hard sound, which the Greeks have not, as *f* and *q*. Again, many Latin words end in *m*; a letter of a broad and hollow sound, which never terminates any Greek word; but *ν* does frequently, whose sound is much softer and sweeter. Besides, in the combination of syllables, the letters *b* and *d* are often so situated, as to require too strong and unequal a force to be laid upon them, as in the words *obversus* and *adjungo*. Another advantage of the Greek tongue arises from the variety and different seat of the accents: for the Greeks often accent the last syllable, which both enlivens the pronunciation and renders it more musical; whereas the Latins never do this. But the greatest advantage of the Greeks lies in their plenty and variety of words; for which reason they have less occasion for tropes or circumlocutions, which, when used from necessity, have generally less force, and weaken the style. But under these disadvantages,

Elocution.

Quin-

**Elocution.** Quintilian seems to give his countrymen the best advice the case will admit of: That what they cannot do in words, they should make up in sense. If their expressions are not so soft and tender, they should exceed in strength; if they are less subtle, they should be more sublime; and if they have fewer proper words, they should excel in the beauty as well as number of their figures. If this account of Quintilian be just, that the Greek tongue does surpass the Latin in all these instances, it is certain that both of them have much greater advantages over some modern languages. Their varying all their declinable words, both nouns and verbs, by terminations, and not by signs, contributes very much to the smoothness and harmony of their periods. Whereas in the modern languages, those small particles and pronouns which distinguish the cases of nouns and the tenses and persons of verbs, hinder the run of a period, and render the sound much more rough and uneven. Besides, the ancient languages seem to have a better and more equal mixture of vowels and consonants, which makes their pronunciation more easy and musical.

But the chief distinction of style arises from the different subjects of matter of discourse. The same way of speaking no more suits all subjects, than the same garment would all persons. A prince and a peasant ought not to have the same dress; and another different from both becomes those of a middle station in life. The style therefore should always be adapted to the nature of the subject, which rhetoricians have reduced to three ranks or degrees; the *low* or *plain* style, the *middle* or *temperate*, and the *lofty* or *sublime*: Which are likewise called *characters*, because they denote the quality of the subject, upon which they treat. This division of style into three characters, was taken notice of very early by ancient writers. Some have observed it even in Homer, who seems to assign the *sublime* or magnificent to Ulysses, when he represents him so copious and vehement an orator, that his words came from him *like winter snow*. On the contrary, he describes Menelaus as a *polite* speaker, but *concise* and *moderate*. And when he mentions Nestor, he represents his manner as between these two, not so high and lofty as the one, nor yet so low and depressed as the other; but smooth, even, and pleasant, or, as he expresses it, *more sweet than honey*. Quintilian observes, that although accuracy and politeness were general characters of the Attic writers; yet among their orators, Lysias excelled in the *low* and *familiar* way; Isocrates for his *elegancy*, *smoothness*, and the *fine turn of his periods*; and Demosthenes for his *force and rapidity*, by which he carried all before him. And Gellius tells us, that the like difference was found in the three philosophers who were sent from the Athenians to Rome (before the Romans had any relish for the polite arts) to solicit the remittance of a fine laid upon them for an injury done to a neighbouring state. Carneades, one of those ambassadors, was *vehement and rapid* in his harangues; Critolaus *neat and smooth*; and Diogenes, *modest and sober*. The eloquence of these orators, and the agreeable variety of their different manner, so captivated the Roman youth, and inflamed them with a love of the Grecian arts, that old Cato, who did all he could to check it by hurrying away the ambassa-

dors, could not prevent their vigorous pursuit of them, till the study became in a manner universal. And the old gentleman afterwards learned the Greek language himself, when it became more fashionable. Which an English writer \* represents as a *punishment upon him for his former crime*. It seldom happens that the same person excels in each of these characters. They seem to require a different genius, and most people are naturally led to one of them more than another; tho' all of them are requisite for an orator upon different occasions, as we shall show hereafter.

#### CHAP. V. Of the Low Style.

THIS we shall consider under two heads, *thoughts* and *language*; in each of which the several characters are distinguished from one another.

I. And with respect to the former, as the subjects proper for this style are either common things, or such as should be treated in a plain and familiar way; so plain thoughts are most suitable to it, and distinguish it from the other characters.

Now, by plain thoughts, are meant such as are simple and obvious, and seem to rise naturally from the subject, when duly considered; so that any one, upon first hearing them, would be apt to imagine they must have occurred to himself. Not that this is really the case, but because the more natural a thing is, the more easy it seems to be; though in reality it is often otherwise; and the perfection of art lies in its nearest resemblance to nature. And therefore, in order to speak plainly and clearly upon any subject, it must first be duly considered, well understood, and thoroughly digested in the mind; which, though it require labour and study, yet the more a person is master of what he says, the less that labour will appear in his discourse. This natural plainness and simplicity, without any disguise or affectation, very much contributes to give credit to what is said. Nor is any thing more apt to impose on us, than the appearance of this, when artfully assumed. Cicero's account of the fight between Milo and Clodius, in which Clodius was killed, is a remarkable instance of this. "When Clodius knew (says he) that Milo was obliged to go to Lanuvium upon a solemn and necessary occasion, he immediately hastened from Rome, the day before, to assassinate him before Clodius's own house, as appeared afterwards by the event. And this he did at a time, when his turbulent mob in the city wanted his assistance; whom he would not have left, but for the advantage of that place and season to execute his wicked design. But the next day Milo was in the senate, where he continued till they broke up; then went home; changed his dress; staid there some time till his wife was ready; and afterwards set forward so late, that if Clodius had designed to return to Rome that day, he might have been here by that time. Clodius, prepared for his design, met him on horseback, having no chariot, no equipage, no Greek attendants as usual; and without his wife, which was scarce ever known: whereas Milo was in a chariot with his wife, wrapt up in a cloak, and attended by a large retinue of maid servants, pages, and other persons unfit for an engagement. He met with Clodius before his house, about five o'clock in the evening; and was presently assault-

**Elocution.**  
The low style considered both as to thoughts and language.

100

The low style considered both as to thoughts and language.

101

Elocution ed from an higher ground by many armed men, who killed the coachman. Upon which, Milo, throwing off his cloak, leaped out of his chariot, and bravely defended himself: and those who were with Clodius, having their swords drawn, some made up to the chariot to attack Milo; and others, who now thought he had been killed, began to fall upon his servants, who were behind. And of these, such as had courage, and were faithful to their master, some were killed; and others when they saw the skirmish at the chariot, and could do their master no service (for they heard Clodius himself say that Milo was killed, and really thought it was so), did that, not by their master's order, nor with his knowledge, nor when he was present, which every one would have his own servants to do in the like circumstances. I do not say this to fix any crime upon them, but only to relate what happened." His meaning is, they killed Clodius; which he avoids mentioning, to render what he says less offensive. Can any thing be told in a more plain and simple manner than this? Here is nothing said, but what in itself seems highly probable, and what one would imagine the fact might easily suggest to any ordinary spectator. But in this, both the art and skill of it consist. For in the whole account, as, on the one hand, Milo is so described as to render it highly improbable he could have any design at that time against Clodius; so on the other, no one circumstance is omitted which might seem proper to persuade the hearers that Clodius was the aggressor in that engagement. And yet, if we may believe Asconius, the quarrel was begun by some of Milo's retinue, and Clodius was afterwards killed by his express order. But as things are sometimes best illustrated by their opposites, we shall here produce a contrary instance of a very affected and unnatural way of relating a fact. Val. Maximus tells us of a learned man at Athens, who, by a blow which he received by a stone upon his head, entirely forgot all his learning, though he continued to remember every thing else. And therefore, as he says, since this misfortune deprived him of the greatest enjoyment of his life, it had been happier for him never to have been learned, than afterwards to lose that pleasure. This is the plain sense of the story. But now let us hear him relate it. "A man (says he) of great learning at Athens, having received a blow upon his head by a stone, retained the memory of all other things very perfectly, and only forgot his learning, to which he had chiefly devoted himself. The direful and malignant wound invading his mind, and as it were designedly surveying the knowledge repositied there, cruelly seized on that part of it in particular from which he received the greatest pleasure, and buried the singular learning of the man with an invidious funeral. Who since he was not permitted to enjoy his studies, had better never have obtained access to them, than afterwards to have been deprived of the delight they afforded him." What an unnatural way is this of relating such an accident, to talk of a wound invading the mind, and surveying the knowledge repositied there, and cruelly seizing a particular part of it, and burying it with an invidious funeral? There is nothing in the story could lead him to this, but an over-sondness to refine upon it in a very affected manner. But there are two properties of plain thoughts, one of which

ought constantly to attend them in common with all Elocution, thoughts, and the other is often necessary to animate and enliven this character.

The former of these is justness and propriety, which is what reason dictates in all cases. That Cicero says of the death of Crassus the orator, seems very just, as well as natural. "It was (says he) an affliction to his friends, a loss to his country, and a concern to all good men; but such public calamities followed upon it, that heaven seemed rather to have favoured him with death, than to have deprived him of life." This thought seems very just, and agreeable to the sentiments of a good man, as Crassus was; to choose death rather than to outlive the happiness of his country, to which he himself had so much contributed. Quintilian has a reflection upon a like occasion, which is not so just and becoming. It is upon the death of his only son, a youth of very uncommon parts, as he represents him; and for whose use he had designed his *Institutions of Oratory*; but he died before they were finished. The passage is this: "I have lost him of whom I had formed the greatest hopes, and in whom I had reposed the greatest comfort of my old age. What can I do now? or of what farther use can I think myself to be, thus disappointed by heaven? What good parent will pardon me, if I can any longer study? and not condemn such resolution, if, thus surviving all my family, I can make any other use of my voice, than to accuse the gods, and declare that providence does not govern the world?" Allowance may be made for the fallies of passion, even in wise men, upon some shocking occasions; but when it proceeds to such a degree as to become impious, it is very indecent, as well as unjust. And all indecency is unnatural, as it is disagreeable to reason, which always directs to a decorum. That seems to be a very natural as well as just thought of Pliny the Younger, when he says, "The death of those persons always appear to me too hasty and unseasonable, who are preparing some lasting work. For persons wholly devoted to pleasures, live, as it were, from day to day, and daily finish the end for which they live; but those who have a view to posterity, and preserve their memory by their labours, always die untimely, because they leave something unfinished." We shall mention but one more instance; and that in a comparative view, to make it the more evident. The two sons of Junius Brutus, the first Roman consul, having been convicted of treason in associating with Tarquin's party, were ordered, among others, to be put to death; and their father not only pronounced the sentence, but presided at the execution. This fact is mentioned by several of the Roman historians; and, as it carries in it not only the appearance of rigorous justice, but likewise of cruelty in Brutus, to have been present at the execution of his sons, they endeavour to vindicate him different ways. What Florus says, seems rather an affectation of wit, than a just defence of the fact. "He beheaded them (says he), that being a public parent, he might appear to have adopted the whole body of the people." Nor does Val. Maximus come up to the case, who says, "He put off the father to act the consul; and chose rather to lose the sons, than be wanting to public justice." This might be a reason for condemning them; and would have been equally true, had he not been

Elocution.

been present at their execution. But Livy, whose thoughts are generally very just and natural, assigns the best reason which perhaps can be given for his vindication, when he says, "Fortune made him the executioner of the sentence, who ought not to have been a spectator." By saying *fortune made him* so, he represents it not as a matter of choice, like the other historians, but of necessity, from the nature of his office, which then obliged him to see the execution of that sentence he had himself before pronounced; as is the custom at present, in some popular governments.

The other property, which should often accompany plain and simple thoughts, is, that they be gay and sprightly. This, as has been said, is necessary to animate and enliven such discourses as require the low style. The fewer ornaments it admits of, the greater spirit and vivacity is requisite to prevent its being dry and jejune. A thought may be very brisk and lively, and at the same time appear very natural, as the effect of a ready and flowing wit. Such thoughts, attended with agreeable turns, are very suitable to this style; but care should be taken, lest, while fancy is too much indulged, the justness of them be overlooked. We shall give one instance, in which this seems to have been the case, from a celebrated English work, where the ingenious writer endeavours to show the disadvantages of persons not attending to their natural genius, but affecting to imitate others in those things for which they were not formed. "The great misfortune (says he) of this affectation is, that men not only lose a good quality, but also contract a bad one; they not only are unfit for what they are designed, but they assign themselves to what they are unfit for; and instead of making a very good figure one way, make a very ridiculous one another. Could the world be reformed to the obedience of that famed dictate, *Follow nature*, which the oracle of Delphos pronounced to Cicero when he consulted what course of studies he should pursue, we should see almost every man as eminent in his proper sphere as Tully was in his. For my part, I could never consider this preposterous repugnancy to nature any otherwise, than not only as the greatest folly, but also one of the most heinous crimes; since it is a direct opposition to the disposition of providence, and (as Tully expresses it) like the sin of the giants, an actual rebellion against heaven." The advantages that arise from persons attending to their own genius, and pursuing its dictates, are here represented in a very lively and agreeable manner. But there is one thing asserted, which we fear will not hold; which is, that, *Could the world be reformed to that dictate, "Follow nature," we should see almost every man as eminent in his proper sphere as Tully was in his.* For though doubtless persons would generally succeed best if they kept to this rule; yet different degrees of ability are often found, where the bias and inclination is the same, and that accompanied with equal labour and diligence. If this was not so, how happened it that no one came up to Tully in the art of oratory; especially in his own age, when there were the greatest opportunities for that study, and the highest encouragements were given to it, as it paved the way to riches, honours, and all the grand offices of the state? It cannot well be questioned, but that there were other gentlemen, who had all the same ad-

VOL. XIII.

vantages, accompanied with as strong a passion for this art, as Tully had, who yet fell much short of him in point of success. And experience shows, that the case has been the same in all other pursuits.

III. But it is time to proceed to the other head, the *language* proper for this style. And here it may be observed in general, that the dress ought to be agreeable to the thoughts, plain, simple, and unaffected.

But the first thing that comes under consideration is elegance, or a proper choice of words and expressions; which ought always to suit the idea they are designed to convey. And therefore when an ancient writer, speaking of *cruelty*, calls it *navus crudelitatis*, the *blemish of cruelty*; and another, applying the same word to *ingratitude*, says *navus ingritudinis*, the *blemish of ingratitude*; that term does not sufficiently convey to us the odious nature of either of those vices, as indeed it was not their design it should. But otherwise, where the speaker has not some particular view in doing it, to sink too low is as much a fault as to rise too high. So to call ancient Rome *the mistress of Italy*, would as much lessen the just notion of the extent of her power, as the Roman writers aggrandise it when they style her *mistress of the world*. But purity, both in the choice of words and expressions, is never more necessary than it is here. This may be called *neatness in language*. And to be plain and neat at the same time, is not only very consistent, but the former can no other way recommend itself, than as joined with the latter. Besides, the fewer advantages any thing has to set it off, the more carefully they ought to be observed. Perspicuity is always to be regarded; and serves very much to keep up the attention, where other ornaments are wanting. Epithets should be sparingly used, since they enlarge the images of things, and contribute very much to heighten the style. Indeed they are sometimes necessary to set a thing in its just light; and then they should not be dropped. Thus, in speaking of Xerxes, it would be too low and flat to say, *He descended with his army into Greece*. Here is no intimation given of their vast and unparalleled numbers, which ought to be done. Herodotus says, his whole army, of sea and land forces, amounted to 2,317,000 and upwards. Therefore, unless the number be mentioned, the least that can be said is, that *he descended with a vast army*.

The next thing to be regarded is composition, which here does not require the greatest accuracy and exactness. A seeming negligence is sometimes a beauty in this style, as it appears more natural. Short sentences, or those of a moderate length, are likewise upon the whole best suited to this character. Long and accurate periods, finely wrought up with a gradual rise, harmonious numbers, a due proportion of the several parts, and a just cadency, are therefore improper, as they are plainly the effect of art. But yet some proportion should be observed in the members, that neither the ears be too much defrauded, nor the sense obscured. Of this kind is that expression of a Greek orator, blamed by Demetrius: *Ceres came readily to our assistance, but Arisides not*. The latter member of this sentence is too short; and by dropping so suddenly, both disappoints the ears, and is somewhat obscure. It would have been plainer and more agreeable

3 L

agreeable

Elocution.

102  
The language proper for this style.

Elocution.

agreeable thus, *but Aristides did not come*. As to order, the plainest and clearest disposition, both of the words and members of sentences, and what is most agreeable to the natural construction, best suits with this character. For one of its principal beauties is perspicuity. And a proper connection likewise of sentences, with a regular order in the dependence of things one upon another, very much contribute to this end. With regard to the collision of syllables in different words, for preventing either an hollowness or asperity of sound, greater liberty may be taken in this style than in the other characters. Here it may be allowed to say, *Virtue is amiable to all, though all do not pursue it*. But in an higher character, perhaps, in order to prevent the hollow sound of the words *though all*, a person would choose to vary the expression a little, and say, *though few pursue it*. So, *Xerxes' expedition*, may be tolerable here; but in the florid style, *the expedition of Xerxes* would sound much better.

The last thing to be considered, with respect to the language, is dignity, or the use of tropes and figures. And as to tropes, they ought to be used cautiously; unless such as are very common, and by time have either come into the place of proper words, or at least are equally plain and clear. So in the instance mentioned above, Diodorus Siculus, speaking of the forces of Xerxes, calls them an *innumerable company*. Where, by a *synecdoche*, he has chosen to make use of an uncertain number for a certain, as less liable perhaps to exception. Other examples might be given if necessary. And with regard to figures, as most of those which consist in words, and are therefore called *verbal figures*, serve chiefly to enliven an expression, and give an agreeable turn, they are often not improper for this character. Nor are figures of sentences wholly to be excluded, especially such as are chiefly used in reasoning or demonstration. But those which are more peculiarly adapted to touch the passions, or paint things in the strongest colours, are the more proper ornaments of the higher styles, as will be shown hereafter.

Upon the whole, therefore, pure nature, without any colouring, or appearance of art, is the distinguishing mark of the low style. The design of it is to make things plain and intelligible, and to set them in an easy light. And therefore the proper subjects of it are epistles, dialogues, philosophical dissertations, or any other discourses, that ought to be treated in a plain and familiar manner, without much ornament, or address to the passions. A freedom and ease both of thought and expression, attended with an agreeable humour and pleasantry, are its peculiar beauties that engage us. As we see persons of fashion and good breeding, though in the plainest habit, have yet something in their air and manner of behaviour that is very taking and amiable. Somewhat of the like nature attends this style. It has its difficulties, which are not so easily discerned but from experience. For it requires no small skill to treat a common subject in such a manner as to make it entertaining. The fewer ornaments it admits of, the greater art is necessary to attain this end. Lofty subjects often engage and captivate the mind by the sublimity of the ideas. And the florid style calls in all the assistance of language

and eloquence. But the plain style is in a great measure stripped of those advantages; and has little more to recommend it, than its own native beauty and simplicity.

CHAP. VI. *Of the Middle Style.*

THIS we shall treat in the same manner as we did the former, by considering first the *matter*, and then the *language* proper for it. 103

I. And as the subjects proper for this style are things of weight and importance, which require both a gravity and accuracy of expression; so fine thoughts are its distinguishing mark, as plain thoughts are of the low character, and lofty thoughts of the sublime. Now a fine thought may deserve that character from some or other of the following properties. 104

And the first property we shall mention is gravity and dignity. Thus Cicero, in a speech to Cæsar, says, "It has been often told me, that you have frequently said, you have lived long enough for yourself. I believe it, if you either lived, or was born for yourself only." Nothing could either be more fit and proper than this was, when it was spoken; or at the same time a finer compliment upon Cæsar. For the civil war was now over, and the whole power of the Roman government in the hands of Cæsar; so that he might venture to say, he had lived long enough for himself, there being no higher pitch of glory to which his ambition could aspire. But then there were many things in the state that wanted redressing, after those times of disorder and confusion, which he had not yet been able to effect, and of which Cicero here takes an opportunity to remind him. We shall produce another example from Curtius. Philotas, one of Alexander's captains, having formed a conspiracy against him, was convicted of it, and put to death. Amintas, who was suspected of the same crime, by reason of his great intimacy with Philotas, when he comes to make his defence, among other things speaks thus: "I am so far from denying my intimacy with Philotas, that I own I courted his friendship. Do you wonder that we showed a regard to the son of Parmenio, whom you would have to be next to yourself, giving him the preference to all your other friends? You, Sir, if I may be allowed to speak the truth, have brought me into this danger. For to whom else is it owing, that those who endeavoured to please you, addressed themselves to Philotas? By his recommendation we have been raised to this share of your friendship. Such was his interest with you, that we courted his favour, and feared his displeasure. Did we not all in a manner engage ourselves by oath, to have the same friends, and the same enemies, which you had? Should we have refused to take this, which you as it were proposed to us? Therefore, if this be a crime, you have few innocent persons about you; nay, indeed none. For all desired to be the friends of Philotas; though all could not be so who desired it. Therefore, if you make no difference between his friends and accomplices, neither ought you to make any between those who desired to be his friends, and those who really were so." Could any thing be finer spoken, more proper, and becoming the character of a soldier, 105

Elocution.

The middle style considered as to matter and language.

**Elocution.** dier, than this defence; especially to a prince of so great and generous a spirit as Alexander? There is something which appears like this in Tacitus with relation to the emperor Tiberius, but falls vastly short of it in the justness and dignity of the sentiment. Sejanus, his great favourite, and partner in his crimes, falling under his displeasure, was, like Philotas put to death for a conspiracy. Now a Roman knight, who apprehended himself in danger on account of his friendship with Sejanus, thus apologizes for himself to the emperor, in the manner of Amintas: "It is not for us to examine the merit of a person whom you raise above others, nor your reasons for doing it. The gods have given you the sovereign power of all things, to us the glory of obeying. Let conspiracies formed against the state, or the life of the emperor, be punished; but as to friendships and private regards, the same reason that justifies you, Cæsar, renders us innocent." The turn of the expressions is not much different from that in the case of Amintas; but the beauty of the thought is spoiled by the flattery of complimenting Tiberius upon an excess of power, which he employed to the destruction of many excellent men. There is not that inpropriety in the defence of Amintas, which is equally brave and just.

Another property of a fine thought is *beauty* and *elegance*. It is a fine compliment which Pliny pays to the emperor Trajan, when he says, "It has happened to you alone, that you was father of your country, before you was made so. Some of the Roman emperors had been complimented with the title of *father of their country*, who little deserved it. But Trajan had a long time refused it, though he was really so, both by his good government, and in the esteem of his subjects, before he thought fit to accept of it. And Pliny, among other instances of the generosity of that prince, which he mentions in the same discourse, speaking of the liberty that he gave the Romans to purchase estates which had belonged to the emperors, and the peaceable possession they had of them, does it by a turn of thought no less beautiful than the former. "Such (says he) is the prince's bounty, such the security of the times, that he thinks us worthy to enjoy what has been possessed by emperors; and we are not afraid to be thought so." There is a sprightliness in this image, which gives it a beauty; as there is likewise in the following passage of the same discourse, where he says to Trajan, "Your life is displeasing to you, if it be not joined with the public safety; and you suffer us to wish you nothing but what is for the good of those who wish it." And of the same kind is that of Cicero to Cæsar, when he says, "You, Cæsar, are wont to forget nothing but injuries." It is a very handsome, as well as just reflection, made by Tacitus upon Galba's government, that, "He seemed too great for a private man, while he was but a private man; and all would have thought him worthy of the empire, had he never been emperor." The beauty of a thought may give us delight, though the subject be sorrowful; and the images of things in themselves unpleasant may be so represented as to become agreeable. Sisigambis, the mother of Darius, after the death of her son, had been treated by Alexander

**Elocution.** with the greatest regard and tenderness, in whose power she then was. So soon as she heard therefore that he was dead, she grew weary of life, and could not bear to outlive him. Upon which Q. Curtius makes this fine reflection: "Though she had courage to survive Darius, yet she was ashamed to outlive Alexander."

The next property of a fine thought which we shall mention, is *delicacy*. As, in the objects of our senses, those things are said to be delicate which affect us gradually in a soft and agreeable manner; so a delicate thought is that which is not wholly discovered at once, but by degrees opening and unfolding itself to the mind, discloses more than was at first perceived. Quintilian seems to refer to this, when he says, "Those things are grateful to the hearers, which when they apprehend, they are delighted with their own sagacity; and please themselves, as though they had not heard, but discovered them." Such thoughts are not unlike the sketches of some pictures, which let us into the design of the artist, and help us to discern more than the lines themselves express. Of this kind is that of Sallust. "In the greatest fortunes, there is the least liberty." This is not often so in fact, but ought to be; both to guard against an abuse of power, and to prevent the effects of a bad example to inferiors. Pliny speaking of the emperor Trajan's entry into Rome, says, "Some declared, upon seeing you, they had lived long enough; others, that now they were more desirous to live." The compliment is fine either way, since both must esteem the sight of him the greatest happiness in life; and in that consistency lies the delicacy of the thought. It was a fine character given of Grotius, when very young, on the account of his surprising genius and uncommon proficiency in learning, that *he was born a man*: As it nature, at his coming into the world, had at once furnished him with those endowments which others gradually acquire by study and application.

The last property of a fine thought, which we shall take notice of, is *novelty*. Mankind is naturally pleased with new things; and when at the same time they are set in an agreeable light, this very much heightens the pleasure. Indeed there are few subjects, but what have been so often considered, that it is not to be expected they should afford many thoughts entirely new; but the same thought set in a different light, or applied to a different occasion, has in some degree a claim of novelty. And even where a thing hath been so well said already, that it cannot easily be mended, the revival of a fine thought often affords a pleasure and entertainment to the mind though it can have no longer the claim of novelty. Cicero, in his treatise of an orator, among several other encomiums which he there gives to Crassus, says of him, "Crassus always excelled every other person, but that day he excelled himself." He means as an orator. But elsewhere he applies the same thought to Cæsar, upon another account; and with some addition to it. "You had (says he) before conquered all other conquerors by your equity and clemency, but to-day you have conquered yourself; you seem to have vanquished even victory herself, therefore you alone are truly invincible." This thought, with a little variation of the phrase,

**Elocution.** phrase, has since appeared in several later writers; and it is now grown common to say of a person, who excels in any way, upon his doing better than he did before, that he has outdone himself. The like has happened to another thought, which, with a little alteration, has been variously applied. It was said by Varro, *That if the Muses were to talk Latin, they would talk like Plautus.* The younger Pliny, applying this compliment to a friend of his, says, *His letters are so finely written, that you would think the Muses themselves talked Latin.* And Cicero tells us, *It was said of Xenophon, that the Muses themselves seemed to speak Greek with his voice.* And elsewhere that *Philosophers say, if Jupiter speaks Greek, he must speak like Plato.* The thought is much the same in all these instances, and has been since revived by some modern writers.

105  
The language of the middle style.

II. We shall now consider the *language* proper for the middle style. And in general it may be observed, that as the proper subjects of it are things of weight and importance, though not of that exalted nature as wholly to captivate the mind and divert it from attending to the diction; so all the ornaments of speech, and beauties of eloquence, have place here.

And first with regard to elegance, it is plain that a different choice of words makes a very great difference in the style, where the sense is the same. Sometimes one single word adds a grace and weight to an expression, which, if removed, the sense becomes flat and lifeless. Now such words as are most full and expressive suit best with his character. Epithets also, which are proper and well chosen, serve very much to beautify and enliven it, as they enlarge the ideas of things, and set them in a fuller light.

The most accurate composition, in all the parts of it, has place here. Periods, the most beautiful and harmonious, of a due length, and wrought up with the exact order, just cadency, easy and smooth connection of the words, and flowing numbers, are the genuine ornaments, which greatly contribute to form this character.

But the principal distinction of style arises from tropes and figures. By these it is chiefly animated and raised to its different degrees or characters, as it receives a lesser or greater number of them; and those either more mild, or strong and powerful.

As to tropes, those which afford the most lively and pleasing ideas, especially metaphors, suit the middle character. It is a pretty remark, which has been made by some critics upon two verses of Virgil; one in his Eclogues, and the other in his Georgics. The former of these works is for the most part written in the low style, as the language of shepherds ought to be; but the latter in the middle style, suitable to the nature of the subject, and the persons for whom it was designed, the greatest men in Rome not thinking it below them to entertain themselves with rural affairs. Now in the Eclogue, as some copies read the verse, the shepherd complaining of the barrenness of his land, says,

*Infelix lolium et steriles nascuntur avenæ.*

In English thus:

Wild oats and darnel grow instead of corn.

But in the Georgic, where the same sense is intended, instead of the proper word *nascuntur*, grow, the author substitutes a metaphor, *dominantur*, command, and says,

*Infelix lolium et steriles dominantur avenæ.*

That is in English:

Where corn is sown, darnel and oats command.

It was fit and natural for the shepherd to express his sense in the plainest terms; and it would have been wrong to represent him going so far out of his way, as to fetch a metaphor from government, in talking upon his own affairs. But in the Georgic, where the poet speaks in his own person, the metaphor is much more beautiful, and agreeable to the dignity of the work. This instance may show in some measure how the style is heightened by tropes, and the same thought may be accommodated to the several characters of style by the different manner of expression.

The like may also be said of figures either of words or sentences, in reference to this character; which admits of the finest descriptions, most lively images, and brightest figures, that serve either for delight, or to influence the passions without transport or ecstacy, which is the property of the sublime. This is indeed the proper seat of such embellishments, which support and make up a principal part of the middle or florid style. Having treated largely upon these in several preceding chapters, we shall here only briefly mention some of the most considerable.

*Descriptions* are not only a great ornament to a discourse, but represent things in a very lively and agreeable manner. In what a beautiful light has Cicero placed the polite arts and sciences, when, describing them from their effects, he thus represents to us the great advantages, as well as pleasure, which they afford to the mind? "Other studies neither suit with all times, nor all ages, nor all places; but these improve youth, delight old age, adorn prosperity, afford a refuge and solace in adversity; please at home, are no hinderance abroad; sleep, travel, and retire with us." And they often affect us very powerfully, when they are addressed to the senses. Quintilian has painted the calamities of a city taken by storm, in the brightest and strongest colours, which he represents by "Flames spreading themselves over the houses and temples, the cracking of falling buildings, and a confused noise from a variety of cries and shouts; some running they know not where, others in the last embraces of their friends, the shrieks of children, women, and old men unhappily reserved to such distress; the plundering of all places civil and sacred, the hurry and confusion in carrying off the booty, captives driven before their victors, mothers endeavouring to guard their infants, and quarrels among the conquerors where the plunder is largest." This seems to be a very natural, as well as moving, image of so dreadful a calamity.

106  
Descriptions ornamental and pleasant.

*Prosopopœia* is another very strong and beautiful figure, very proper for this character. Seneca has a fine instance of it in his *Consolatory letter to Marcia*, upon the death of her son. After many arguments he had made use of to alleviate her grief, he at last introduces her father, Crematius Cordus, as thus addressing

107  
Prosopopœia well fitted for this character.

**Elocution.** dressing her: "Imagine your father (says he) from the celestial regions, speaking to you in this manner: Daughter, why do you so long indulge your grief? why are you so ignorant, as to think it unhappy for your son, that, weary of life, he has withdrawn himself to his ancestors? Are you not sensible what disorders fortune occasions everywhere? and that she is kindest to those who have least concern with her? Need I mention to you princes who have been extremely happy, had a more timely death secured them from impending evils? or Roman generals, who wanted nothing to consummate their glory, but that they lived too long? Why then is he bewailed longest in our family who died most happily? There is nothing, as you imagine, desirable among you, nothing great, nothing noble; but, on the contrary, all things are mean, full of trouble and anxiety, and partake very little of the light which we enjoy." This advice was very suitable for a philosopher; and he seems to have chosen this way of introducing it, to enforce the argument drawn from the happiness of good men in a future state, from the testimony of a person who was actually in the possession of it.

108  
Similitudes  
both orna-  
mental and  
frequent  
here.

*Similitudes* and comparisons are another great ornament of this style, and oftener found here. Nothing can be finer than the comparison between those two great orators, Demosthenes and Cicero, made by Quintilian, when he says, "Demosthenes and Cicero differ in their elocution; one is more close, and the other more copious; the former concludes more concisely, and the latter takes a larger compass; the one always with pungency, and the other generally with weight; one can have nothing taken from him, and the other nothing added to him; the latter has more of art, and the former more of nature. But this must be allowed to Demosthenes, that he made Cicero in a great measure what he was. For as Tully gave himself wholly to an imitation of the Greeks, he seems to me to have expressed the force of Demosthenes, the fluency of Plato, and the pleasantries of Isocrates." *Similitudes*, taken from natural things, serve very much to enliven the style, and give it a cheerfulness; which is a thing so common and well known, that we need not stay to give any instances of it.

109  
Antithesis  
has also a  
fine effect.

*Antithesis*, or opposition, both in the words and sense, has often the like beautiful effect. There is an agreeable contrast in that passage of Seneca: "Cæsar does not allow himself many things, because he can do all things: his watching defends all others sleep, his labour their quiet, his industry their pleasure, his business their ease; since he has governed the world, he has deprived himself of it." Had he said no more than only in general, that *Cæsar does not allow himself many things, because he can do all things*, it might have passed for a fine thought; but, by adding so many particulars, all in the same form of expression, and beginning each member with the same word, he has both enlarged the idea, and beautified the antithesis, by a bright verbal figure.

These, and such like florid figures, are sometimes found in historians, but oftener in orators; and indeed this middle character, in the whole of it, is best accommodated to the subjects of history and oratory.

# CHAP. VII. Of the Sublime Style.

**Elocution.**

120

THE *sublime* is the most noble, as well as the most difficult, part of an orator's province. It is this principally which Cicero requires in his perfect orator, whom he could not describe in words, but only conceive of in his mind. And indeed, the noblest genius and greatest art are both requisite to form this character. For where nature has been most liberal in furnishing the mind with lofty thoughts, bright images, and strong expressions; yet without the assistance of art there will sometimes be found a mixture of what is low, improper, or misplaced. And a great genius, like a too rich soil, must produce flowers and weeds promiscuously, without cultivation. But the justest propriety, joined with the greatest strength and highest elevation of thought, are required to complete the true sublime. Art therefore is necessary to regulate and perfect the taste of those who are desirous to excel in this character.

The noblest and the most difficult part of an orator's province is the sublime

In explaining the nature and properties of this character, we shall, as in the two former, consider first the *thoughts*, and then the *language*, in each of which it is distinguished from them.

## § 1. Sublime, as it relates to Thoughts.

LOFTY and grand sentiments are the basis and foundation of the true sublime. Longinus therefore advises those who aspire at this excellence, to accustom themselves to think upon the noblest subjects. A mind that always dwells upon low and common subjects, can never raise itself sufficiently to represent things great and magnificent in their full extent and proper light. But he who inures himself to conceive the highest and most exalted ideas, and renders them familiar to his thoughts, will not often be at a loss how to express them; for where proper words are wanting, by metaphors and images taken from other things he will be able to convey them in a just and adequate manner. What is more common than for two persons to conceive very differently of the same thing from the different manner of thinking to which they have been accustomed? After the great battle in Cilicia, between Alexander and Darius, in which the latter was routed, he sent ambassadors to Alexander with proposals of peace, offering him half his kingdom with his daughter in marriage. Parmenio, one of Alexander's chief captains, says to him upon this occasion, "For my part, was I Alexander, I would accept of these conditions." And so would I (replies that aspiring monarch), was I Parmenio." The half of so vast a kingdom at present, and a right of succession to the whole by marriage, was the highest ambition to which the thoughts of Parmenio could rise. But Alexander had vastly higher views; he aimed at nothing less than universal monarchy; and therefore such a proposal seemed much beneath his regard. Noble and lofty thoughts are principally those which either relate to divine objects, or such things as among men are generally esteemed the greatest and most illustrious.

III  
Sublimity  
as it relates  
to thoughts

Of the former sort is that of Homer, when describing the goddesses discord, he says, that she

Walks on the ground, and hides her head in clouds.

This

Elocution.

This stretch of thought, says Longinus, as great as the distance between heaven and earth, does not more represent the stature of the goddess, than the measure of the poet's genius and capacity. But such images, however beautiful in poetry, are not so proper for an orator, whose business it is to make choice of those which are suited to the nature of things and the common reason of mankind. When Numa the second king of Rome was settled in his government, and at peace with his neighbours, in order to soften the fierce and martial temper of his subjects, who have been always accustomed to wars during the reign of his predecessor Romulus, he endeavoured to impress their minds with an awe of the Deity; and for that end introduced a number of religious ceremonies, which he pretended to have received from the goddess Egeria\*. This must be esteemed an artful piece of policy at that time. But that sentiment is far more just and noble, with which Cicero endeavours to inspire the members of a community, in his treatise Of Laws, when he says, that "Citizens ought first to be persuaded, that all things are under the rule and government of the gods; that every affair is directed by their wisdom and power; that the highest regard is due to them from men, since they observe every one's conduct, how he acts and behaves himself, and with what temper and devotion he worships them; and that they make a difference between the pious and impious." Persons under the influence of such a persuasion, could not fail of behaving well in society. And what he says to Cæsar is no less in this style, when, interceding for Ligarius, he tells him, that "men in nothing approach nearer to deity, than in giving life to men." And Velleius Paterculus, speaking of Cato, gives him this sublime character, "That he was more like the gods than men; who never did a good thing, that he might seem to do it."

\* See EGERIA.

The other kind of lofty thoughts mentioned above, are those which relate to power, wisdom, courage, beneficence, and such other things as are of the highest esteem among mankind. "Your fortune (says Tully to Cæsar) has nothing greater than a power, nor your nature than a will, to save many." He subjoins this compliment to what we just now cited from him; and applies that to Cæsar, which was before only expressed in general, leaving him to draw the inference of his similitude to deity from the clemency of his nature. And elsewhere, as in a sort of transport for his success in defeating the conspiracy of Catiline, he thus bespeaks the Roman senate: "You have always decreed public thanks to others for their good government of the state, but to me alone for its preservation. Let that Scipio shine, by whose conduct and valour Hannibal was forced to leave Italy, and retire to Africa; let the other Scipio be greatly honoured, who destroyed Carthage and Numantia, two cities the most dangerous to this empire; let Lucius Paulus be in high esteem, whose triumphal chariot was adorned with Perseus, once a most powerful and noble prince; let Marius be in eternal honour, who twice delivered Italy from an invasion and the dread of servitude; let Pompey's name excel all these, whose actions and virtues are terminated by no other bounds but the course of the sun:—yet, among all their praises, there will still

some place be left for my glory; unless indeed it be a greater thing to open for us new provinces to which we may resort, than to secure a place for our victorious generals to return in triumph." And Velleius Paterculus, as if he thought no encomium too high for this great orator, laments his unhappy fate in these lofty strains, addressed to M. Antony, by whose order he was put to death: "You have taken from Cicero old age, and a life more miserable than death under your government; but his fame, and the glory of his actions and words, you have been so far from destroying, that you have increased them. He lives, and will live in the memory of all ages; and while this system of nature, however constituted, shall remain (which scarce any Roman but himself conceived in his mind, comprehended by his genius, and illustrated with his eloquence), the praise of Cicero shall accompany it; and all posterity, while it admires his writings against you, will curse your treatment of him; and sooner shall mankind be lost to the world than his name." It was a noble reply of Porus the Indian king, when, after his defeat by Alexander, being brought before him, and asked, *how he expected to be treated?* he answered, *Like a king.* And Valerius Maximus, speaking of Pompey's treatment of Tigranes king of Armenia after he had vanquished him, expresses it in a manner suited to the dignity and beneficence of the action, when he says, "He restored him to his former fortune, esteeming it as glorious to make kings as to conquer them."

But the true sublime is consistent with the greatest plainness and simplicity of expression. And, generally speaking, the more plain and natural the images appear, the more they surprise us. How succinct, and yet how majestic, is that expression of Cæsar upon his victory over Pharnaces? *I came, I saw, I conquered.* But there cannot be a greater or more beautiful example of this, than what Longinus has taken notice of from Moses. "The legislator of the Jews (says he), no ordinary person, having a just notion of the power and majesty of the Deity, has expressed it in the beginning of his laws in the following words: *And God said—what? Let there be light; and there was light. Let the earth be made; and it was made.*" This instance from the divine writer, and the character here given of him by that excellent critic, is the more remarkable, as he was himself a Pagan. And certainly no laboured description could raise in the mind an higher conception of the infinite power of the Deity, than this plain and short narration. To command nature itself into being by a *word*, represents it at once altogether boundless and unlimited.

It sometimes very much contributes to heighten the image of a thing, when it is expressed in so undetermined a manner, as to leave the mind in suspense what bounds to fix to the thought. Of this kind is that of Cicero, when he first raises an objection against the necessity of an acquaintance with polite literature in order to form a great man, and then answers it. The objection is founded upon the examples of several great and excellent persons among the Romans, who had raised themselves to the highest pitch of honour and dignity, and been very serviceable to their country, by the help of a good genius, without the advantage

Elocution.

**Elocution.** tage of much learning. In reply to which, he allows, that, where these are not united, nature or genius is of itself much preferable, and will carry a person further in the pursuit of great and noble designs, than learning without a genius; but that both are necessary to complete and perfect a truly great man. But we shall give what he says himself on this head, by which that property of a sublime thought we are now endeavouring to explain, will appear from his manner of expression: "I a knowledge (says he) that many persons of an exalted mind and virtue have, from a divine temper, without instruction, become moderate and grave; and I add likewise, that nature, without the assistance of learning, has frequently more contributed to honour and virtue, than learning where a genius has been wanting: But yet I must say, that where the direction and improvement of learning is added to a great and excellent genius, it is wont to produce something admirable and singular, which I know not how to describe." He knew very well, that by leaving the minds of his hearers thus in suspense, they would form to themselves higher conceptions of what he intended, than from any idea he could convey to them in words. We may add to this another example from the same great orator, where he says, "Truly if the mind had no views to posterity, and all its thoughts were terminated by those bounds in which the space of life is confined, it would neither fatigue itself with so great labours, nor be disquieted with so many cares and watchings, nor so often expose itself to death. But there is a certain active principle in every good man, which constantly excites his mind by motives of glory; and reminds him, that the remembrance of his name is not to end with his life, but extend itself to all posterity." Of the like nature is that of Milton, when he describes Satan as flying from hell in quest of our earth, then newly formed. For, having represented that his wings failed him in the vast vacuity, he thus describes his fall:

Down he drops  
Ten thousand fathom deep; and to this hour  
Down had been falling, had not by ill chance  
The strong rebuff of some tumultuous cloud,  
Instinct with fire and nitre, hurried him  
As many miles aloft.

Those words, by which his fall is expressed,

And to this hour  
Down had been falling,

leave the mind in suspense, and unable to fix any bound to the vacuity; and by that means raise a greater and more surprising idea of its space than any direct expression could have done. This image is very beautiful where it stands; but so much out of the common way of thinking, as to suit better with an epic poem than the discourse of an orator.

#### § 2. *The Sublime, with regard to Language.*

112  
Sublimity  
as to lan-  
guage.

WHAT we have to offer upon this subject will come under the three heads of *Elegance*, *Composition*, and *Dignity*; which comprehend all the properties of style.

I. *Elegance*. Those words and expressions chiefly contribute to form the sublime, which are most sono-

rous, and have the greatest splendor, force, and dignity. And they are principally such as these. Long words, when equally expressive, are rather to be chosen than short ones, and especially monosyllables. So to conquer or vanquish an enemy, carries in it a fuller and more grand sound, than to beat an enemy. For which reason, likewise, compound words are often preferable to simple ones. So, if we say, *Cæsar's army, when he was present, was always invincible*; this manner of expression has more of sublimity in it, than should we say, *Cæsar's army, when he was present, could never be conquered*. But the ancient languages have much the advantage of our's in both these respects; for their words are generally longer, and they are abundantly more happy in their compositions. The use of proper epithets does also in a particular manner contribute to this character. For as they denote the qualities and modes of things, they are as it were short descriptions; so that being joined to their subjects, they often greatly enlarge and heighten their image. Thus when the character of *divine poet* is given to Homer or Virgil, or *prince of orators* to Demosthenes or Cicero; it conveys to the mind a more sublime idea of them, than the bare mention of their name.

**Elocution.**

II. *Composition*: The force of which, as Longinus observes, is so great, that sometimes it creates a kind of sublime where the thoughts themselves are but mean, and gives a certain appearance of grandeur to that which otherwise would seem but common. But composition consists of several parts; the first of which, in the order we have hitherto considered them, is *period*. And here the case is much the same as with animal bodies, which owe their chief excellency to the union and just proportion of their parts. The several members, when separate from each other, lose both that beauty and force, which they have when joined together in a complete body. In like manner, sublimity arises from the several parts of a period so connected, as to give force, as well as beauty, to the whole. The periods therefore in this character should be of a proper length. If they are too short, they lose their just weight and grandeur, and are gone almost before they reach the ear; as on the contrary, when they are too prolix, they become heavy and unwieldy, and by that means lose their force. But more especially, nothing superfluous ought to be admitted, which very much enervates the force of a sentence. We shall exemplify this in a passage from Herodotus, where he is giving an account of the famous battle at Thermopylæ between the Persians and Lacedæmonians. "Dieneces (says he) the Spartan, being told by a Trachinian, before the engagement with the Medes, that when the barbarians came to shoot their arrows, they would fly so thick as to obscure the light of the sun; he was so far from being terrified at this, that despising their number, he replied, he "was pleased with what his friend told him, since if the sun was obscured, they should fight in the shade, and not in the sun." The sense here is great and noble, but the sublimity of expression is spoiled in a great measure by those last words, *and not in the sun*, which are wholly superfluous. Cicero was sensible of this, and therefore he omits that member in relating the same story, and says only, "A Spartan, hearing that one of the Persians should say in an insulting manner, that when they

114

**Elocution.** they came to engage, they should not be able to see the sun, for the multitude of their darts and arrows, replies, Then we shall fight in the shade." By stopping here, he gives the sentence much more life and emphasis. The next thing to be considered in composition, is the order and disposition of the several words and members of a sentence. The different placing of but one or two words will sometimes wholly destroy the grandeur of a sentence, and make it extremely flat. "This public act (says Demosthenes) dispelled the danger which at that time, like a cloud, hung over the city." Let us vary the order a little, and read it thus: "This public act dispelled the danger, which like a cloud hung over the city at that time." What a different turn does the expression receive for the worse! The spirit and majesty of it are entirely lost. And in placing the several parts of members, they ought to be so disposed, that what is most weighty and important should stand last. So Tully says of Catiline, "We ought to return thanks to heaven, that we have so often escaped so odious, so frightful, so dangerous a plague of the state." A thing may be odious and frightful, and yet not dangerous; therefore he puts this in the last place, to give it the greater force, and make the deeper impression. Another thing to be attended to in composition, is the connection of the words with regard to the sound; that the pronunciation, in passing from one to another, may be most agreeable to the ear, and best suited to the nature of the subject. And as this is generally something grand and magnificent; such a contexture of them as will give the greatest force and energy to the expression is most proper for the sublime. Soft and languid sounds are very unsuitable to this character. They soothe and please the ear; but rather sink and depress the mind, than excite it to things great and noble. In this respect, therefore, our tongue, by its multitude of consonants, is more suitable for sublime discourses than some other modern languages, which abound with vowels.

115 **III.** The last head to be considered, is the proper use of tropes and figures; which is here so necessary, that the title of *dignity* seems to have been given to this part of elocution, from the assistance it more especially affords to this character. For if, as has been observed from Longinus, compositions will sometimes create a sort of sublimity; this much oftener happens from the force and efficacy of some lively tropes and strong figures.

And as to *tropes*, bright metaphors are peculiarly suited to raise and animate the style. This is manifest from the nature of them, as they consist of contracted similes, reduced to a single word; which, if taken from things lofty and grand, must of consequence give a sublimity to the style. What can suggest to us a greater idea of the valour of Ajax, than Homer's calling him *the bulwark of the Greeks*; or of the Scipios, than when they are styled by Virgil, *the two thunderbolts of war*. A number of these, well chosen, contribute no less to the grandeur than to the beauty of discourse. Hyperbole sometimes gives the same force to an expression, if cautiously used, and so as not to exceed all appearance of truth. But the chief use of it is, where proper words will not express the just idea of the thing designed to be conveyed;

and it may seem rather the offspring of necessity than choice. Of this nature is that of Herodotus, when speaking of the Lacedemonians at Thermopylæ, he says, "They defended themselves with the swords they had left, and even with their hands and teeth, till the barbarians buried them under their arrows." It cannot be supposed strictly true, that so many arrows were thrown at them as to bury them; but having in the former part of the sentence represented their resolute defence in the strongest terms, by saying, that, naked and without arms, they engaged armed men with their hands and teeth, the following hyperbole seems not unnatural, and to intimate nothing more than what was necessary to quell such obstinate resolution and courage.

As to *figures*, whether verbal or those which consist in the sense, the nature of this character will easily direct to such as are most proper. But with respect to the latter, poets take greater liberties in the use of them than would be allowed in an orator. As their images are often formed for pleasure and delight, so they carry in them more of rapture and transport. But the orator's use of them being to set things in a stronger and clearer light, they are more sedate and moderate. Besides, an orator scarce ever has occasion for such fictitious images as we often meet with in poetry; though his ought to appear as natural, and its painting as strong and lively. We shall just mention some of the chief of those figures which seem best suited for this purpose; though they are no less suited to the middle style, as has been shown already, when taken from subjects of an inferior nature.

1. *Description.* Of this Justin gives us a fine instance, in a speech of King Philip the fifth of Macedon, wherein he represents the necessity of falling upon the Romans, who at that time were engaged in a war with Hannibal. "I behold (says he) a cloud of a most dreadful and bloody war rising in Italy. I see a storm of thunder and lightning, from the west, which will overspread all places with a vast shower of blood, into whatever country the tempest of victory shall drive it. Greece has undergone many violent shocks in the Persian, Gallic, and Macedonian wars; but these would all be found unworthy of regard, if the armies now engaged in Italy should march out of that country. I view the terrible and cruel wars which involve those nations through the courage of their forces, and skill of their generals. This rage and fury cannot cease by the destruction of one party, without the ruin of their neighbours. Indeed, Macedon has less reason to dread the savage conquerors than Greece; because more prepared, and better able to defend itself; but I am sensible, those who attack each other so impetuously will not confine their victories within those bounds, and that it will be our lot to engage the conquerors." So lively a picture of imminent and threatening danger must needs alarm the most timorous, and excite them to a resolution to defend their country, and all that was dear to them. Such images give life and vigour to a discourse, and being artfully interwoven with proper arguments, influence the mind, and carry it away by an irresistible force, so that the hearer is not barely left to conclude the certainty of the thing, but moved by it, as it were, from ocular demonstration. The images there-  
fore

**Elocution.** fore of an orator ought to be drawn from real things, or at least such as are probable; for if they are wholly fictitious and incredible, as many poetical images are, they may give pleasure, but will not convince the mind, nor sway the passions.

117

2. *Enumeration* has some affinity with the former figure; by which, if the several parts have each something grand in them, the whole, when brought together, and disposed in a just order, very much contributes to the sublimity. We shall produce an example of this from an English writer, containing a description of our globe, upon a survey of it after the general conflagration, which he represents in this strong light: "Such is the vanity and transient glory of this habitable world! By the force of one element breaking loose upon the rest, all the varieties of nature, all the works of art, all the labours of man, are reduced to nothing; all that we admired and loved before, as great and magnificent, is obliterated and vanished, and another form and face of things, plain, simple, and everywhere the same, overpreads the whole earth. Where are now the great empires of the world, and their great imperial cities? their pillars, trophies, and monuments of glory? Show me where they stood, read the inscription, tell me the victor's name. What remains, what impressions, what difference or distinction, do you see in this mass of fire? Rome itself, eternal Rome, the great city, the empress of the world, whose domination or superstition, ancient or modern, make a great part of the history of the earth, what is become of her now? She laid her foundations deep, and her palaces were strong and sumptuous; *she glorified herself, and lived deliciously, and said in her heart I sit a queen, and shall see no sorrow*: but her hour is come; she is wiped away from the face of the earth, and buried in everlasting oblivion. But it is not cities only, and the work of men's hands; the everlasting hills, the mountains and rocks of the earth, are melted as wax before the sun, *and their place is nowhere found*. Here stood the Alps, the load of the earth, that covered many countries, and reached their arms from the ocean to the Black sea. This huge mass of stone is softened and dissolved, as a tender cloud into rain. Here stood the African mountains, and Atlas with his top above the clouds. There was frozen Caucasus, and Taurus, and Imaus, and the mountains of Asia; and yonder, towards the north stood the Riphean hills, clothed in ice and snow; all these are vanished, dropped away, as the snow upon their heads.\*" These particulars considered separately are all truly great and noble, and every way suited to the nature of the subject; but as they are here disposed, and rise in order, they both enlarge the idea, and heighten the image, of that grand catastrophe.

\* Burnet's Theory.

118

3. *Similitude*: Which serves very much for beauty and ornament; and, when taken from great and sublime objects adds a grandeur and magnificence to the things illustrated by it. We need go no farther for an example of this, than to the great critic so often mentioned already, who has treated upon the sublime in a style every way equal to the subject. He, then, comparing those two great works of Homer, his *Iliad* and *Odyssey*, thus describes them: "Homer composed

Vol. XIII.

his *Iliad* when his mind was in its full strength and vigour; the whole body of the poem is dramatic, and full of action: whereas the best part of the *Odyssey* is taken up in narrations, which seem to be the genius of old age. So that one may compare him in this latter work to the setting sun, which still appears with the same magnificence, but has no longer the same heat and force." And soon after, speaking of the *Odyssey*, he says, "That piece may be called the reflux of his genius, which like the ocean ebbs, and deserts its shores." What nobler idea could possibly have been given of that great poet, than by those two similitudes of the sun and the ocean? And elsewhere, comparing those two great orators Demosthenes and Cicero, he shows the like sublimity of thought. "Demosthenes (says he) is sublime, in that he is close and concise; Cicero, in that he is diffused and extensive. The former, by reason of the violence, rapidity, strength, and fury, with which he rages and bears all before him, may be compared to a tempest and thunder; but the latter, like a great conflagration, devours and consumes all he meets, with a fire that is never extinguished, but wherever it advances continually gathers new strength."

**Elocution.**

4. *Antithesis*, or a sentence consisting of opposite parts, has often the same effect; as in the following instance of Cicero, where his view is to represent Pompey as a most consummate general. "Who," says he, "ever was, or need be more knowing, than this man? who from his childhood, and instruction at school, went into the army of his father, and learned the military art, in a very great war against the fiercest enemies: who, while yet a boy, became a soldier under the greatest general; and when but a youth was himself commander of a very great army: who has oftener engaged with the enemy in battle, than any other person with his adversary in private contests; has waged more wars than others have read, and conquered more provinces than others have wished to govern; whose youth has been spent in acquiring the art of war, not by the precepts of others, but his own commands; not by defeats, but victories; not by campaigns, but triumphs."

119

5. *Apostrophe*. Among the articles charged against Demosthenes by his great adversary and rival Æschines, one was, that he had advised the Athenians to engage in a war against King Philip, wherein they had received a very great defeat. When Demosthenes comes to answer that part of the charge, he does not say as he might, "You have not been misled, my fellow-citizens, in exposing your lives for the liberties and safety of Greece; you are not without the most illustrious examples of such conduct: for who can say these great men were misled, who fought for the same cause in the plains of Marathon?" But instead of expressing himself thus, he gives the matter quite a different turn; and in a sort of rapture, appealing to those brave defenders of their country, says, "No, my fellow-citizens, you have not done wrong, you have not: I protest by the ghosts of those great men who fought for the same cause in the plains of Marathon." By this appeal to those ancient worthies whose memories were in the highest esteem at Athens, that it was the cause, and not the success, which rendered their actions

120

*Elocution.* so glorious, he artfully corroborates his assertion in a way which he knew must have the greatest weight with his audience.

As the proper subjects of this character are either divine things, or such as are in the highest esteem and regard among mankind, which often require laudatory discourses, or panegyric; these naturally admit of all the ornaments and assistance of eloquence. Which, however, must be used with discretion: for when the mind is wrapped up in thought, and stretched to the utmost of its powers in the pursuit of some noble and sublime idea, it cannot attend to all the lesser fineries and niceties of language; but from its own vigour, and lively conception of things, will be led to express them in terms the most emphatical and best suited to their nature. In such cases, therefore, the sublimity must appear rather from the elevation of the thought, attended with a simplicity of expression, than from the ornaments and dress of the language. These things seem more natural when the mind is relaxed, and employed upon lower objects. Though, upon the whole, grandeur and majesty of expression is the proper mark of this character with relation to the language, as beauty and splendor is of the middle style.

#### CHAP. VIII. *Of the Style of an Orator.*

121  
The low,  
middle, and  
sublime  
style requi-  
site for an  
orator.

THE style of an orator comprehends all the characters already explained, of *low*, *middle*, and *sublime*, as they are applied by him in the different parts of his province. For that the language must be suited to the nature of the subject, we have had occasion often to observe already; and the different view of the speaker or writer necessarily occasions a variety in the manner of expression. Now an orator has three things in his view; to prove what he asserts, to represent it in an agreeable light, and to move the passions. These are all necessary, we do not mean in the order wherein we have now mentioned them, but that the discourse may upon the whole have its desired effect upon the audience. For unless the mind be convinced of the truth of what is offered by solid and cogent arguments, neither will the most eloquent discourse afford a lasting pleasure, nor the most pathetic long influence the affections. Though, on the other hand, the hearers expect to be entertained at the same time they are informed; and therefore, unless the language be agreeable to their taste, they will soon call off their attention, and think but meanly of the speaker. And unless both these are warmed and animated by a becoming pathos, the speaker may very probably miss of his end in bringing his audience over to his sentiments. For bare conviction is not sufficient with many persons to excite them to action. They will acquiesce in the truth of a thing which they cannot contradict, or will not give themselves the trouble to examine; and at the same time remain unconcerned to prosecute it. And the pleasure of a florid discourse will of itself soon vanish, like the harmony of music, or the charms of a fine poem. And therefore to captivate his audience, secure them in his interest, and push them upon action, it is necessary for the orator to engage their affections; these are, as it were, the springs of the soul, which, managed

*Elocution.* by a skilful hand, move and direct it at pleasure. Now each of these parts of an orator's province requires a different style. The *low style* is most proper for proof and information; because he has no other view here but to represent things to the mind in the plainest light, as they really are in themselves, without colouring or ornament. The *middle style* is most suited for pleasure and entertainment, because it consists of smooth and well turned periods, harmonious numbers, with florid and bright figures. But the *sublime* is necessary in order to sway and influence the passions. Here the orator calls in all the assistance both of nature and art; the most raised and lofty thoughts, clothed with the brightest and strongest colouring, enter into this character.

But as an orator has frequently each of these views in the same discourse, we shall first give a summary description of the several characters of style, which we have formerly discoursed on more at large; that by placing them together in one view, the difference between them may be more plain and obvious: and then we shall proceed to shew to what particular parts of a discourse each of them is more especially to be applied.

I. First, then, as shorter periods are proper in the *low style*, so less care is necessary in their turn and cadency. If a sentence now and then drop unexpectedly, and disappoint the ear, or has something rough and harsh in its composition, it is no blemish in this character. For as it is suited to the manner of common discourse, an appearance of regard to the subject, rather than the form of expression, is more becoming than any beauties of art. But the words should be well chosen and proper, suited to the ideas they are designed to convey; the expressions plain and clear, and the artificial ornaments few and modest. By *artificial ornaments* are here meant *tropes* and *figures*; and they are called *artificial*, because they vary from the natural dress of language, either in the words or manner of expression: though they are often used by those who are wholly unacquainted with the rules of art; and particularly metaphors, which persons who have the least command of language frequently run into, through mere necessity, for want of a sufficient stock of proper words to convey their ideas. The *low style* therefore admits of these: but care should be taken to choose such as have been rendered familiar by use, or at least where the similitude is very plain and evident. Bold or lofty metaphors, or where the allusion is dark and remote, ought to be avoided. Nor is the moderate use of the other tropes wholly disagreeable to this style. And the same thing is to be said with respect to verbal figures, or such as consist in the particular disposition of the sentence, so that if the form of it be changed, the figure is lost. Of these, such as come nearest to the natural way of expression are most proper for this style; and therefore those which consist in a jingle of words, arising from the same or like sound, are to be avoided, as carrying in them too much the appearance of art. Those likewise which consist in a repetition of the same word have often too great a force and vehemence for this mild and gentle character. And as to figures of sentences, which do not depend on the construction of words, but lie in the sense, many of them are too gay and

**Elocution.** and sprightly, and others too rapid and impetuous, for the simplicity of the low style; so that only the more moderate and sedate ones are to be allowed a place here. It is therefore no wonder if persons are often mistaken in their notions of this character; the beauty of which consisting in a certain plainness and simplicity, without any thing in it but what seems natural and common, every one is apt to imagine he can readily be master of it, till by experience he finds the contrary. For the case is much the same here, as in persons of fashion and good breeding, whose behaviour and address is attended with that agreeable freedom and seeming negligence, which in appearance is very easy to express, but in reality is scarce imitable by others.

As the *middle style* is more adapted for pleasure and delight, it admits of all those beauties and ornaments which soothe and entertain the mind. It has more force and energy than the low style, but less than the sublime. Smooth and harmonious numbers, well-turned periods, of a just length, delightful cadency, and accurate disposition of the words, are suited to this style. The most beautiful and shining tropes, which strike the fancy, and all those verbal figures which, by a repetition, similitude, or proportion of sounds, please and gratify the ear, help to form this character. The like is to be said as to figures of sentences: The most florid and beautiful, such as enumeration, description, similitude, and the like, are here the most proper.

But it is the *sublime style* which perfects the orator. This requires the most forcible and emphatical words, the boldest metaphors, and strongest figures. In verbal figures, repetitions, synonyms, gradations, contraries, with others of a like force and energy, are chiefly employed here. But figures of sentences are the most considerable, and principally contribute to make up this character. Among these are similes taken from lofty subjects, prosopopœia, apostrophe, exclamation, epiphonema, aposiopesis, and others of a like nature. But due care must likewise be taken of the form, construction, and harmony of the periods; which seem best disposed, when long and short ones are intermixed. For though round and swelling periods carry in them something grand and majestic, yet many times they move too slow to strike the passions; whereas short ones are more acute and pungent, and by returning quick, awaken the mind, and raise the passions. But to render it complete, it must be supported with strong reason, grandeur of thought, and sentiments every way equal to the expression; without which it will be very liable to swell into bombast, and end barely in amusement.

II. Having given a short sketch of this part of the orator's furniture, we shall now go on to show where, and in what manner, he is to make use of it. This will best appear by considering his principal view in each part of his discourse. Now the parts of a just oration (as we have formerly shown) are six; *Introduction, Narration, Proposition, Confirmation, Confutation, and Conclusion*. Not that all these are necessary in every discourse, but it is proper they should all be mentioned, that we may consider what style is fittest for them when they are necessary.

In the *Introduction*, the orator has three things before him; to gain the esteem of his hearers, to secure

their attention, and to give them some general notion of his subject. To set out modestly is undoubtedly the most likely way to recommend himself. For to attempt to inflame an audience, before they are prepared for it, or see the reason of much warmth, is highly improper. A prudent speaker will, like Demosthenes, begin with temper, and rise gradually, till he has insensibly warmed his hearers, and in some degree engaged their affections in his favour. So that this part scarce rises above the middle style. And if it carry in it an air of pleasantry and good-humour, it is generally the more apt to engage the attention.

The introduction is usually followed by the *narration*, or a recital of such things as either preceded, accompanied, or followed upon the subject under consideration. Now, as the qualities that recommend a narration are clearness, brevity, and probability; these sufficiently point out the style. Perspicuity arises from the choice of proper words, and such tropes as have been rendered most familiar by use; brevity requires moderate periods, whose parts are but little transposed; and a plain and simple dress without ornament or colouring, is best suited to represent things probable: all which are the properties of the low style. And therefore Cicero says, *narrations come pretty near to our ordinary discourse*. Indeed, sometimes it is necessary not only to relate the facts themselves, but likewise to describe the manner in which they were performed. And then a further degree of art may be requisite to represent them with all their circumstances, and paint them to the mind in their proper colours.

The next part in order is the *proposition*, or subject of the discourse, in which there can be no room for ornament. But as it is the basis and foundation of the orator's whole design, it ought to be laid down in the plainest and clearest terms, so as to leave no room for doubt or uncertainty what it is which he intends to discourse upon.

The next thing is *confirmation*, wherein the orator endeavours to maintain and defend his own cause, and to convince his hearers of the truth of it by reason and argument. Now the low style is certainly fittest for cool reasoning and debate. But the orator's method of reasoning often very much differs from that of the philosopher. The latter contents himself with the most plain and familiar manner of representing the truth, and thinks it sufficient if what he says be clearly understood. But the former, at the same time that he convinces the judgment, endeavours likewise to affect the passions, and that in a great variety of ways. So that in this part of the discourse the style is very different, according to the nature and circumstances of the case. Sometimes, while he is dwelling upon the proof of a thing, he talks coolly, and reasons with the sedateness of a philosopher; and where any part of his argument appears doubtful or obscure, he endeavours with the same even temper to explain and clear it up. But frequently he intermixes with his proofs all the arts of persuasion, and embellishes his reasons with the greatest ornaments and beauties of eloquence.

Confirmation is usually followed by *confutation*, in which the orator endeavours to enervate and overthrow

Elocution

all that has been advanced in favour of the opposite side of the question. But as the style is much the same here as in the former part, what has been said upon that may be sufficient for this likewise.

127

The last part abovementioned is the *conclusion*. This consists of two branches, *recapitulation* and *address*. Recapitulation is a short recital of the several arguments, or at least of the chief of them, which were before advanced in support of the cause; that, being brought together into a narrow compass, they may appear in a stronger light. Wherefore the language here ought rather to be forcible and strong than florid, because brevity and conciseness is a necessary quality. The other branch of the conclusion consists in an address to the passions, and is wholly persuasive; for which the speaker is now entirely at leisure. Indeed, this is often done occasionally in other parts of the discourse, particularly in the introduction and confirmation: But as in the former of these, his view is principally to secure the good opinion of the hearers, and excite their attention; and in the latter to defend his own side of the question by reason and argument; when these two points are gained, he has nothing left but to prevail with them to fall in with the design, and declare for him. And the best way to attain this is, by engaging their passions in his interest. Hence, then, to use Quintilian's words, "All the springs of eloquence are to be opened. Now we are past the rocks and shallows, all the sails may be hoisted." And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here.

All the variety abovementioned, however, is not always necessary. Regard must be had to the nature

of the subject, the time, place, persons, and other circumstances; by all which the style is to be regulated. To discourse in a lofty and grand way upon a common topic, or in a low and flat manner upon a sublime argument, are both equally injudicious. Cicero refers us to some discourses of his own, as instances of each kind. His oration for Cæcina, he says, is written in the low style, that for the Manilian law in the middle style, and that for Rabirius in the sublime; and his Actions against Verres, with some others, are patterns of the variety here mentioned. And he gives us a very comprehensive description of a perfect orator in very few words, when he says: "He is one who can speak upon a low subject acutely, upon a lofty subject with sublimity, and upon a moderate subject temperately." By which he means no more, than one who is master of the three characters here described, and knows when and how to use them. But although he mentions several among the Greeks, and some few among the Romans, who excelled in one or other of these different kinds; yet one who excelled in them all, he supposes never to have existed, except in the imagination. The reason perhaps may be, because each of them seems to require a very different genius, so that it is scarce possible for the same person to succeed in them all. Since therefore it is so rare and difficult a matter to gain the command of each in any good degree, it is better perhaps for every one to pursue that which nature seems most inclined to, and to excel in it, than to strive against their genius. For every kind has its perfections; and it is more commendable to be a master of one thing, than to do several but indifferently.

Elocution.

## PART IV. OF PRONUNCIATION.

### CHAP. I. Of Pronunciation in general.

123  
Pronunciation a conformity of the voice and gesture to the subject.

**P**RONUNCIATION is also called *Action* by some of the ancients. Though, if we attend to the proper signification of each of these words, the former respects the voice, and the latter the gestures and motions of the body. But if we consider them as synonymous terms, in this large sense pronunciation or action may be said to be *a suitable conformity of the voice, and the several motions of the body, in speaking to the subject matter of the discourse*.

The best judges among the ancients have represented this as the principal part of an orator's province, from whence he is chiefly to expect success in the art of persuasion. When Cicero, in the person of Crassus, has largely and elegantly discoursed upon all the other parts of oratory, coming at last to speak of this, he says: "All the former have their effect as they are pronounced. It is the action alone that governs in speaking; without which the best orator is of no value, and is often defeated by one in other respects much his inferior." And he lets us know, that Demosthenes was of the same opinion, who, when he was asked what was the principal thing in oratory, replied, Action; and being asked again a second and a

third time, what was next considerable, he still made the same answer. By which he seemed to intimate, that he thought the whole art did in a manner consist in it. And indeed, if he had not judged this highly necessary for an orator, he would scarce have taken so much pains in correcting those natural defects, under which he laboured at first, in order to acquire it. For he had both a weak voice, and likewise an impediment in his speech, so that he could not pronounce distinctly some particular letters. The former of which defects he conquered, partly by speaking as loud as he could upon the shore, when the sea roared and was boisterous; and partly, by pronouncing long periods as he walked up hill; both of which methods contributed to the strengthening of his voice. And he found means to render his pronunciation more clear and articulate, by the help of some little stones put under his tongue. Nor was he less careful in endeavouring to gain the habit of a becoming and decent gesture; for which purpose he used to pronounce his discourses alone before a large glass. And because he had got an ill custom of drawing up his shoulders when he spoke; to amend that, he used to place them under a sword, which hung over him with the point downward. Such pains did this prince of the Grecian orators take to remove those difficulties, which would have

Pronunciation.

have been sufficient to discourage an inferior and less aspiring genius. And to how great a perfection he arrived in his action, under all these disadvantages, by his indefatigable diligence and application, is evident from the confession of his great adversary and rival in oratory, *Æschines*. Who, when he could not bear the disgrace of being worsted by *Demosthenes* in the cause of *Ctesiphon*, retired to *Rhodes*. And being desired by the inhabitants to recite to them his own oration upon that occasion, which accordingly he did; the next day they requested of him to let them hear that of *Demosthenes*; which having pronounced in a most graceful manner to the admiration of all who were present, "How much more (says he) would you have wondered if you had heard him speak it himself!" By which he plainly gave *Demosthenes* the preference in that respect. We might add to these authorities the judgment of *Quintilian* who says, that "it is not of so much moment what our compositions are, as how they are pronounced; since it is the manner of the delivery, by which the audience is moved." And therefore he ventures to assert, that "an indifferent discourse, assisted by a lively and graceful action, will have greater efficacy than the finest harangue which wants that advantage."

The truth of this sentiment of the ancients concerning the power and efficacy of pronunciation, might be proved from many instances; but one or two may here suffice. *Hortensius*, a cotemporary with *Cicero*, and while living next to him in reputation as an orator, was highly applauded for his action. But his orations after his death, as *Quintilian* tells us (for we have none of them now remaining), did not appear answerable to his character; from whence he justly concludes, there must have been something pleasing when he spoke by which he gained his character, which was lost in reading them. But perhaps there is scarce a more considerable instance of this than in *Cicero* himself. After the death of *Pompey*, when *Cæsar* had got the government into his own hands, many of his acquaintance interceded with him in behalf of their relations and friends, who had been of the contrary party in the late wars. Among others, *Cicero* solicited for his friend *Ligarius*; which *Tubero* understanding, who owed *Ligarius* a grudge, he opposed it, and undertook to represent him to *Cæsar* as unworthy of his mercy. *Cæsar* himself was prejudiced against *Ligarius*; and therefore, when the cause was to come before him, he said, "We may venture to hear *Cicero* display his eloquence; for I know the person he pleads for to be an ill man, and my enemy." But, however, in the course of his oration, *Cicero* so worked upon his passions, that by the frequent alteration of his countenance, the emotions of his mind were very conspicuous. And when he came to touch upon the battle of *Pharsalia*, which had given *Cæsar* the empire of the world, he represented it in that moving and lively manner, that *Cæsar* could no longer contain himself, but was thrown into such a fit of shivering, that he dropped the papers which he held in his hand. This was the more remarkable, because *Cæsar* was himself one of the greatest orators of that age, knew all the arts of address, and avenues to the passions, and consequently was better prepared to guard against them. But neither his skill, nor resolution of

Pronunciation.

mind, was of sufficient force against the power of oratory; but the conqueror of the world became a conquest to the charms of *Cicero's* eloquence; so that, contrary to his intention, he gave into his plea, and pardoned *Ligarius*. Now that oration is still extant, and appears exceedingly well calculated to touch the soft and tender passions and springs of the soul; but we believe it can scarce be discernible to any in reading it, how it should have had so surprising an effect; which must therefore have been chiefly owing to the wonderful address and conduct of the speaker.

The more natural the pronunciation is, it will of consequence be the more moving, since the perfection of art consists in its nearest resemblance to nature. And therefore it is not without good reason, that the ancients make it one qualification of an orator, that he be a good man; because a person of this character will make the cause he espouses his own, and the more sensibly he is touched with it himself, his action will be the more natural, and by that means the more easily affect others in the same manner. *Cicero*, speaking upon this subject, says, "It is certain that truth (by which he means nature) in every thing excels imitation; but if that was sufficient of itself in action, we should have no occasion for art." In his opinion therefore (and who was ever a better judge), art, in this case as well as in many others, if well managed, will assist and improve nature. But this is not all; for sometimes we find the force of it so great and powerful, that, where it is wholly counterfeited, it will for the time work the same effect as if it was founded in truth. This is well known to those who have been conversant with the representations of the theatre. In tragedies, though we are sensible that every thing we see and hear is feigned and counterfeited, yet such is the power of action, that we are oftentimes affected by it in the same manner as if they were all realities. Anger and resentment at the appearance of cruelty, concern and solicitude for distressed virtue, rise in our breasts; and tears are extorted from us for oppressed innocence: though at the same time, perhaps, we are ready to laugh at ourselves for being thus decoyed. If art then has so great an influence upon us, when supported only by fancy and imagination, how powerful must be the effect of a just and lively representation of what we know to be true and real?

How agreeable it is both to nature and reason, that a warmth of expression and vehemency of motion should rise in proportion to the importance of the subject and concern of the speaker, will further appear, by looking back a little into the more early and simple ages of the world. For the higher we go, the more we shall find of both. We shall give the observation of a very great man upon this head, in his own words. "The Romans (says he) had a very great talent this way, and the Greeks a greater. The eastern nations excelled in it, and particularly the Hebrews. Nothing can equal the strength and vivacity of the figures they employed in their discourse; and the very actions they used to express their sentiments; such as putting ashes on their heads, and tearing their garments, and covering themselves with sackcloth under any deep distress and sorrow of mind. I do not speak of what the prophets did to give a more lively representation of the things they foretold, because such

Dial. of  
Eloquence,  
p. 92.

Pronunciation.

such figurative actions were the effect of divine inspiration. But even in other cases we find those people understood much better than we do how to express their grief, and fear and other passions. And hence, no doubt, arose those surprising effects of eloquence, which we never experience now." Thus far this excellent writer. And what he says here with respect to the actions of the eastern nations, was in a good measure customary among the Greeks and Romans; if not entirely of the same kind, yet perhaps as vehement and expressive. They did not think language of itself sufficient to express the height of their passions, unless enforced by uncommon motions and gestures. Thus, when Achilles had driven the Trojans into their city with the greatest precipitation and terror, and only Hector ventured to tarry without the gates to engage him; Homer represents both king Priam and his queen under the highest consternation for the danger of their son. And therefore, in order to prevail with him to come into the city, and not fight with Achilles, they not only entreat him from the walls in the most tender and moving language imaginable; but he tears off his grey locks with his hands; and she in a flood of tears exposes her breasts, and adjures him by those paps which suckled him, to comply with their request. The poet knew very well, that no words of themselves could represent those agonies of mind he endeavoured to convey, unless heightened by the idea of such actions as were expressive of the deepest sorrow. And indeed this was anciently esteemed so requisite in an orator, that in matters of importance he was scarce thought to be in earnest who wanted it. In one of Cicero's orations, he does not stick to argue in that manner with his adversary. "Would you talk thus (says he) if you was serious? Would you, who are wont to display your eloquence so warmly in the danger of others, act so coldly in your own? Where is that concern, that ardour, which used to extort pity even from children? Here is no emotion of either of mind or body; neither the forehead struck, nor the thigh, not so much as a stamp of the foot. Therefore, you have been so far from inflaming our minds, that you have scarce kept us awake."

As action therefore was judged so necessary a qualification in an orator among the ancients, so they made use of several methods and expedients for the better attaining it. The principal of which we shall briefly mention.

*Decency* of pronunciation is an habit. And as all habits are gained by time, so the sooner they are learned, they are generally acquired with greater ease. For while persons are young, they are not only more flexible, and capable of any particular bent, but they are likewise free from the trouble of encountering and subduing contrary habits, which doubles the labour, and increases the difficulty of attaining any laudable quality. Quintilian was very sensible of this in the case here before us; and therefore, in order to have persons trained up to it, he begins with them in their childhood, and descends so low as even to give directions how they should be taught to pronounce when they first learn to read. And he advises, that they should then be instructed where to suspend their voice, and make the proper pauses, both in distinguishing the several parts of the same sentence, and in separa-

ting one sentence from another: likewise when to raise or sink their voice, or give it a proper inflection; to be slower or faster, more vehement or sedate, as the nature of the things may require; and that the tone of their voice be always manly and grave, but at the same time mixed with an agreeable sweetness; These things may perhaps appear in themselves small; but if duly attended to, they will be found of considerable service to bring us to a just and proper pronunciation. For in every thing that is to be attained by practice, it is a great advantage to set out right at first.

The ancients likewise had persons whom they called *phonascei*, whose proper business it was to teach them how to regulate and manage their voice; and others, who instructed them in the whole art of pronunciation, both as to their voice and gestures. These latter were generally taken from the theatre, being some eminent experienced actors. So Quintilian, treating of the province of these persons, says, "The comedian ought to teach them how to relate facts, with what authority to advise, with what vehemence to express anger, and with what softness compassion." And speaking of gestures, he says, "He should admonish them to raise their countenance, not distort their lips, or stretch their mouths." With several other directions of the like kind. And we are told concerning the emperor M. Antoninus, usually called the philosopher, that *His first masters were Euphorio the grammarian, and Geminus the comedian.*

But though they made use of actors to instruct their youth in forming their speech and gestures, yet the action of an orator was much different from that of the theatre. Cicero very plainly represents this distinction, in the words of Crassus, when speaking of orators, he says, "The motions of the body ought to be suited to the expressions, not in a theatrical way, mimicking the words by particular gesticulations, but in a manner expressive of the general sense, with a sedate and manly inflection of the sides; not taken from the stage and actors, but from the exercise of arms and the palestra." And Quintilian says to the same purpose, "Every gesture and motion of the comedians is not to be imitated, nor to the same degree." They thought the action of the theatre too light and extravagant for the imitation of an orator; and therefore, though they employed actors to inform young persons in the first rudiments, yet they were afterwards sent to the palestra, or schools designed on purpose to teach them a decent and graceful management of their bodies. And such schools, as Quintilian informs us, were in use both among the Greeks and Romans: Just as of later ages children learn to dance, in some measure with the same intention.

Being thus far prepared, they were afterwards sent to the schools of the rhetoricians. And here, as their business was to cultivate their style, and gain the whole art of eloquence; so particularly to acquire a just and accurate pronunciation by those exercises, in which for that end they were constantly employed. And as the Greeks were most celebrated for their skill in all the polite arts, and especially oratory; the Roman gentry and nobility generally sent their sons abroad, and placed them under the tuition of some Grecian master, to instruct them in the art of speaking,

Pronunciation.

Pronun-  
cia-  
tion.

ing, and by that means to fit them for the service of their country, either in the courts of judicature or the senate. Thus Cicero was sent to Rhodes, to study under the famous Molo, and Brutus under Pammenas; Cæsar was going to the same place when taken by pirates; and Augustus afterwards studied there under Apollodorus.

Nor, after all this pains and industry, did they yet think themselves sufficiently qualified to take upon them the character of orators. But it was their constant custom to get together some of their friends and acquaintance who were proper judges of such performances, and declaim before them in private. The business of these persons was to make observations both on their language and pronunciation. And they were allowed the greatest freedom to take notice of any thing they thought amiss, either as to inaccuracy of method, impropriety of style, or indecency of their voice or actions. This gave them an opportunity to correct any such defects at first, before they became habitual. What effects might not justly be expected from such an institution? Persons trained up in this manner, with all those advantages, joined to a good natural genius, could not fail of making very complete orators. Though even after they came to appear in public, they did not lay aside the custom of declaiming. For Quintilian tells us, that *C. Carbo used to practise it daily in his tent*. And Augustus is reported to have continued it during the war of Mutina against M. Anthony. Nor is it to be supposed, that so constant an attendance to this practice was only serviceable to them in their public performances; but it must necessarily affect their whole conduct, give them a freedom of speech, easiness of address and behaviour, and render them in all respects fine gentlemen, as well as excellent orators. And from hence perhaps we may see less reason to wonder at the surprising effects of some of their discourses, when we consider what pains they took to arrive at those abilities.

Having thus far treated on pronunciation in general, we shall now proceed to consider the parts of it separately; which are *voice* and *gesture*.

#### CHAP. II. Of the Voice.

129  
Voice, a  
kind of  
sound  
which al-  
ways in-  
fluences the  
passions,  
either by  
raising or  
allaying  
them.

VOICE is one kind of sound. Now the influence of sounds, either to raise or allay our passions, is evident from music. And certainly the harmony of a fine discourse, well and gracefully pronounced, is as capable to move us, if not in a way so violent and ecstatic, yet not less powerful, and more agreeable to our rational faculties. As the business of this chapter is to offer some considerations for the just and decent management of the voice, it may not be improper in the first place to observe in general what nature does when free and unconstrained. As persons are differently affected when they speak; so they naturally alter the tone of their voice, though they do not attend to it. It rises, sinks, and has various inflections given it, according to the present state and disposition of the mind. When the mind is calm and sedate, the voice is moderate and even; when the former is dejected with sorrow, the latter is languid; and when that is inflamed by passion, this is raised and elevated. It is the orator's business, therefore, to follow nature, and

Pronun-  
cia-  
tion.

to endeavour that the tone of his voice appear natural and unaffected. And for this end, he must take care to suit it to the nature of the subject; but still so as to be always grave and decent. Some persons continue a discourse in such a low and drawling manner, that they can scarce be heard by their audience. Others again hurry on in so loud and boisterous a manner as if they imagined their hearers were deaf. But all the music and harmony of speech lies in the proper temperament of the voice between these extremes. In order to set this matter in a just light, it will be necessary to consider the principal affections or properties of the voice, and how they are to be regulated by an orator. Now these may all be referred either to *quantity* or *quality*.

The *quantity* of the voice consists in its *highness*, or *lowness*, *swiftness* or *slowness*, and the intermediate degrees between them.

Every person who speaks in public, should endeavour, if he can, to fill the place where he speaks. But still he ought to be careful not to exceed the natural key of his voice. If he does, it will neither be soft nor agreeable; but either harsh and rough, or too shrill and squeaking. Besides, he will not be able to give every syllable its full and distinct sound; which will render what he says obscure, and difficult to be understood. He should therefore take care to keep his voice within reach, so as to have it under management, that he may raise or sink it, or give it any inflection he thinks proper: Which it will not be in his power to do, if he put a force upon it, and strain it beyond its natural tone.

The like caution is to be used against the contrary extreme, that the voice be not dropped, and suffered to sink too low. This will give the speaker pain in raising it again to its proper pitch, and be no less offensive to the hearers. For though the music of speech consists in the variations of the voice, yet they must be gradual to render them pleasant. Such sudden and great changes at once are rather to be esteemed chafms in speaking, than variations. Besides, as they often prevent the hearers from taking in the sense of what is said, it gives them no small uneasiness that they are obliged to stretch their attention. Many persons are too apt to be guilty of this, especially at the end of a sentence, by dropping the last word; which ought in a particular manner to be expressed distinctly, because the meaning of the whole sentence often depends upon it.

The medium between these two is a moderate and even voice. But this is not the same in all; that which is moderate in one would be high in another. Every person therefore must regulate it by the natural key of his own voice. A calm and sedate voice is generally best; as a moderate sound is most pleasing to the ear, if it be clear and distinct. But this equality of the voice must also be accompanied with a variety, otherwise there can be no harmony; since all harmony consists in variety. Nothing is less pleasing than a discourse pronounced throughout in one continued tone of the voice, without any change or alteration. Besides, a variation of the voice is an ease to the speaker; as the body is relieved by shifting its posture. The equality therefore we are here speaking of admits a variety of inflections and changes within the same pitch.

**Pronunciation.** pitch. And when that is altered, the gradations, whether higher or lower, should be so gentle and regular as to preserve a due proportion of the parts and harmony of the whole; which cannot be done, when the voice is suddenly varied with too great a distinction. And therefore it should move from one key to another, so as rather to glide like a gentle stream, than pour down like a rapid torrent, as an ingenious writer has well expressed it. An even voice is best fitted to keep the mind to close attention. And therefore, in subjects designed only for instruction, without any address to the passions, there is little room for a variety of voice. For the voice ought to agree with the style; and as upon such subjects this should be equal, moderate, and smooth, so should the other. Every thing, as we say, is beautiful in its season; and there is a certain propriety in things which ought always to be regarded. And therefore, an affected variety, ill placed, is as disagreeable to a judicious audience, as the want of it, where the subject requires it. We may find some persons, in pronouncing a grave and plain discourse, affect as many different tones, changes, and variations of their voice, as if they were acting a comedy; which is doubtless a very great impropriety. But the orator's province is not barely to apply to the mind, but likewise to the passions; which require a great variety of the voice, high or low, vehement or languid, according to the nature of the passions he designs to affect. So that for an orator always to use the same tone or degree of his voice, and expect to answer all his views by it, would be much the same thing as if a physician should propose to cure all distempers by one medicine. From hence it is evident, that although various inflections and tones of the voice are requisite to make it harmonious and pleasing to the ear; yet the degree of it should differ according to the nature of the subject and design of the speaker. And, as a perfect monotony is always unpleasant, so it can never be necessary in any discourse.

The next property of the voice abovementioned was *swiftness*. That some expressions ought to be pronounced faster and swifter than others, is very manifest. Gay and sprightly ideas should not only be expressed louder, but also faster, than such as are sad and melancholy. And when we press an adversary, the voice should be brisk and quick. But to hurry on in a precipitant manner without pausing, till stopt for want of breath, is certainly a very great fault. This destroys not only the necessary distinction between sentence and sentence, but likewise between the several words of the same sentence; nay, and often occasions us to express our words by halves, while one is thrown so fast upon another, that we are not able to give each its full and just sound. By this means all the grace of speaking is lost, and in a great measure the advantage of hearing. For when the ears of the hearers cannot keep pace with the volubility of the speaker's tongue, they will be little the better for what he says. Besides, by not commanding his voice, and easing his breath at the proper pauses and points of distinction, he is often obliged to stop in the middle of a sentence; and so divides what should be continued, and joins what should be separated; which must necessarily destroy the sense, and confound his

discourse. Young persons are very liable to this, especially at first setting out. And it often arises from diffidence. They are jealous of their performances, and the success they may have in speaking, which gives them a pain till it is over; and this puts them into a hurry of mind, which incapacitates them from governing their voice, and keeping it under that due regulation which perhaps they proposed to themselves before they began to speak. And the greater degree such persons have of a native and ingenuous modesty, accompanied with a laudable ambition to excel, they are commonly more exposed to this. For while on the one hand they are fired with an ardent desire to recommend themselves, and on the other are fearful of the event, this dubious state of mind is very apt to throw them off their guard, and run them into this excess. From which we may see the great advantage of having the voice well formed betimes; for when once it is become habitual to speak with justness and propriety, persons readily practise it without much attention or concern.

And as a precipitant and hasty pronunciation is culpable, so likewise on the other hand, it is a fault to speak too slow. This seems to argue a heaviness in the speaker. And as he appears cool himself, he can never expect to warm his hearers, and excite their affections. When not only every word, but every syllable is drawn out to too great a length, the ideas do not come fast enough to keep up the attention without much uneasiness. For till the sense is completed, the mind is in suspense; and, if it be held long in that situation, it will of course flag and grow tired. Indeed, in some cases, it is requisite the pronunciation should be slower than in others; as in representing things great and difficult; or in expressing some particular passions, as admiration or grief. But the extreme we are now speaking of, is a slowness equally continued through a whole discourse, which must necessarily render it flat and lifeless.

Now, to avoid either of the two extremes last mentioned, the voice ought to be sedate and distinct. And in order to render it distinct, it is necessary, not only that each word and syllable should have its just and full sound, both as to time and accent; but likewise that every sentence, and part of a sentence, should be separated by its proper pause and interval. This is more easy to be done in reading, from the assistance of the points; but it is no less to be attended to in speaking, if we would pronounce in a distinct and graceful manner. For every one should speak in the same manner as he ought to read, if he could arrive at that exactness. Now the common rule given in pausing is, that we stop our voice at a comma till we can tell one, at a semicolon two, at a colon three, and at a full period four. And as these points are either accommodated to the several parts of the same sentence, as the first three; or different sentences, as the last; this occasions the different length of the pause, by which either the dependence of what precedes upon that which follows, or its distinction from it, is represented. And therefore, in the first three stops, the voice is rather to be suspended in different degrees or measures of time, than entirely dropt, to show that the sense is not yet completed. But between sentence and sentence we respire, and begin anew. So that

**Pronunciation.** that in long periods, the voice should be favoured by beginning low and sedately, that it may hold to the end without respiration; or if it will not, the breath ought to be recovered without sinking the voice. For if once the voice drop for want of breath before the period be finished, not only the beauty, but likewise, the sense of it will be lost. Quintilian lays a great stress upon a due attention to these pauses; and says, "Though it may appear not so considerable in itself, yet all the other virtues of a good pronunciation are deficient without it."

Hitherto we have considered such properties of the voice as respect *quantity*, we come to speak of its *qualities*. And the chief of these are *strength* or *weakness*, *clearness* or *obscurity*, *fullness* or *smallness*, *smoothness* or *roughness*. Now, one half of these is what every one would willingly choose, as he would wish to be free from the others. But it is not in our power to give ourselves what qualities of the voice we please; but only to make the best use we can of what nature has bestowed upon us. However, several defects of the voice are capable of being helped by care and proper means; as, on the other hand, the best voice may be greatly hurt by ill management and indiscretion. Temperance is a great preservative of the voice, and all excess is highly prejudicial to it. The voice must necessarily suffer, if the organs of speech have not their proper tone. And in order to their having this, they must be kept in a due temperature; that is, they must neither be too moist nor too dry. If they abound with fluids, these will obstruct the clearness of the voice, and render it obscure and confused; and if they are parched with drought, the voice will be harsh and rough. Now all excesses, as well as some bodily indispositions, are apt to affect the organs one or other of these ways.

A strong voice is very serviceable to an orator, because, if it want some other advantages, he is however, capable to make himself heard. And if at any time he is forced to strain it, he is in less danger of its failing him before he has finished his discourse. But he who has a weak voice, should be very careful not to strain it, especially at first. He ought to begin low, and rise gradually to such a pitch as the key of his voice will well carry him, without being obliged to sink again afterwards. Frequent inflections of the voice will likewise be some assistance to him. But especially he should take care to speak deliberately, and ease his voice, by allowing due time for respiration at all the proper pauses. It is an extreme much less inconvenient for such a person rather to speak too slow, than too fast. But this defect of a weak voice is sometimes capable of being helped by the use of proper methods; as is evident from the instance of Demosthenes, before-mentioned.

A voice is said to be *clear*, when the organs of speech are suited to give every single letter, and all the combinations of them in syllables and words, their proper and distinct sound. Such a voice is very pleasing and agreeable to the hearers; and no less an happiness to the speaker, as it saves him a great expence of spirits. For a moderate voice, if clear, will be as distinctly heard, as one much louder, if thick and obscure. Which is a great advantage to the speaker, because he can better keep his voice under

Vol. XIII.

command, and modulate it at pleasure, as the several parts and circumstances of his discourse may require. On the contrary an obscure and confused voice is not always occasioned from a deficiency in the organ; but many times is the effect of custom and a bad habit. Some persons, either from want of due care in their education at first, or from inadvertency and negligence afterwards, run into a very irregular and confused manner of expressing their words; either by misplacing the accent, confounding the sound of the letters, or huddling the syllables one upon another, so as to render what they say often unintelligible. Indeed, sometimes this arises from a natural defect, as in the case of Demosthenes; who found a method to rectify that, as well as the weakness of his voice. But in faults of this kind, which proceed from habit, doubtless the most likely way to mend them is to speak deliberately.

A full voice is not the same as a strong or a loud voice. It fills the ear, but it is not pleasant. And therefore to render it so, as well as audible, it should be frequently varied. However this seems better suited to the character of an orator, than a small and shrill voice; because it has something in it more grave and manly. And those who have the misfortune of a very small voice, should be cautious of raising it to too high a pitch, especially at once; because the sudden compression of the organ is apt to occasion a squeaking and very disagreeable sound.

A soft and smooth voice is of all the most musical, especially if it be flexible. And on the contrary, nothing is less harmonious than a voice that is harsh and rough. For the one grates as disagreeably upon the ear, as the other gives it pleasure and delight.

From the consideration of these several properties of the voice, we may conclude that to be the best, and fittest for an orator, which is moderate, distinct, firm, clear, and smooth, and withal easily flexible to the several degrees and variations of sound which every part of the discourse may require.

### CHAP. III. Of Gesture.

By this is meant, a suitable conformity of the motions of the countenance, and several parts of the body in speaking, to the subject-matter of the discourse. The word *gesture* is here used in a larger sense than is ordinarily done in common language. For we rarely make use of that word to denote the motions of the countenance, or any parts of it; but as these make a considerable part of our present subject, they must here be comprehended under this term.

It is not agreed among the learned, whether voice or gesture has the greater influence upon us. But as the latter affects us by the eye, as the former does by the ear, gesture in the nature of it seems to have this advantage, that it conveys the impression more speedily to the mind; for the sight is the quickest of all our senses. Nor is its influence less upon our passions; nay, in some instances it appears to act more powerfully. A cast of the eye shall express desire in as moving a manner as the softest language; and a different motion of it, resentment. To wring the hands, tear the hair, or strike the breast, are all strong indica-

130  
Gesture is the conformity of the motions of the countenance, &c. to the nature of the discourse.

Pronun-  
tation.

tions of sorrow. And he who claps his hand to his sword; throws us into a greater panic than one who only threatens to kill us. Nor is it in some respects less various and extensive than language. Cicero tells us, he often diverted himself by trying this with Roscius the comedian; who could express a sentence as many ways by his gestures, as he himself by words. And some dramas, called *pantomimes*, have been carried on wholly by mutes, who have performed every part by gestures only, without words, in a way very intelligent, as well as entertaining to the spectators. Well therefore might Cicero call *action* (or gesture) *the language of the body*, since it is capable in so lively a manner to convey both our ideas and passions. But with respect to oratory, gesture may very properly be called the *second part of pronunciation*; in which, as the voice should be suited to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural than violent motion, in discoursing upon ordinary and familiar subjects. The motions of the body should rise therefore in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

But as gesture is very different and various as to the manner of it, which depends upon the decent conduct of several parts of the body; it will not be amiss to consider more particularly the proper management of each of those parts. Now all gesture is either natural, or from imitation. By natural gesture we mean such actions and motions of the body, as naturally accompany our words, as these do the impressions of our mind. And these either respect the whole body, or some particular part of it. But before we enter upon this, give us leave just to observe, that it has been customary in all ages and countries, in making a set discourse before an assembly, to do it standing. Thus we read, that *Abraham stood up, and spake unto the children of Heth*. And it seems as if he sat down, when he had ended his speech; because, immediately after the account of their answer, it is said again that *Abraham stood up and bowed himself to the people of the land, the children of Heth*. In like manner Homer represents the Grecian princes, as standing up, when they made a speech, either to the army, or in their councils. So when Achilles has assembled the army, to inquire into the reason of the great plague which at that time raged among them, he rises up before he begins to speak, and sits down again when he has done. After him the prophet Calchas rises, and charges it upon Agamemnon: who rising up in a passion, does not refuse to comply with what Calchas proposed, but expresses his resentment at him for saying it. And upon another occasion, both Agamemnon and Nestor do the same in council. And Cicero acquaints us; that when Lentulus had been charged in the senate as an associate with Catiline, he stood up to make his defence. Nor does the advantage of being better heard, seem to have been the only reason for so general an agreement in this posture; but it appears likewise to have been chosen, as the most decent and respectful. Sitting carries in it an air of authority, and is therefore a

posture scarce used upon such occasions, unless perhaps where that is designed to be expressed by it. Wherefore it was a thing very much resented, that when Cæsar, after he had got the power into his hands, once addressed the senate, either refused to rise, as some say, or as others, one of his friends held him down by his gown.

But though standing appears to be the most proper posture for speaking in public, yet it is very unbecoming for the body to be entirely without any motion like a statue. It should not long continue in the same position, but be constantly changing, though the motion be very moderate. There ought to be no appearance of stiffness, but a certain ease and pliability, naturally suiting itself to every expression; by which means, when a greater degree of motion is necessary, it will appear less sudden and vehement: For as the raising, sinking, and various inflections of the voice must be gradual; so likewise should the motions of the body. It is only on some particular occasions that an hasty vehemence and impetuosity is proper in either case.

As to the several parts of the body, the head is the most considerable. To lift it up too high has the air of arrogance and pride; to stretch it out too far, or throw it back, looks clownish and unmannerly; to hang it downwards on the breast, shows an unmanly bashfulness and want of spirit: and to suffer it to lean on either shoulder, argues both sloth and indolence. Wherefore in calm and sedate discourse it ought to keep its natural state, an upright posture. However, it should not be long without motion, nor yet always moving; but gently turn sometimes on one side, and sometimes on the other, as occasion requires, that the voice may be heard by all who are present; and then return again to its natural position. It should always accompany the other actions of the body, and turn on the same side with them; except when aversion to any thing is expressed, which is done by stretching out the right hand, and turning the head to the left. The ancients erected a statue of Venus in this posture, who was called by the Greeks *ανωστροφια*, and by the Latins *Verticordia*, and in English may be termed the *forbidding Venus*. But nothing is more indecent than violent motions and agitations of the head. And therefore, when a witty writer, who is well known among us, would convey the most ridiculous idea of a pretender to knowledge, he expresses it thus:

For having three times shook his head  
To stir his wit up, thus he said. HUDIB.

But it is the countenance, that chiefly represents both the passions and dispositions of the mind. By this we express love, hatred, joy, sorrow, modesty, and confidence: by this we supplicate, threaten, soothe, invite, forbid, consent, or refuse; and all this without speaking. Nay, from hence we form a judgment not only of a person's present temper, but of his capacity and natural disposition. And therefore it is common to say, *such an one has a promising countenance*, or *that he promises little by his countenance*. It is true, this is no certain rule of judging; nor is it in the power of any one to alter the natural make of his countenance: however, it may put us upon endeavouring to gain the most pleasing aspect we can; since it is so natural  
for

Pronun-  
tation.

**Pronunciation.** for mankind to draw such conclusions from it; and some persons are so unhappy, as to render their countenance more disagreeable than otherwise it would be, by ill habits.

But the several parts of the face bear their part, and contribute to the proper and decent motion of the whole. In a calm and sedate discourse, all the features retain their natural state and situation. In sorrow, the forehead and eyebrows lour, and the cheeks hang down. But in expressions of joy and cheerfulness, the forehead and eyebrows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips. And terror elevates both the brows and forehead. As these are the natural signs of such passions, the orator should endeavour to conform to them.

But as the eyes are most active and significant, it is the advice of Cicero that the greatest care should be taken in their management. And he gives this reason for it, "Because other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes, by so many different actions, which cannot possibly be represented by any gestures of the body, if the eyes are kept in a fixed posture." Common experience does in a great measure confirm the truth of this observation. We readily guess at a person's intention, or how he is affected to us, by his eyes. And any sudden change or emotion of the mind is presently followed by an alteration in the look. In speaking therefore upon pleasant and delightful subjects, the eyes are brisk and cheerful; as, on the contrary, they sink and are languid in delivering any thing melancholy and sorrowful. This is so agreeable to nature, that before a person speaks, we are prepared with the expectation of one or the other from his different aspect. So likewise in anger, a certain vehemence and intenseness appears in the eyes, which, for want of proper words to express it by, we endeavour to represent it by metaphors taken from fire, the most violent and rapid element, and say in such cases, the eyes *sparkle*, *burn*, or are *inflamed*. In expressions of hatred or detestation, it is natural to alter the look, either by turning the eyes aside, or downwards. Virgil has very justly observed this: for when he describes Æneas meeting with Dido in the Elysian shades, and addressing her, he represents her disregard of him, by saying,

Disdainfully she look'd; then turning round,  
Still fix'd her eyes unmov'd upon the ground.

She showed her resentment for his former treatment of her, by not vouchsafing to look on him. Indeed, the eyes are sometimes turned downwards upon other occasions, as to express modesty. And if at any time a particular object be addressed to, whatever it be, the eyes should be turned that way. And therefore Philostratus very deservedly ridicules a certain rhetorician as guilty of a solecism in gesture, who, upon saying, *O Jupiter!* turned his eyes downward; and when he said, *O Earth!* looked upward. A staring look has the appearance of giddiness and want of thought; and to contract the eyes gives suspicion of craft and design. A fixed look may be occasioned from intenseness of thought, but at the same time shows a disre-

**Pronunciation.** gard to the audience; and a too quick and wandering motion of the eyes denotes levity and wantonness. A gentle and moderate motion of the eyes is therefore in common most suitable, always directed to some of the audience, and gradually turning from side to side with an air of respect and modesty, and looking them decently in the face, as in common discourse: Such a behaviour will of course draw an attention. As in conversation, when a person addresses us in an handsome and becoming manner, we presently put ourselves in a posture to give what he says a proper reception. But as all the passions are in the most lively manner expressed in the eyes, their motions ought to vary according to the different nature of those passions they are suited both to discover in the speaker and convey to his hearers; since, as the quickest access to the mind is by the sight, a proper well-timed look will sometimes sooner effect this than it can be done by words; as in discharging a cannon, we are struck with the light before we hear the sound.

As to the other parts of the body distinct from the head, the shoulders ought not to be elevated; for this is not only in itself indecent, but it likewise contracts the neck, and hinders the proper motion of the head. Nor, on the other hand, should they be drawn down and depressed; because this occasions a stiffness both to the neck and the whole body. Their natural posture therefore is best, as being most easy and graceful. To shrug the shoulders has an abject and servile air; and frequently to heave them upwards and downwards is a very disagreeable sight.

A continued motion of the arms any way, is by all means to be avoided. Their action should generally be very moderate, and follow that of the hands, unless in very pathetic expressions, where it may be proper to give them a more lively spring.

The hands need never be idle. Quintilian seems to think them as necessary and powerful in action, as Cicero does the eyes. "The hands (says he), without which all gesture is lame and weak, have a greater variety of motions than can well be expressed; for they are almost equal to our words. Do not we desire with them, promise, call, dismiss, threaten, beseech, detest, fear, inquire, deny? Do not they express joy, sorrow, doubt, confession, penitence, measure, plenty, number, and time? Do not they excite, restrain, prove, admire, and shame? That in so great a variety of speech among all nations and countries, this seems to me the common language of all mankind." Thus far Quintilian. Now, all bodily motion is either upward or downward, to the right or left, forward or backward, or else circular. The hands are employed by the orator in all these except the last. And as they ought to correspond with our expressions, so they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right. In demonstrating, addressing, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back. But when the orator speaks of himself, his right hand should be gently laid on his breast. When no other motion is necessary, the hands should be kept about as high as

**Pronunciation.** the breast, so as to make near a right angle with the arm. This is not only graceful, but likewise the most easy posture, and gives the least strain to the muscles. They should never be suffered to hang down, nor to loll upon the cushion or bar. The left hand should never move alone, but accommodate itself to the motions of the right. In motions to the left side, the right hand should not be carried beyond the left shoulder. In promises, and expressions of compliment, the motion of the hands should be gentle and slow; but in exhortations and applause more swift. The hands should generally be open; but in expressions of compunction and anger they may be closed. All finical and trifling actions of the fingers ought to be avoided; nor should they be stretched out and expanded in a stiff and rigid posture, but kept easy and pliable.

Neither the breast nor the belly should be thrust out: which in itself looks ungainly, and hinders the free motion of the trunk; which ought not to be kept too stiff and upright, but easy and flexible, always suiting itself to the motions of the head and hands. The feet should continue steady, and not give the body a wavering and giddy motion by frequently shifting; tho' some persons fall into that habit without moving their feet. Curio, a Roman orator, as Cicero tells us, was addicted to this; which occasioned a friend of his once to pass a joke upon him by asking, *Who that was talking out of a boat?* The jest is too plain to need explication; for every one knows the waving of a boat will give the body such a motion.

The gestures we have hitherto discoursed of, are such as naturally accompany our expressions. And we believe those we have mentioned if duly attended to, will be found sufficient to answer all the purposes of our modern pronunciation. The ancients, indeed, used several more vehement actions and gestures than we are accustomed to; as we have formerly shown. Philip the Roman orator, as Cicero informs us, did not use to prepare his discourses; but spoke, as we say, *off-hand*. And he was wont to tell his friends, "he was never fit to talk till he had warmed his arm." He doubtless, therefore, used a more violent motion with his arms and hands than is common with us. And Cicero calls the arm projected *the orator's weapon*. Indeed, to extend or brandish the arm, carries in it an air of command and authority, which was not unbecoming the character of Philip, who was a person of the highest rank and quality. And therefore young orators, both among the Greeks and Romans, for a time used no motion of the arm, but kept it confined in their garment, as an argument of modesty, till age and experience allowed them to use greater freedom. Nor was it uncommon for the ancient orators to express the excess of their passions by tears. They thought nothing unbecoming that was natural; and judged it agreeable to the characters even of the bravest men, to be touched with a sense of humanity in great calamities: And therefore we find both Homer and Virgil make their greatest heroes shed tears on some occasions.

The other sort of gestures abovementioned are such as arise from imitation; as where the orator describes some action, or personates another speaking. But here great care is to be taken not to over act his

part by running into any ludicrous or theatrical mimicry. It is sufficient for him to represent things of this nature, as may best convey the image of them in a lively manner to the minds of the hearers; without any such change either of his actions or voice as are not suitable to his own character.

#### CHAP. IV. *Some particular rules for the Voice and gesture.*

**131** THE subject of pronunciation is of so great importance to an orator, that it can neither be too clearly laid down, nor too strongly inculcated. If we inquire into the causes of that surprising power it has over us, and by what means it so strongly affects us, this may in some measure appear by reflecting on the frame and constitution of human nature. For our infinitely great and wise Maker has so formed us, that not only the actions of the body are subject to the direction of the mind, but we are likewise endowed with various passions and affections, that excite us to pursue those things which make for our happiness, and avoid others which are hurtful to us. And as we are made for society; we are also furnished with speech, which enables us to converse one with another. And such is the contrivance of our make, and influence of our minds upon the mechanism of our bodies, that we can not only communicate our thoughts to each others but likewise our passions. For, as Cicero well observes, "Every motion of the mind has naturally its peculiar countenance, voice and gesture; and the whole body, every position of the face, and sound of the voice, like the strings of an instrument, act agreeably to the impression they receive from the mind." Nor is this all: but as every one is differently affected himself; he is capable to make the like impressions upon others, and excite them to the same motions which he feels in himself. As when two instruments are set to the same pitch, the strings of the one being touched, produce in the other the like sound. This common sympathy in the human frame shows how necessary it is that an orator should not only in general be well acquainted with the rules of pronunciation, but likewise know how to use them as occasion requires. For a general knowledge of the rules of art is not of itself sufficient to perfect an artist, without a farther acquaintance with the particular application of them to their several cases and circumstances. Thus, for instance, it is not enough for an orator to understand all the beauties and ornaments of language, and which of them are suited to form the several kinds of style, unless he can likewise accommodate each of these characters to their proper subject. And so likewise in pronunciation, he ought not only to know the several qualities of the voice, and proper gestures of the body, but also when and where to make use of them. For not only different subjects, but also different parts of the same discourse, and even particular expressions, often require a difference in the manner of pronunciation, both as to the voice and gesture. Having therefore treated on both these parts of pronunciation in general, it may not be amiss now to consider how they are to be applied in each of the two respects last mentioned.

We shall begin with the parts of a discourse, and treat

**Pronunciation.**

**131** Rules for the voice and gesture.

**Pronunciation.** treat of them in their natural order. And here the view and design of the speaker in each of them will easily help us to see the proper manner of pronunciation.

Let us suppose then a person presenting himself before an assembly, in order to make a discourse to them. It cannot be decent immediately to begin to speak so soon as ever he makes his appearance. He will first settle himself, compose his countenance, and take a respectful view of his audience. This prepares them for silence and attention. To begin presently, and hurry on, without first allowing either himself or his hearers time to compose themselves, looks as if he was rather performing a task than had any design to please them; which will be very apt to make them as uneasy till he has done, as he seems to be himself. Persons commonly form some opinion of a speaker from their first view of him, which prejudices him either in his favour or otherwise, as to what he says afterwards. A grave and sedate aspect inclines them to think him serious; that he had considered his subject, and may have something to offer worth their attention. A haughty and forbidding air occasions distaste, as it looks like disrespect. A wandering giddy countenance argues levity. A dejected drooping appearance is apt to raise contempt, unless where the subject is melancholy. And a cheerful aspect is a proper prelude to a pleasant and agreeable argument.

To speak low at first has the appearance of modesty, and is best for the voice; which, by rising gradually, will with more ease be carried to any pitch that may be afterwards necessary, without straining it. However, some variation of the voice is always proper to give it an harmony. Nay, and sometimes it is not improper for an orator to set out with a considerable degree of warmth, expressed by such an elevation of the voice, and gestures of the body, as are suited to represent the emotions of his mind. But this is not ordinarily the case. We have some few instances of this in Cicero; as in his oration for Roscius Amerinus, where the heinousness of the charge could not but excite his indignation against the accusers. And so likewise in that against Piso, and the two first against Catiline, which begin in the same manner, from the resentment he had conceived against their persons and conduct.

In the narration, the voice ought to be raised to somewhat an higher pitch. Matters of fact should be related in a very plain and distinct manner, with a proper stress and emphasis laid upon each circumstance, accompanied with a suitable address and motions of the body to engage the attention of the hearers. For there is a certain grace in telling a story, by which those who are masters of it seldom fail to recommend themselves in conversation. The beauty of it consists in an easy and familiar manner of expression, attended with such actions and gestures as are suited to the nature of the things related, and help to enliven each particular circumstance and part of the discourse.

The proposition, or subject of the discourse, should be delivered with a very clear and audible voice. For if this be not plainly heard, all that follows in proof of it it cannot well be understood. And for the same reason if it be divided into several parts or branches they should each be expressed very deliberately and di-

stinately. But as the design here is only information, there can be little room for gesture. **Pronunciation.**

The confirmation admits of great variety both of the voice and gestures. In reasoning, the voice is quick and pungent, and should be enforced with suitable actions. And as descriptions likewise have often a place here, in painting out the images of things, the orator should so endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands, as may best help the imagination of his hearers. Where he introduces another person speaking, or addresses to an absent person, it should be with some degree of imitation. And in dialogue the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In confutation, the arguments of the adverse party ought first to be repeated in a plain and distinct manner, that the speaker may not seem to conceal, or avoid the force of them. Unless they appear trifling and unworthy of a serious answer; and then a facetious manner, both of expression and gesture, may be the properest way to confute them. For to attempt to answer in a grave and serious manner, what is in itself empty and ludicrous, is apt to create a suspicion of its having more in it than it really has. So when Tubero in his accusation of Ligarius before Cæsar, had made it part of his charge, that Ligarius was in Africa during some part of the civil war between Cæsar and Pompey; Cicero in his answer, not thinking it deserved a serious reply, contents himself with barely mentioning it ironically. For thus he begins his defence of Ligarius: "Cæsar, my kinsman Tubero has laid before you a new crime, and till this day unheard of, that Q. Ligarius was in Africa." Every one must easily perceive by the manner in which these words were pronounced, that the design of them was to make the charge appear ridiculous. But caution should be used not to represent any argument of weight in a ludicrous way, lest by so doing the speaker should more expose himself than his adversary.

In the conclusion both the voice and gesture should be brisk and sprightly, which may seem to arise from a sense of the speaker's opinion of the goodness of his cause, and that he has offered nothing but what is agreeable to reason and truth; as likewise from his assurance that the audience agree with him in the same sentiment. In every undertaking that requires care and thought, persons are apt at first to be sedate and moderate; but when it is drawn to an end, and is near finished, it is very natural to appear more gay. If an enumeration of the principal arguments of the discourse be convenient, as it sometimes is, where they are pretty numerous, or the discourse is long, they ought to be expressed in the most clear and forcible manner. And if there be an address to the passions, both the voice and gesture must be suited to the nature of them, of which more will be said presently.

We proceed now to the consideration of particular expressions. And what we shall offer here, will be first in relation to single words, then sentences, and lastly the passions.

I. Even in those sentences which are expressed in the

Pronunciation.

the most even and sedate manner, there is often one or more words which require an emphasis and distinction of the voice. Pronouns are often of this kind: as, *This is the man*. And such are many words that denote the circumstances and qualities of things. Such as heighten or magnify the idea of the thing to which they are joined, elevate the voice; as *unalle, admirable, majestic, greatly*, and the like. On the contrary, those which lessen the idea, or debase it, depress the voice, or at least protract the tone: of which sort are the words *little, mean, poorly, contemptible*, with many others. Some tropes likewise, as metaphors and verbal figures, which consist in the repetition of a single word, should have a particular emphasis. As when Virgil says of the river Araxes, *It disdained a bridge*. And Nisus of himself, in the same poet, *I, I am the man*; where the repeated word is loudest. This distinction of words, and giving them their proper emphasis, does not only render the expression more clear and intelligible, but very much contributes to the variation of the voice, and the preventing a monotony. And the different pronounciation of these words will also require a peculiar gesture.

231

II. In sentences, regard should be had to their length, and the number of their parts, in order to distinguish them by proper pauses. The frame and structure of the period ought likewise to be considered, that the voice may be so managed as to give it the most musical accent. Unless there be some special reason for the contrary, it should end louder than it begins. And this difference of tone between the end of the former sentence and the beginning of the next, not only helps to distinguish the sense, but adds to the harmony of the voice. And that the last syllables of a sentence might become more audible and distinct, was doubtless one reason why the ancient rhetoricians dislike short feet at the end of a period. In an antithesis, or a sentence consisting of opposite parts, one contrary must be louder than the other. As, "*He is gone, but by a gainful remove, from painful labour to quiet rest; from unquiet desires to happy contentment: from sorrow to joy; and from transitory time to immortality.*" In a climax or gradation, the voice should rise with it. So, "*There is no enjoyment of property without government; no government without a magistrate; no magistrate without obedience; no obedience where every one acts as he pleases.*" And so in other gradations of a different form. As, "*Since concord was lost, friendship was lost, fidelity was lost, liberty was lost, all was lost.*" And again, "*You would pardon him whom the senate hath condemned, whom the people of Rome have condemned, whom all mankind have condemned.*" We might mention several other figurative expressions, which require a particular conformation and management of the voice; but these, we presume, with some others we shall have occasion to name presently when we come to the passions, may be sufficient to guide us in the rest. But that it may appear more evidently how necessary a different inflection and variation of the voice is in most sentences, give us leave to show how Quintilian illustrates it, by a passage which he takes from Cicero. The place is the beginning of Cicero's defence for Milo, and the words are these: "*Although I am apprehensive it may seem base to discover fear when I enter upon the defence of a most courageous*

man, and it may appear very indecent, when Milo discovers more concern for the public safety than for his own, not to show a greatness of mind equal to his cause, yet this new form of the court terrifies my eyes, which cannot discern the ancient manner of the forum, and former custom of trials, whatever way they look: your bench is not surrounded with its usual attendants." This sentence consists of four members. And Quintilian supposes, that though these words are the beginning of a speech, and were accordingly expressed in a calm and submissive manner, yet that the orator used a great deal of variety in the pronounciation of their several parts. In the first member (as he imagines) his voice was more elevated in expressing the words, *a most courageous man*, than in those other parts of it, *I am apprehensive it may seem base*, and, *to discover fear*. In the second member he rose higher, in saying *when Milo discovers more concern for the public safety than for his own*; and then again, as it were, checked himself in what follows, *not to show a greatness of mind equal to his cause*. The beginning of the third member, carrying a reflection in it, was spoke with a different tone of the voice, *this new form of the court terrifies my eyes*; and the other part of it more loud and distinctly, *which cannot discern the ancient manner of the forum, and former custom of trials*. And the last member was still more raised and audible, *your bench is not surrounded with its usual attendants*. And it must be supposed, that while he was saying this, he cast his eyes round the assembly, and viewed the soldiers whom Pompey had placed there, which renders the expression still more grave and solemn. If this was the manner of the ancient orators, and they were so exact and accurate in expressing their periods, and the several parts of them, as we have reason to believe they were, it must have given a very great force, as well as beauty, to their pronounciation.

III. That the passions have each of them both a different voice and action, is evident from hence; that we know in what manner a person is affected, by the tone of his voice, though we do not understand the sense of what he says, or many times so much as see him; and we can often make the same judgment from his countenance and gestures. Love and esteem are expressed in a smooth and cheerful tone; but anger and resentment, with a rough, harsh, and interrupted voice, for when the spirits are distributed and ruffled; the organs are moved unequally. Joy raises and dilates the voice, as sorrow sinks and contracts it. Cicero takes notice of a passage in an oration of Gracchus, wherein he bewails the death of his brother, who was killed by Scipio which in his time was thought very moving: "*Unhappy man (says he), whither shall I betake myself? Where shall I go? Into the capitol? that flows with my brother's blood. Shall I go home? and behold my unhappy mother all in tears and despair?*" Though Gracchus had a very ill design in that speech, and his view was to excite the populace against their governors, yet (as Cicero tells us) when he came to this passage, he expressed himself in such moving accents and gestures, that he extorted tears even from his enemies. Fear occasions a tremor and hesitation of the voice, and assurance gives it strength and firmness. Admiration elevates the voice, and should be expressed with pomp and magnificence: *O surprising*

135

**Pronunciation.** *surprising clemency, worthy of the highest praise and greatest encomiums, and fit to be perpetuated in lasting monuments!* This is Cicero's compliment to Cæsar, when he thought it for his purpose. And oftentimes this passion is accompanied with an elevation both of the eyes and hands. On the contrary, contempt sinks and protracts the voice. In the dispute between Cicero and Cecilius, which of them should accuse Verres, Cicero puts this contemptuous question to him: "How are you qualified, Cecilius, for such an undertaking? I will not ask, when you ever gave a proof of it; but when you so much as attempted it? Do you consider the difficulty of managing a public cause?" with much more to the same purpose. Though such kind of expressions require little gesture, yet sometimes a motion of the hand may not be improper, to signify disdain or aversion. We may suppose Cicero to have acted thus in his defence of Rabirius. For to show his assurance of his client's cause, having used this expression in a very audible manner, "I wish I had it to say, that Rabirius had with his own hand killed Saturninus, who was an enemy to the Roman state," some persons in the crowd began to raise a clamour, just as of later times hissing has been practised on the like occasions. Upon which Cicero immediately replies, "This noise does not disturb me, but please me, since it shows, though there are some weak persons, yet they are but few." Then presently after follows the expression we refer to: "Why do not you cease your clamour, since it only discovers your folly, and the smallness of your number?" All exclamations

**Pronunciation.** should be violent. When we address to inanimate things, the voice should be higher than when to animated beings; and appeals to heaven must be made in a loftier tone than those to men.

These few hints for expressing the principal passions may, if duly attended to, suffice to direct our practice in others. Though after all, it is impossible to gain a just and decent pronunciation of voice and gesture merely from rules, without practice and an imitation of the best examples. Which shows the wisdom of the ancients, in training up their youth to it, by the assistance of masters, to form both their speech and actions.

But there is one thing which ought always to be attended to; namely, that persons should well consider their own make and genius, especially with respect to the passions. We seldom find, that any actor can excel in all characters; but if he performs one well he is deficient in another: And therefore they are commonly so prudent as to confine themselves to such as best suit them. The case is the same in an orator; who should therefore keep within those bounds which nature seems to have prescribed for him. Some are better fitted for action than others, and most for some particular actions rather than others; and what fits well upon one would appear very awkward in another. Every one, therefore, should first endeavour to know himself, and manage accordingly. Though in most cases, nature may be much assisted and improved by art and exercise. See professor Ward's *System of Oratory*.

## O R A

**Oratory**  
||  
**Orchard.**

**ORATORY**, among the Romanists, a closet or like apartment near a bed-chamber, furnished with an altar, crucifix, &c. for private devotions.

**ORB**, in astronomy, denotes an hollow globe or sphere.

**ORB**, in tactics, is the disposing of a number of soldiers in circular form of defence. The orb has been thought of consequence enough to employ the attention of the famous marshal de Puysegur in his art of war, who prefers this position to throw a body of infantry in an open country to resist cavalry, or, even a superior force of infantry; because it is regular, and equally strong, and gives an enemy no reason to expect better success by attacking one place than another. Cæsar drew his whole army in this form, when he fought against Labienus. The whole army of the Gauls were formed into an orb, under the command of Sabinus and Cotta, when fighting against the Romans. The orb was generally formed six deep.

**ORBIT**, in astronomy, the path of a planet or comet, or the curve that it describes in its revolution round its central body; thus, the earth's orbit is the curve which it describes in its annual course round the sun, and usually called the *ecliptic*. See **ASTRONOMY**, *passim*.

**ORCADES**, the *Orkney Islands*. See **ORKNEY**.

**ORCHARD**, a garden-department, consigned entirely to the growth of standard fruit trees, for furnishing a large supply of the most useful kinds of fruit.

In the orchard you may have, as standards, all sorts

of apple-trees, most sorts of pears and plums, and all sorts of cherries; which four species are the capital orchard fruits; each of them comprising numerous valuable varieties. But to have a complete orchard you may also have quinces, medlars, mulberries; service trees, filberts, Spanish nuts, berberries; likewise walnuts and chestnuts; which two latter are particularly applicable for the boundaries of orchards, to screen the other trees from the insults of impetuous winds and cold blasts. All the trees ought to be arranged in rows from 20 to 30 feet distance, as hereafter directed.

But sometimes orchards consist entirely of apple-trees, particularly in the cider making countries, where they are cultivated in very great quantities in large fields, and in hedge-rows, for the fruit to make cyder for public supply.

And sometimes whole orchards of very considerable extent are entirely of cherry-trees. But in this case, it is when the fruit is designed for sale in some great city as London, &c. For the supply of which city, great numbers of large cherry orchards are in some of the adjacent counties, but more particularly in Kent, which is famous for very extensive cherry-orchards; many of which are entirely of that sort called *Kentish-cherry*, as being generally a great bearer; others are stored with all the principal sorts of cultivated cherries, from the earliest to the latest kinds. See *PRUNUS Cerasus*.

A general orchard, however composed of all the beforementioned fruit-trees, should consist of a double portion

**Orchard.**

Orchard. portion of apple-trees or more, because they are considerably the most useful fruit, and may be continued for use the year round.

The utility of a general orchard, both for private use and profit, stored with the various sorts of fruit-trees, must be very great, as well as afford infinite pleasure from the delightful appearance it makes from early spring till late in autumn: In spring the various trees in blossom are highly ornamental; in summer, the pleasure is heightened by observing the various fruits advancing to perfection; and as the season advances, the mature growth of the different species arriving to perfection in regular succession, from May or June, until the end of October, must afford exceeding delight, as well as great profit.

*Of the proper Extent, Situation, and Soil for this Department.]* As to the proper extent of ground for an orchard, this must be proportioned, in some measure, to the extent of land you have to work on, and the quantity of fruit required either for private use or for public supply? so that an orchard may be from half an acre to 20 or more in extent.

With respect to the situation and aspect for an orchard, we may observe very thriving orchards both in low and high situations, and on declivities and plains, in various aspects or exposures, provided the natural soil is good; we should, however, avoid very low damp situations as much as the nature of the place will admit; for in very wet soils no fruit trees will prosper, nor the fruit be fine: but a moderately low situation, free from copious wet, may be more eligible than an elevated ground, as being less exposed to tempestuous winds; though a situation having a small declivity is very desirable, especially if its aspect incline towards the east, south-east, or southerly, which are rather more eligible than a westerly aspect; but a north aspect is the worst of all for an orchard, unless particularly compensated by the peculiar temperament or good quality of the soil.

And as for soil, any common field or pasture that produces good crops of corn, grass or kitchen-garden vegetables, is suitable for an orchard; if it should prove of a loamy nature, it will be a particular advantage: any soil, however, of a good quality, not too light and dry, or too heavy, stubborn, or wet, but of a medium nature, of a soft, pliant temperature, not less than one spade deep of good staple, will be proper for this purpose.

*Preparation of the Ground.]* The preparation of the ground for the reception of trees, is by trenching; or, if for very considerable orchards, by deep ploughing; but trench-digging, one or two spades, as the soil will admit, is the most eligible, either wholly or only for the present in the places where the lines of trees are to stand, a space of six or eight feet wide, all the way in each row, especially if it be grass-ground, and intended to be kept in the sward: or if any under-crops are designed to be raised, the ground may be wholly trenched at first: in either case trench the ground in the usual way to the depth of the natural soil; and if in grass, turn the sward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.

In planting orchards, however, on grass-grounds, some only dig pits for each tree, capacious enough for

the reception of the roots, loosening the bottom well without the labour of digging any other part of the ground.

The ground must be fenced securely against cattle, &c. either with a good ditch and hedge, or with a paling-fence, as may be most convenient. See HEDGES.

*Method of planting the Trees.]* The best season for planting all the sorts of fruit-trees is autumn, soon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.

Choose principally full standards, with straight clean stems, six feet high; each with a branchy well-formed head, or from two or three to four or five years growth; and let several varieties of each particular species be chosen, that ripen their fruit at different times, from the earliest to the latest, according to the nature of the different sorts, that there may be a proper supply of every sort regularly during their proper season. Of apples and pears in particular, choose a much greater quantity of the autumnal and late ripening kinds than of the early sorts; but most of all of apples: for the summer ripening fruit is but of short duration, only proper for temporary service; but the latter ripening kinds keep found some considerable time for autumnal use; and the latest sorts that ripen in October, continue in perfection for various uses all winter, and several sorts until the season of apples come again.

Having made choice of the proper sorts, and marked them, let them be taken up with the utmost care, so as to preserve all their roots as entire as possible; and when taken up, prune off any broken or bruised parts of the roots, and just tip the ends of the principal roots, in general, with the knife on the under side, with a kind of slope outward.

If the trees have been already headed, or so trained as to have branched out into regular shoots to form each a proper head, they must be planted with the said heads entire, only retrenching or shortening any irregular or ill-placed shoot that takes an awkward direction, or grows across its neighbours, or such as may run considerably longer than all the rest, &c.

The arrangement of the trees in the orchard must be in rows, each kind separate, at distances according to the nature of the growth of the different sorts; but for the larger growing kinds, such as apples, pears, plums, cherries, &c. they should stand from 25 to 30, or 40 feet every way asunder, though 25 or 30 feet at most is a reasonable distance for all these kinds.

Each species and its varieties should generally be in rows by themselves, the better to suit their respective modes of growth: though for variety there may be some rows of apples and pears arranged alternately, as also of plums and cherries; and towards the boundaries there may be ranges of lesser growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut trees and some chefnuts, set pretty close to defend the other trees from violent winds.

According to the above distances, proceed to stake out the ground for making the holes for the reception of the trees; which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the sun's influence more effectually.

But in planting very extensive orchards, some divide

Orchard,  
Orcheston.

vide the ground into large squares or quarters, of different dimensions with intervals of fifty feet wide between; serving both as walks, and for admitting a greater currency of air; in different quarters planting different sorts of fruit, as apples in one, pears in another, and plums and cherries in others, &c. and thus it may be repeated to as many quarters for each species and its varieties as may be convenient.

As to the mode of planting the trees: A wide hole must be dug for each tree, capacious enough to receive all the roots freely every way without touching the sides. When the holes are all ready, proceed to planting, one tree in each hole, a person holding the stem erect, whilst another trims in the earth, previously breaking it small, and casting it in equally all about the roots, frequently shaking the tree to cause the mould to settle in close about all the smaller roots and fibres, and so as to raise the tree gradually up, that the crown of the roots may be but two or three inches below the general surface; and when the hole is filled up, tread it gently, first round the outside, then near the stem of the tree, forming the surface a little hollow; and then if on the top of all is laid some inverted turf to the width of the holes, forming it with a sort of circular bank, three or four inches high, it will support the tree, and guard the roots from drying winds and the summer's drought: observing that each tree stand perfectly upright, and that they range exactly in their proper rows.

ORCHESTON ST MARY'S, on Salisbury plain in Wiltshire, about nine miles from Salisbury. There is a curious species of grass found at this place in a meadow belonging to Lord Rivers, at present in the possession of a farmer.

The meadow is situated on a small brook, is frequently overflowed, and sometimes continues so a great part of the winter. It bears the greatest burden in a wet season.

We have the following account of this peculiar species of grass in Letters and Papers in Agriculture, &c. The farmer in whose possession the meadow is, informs us, "That it generally grows to the height of about 18 inches, and then falls and runs along the ground in knots to the length of 16 or 18 feet, but that he has known instances of its running to the length of 25 feet.

"The meadow contains about two acres and a half. It is mowed twice in a season and the average quantity is generally about twelve loads (tons) of hay the first mowing, and six the second; though sometimes considerably more. The tithe of the meadow has been compounded for at 9l. a year. The grass is of a very sweet nature: all cattle, and even pigs, eat it very eagerly. When made into hay, it is excellent, and improves beasts greatly. The farmer says, his horses will eat it in preference to corn mixed with chaff, when both are set before them together."

"This account appeared to us so singular, and the crop of grass so very extraordinary, that our secretary went to Orcheston to examine more particularly into it. The farmer, and divers other persons in the village, confirmed the account contained in this letter, of its amazing produce in summers when the meadows had been overflowed in the preceding winter and spring; but when the winter had been dry, and the

Vol. XIII.

meadow not overflowed, the crop of grass was not near so large. There did not appear to be any thing peculiar in the soil; nor were the other plants or weeds growing on it more luxuriant than in many other similar situations. Some of this grass was sent to the society at Norwich; some ingenious members of which inform us, that they think it is a species of the *agrostis polymorpha*, mentioned by Hudson in his *Flora Anglica*, of which there are several varieties.

"Camden mentions, in his *Britannia*, a grass growing near the place where this is found, which he calls *trailing Dog's grass*, and says, that hogs were fed with it."

"From all the inquiry made, we have not found this species of grass growing in any other part of the kingdom; hence it is possible that there may be something in the soil of this meadow peculiarly favourable to its growth. We shall not, however, determine on this point, but recommend trials to be made of propagating it, by sowing the seed in other places subject to be overflowed in the same manner. If it can be propagated generally, it must turn out the most profitable to the farmer of any grass yet discovered, and be of great benefit to the community."

We have this further account of it in the Gentleman's Magazine for March 1782; "The first notices of the Orcheston or Maddington grass, as far as I can find, are to be met with in Dr How's *Philologia Britannica*, printed in 1650, where it is called '*Gramen caninum supinum longissimum non descriptum*, and is said to grow nine miles from Salisbury, by Mr Tucker's at Maddington, wherewith they fatten hogs, and which is 24 feet long; and which', the author adds, 'may happily be a kind of *gramen caninum supinum*, though Gerard Englishes it *upright dog's grass*.' Mr Stonehouse, p. 25. I have not been able to ascertain the residence of Mr Stonehouse, who seems to have been the first that made the knowledge of this grass public. He is mentioned several times in Ray's *Synopsis Stirpium*; but I can find no anecdotes relative to him. Dr How's account is taken into Merret's *Pinax*, printed in 1667, the author having added, that 'this grass is also found in some parts of Wales.' Mr Ray mentions it from both these authors, in his *Catalogus Plantarum Angliæ*, 1670; and refers to Fuller's *Worthies* for a further account of it, which work was printed in 1662. It does not appear that Ray had any opportunity of examining this remarkable production, since he has not introduced it into his *Synopsis*, in either of the editions which were published in his lifetime; and in the list of Wiltshire plants printed in Camden's *Britannia*, he recommends it to the inquisition of the industrious herbalists of that county. Dr Dillenius afterwards introduced it into the *Indiculus plantarum dubiarum*, subjoined to the third edition of Ray's *Synopsis*.

"Since the spirit of improvement in agriculture has been excited of late years, the curiosity of the public has been raised relating to it, but the species was not sufficiently determined. It has been thought by some to be the *apocyrus, geniculatus*, or *steep fox tail grass*, of Hudson's *Flora Angl.* 2d edit. p. 27. by others to be the *agrostis flexuifolia*, or *creeping bent grass*, ib. p. 31. See *The Farmers Magazine* for 1778, p. 232, 239, 289, 290.

"Being very desirous of having this matter cleared

3 O

up,

Orcheston  
||  
Orchis.

up, I procured in July last, from the farmer himself at Maddington, a bundle of this grafs when it was in spike; and by this means I found it to be no other than the *tritium repens*, Hudfon p. 57. or *common dogs grafs*, *quick-grafs*, or *couch-grafs*, in a most luxuriant state of growth. The length of the culm is greatly influenced by the nature of the seasons. Its place of growth is in a meadow that is covered with water during the greatest part of the winter and spring. In this inundated soil it acquires a length of stalk, a succulency, and vigour, which are indeed very surprizing. Of the bundle that was sent to me, most of the plants were seven feet long, and many of the spikes or ears contained 33 and 40 glumes, or flower-bearing husks; whereas the plant in common does not contain more than half that number: and it was said by the people of that neighbourhood to have been a very unfavourable season for this grafs.

“That the above-mentioned species is the grafs which at this time constitutes the bulk of that astonishing crop which we read of, is to me sufficiently ascertained; but whether, ever since the first notice of this grafs, this species alone has been the cultured one in this situation, I do not decide, but think it a matter worthy of further investigation; since it should seem that the soil and situation are in a peculiar manner adapted to certain plants of the graminous tribe. I observed that a plant or two of the *phalaris arundinacea*, or *reed Canary grafs*, Hudfon, p. 23. which by accident were sent with the above-mentioned grafs, exceeded in the thickness and succulency of the stalk the ordinary size, and were also equal to the dogs grafs in length.”

These extracts we thought it our duty to lay before our readers; and we have done it without any observation or comment of our own; because we wish to give them every information which is either curious or may be useful; and with this we rest satisfied, not wishing to obtrude our remarks, where, from the scantiness of information or the doubtfulness of the case, they cannot be made with confidence.

ORCHESTRA, in the Grecian theatres, was that part of the *proscenium* or stage where the chorus used to dance. In the middle of it was placed the *Λόγιον* or *pulpit*. The orchestra was semicircular, and surrounded with seats. In the Roman theatres it made no part of the *scena*, but answered pretty nearly to the pit in our playhouses, being taken up with seats for senators, magistrates, vestals, and other persons of distinction. The actors never went down into it. See THEATRE.

ORCHIA LEX, instituted by Orchius the tribune in the year of Rome 566. Its intention was to limit the number of guests that were to be admitted at an entertainment; and it also enforced, that during supper, which was the chief meal among the Romans, the doors of every house should be left open.

ORCHIS, FOOL-STONES; A genus of the diandria order, belonging to the gynandria class of plants; and in the natural method giving name to the seventh order, *Orchidæ*. Its characters are these: It has a single stalk, with a vague sheath, and no empalement; the flower hath five petals, three without and two within; the nectarium is of one leaf, fixed to the side of the

receptacle, between the division of the petals; the upper lip is short and erect, the under large, broad, and spreading; the tube is pendulous, corniform, or like a horn, and prominent behind; it hath two short slender stamina, fitting upon the point, with oval erect summits, fixed to the upper lip of the nectarium; it hath an oblong contorted germen, under the flower, with a short style, fastened to the upper lip of the nectarium; the germen afterward turns to an oblong capful, with one cell, having three keel-shaped valves, opening on the three sides, but jointed at top and bottom, filled with small seeds like dust. Miller enumerates 10, and Linnæus 33 species.

All those sorts of orchis described by Miller grow wild in several parts of England, but on account of the extreme oddness and beauty of their flowers, deserve a place in every good garden: and the reason of their not being cultivated in gardens, proceeds from the difficulty of transplanting them: though this may be easily overcome, where a person has an opportunity of marking their roots, in their time of flowering, and letting them remain until their leaves are decayed, when they may be transplanted with safety; for it is the same with most sorts of bulbous or fleshy-rooted plants, which, if transplanted before their leaves decay, seldom live, notwithstanding you preserve a large ball of earth about them; for the extreme parts of their fibres extend to a great depth in the ground, from whence they receive their nourishment, which if broken or damaged by taking up their roots, seldom thrive after; for though they may sometimes remain alive a year or two, yet they grow weaker until they quite decay; which is also the case with tulips, fritillarias, and other bulbous roots. But if their soil and situation be adapted to their various sorts, they will thrive and continue several years, and during their season of flowering will afford as great varieties as any flowers which are at present cultivated.

The most remarkable species are the following;  
1. The mascula, or male fool-stones, hath a root composed of two bulbs, crowned with oblong, broad, spotted leaves; upright stalks, a foot high; garnished with one or two narrow amplexicaule leaves; and terminated by a long spike of reddish purple flowers having the petals reflexed backward; a quadrilobed crenated lip to the nectarium, and an obtuse horn. The flowers of the species possess a very agreeable odour. The orchis mascula, Lin. sp. pl. is the most valuable; although the roots of some of the palmated sorts particularly of the orchis latifolia, are found to answer almost equally well.

2 The morio, or female orchis, hath a double bulbous root, crowned with oblong, ribbed, spreading leaves; erect flower-stalks, eight or ten inches high; garnished with a few amplexicaule leaves; and terminated by a short loose spike of flowers, having connivent petals, a quadrifid crenated lip to the nectarium, and an obtuse horn.

3. The militaris, or man-orchis, hath a double bulbous root, crowned with oblong amplexicaule leaves; erect flower-stalks, eight or ten inches high; terminated by a loose spike of ash-coloured and reddish flowers, having confluent petals; a quinquefid, rough, spotted lip to the nectarium, and an obtuse horn. The structure

Orchis.

Plate  
CCCL.

Orchis  
||  
Ordeal.

structure of the flowers exhibit the figure of a naked man; and are often of different colours in the same flower, as ash colour, red, brown, and dark striped.

*Culture and Properties.* All the orchises are very hardy perennials, with bulbous fleshy roots. The flowers appear in May, June and July, but principally in June: their mode of flowering is universally in spikes, many flowers in each spike; and each flower is composed of five petals in two series, and a nectarium. The season for removing them is in summer, after they have done flowering, when their leaves and stalks decay: plant them three inches deep, and let them remain undisturbed several years, for the less they are removed, the stronger they will flower.

The roots of all the species have a remarkable resemblance to the scrotum of animals, whence the name. This plant flourishes in various parts of Europe and Asia, and grows in our country spontaneously, and in great abundance. It is assiduously cultivated in the East; and the root of it forms a considerable part of the diet of the inhabitants of Turkey, Persia, and Syria. From it is made the alimentary powder called *SALEP*; which prepared from foreign roots, is sold at five or six shillings per pound, though it might be furnished by ourselves at the sixth part of that price, if we chose to pay any attention to the culture of this plant. The orchis mascula is the most valued for this purpose. A dry and not very fertile soil is best adapted to its growth.

The properest time for gathering the roots, is when the seed is formed, and the stalk is ready to fall; because the new bulb, of which the salep is made, is then arrived to its full maturity, and may be distinguished from the old one, by a white bud rising from the top of it, which is the germ of the orchis of the succeeding year.

The culture of the orchis is an object highly deserving of encouragement from all the lovers of agriculture. And as the root, if introduced into common use, would furnish a cheap, wholesome, and most nutritious article of diet, the growth of it would be sufficiently profitable to the farmer. See *SALEP*.

*ORCUS*, god of the infernal regions, the same with Pluto, so called from the Greek word *ορχος*, signifying a "tomb or sepulchre," or from *ορκος*, "an oath by the river Styx." The ancients gave this name to all the divinities of the infernal regions, even to Cerberus. There was a river of the same name in Thessaly, which took its rise from the marshes of the Styx, and the waters of which were so thick that they floated like oil upon the surface of the river Peneus, into which they discharged themselves. This river probably suggested to the poets the idea of the infernal abodes, which they denominated *Orcus*. This deity has been confounded with Charon: he had a temple at Rome.

*ORDEAL*, an ancient form of trial. See *TRIAL*. —It was an appeal to the immediate interposition of

divine power, and was peculiarly distinguished by the appellation of *judicium Dei*; and sometimes *vulgaris purgatio*, to distinguish it from the canonical purgation, which was by the oath of the party. There were two sorts of it more common than the rest, at least in Europe, fire-ordeal, and water ordeal. The former was confined to persons of higher rank, the latter to the common people. Both these might be performed by deputy: but the principal was to answer for the success of the trial; the deputy only venturing some corporeal pain, for hire or perhaps for friendship.

That the purgation by ordeal, of some one kind or other, is very ancient, admits not of a doubt; and that it was very universal in the times of superstitious barbarity, is equally certain. It seems even to have been known to the ancient Greeks: for in the *Antigone* of Sophocles, a person suspected by Creon of a misdemeanour, declares himself ready "to handle hot iron and to walk over fire" in order to manifest his innocence; which the scholiast tells us was then a very usual purgation. And Grotius gives us many instances of water-ordeal in Bithynia, Sardinia, and other places. It seems however to be carried to a greater height among the Hindoos, than ever it has been in any nation or among any people however rude or barbarous; for in a paper of the Asiatic Researches communicated by the celebrated Warren Hastings, Esq; we find that the *trial by ordeal* among them is conducted in nine different ways: first, by the balance; secondly, by fire; thirdly, by water; fourthly, by poison; fifthly, by the Colcha, or water in which an idol has been washed; sixthly, by rice; seventhly, by boiling oil; eighthly, by red hot iron; ninthly, by images.

I. Ordeal by the balance is thus performed. The beam having been previously adjusted, the cord fixed, and both scales made perfectly even, the persons accused and a Pandit fast a whole day; then, after the accused has been bathed in sacred water, the *homa*, or oblation, presented to fire, and the deities worshipped, he is carefully weighed; and, when he is taken out of the scale, the Pandits prostrate themselves before it, pronounce a certain *mentra* or incantation, agreeable to the Sastras, and having written the substance of the accusation on a piece of paper, bind it on his head. Six minutes after, they place him again in the scale; and, if he weigh more than before, he is held guilty; if less, innocent; if exactly the same, he must be weighed a third time; when as it is written in the *Metaphera*, there will certainly be a difference in his weight. Should the balance though well fixed break down, this would be considered as a proof of his guilt.

II. For the fire ordeal, an excavation, nine hands long, two spans broad, and one span deep, is made in the ground, and filled with a fire of pippal wood, into this the person accused must walk bare footed; and, if his foot be unhurt, they hold him blameless; if burned, guilty (A).

(A) In Europe fire ordeal was performed either by taking up in the hand, unhurt, a piece of red-hot iron of one, two, or three pounds weight; or else by walking, barefoot, and blindfold, over nine red-hot ploughshares, laid lengthways at unequal distances; and if the party escaped being hurt, he was adjudged innocent; but if it happened otherwise, as without collusion it usually did, he was then condemned as guilty. However by this latter method Queen Emma, the mother of Edward the Confessor, is mentioned to have cleared

Ordeal.

III. Water ordeal is performed by causing the person accused to stand in a sufficient depth of water, either flowing or stagnant, to reach his navel; but care should be taken, that no ravenous animal be in it, and that it be not moved by much air: a brahman is then directed to go into the water, holding a staff in his hand; and a soldier shoots three arrows on dry ground from a bow of cane: a man is next dispatched to bring the arrow which has been shot farthest; and, after he has taken it up, another is ordered to run from the edge of the water; at which instant the person accused is told to grasp the foot or the staff of the brahman, who stands near him in the water, and, immediately to dive into it. He must remain under water, till the two men who went to fetch the arrows, are returned; for, if he raise his head or body above the surface, before the arrows are brought back, his guilt is considered as fully proved. In the villages near Benares, it is the practice for the person who is to be tried by this kind of ordeal, to stand in water up to his navel, and then holding the foot of a brahman, to dive under it as long as a man can walk 50 paces very gently; if, before the man has walked thus far, the accused rise above the water, he is condemned; if not, acquitted (B).

IV. There are two sorts of trial by poison; first the Pandits having performed their homo, and the person accused his ablution, two *rettis* and a half, or seven barley corns, of *visbanaga*, a poisonous root, or

of *sanc'hyā*, that is, white arsenic, are mixed in eight *masbas*, or 64 *rettis*, of clarified butter, which the accused must eat from the hand of a brahman: if the poison produce no visible effect, he is absolved; otherwise, condemned. Secondly the hooded snake, called *naga*, is thrown into a deep earthen pot, into which is dropped a ring, a seal or a coin: this the person accused is ordered to take out with his hand; and, if the serpent bite him, he is pronounced guilty; if not, innocent.

V. Trial by the *cosha* is as follows: the accused is made to drink three draughts of the water, in which the images of the sun, of devi, and other deities, have been washed for that purpose; and if, within 14 days, he has any sickness or indisposition, his crime is considered as proved.

VI. When several persons are suspected of theft, some dry rice is weighed with the sacred stone called *salgram*, or certain *flocas* are read over it: after which the suspected persons are severally ordered to chew a quantity of it; as soon as they have chewed it, they are to throw it on some leaves of *pippal*, or, if none be at hand, on some *l'burja patra*, or bark of a tree from Nepal or Cashmir. The man from whose mouth the rice comes dry or stained with blood, is holden guilty; the rest are acquitted.

VII. The ordeal by *hot oil* is very simple: when it is heated sufficiently, the accused thrusts his hands into it; and, if he be not burned, is held innocent (C).

VIII.

ed her character when suspected of familiarity with Alwyn bishop of Winchester. The first account we have of Christians appealing to the fire-ordeal, as a proof of their innocence, is that of Simplicius, bishop of Autun, who lived in the fourth century. This prelate, as the story is related, before his promotion to the episcopal order, had married a wife, who loved him tenderly, and who unwilling to quit him after his advancement, continued to sleep in the same chamber with him. The sanctity of Simplicius suffered, at least in the voice of fame, by the constancy of his wife's affection; and it was rumoured about, that the holy man, though a bishop, persisted, in opposition to the ecclesiastical canons, to taste the sweets of matrimony: upon which his wife in the presence of a great concourse of people, took up a considerable quantity of burning coals, which she held in her clothes, and applied to her breasts, without the least hurt to her person or her garments, as the legend says; and her example being followed by her husband with the like success, the silly multitude admired the miracle, and proclaimed the innocence of the loving pair. A similar trick was played by St Brice, in the fifth century. *Mosh. Eccl. Hist.* v. 2.

(B) A very peculiar species of water-ordeal is said to prevail among the Indians on the coast of Malabar. A person accused of an enormous crime is obliged to swim over a river abounding with large crocodiles; and if he escapes unhurt, he is esteemed innocent.

At Siam, besides the usual methods of fire and water ordeal, both parties are sometimes exposed to the fury of a tyger let loose for that purpose; and if the beast spares either, that person is accounted innocent; if neither, both are held to be guilty; but if he spares both, the trial is incomplete, and they proceed to a more certain criterion.

In Europe water-ordeal was performed, either by plunging the bare arm up to the elbow in boiling water and escaping unhurt thereby, or by casting the person suspected into a river or pond of cold water; and if he floated therein without any action of swimming, it was deemed an evidence of his guilt; but if he sunk he was acquitted. It is easy to trace out the traditional relics of this water-ordeal, in the ignorant barbarity still practised in many countries to discover witches, by casting them into a pool of water, and drowning them to prove their innocence. And in the Eastern empire the fire ordeal was used for the same purpose by the emperor Theodore Lascaris; who, attributing his sickness to magic, caused all those whom he suspected to handle the hot iron: thus joining (as has been well remarked) to the most dubious crime in the world, the most dubious proof of innocence.

(C) This species of trial by ordeal is thus performed: The ground appointed for the trial is cleared and rubbed with cow-dung; and the next day at sun-rise the *Pandit* worships *Ganésa* or the Hindoo Janus, presents his oblations, and pays adoration to other deities, conformably to the *Sastrá*: then having read the incantation prescribed, he places a round pan of gold, silver, copper, iron, or clay, with a diameter of sixteen fingers, and four fingers deep; and throws into it one *ser*, or eighty *sicca* weight of clarified butter or oil of *sesamum*. After this a ring of gold,

Ordeal.

VIII. In the same manner, they make an *iron-ball*, or the *head of a lance*, red-hot, and place it in the hands of the person accused; who, if it burn him not is judged guiltless.

IX. To perform the ordeal by *dharmārch*, which is the name of the *śloka* appropriated to this mode of trial, either an image, named *Dharma*, or the genius of justice, is made of silver, and another, called *Adharma*, of clay or iron, both of which are thrown into a large earthen jar; and the accused having thrust his hand into it, is acquitted if he bring out the silver image, but condemned if he draw forth the iron; or, the figure of a deity is painted on white cloth, and another on black; the first of which they name *dharmā*, and the second *adharma*: these are severally rolled up in cowdung, and thrown into a large jar without having ever been shown to the accused; who must put his hand into the jar, and is acquitted or convicted as he draws out the figure on white or on black cloth.

Though we have proceeded thus far, we have not exhausted Mr Hastings's communications. He goes on to show (to greater extent than our limits permit us to follow him) the manner in which each ordeal abovementioned was executed, giving examples, and unfolding other particulars of some importance in developing the nature of these barbarous customs. For these particulars, however, we must refer to the book itself. But as this subject unquestionably occupies an important department in the history of human superstition, we shall give the Indian law of ordeal from the same paper; when we shall introduce some further particulars concerning this extraordinary custom, which are not to be found in the above account, but which deserve to be noticed.

“ 1. The balance, fire, water, poison, the idol—these are the ordeals used here below for the proof of innocence, when the accusations are heavy, and when the accuser offers to hazard a mulct (if he should fail):

2. Or one party may be tried if he please, by ordeal, and the other must then risk an amercement; but the trial may take place even without any wager, if the crime committed be injurious to the prince.

3. The sovereign, having summoned the accused while his clothes are yet moist from bathing, at sunrise, before he has broken his fast, shall cause all trials by ordeal to be conducted in the presence of *Brāhmins*.

4. The balance is for women, children, old men, the blind, the lame, *Brāhmins*, and the sick; for the *Sūdra*, fire or water, or seven barley-corns of poison.

5. Unless the loss of the accuser amount to a thousand pieces of silver, the accused must not be tried by the red-hot ball, nor by poison, nor by the scales; but if the offence be against the king, or if the crime be heinous, he must acquit himself by one of those trials in all cases.

6. He who has recourse to the balance must be attended by persons experienced in weighing, and go down into one scale, with an equal weight placed in the other, and a groove (with water in it) marked on the beam.

7. ‘Thou, O balance, art the mansion of truth: thou wast anciently contrived by deities: declare the truth, therefore, O giver of success, and clear me from all suspicion.’

8. ‘If I am guilty, O venerable as my own mother, then sink me down; but if innocent, raise me aloft.’ Thus shall he address the balance.

9. If he sink he is convicted, or if the scales be broken; but if the string be not broken, and he rise aloft, he must be acquitted.

10. On the trial by fire, let both hands of the accused be rubbed with rice in the husk, and well examined: then let seven leaves of the *Aśwatt'ha* (the religious fig-tree) be placed on them, and bound with seven threads.

11. ‘Thou, O fire, prevadest all beings; O cause of purity, who givest evidence of virtue and of sin, declare the truth in this my hand.’

12. When he has pronounced this, the priest shall place in both his hands an iron ball, red-hot, and weighing fifty (D) *palas*.

13. Having taken it, he shall step gradually into seven circles, each with a diameter of sixteen fingers, and separated from the next by the same space.

14. If, having cast away the hot ball, he shall again have his hands rubbed with rice in the husk, and shall show them unburned, he will prove his innocence. Should the iron fall during the trial, or should a doubt arise (on the regularity of the proceedings), he must be tried again.

15. ‘Preserve me, O Varuna, by declaring the truth.’ Thus having invoked the god of waters, the accused shall plunge his head into the river or pool, and hold both thighs of a man, who shall stand in it up to his navel?

16. A swift runner shall then hasten to fetch an arrow shot at the moment of his plunging; and if, while the runner is gone the priest shall see the head of

Ordeal.

gold, or silver, or iron is cleaned and washed with water, and cast into the oil; which they proceed to heat, and when it is very hot put into it a fresh leaf of *pippala*, or of *bilwa*: when the leaf is burned, the oil is known to be sufficiently hot. Then, having pronounced a *mentra* over the oil, they order the party accused to take the ring out of the pan; and if he take it out without being burned, or without a blister on his hand, his innocence is considered as proved; if not, his guilt\*.

(D) A *pala* is four *carshas*, and a *carsha* eighty *ratnicās*, or seeds of the *Gungā* creeper, each weighing above a grain and a quarter, or, correctly,  $1\frac{1}{8}$  gr.

\* It is reported, that this custom, with some slight variations, still prevails among the Indians on the coast of Malabar. The process there is said to begin after the accused person has been thoroughly washed in the presence of the prince of the country, the priests, &c.:—the pot is filled with boiling lead; and the accused must take the ring out three times successively. On the Malabar coast, this ordeal seems only to be used when the person is accused of a capital crime; for after the process the arm is bound with cloth and sealed; and after several days, being brought out publicly, and the arm inspected, if it is found burnt he is instantly put to death; if not, his accuser undergoes the same trial, and being burnt, forfeits his life.

Ordeal. of the accused under water, he must be discharged as innocent.

17. 'Thou, O poison, art the child of Brahmá, steadfast in justice and in truth; clear me then from this heavy charge, and, if I have spoken truly, become nectar to me.'

18. Saying this, he shall swallow the poison *Sārnga* from the tree, which grows on the mountain *Hymálaya*; and if he digests it without any inflammations the prince shall pronounce him guiltless.

16. Or the priest shall perform rites to the image of some tremendous deity; and, having bathed the idol, shall make the accused to drink three handfuls of the water that has dropped from it:

20. If in fourteen days after he suffer no dreadful calamity from the act of the deity or of the king, he must indubitably be acquitted."

The superstitious weakness of mankind, when left to themselves, is astonishing. There is indeed nothing so absurd but they may be made most firmly to believe, nor so impious but they will do. Nor can a more notorious instance of the truth of this assertion be possibly given than that of the trial by ordeal. The gross absurdity as well as impiety of pronouncing a man guilty unless he was cleared by a miracle, and of expecting that all the powers of nature should be suspended by an immediate interposition of providence to save the innocent, whenever it was presumptuously required, is self-evident. Yet the origin of it may be traced as well to necessity as to superstition. At the time in which it originated in England, as well as in other countries of Europe, it was no easy matter for an innocent person, when accused of guilt, to get himself cleared by the then established mode of trial (See TRIAL). It was therefore natural for superstition to fly to heaven for those testimonies of innocence which the absurdity of human laws often prevented men from obtaining in the ordinary way; and in this way doubtless did the trial by ordeal commence; and thus begun by necessitous superstition, it was fostered by impious priestcraft and unjust power. There was during all the processes great room for collusion and deceit; and there can be no question but it was often practised; it could not therefore on any account, or in any case, be a sign of innocence or of guilt.

Besides those particular methods of trial which we have already mentioned there were some few more common in European countries; as the judicial combat—the ordeal of the cross—the ordeal of the corsned.

The judicial combat was well suited to the genius and spirit of fierce and warlike nations, and was, as we may reasonably expect, one of the most ancient and universal modes of trial. We know that it was exceedingly common in Germany in very remote ages. It was also used in some countries on the continent at pretty early periods; it is not, however, mentioned in any of the Anglo-Saxon laws; and it does not appear to have been much used in England till after the Conquest. There are, however, two remarkable instances of it upon record, which we shall give in the words of Dr Henry: "Henry de Essex, hereditary standard bearer of England, fled from a battle in Wales A. D. 1158, threw from him the royal standard, and cried out, with others, that the king was slain. Some time af-

ter he was accused of having done this with a treasonable intention, by Robert de Montfort, another great baron, who offered to prove the truth of his accusation by combat. Henry de Essex denied the charge, and accepted the challenge. When all preliminaries were adjusted, this combat was accordingly fought in the presence of Henry II. and all his court. Essex was defeated, and expected to be carried out to immediate execution. But the king who was no friend to this kind of trial, spared his life, and contented himself with confiscating his estate, and making him a monk in the abbey of Reading.

"The priory of Tinmouth, in Northumberland, was a cell of the abbey of St Alban's. One Simon of Tinmouth claimed a right to two corrodies, or the maintenance of two persons in the priory, which the prior and monks denied. This cause was brought before the abbot of St Alban's, and his court baron, who appointed it to be tried by combat on a certain day before him and his barons. Ralf Gubion, prior of Tinmouth, appeared at the time and place appointed, attended by his champion, one William Pegun, a man of gigantic stature. The combat was fought, Pegun was defeated, and the prior lost his cause; at which he was so much chagrined, that he immediately resigned his office. This judicial combat is the more remarkable, that it was fought in the court of a spiritual baron, and that one of the parties was a priest."

We need scarcely add, that this detestable form of trial was the foundation of the no less detestable crime of duelling, which so much disgraces our age and nation; which is defended only by ignorance, false honour, and injustice; which is a relic of barbarous superstition; and which was absolutely unknown to those brave and generous nations, the Greeks and Romans, which it is so much the fashion to admire, and who in this particular so well merit or imitation. See DUEL.

It was so much the custom in the middle ages of Christianity, to respect the cross even to superstition, that it would have been indeed wonderful if the same ignorant bigotry had not converted it into an ordeal; accordingly we find it used for this purpose, in so many different ways as almost to preclude description. We shall however transcribe, for the satisfaction of our readers, Dr Henry's account of it, and of the corsned: "In criminal trials, the judgment of the cross was commonly thus conducted. When the prisoner had declared his innocence upon oath, and appealed to the judgment of the cross, two sticks were prepared exactly like one another; the figure of the cross was cut on one of these sticks, and nothing on the other: each of them was then wrapped up in a quantity of fine white wool, and laid on the altar, or on the relics of the saints; after which a solemn prayer was put up to God, that he would be pleased to discover, by evident signs, whether the prisoner was innocent or guilty. These solemnities being finished, a priest approached the altar, and took up one of the sticks, which was uncovered with much anxiety. If it was the stick marked with the cross, the prisoner was pronounced innocent; if it was the other, he was declared guilty. When the judgment of the cross was appealed to in civil causes, the trial was conducted in this manner: The judges, parties, and all concerned, being assembled in a church, each of the parties chose a priest,

Ordeal

Ordeal.

a priest, the youngest and stoutest that he could find, to be his representative in the trial. These representatives were then placed one on each side of some famous crucifix; and at a signal given, they both at once stretched their arms at full length, so as to form a cross with their body. In this painful posture they continued to stand while divine service was performing; and the party whose representative dropped his arms first, lost his cause.

"The corned, or the consecrated bread and cheese, was the ordeal to which the clergy commonly appealed when they were accused of any crimes: in which they acted a very prudent part, as it was attended with no danger or inconvenience. This ordeal was performed in this manner: A piece of barley-bread, and a piece of cheese, were laid upon the altar, over which a priest pronounced certain conjurations, and prayed with great fervency, that if the person accused was guilty, God would send his angel Gabriel to stop his throat, that he might not be able to swallow that bread and cheese. These prayers being ended, the culprit approached the altar, took up the bread and cheese, and began to eat it. If he swallowed freely, he was declared innocent; but if it stuck in his throat, and he could not swallow, (which we may presume seldom or never happened), he was pronounced guilty."

There were besides these a variety of other ordeals practised in Christian countries, many of which retain the same names as among Pagans, and differ only in the mode of execution. In all nations of Christians where those trials were used, we find the clergy engaged in them. Indeed, in England, so late as King John's time, we find grants to the bishop and clergy to use the *judicium ferri, aquæ, et ignis*. And, both in England and Sweden, the clergy presided at this trial, and it was only performed in the churches or in other consecrated ground: for which Stiernhook gives the reason, *Non desuit illis operæ et laboris pretium; semper enim ab ejusmodi judicio aliquid lucri sacerdotibus obveniat*. But, to give it its due praise, we find the canon law very early declaring against trial by ordeal, or *vulgaris purgatio*, as being the fabric of the devil, *cum sit contra præceptum Domini, Non tentabis Dominum Deum tuum*. Upon this authority, though the canons themselves were of no validity in England, it was thought proper (as had been done in Denmark above a century before) to disuse and abolish this trial entirely in the courts of justice, by an act of parliament in 3 Hen. III. according to Sir Edward Coke, or rather by an order of the king in council.

It may still perhaps be a *postulatium* with some of our readers how the effects of these trials were evaded, and how it was possible to appear to do, what we know could not be really done, without material injury to the persons concerned: and here we find the subject so well handled by the learned historian whom we have already quoted, as far as concerns the ordeals in ancient Britain, which *mutatis mutandis* will answer for others, that we shall finish the article, which has already extended we fear to too great a length, in his words: "If we suppose that few or none escaped conviction who exposed themselves to those fiery trials, we shall be very much mistaken. For the histories of those times contain innumerable examples of persons plunging their naked arms into boiling water, handling

red-hot balls of iron, and walking upon burning plough-shares, without receiving the least injury. Many learned men have been much puzzled to account for this, and disposed to think that Providence graciously interposed, in a miraculous manner, for the preservation of injured innocence. But if we examine every circumstance of those fiery ordeals with due attention, we shall see sufficient reason to suspect that the whole was a gross imposition on the credulity of mankind. The accused person was committed wholly to the priest who was to perform the ceremony three days before the trial, in which he had time enough to bargain with him for his deliverance, and give him instructions how to act his part. On the day of trial, no person was permitted to enter the church but the priest and the accused till after the iron was heated, when twelve friends of the accuser, and twelve of the accused, and no more, were admitted, and ranged along the wall on each side of the church, at a respectful distance. After the iron was taken out of the fire, several prayers were said; the accused drank a cup of holy water, and sprinkled his hand with it, which might take a considerable time, if the priest was indulgent. The space of nine feet was measured by the accused himself with his own feet, and he would probably give but scanty measure. He was obliged only to touch one of the marks with the toe of the right foot, and allowed to stretch the other foot as far towards the other mark as he could, so that the conveyance was almost instantaneous. His hand was not immediately examined, but wrapped in a cloth prepared for that purpose three days. May we not then, from all these precautions, suspect that these priests were in possession of some secret that secured the hand from the impressions of such a momentary touch of hot iron, or removed all appearances of those impressions in three days; and that they made use of this secret when they saw reason? Such readers as are curious in matters of this kind may find two different directions for making ointments that will have this effect, in the work here quoted. What greatly strengthens these suspicions, is, that we meet with no example of any champion of the church who suffered the least injury from the touch of hot iron in this ordeal; but when any one was so fool-hardy as to appeal to it, or to that of hot water with a view to deprive the church of any of her possessions, he never failed to burn his fingers, and lose his cause."

ORDER, in architecture, is a system of the several members, ornaments, and proportions of columns and pilasters, or a regular arrangement of the projecting parts of a building, especially the column, so as to form one beautiful whole. See ARCHITECTURE, Chap. 1. Part 1. page 234, &c.

ORDER is also used for a division or class of any thing; thus the tribe of animals called *birds*, is subdivided into six orders. See ORNITHOLOGY, ZOOLOGY, &c.

ORDER, in rhetoric, is the placing of each word and member of a sentence, in such a manner, as will most contribute to the force, beauty or evidence of the whole; according to the genius and custom of different languages. With regard to order, we may observe in general, that in English, the nearer we keep to the natural or grammatical order, it is generally,

Ordeal,  
Order.Du Cange,  
Gloss. t. 3.  
p. 393.

Order rally the best; but in Latin, we are to follow the use of the best writers; a joint regard being always had to the judgement of the ear, and the perspicuity of the sense, in both languages.

ORDER is also used for a class or division of the members of the body of a state; with regard to assemblies, precedence, &c.

In this sense, order is a kind of dignity, which, under the same name, is common to several persons; and which, of itself, does not give them any particular public authority, but only rank, and a capacity of arriving at honours and employments.

To abridge this definition, order may be said to be a dignity attended with an aptitude for public employ. By which it is distinguished from an office which is the exercise of a public trust.

In this sense, nobility is an order, &c. The clericate is also an order, &c.

ORDER is also the title of certain ancient books, containing the divine office, with the order and manner of its performance.

Roman order is that wherein are laid down the ceremonies which obtain in the Romish church. See RITUAL.

ORDER, in botany, is a name given to a subdivision of plants in the Linnæan system. See BOTANY, p. 431. &c.

ORDERS, by way of eminency, or *holy ORDERS*, denote a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See ORDINATION.

This the Romanists make their sixth sacrament.

In no reformed church are there more than three order; viz. bishops, priests, and deacons. In the Romish church there are seven, exclusive of the episcopate: all which the council of Trent enjoins to be received, and believed, on pain of anathema.

They are distinguished into petty or secular orders: and major, or sacred orders.

ORDERS, the petty, or minor are four; viz. those of doorkeeper, exorcist, reader, and acolyth.

Those in petty orders may marry without any dispensation: in effect, the petty orders are looked on as little other than formalities, and as degrees necessary to arrive at the higher orders. Yet the council of Trent is very jealous about them: enjoins that none be admitted into them without understanding Latin; and recommends it to the bishops, to observe the intervals of conferring them, that the persons may have sufficient time to exercise the function of each order: but it leaves the bishops a power of dispensing with those rules; so that the four orders are usually conferred the same day, and only make the first part of the ceremony of ordination.

The Greeks disavow these petty orders, and pass immediately to the subdiaconate; and the reformed to the diaconate.

Their first rise Fluery dates in the time of the emperor Justinian. There is no call nor benefice required for the four petty orders, and even a bastard may enjoy them without any dispensation: nor does a second marriage disqualify.

ORDERS, sacred, or major, we have already observed are three: viz. those of deacon, priest, and bishop.

The council of Trent retrieving the ancient discipline, forbids any person being admitted to the major

orders, unless he be in peaceable possession of a benefice sufficient for a decent subsistence; allowing no ordinations on patrimonies or pensions; except where the bishop judges it for the service of the church.

A person is said to be promoted to orders *per saltum*, when he has not before passed the inferior orders. The council of Constantinople forbids any bishop being ordained without passing all the degrees; yet church history furnishes us with instances of bishops consecrated, without having passed the order of priesthood; and Panormus still thinks such an ordination valid.

*Military ORDERS*, are companies of knights, instituted by kings and princes, either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

*Religious ORDERS*, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit.—Religious orders may be reduced to five kinds; viz monks, canons, knights, mendicants, and regular clerks. See MONK, CANON, &c.

Father Mabillon proves, that till the ninth century almost all the monasteries in Europe followed the rule of St Benedict; and that the distinction of orders did not commence till upon the reunion of several monasteries into one congregation: that St Odo, abbot of Cluny, first began this reunion, bringing several houses under the dependence of Cluny: that a little afterwards, in the 11th century, the Camaldulians arose; then by degrees the congregation of Vallombrosa; the Cistercians, Carthusians, Augustines; and at last, in the 13th century, the Mendicants. He adds that Lupus Servatus, abbot of Ferrières, in the ninth century, is the first that seems to distinguish the order of St Benedict from the rest, and to speak of it as a particular order.

*White ORDER* denotes the order of regular canons of St Augustine. See AUGUSTINES.

*Black ORDER* denoted the order of BENEDICTINES.

These names were first given these two orders from the colour of their habit; but are disused since the institution of several other orders, who wear the same colours.

*Grey ORDER* was the ancient name of the CISTERCIANS, but since the change of the habit, the name suits them no more.

ORDERS, religious military, are those instituted in defence of the faith, and privileged to say mass; and who are prohibited marriage, &c.

Of this kind are the knights of Malta, or of St John of Jerusalem. Such also were the knights Templars, the knights of Calatrava, knights of St Lazarus, Teutonic knights, &c. See MALTA, TEMPLAR, &c.

Father Putignani accounts those military orders where marriage is not allowed, real religious orders. Papebroch says, it is in vain to search for military orders before the 12th century.

ORDERS, in a military sense, all that is lawfully commanded by superior officers. Orders are given out every day whether in camp, garrison or on a march, by the commanding officer; which orders are afterwards given to every officer in writing by their respective sergeants.

Order.

Ordinal  
||  
Ordinary.

ORDINAL, a book containing the order or manner of performing divine service. See RITUAL.

ORDINAL Numbers, those which express order; as 1st, 2d, 3d, &c.

ORDINANCE, or ORDONNANCE, a law, statute, or command of a sovereign or superior; thus the acts of parliament are sometimes termed *ordinance of parliament*, as in the parliament-rolls. Though in some cases we find a difference made between the two; ordinances being only temporary things, by way of prohibition: and capable of being altered by the commons alone; whereas an act is a perpetual law, and cannot be altered but by king, lords, and commons.

Coke asserts, that an ordinance of parliament differs from an act, as the latter can only be made by the king, and the threefold consent of the estates; whereas the former may be made by one or two of them.

ORDINANCE of the Forest, is a statute made in the 34th year of Henry I. relating to forest matters.

In the French jurisprudence, ordonnances are such laws as are established by the king's authority alone. All ordonnances begin with, *à tous présents & à venir salut*.

ORDINARY, in general, signifies common, usual: thus an ambassador or envoy in ordinary, is one sent to reside stately, and for a number of years, in the court of some foreign prince or state, in order to keep up a good understanding, and watch over the interest of his own nation.—This term is also applied to several officers in a king's household, who attend on common occasions. Thus we say, physician in ordinary, &c.

ORDINARY, in naval language, denotes the establishment of the persons employed by government to take charge of the ships of war, which are laid up in the several harbours adjacent to the royal dockyards. These are principally composed of the warrant-officers of the said ships, as the gunner, boatswain, carpenter, deputy purser, and cook, and three servants. There is besides a crew of labourers inrolled in the list of the ordinary, who pass from ship to ship occasionally, to pump, moor, remove, or clean them, whenever it is necessary.

The term *ordinary* is also applied sometimes to the ships themselves: it is likewise used to distinguish the inferior sailors from the most expert and diligent. The latter are rated *able* on the navy books, and have 1 l. 4 s. *per* month; whereas those who are rated *ordinary* have only 19 s. *per* month.

ORDINARY, in common or canon law, means one who has ordinary or immediate jurisdiction in matters ecclesiastical, in any place. In this sense archdeacons are ordinaries, but the appellation is most frequently applied to the bishop of the diocese, who has of course the ordinary ecclesiastical jurisdiction, and the collation to benefices within such diocese. There are some chapels, chapters, abbeys, &c. exempted from the jurisdiction of the ordinary. The archbishop is ordinary of the whole province, to visit, and receive appeals from the inferior judicatures. The Romish writers on canon law call the pope by way of eminence *ordinary of ordinaries*, since by the Lateran council he has usurped the right of collating, by pro-

VOL. XIII.

bution, to all benefices; in exclusion of the common Ordinary collators.

ORDINARY of Assizes and Sessions, was a deputy of the bishop of the diocese, anciently appointed to give malefactors their neck-veins, and judge whether they read or not; also to perform divine service for them, and assist in preparing them for death. So the

ORDINARY of Newgate, is one who is attendant in ordinary upon the condemned malefactors in that prison, to prepare them for death; and he records the behaviour of such persons.

ORDINARY, or Honourable ORDINARY, in heraldry, a denomination given to certain charges properly belonging to that art. See HERALDRY, Chap. III. sect. i. p. 445. &c.

ORDINATES, in geometry and conics, are lines drawn from any point of the circumference of an ellipse or other conic section, perpendicularly across the axis, to the other side. See CONIC-SECTIONS.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer and the laying on of hands.

Ordination has always been esteemed the principal prerogative of bishops, and they still retain the function as a mark of spiritual sovereignty in their diocese. Without ordination, no person can receive any benefice, parsonage, vicarage, &c. A person must be 23 years of age, or near it, before he can be ordained deacon, or have any share in the ministry; and full 24 before he can be ordained priest, and by that means be permitted to administer the holy communion. A bishop, on the ordination of clergymen, is to examine them in the presence of the ministers, who, in the ordination of priests, but not of deacons, assist him at the imposition of hands; but this is only done as a mark of assent, not because it is thought necessary. In case any crime, as drunkenness, perjury, forgery, &c. be alleged against any one that is to be ordained, either priest or deacon, the bishop ought to desist from ordaining him. The person to be ordained is to bring a testimonial of his life and doctrine to the bishop, and to give account of his faith in Latin; and both priests and deacons are obliged to subscribe the 39 articles.

The ordination of bishops is more properly and more commonly called *consecration*.

In the ancient discipline there was no such thing as a vague and absolute ordination; but every one was to have a church, whereof he was to be ordained clerk, or priest. In the twelfth century they grew more remiss, and ordained without any title or benefice.

The council of Trent restored the ancient discipline, and appointed that none should be ordained but those who were provided of a benefice sufficient to subsist them. Which practice still obtains in England.

The council of Rome in 744, orders, that no ordinations shall be held except on the first, fourth, seventh, and tenth months. In England, by can. 31, ordination-days are the four Sundays immediate following the Ember weeks; being the second Sunday in Lent, Trinity-Sunday, and the Sundays following the first Wednesday after September the 14th, and December the 13th. These are the stated times; but ordinations may take place at any other time, according to the discretion of the bishop or circumstances of the case.

Pope Alexander II. condemns *ordination per sessionem*.

Ordnance. as they call it; *i. e.* the leaping to a superior order without passing through the inferior.

Ordination is one of the sacraments of the church of Rome.

In the establishment of Scotland, where there are no bishops, the power of ordination is lodged in the presbytery and by the Independents in the suffrage of the people. See EPISCOPACY, PRESBYTERIANS, and INDEPENDENTS.

ORDNANCE, a general name for all sorts of great guns used in war. See GUNNERY.

*Boring of ORDNANCE.* Till within these 20 years, iron ordnance were cast with a cylindrical cavity, nearly of the dimension of the caliber of the piece, which was afterwards enlarged to the proper caliber by means of steel-cutters fixed into the dog-head of a boring-bar-iron. Three side-cutters equidistant were requisite to preserve the caliber straight and cylindrical; and a single cutter was used at the end of the bar to smooth the breech of the piece. In boring ordnance cast hollow, the piece was fixed upon a carriage that could be moved backwards and forwards in a direct line with the centre of a water-wheel; in this centre was fixed the boring bar, of a sufficient length to reach up to the breech of the piece, or more properly to the further end of the caliber. The carriage with the piece being drawn backwards from the centre of the water-wheel to introduce the boring and finishing bars and cutters, it is then pressed forwards upon this bar by means of levers, weights, &c. and the water-wheel being set agoing, the bar and fullers are turned round and clean out and smooth the caliber to its proper dimensions.

Experience at last pointed out many inconveniences arising from the method of cast guns *hollow*, and widening the calibers by these boring bars. For the body of iron of the hollow gun, being, at casting, in contact with the core that made the caliber within side, and with the mould without side, began to consolidate towards these sides in the first place, sooner than in the intermediate space, where of course the contraction of the iron takes place; by which means, all guns cast hollow became more or less spongy where they ought to have been most compact; and numberless cavities also were created round the cores, from stagnated air generated in them, which were too deep to be cut out by the boring.

To remedy these defects, iron ordnance is now universally cast solid, by which means the column of iron is greatly enlarged, and the grain more compressed; and the contraction of the iron becomes in the heart of the column, and consequently is cut out by the perforation for the caliber.

Guns are bored out of the solid reversely from the hollow method. The piece A is placed upon two standards BB, by means of two journeys, turned round by the water-wheel C, the breech D being introduced into the centre of the wheel, with the muzzle towards the sliding carriage E, which is pressed forwards by a ratch F, and weights in the same way as the gun-carriage was in hollow-boring. Upon this sliding carriage is fixed, truly horizontal and central to the gun, the drill-bar G, to the end of which is fixed a carp's tongue drill or cutter H; which, being pressed forward upon the piece whilst it is turning round, perforates the bore, which is afterwards finished with bars and cut-

ters as the hollow guns were. The principal difficulty of perforated solid guns truly central, arises from the contraction of the iron above-mentioned; which resisting the drill unequally, tends to throw it out of the central line.

*Office of ORDNANCE*, an office kept within the Tower of London, which superintends and disposes of all the arms, instruments, and utensils of war, both by sea and land, in all the magazines, garrisons, and forts in Great Britain. We have the following copious account of this establishment in Beatson's *Political Index*. In ancient times, before the invention of guns, this office was supplied by officers under the following of names: the *bowyer*, the *cross bowyer*, the *galeator* or *purveyor of helmets*, the *armourer*, and the *keeper of the tents*; and in this state it continued till Henry VIII. placed it under the management of a master, a lieutenant, surveyor, &c. &c.

Some improvements have been since made; and this very important branch is now under the direction of the master general, of the ordnance, having under him a lieutenant general, a surveyor general, a clerk, a storekeeper, a clerk of the deliveries, and a treasurer, with a very great number of inferior officers, employed in the Tower of London, at Woolwich and in almost all the forts, garrisons, and principal ports in his Majesty's dominions. The office of ordnance is divided into two distinct branches, the civil and the military; the latter being subordinate, and under the authority of the former. For the better understanding the business of the different officers, they shall be distinctly treated of, beginning with the principal one, viz.

*Master general of the ORDNANCE* is deemed the principal officer in the civil branch of the ordnance; yet he is always chosen from amongst the first generals in his Majesty's service. His trust is very great, as in him is vested the sole power of storing all the military magazines in the king's dominions with proper munitions of war, and likewise to supply the royal navy with what they may need in his department, the parliament granting money in the most liberal manner for this purpose. He is colonel in chief of the royal regiment of artillery, at present consisting of four battalions; and he is invested with a peculiar jurisdiction over all his Majesty's engineers employed in the several fortifications in his Majesty's dominions; and to him they are all accountable for their proceedings, and from him they receive their particular orders and instructions, according to the directions and commands given by his Majesty in Council. As master general of the ordnance, he has a salary of 1500*l.* per annum, and the appointment of almost all the inferior officers and servants. He has a secretary, who has a salary of 220*l.* a-year, and an under secretary, who has a salary of 180*l.* a-year. There is a secretary to the board of ordnance who has a salary of 200*l.*; and a counsel to the board who has a salary of 300*l.* a-year.

*Lieutenant General of the ORDNANCE* receives all orders and warrants signed by the master general, and from the other principal officers, and sees them duly executed, issues orders as the occasions of the state require, and gives directions for discharging the artillery when required at coronations, birth days, signal victories, and other solemn occasions. It is also his peculiar office to see the train of artillery and all its equipage fitted for motion, when ordered to be drawn into the field,

or

Ordinance, or sent upon any particular service. As lieutenant general of the ordinance, he has a salary of 1100 l. *per annum*. He is colonel *en second* of the royal regiment of artillery, and has a secretary and several inferior officers and clerks under him.

*Surveyor General of the ORDINANCE* inspects the stores and provisions of war in the custody of the storekeeper, and sees that they are ranged and placed in such order as is most proper for their preservation. He allows all bills of debt, and keeps a check upon all labourers and artificers work; sees that the stores received be good and serviceable, duly proved and marked, as they ought to be so, with the king's mark, taking to his assistance the rest of the officers and proof-masters. He has a salary of 700 l. *per annum*; and, in order to assist him in the business of his office, he has under him the proof master of England, and clerks, and other inferior officers.

*Clerk of the ORDINANCE*, an officer whose function is to record all orders and instructions given for the government of the office, all patents and grants, the names of all officers, clerks, artificers, gunners, labourers, &c. who enjoy those grants, or any other fee for the same: to draw all estimates for provisions and supplies to be made, and all letters, instructions, commissions, deputations, and contracts for his Majesty's service: to make all bills of imprest and debentures, for the payment and satisfaction of work done and provisions received in the said office; and all quarter books for the salaries and allowances of all officers, clerks, &c. belonging to the office; and to keep journals and ledgers of the receipts and returns of his Majesty's stores, to serve as a check between the two accountants of the office, the one for money, and the other for stores. He has 500 l. a year salary, and 100 l. a year more for being a check on the storekeeper. In his office he has a number of clerks, under clerks, and ledger-keepers, who have all fixed salaries.

*Storekeeper of the ORDINANCE* takes into his custody all his Majesty's ordinance, munitions and stores belonging thereto, and indents and puts them in legal security, after they have been surveyed by the surveyor-general, any part of which he must not deliver without a warrant signed by the proper officers; nor must he receive back any stores formerly issued till they have been reviewed by the surveyor, and registered by the clerk of the ordinance in the book of remains; and he must take care that whatever is under his custody be kept safe, and in such readiness as to be fit for service upon the most peremptory demand. He has a salary of 400 l. a-year; and in this office he has several clerks at fixed salaries, for the dispatch of business.

*Clerk of the Deliveries of the ORDINANCE* draws all orders for delivery of any stores, and sees them duly executed; charges by indenture the particular receiver of the stores delivered; and in order to discharge the storekeeper, registers the copies of all warrants for the deliveries, as well as the proportions delivered. He has a salary of 400 l. *per annum*, and has several clerks in his office at fixed salaries, for the dispatch of business.

*Treasurer and Paymaster of the ORDINANCE* receives and pays all monies, both salaries and debentures, in and belonging to this office. He has a salary of 500 l. *per annum*. In his office are several clerks, ordinary and extraordinary, for the dispatch of business.

*Office of ORDINANCE*. Besides the principal officers already mentioned, there belongs to this office two proof-masters, who have 20 l. a-year each; a clerk of the works, who has 120 l. a year; a purveyor for the land, who has 100 l. a-year, and a purveyor for the sea, who has 40 l. a-year; an architect, who has 120 l. a-year; an astronomical observer, who has 100 l. a year, and other officers. The other part of this office, which is termed the military branch of the ordinance, is a chief engineer, who has under him two directors, four sub-directors, with an unlimited number of engineers in ordinary, engineers extraordinary, sub-engineers, and practitioner engineers.

*ORDINANCE Bills*, commonly called *ordnance debentures*, are bills issued by the board of ordinance on the treasurer of that office, for the payment of stores, &c. These are not payable at any certain time, and do not bear any interest, so that the discount upon them is often very high; but they are seldom much above two years in arrears.

ORDONNANCE, in architecture, is the composition of a building, and the disposition of its parts, both with regard to the whole and to one another; or, as Mr Evelyn expresses it, determining the measure of what is assigned to the several apartments. Thus ordonnance is the judicious contrivance of the plan or mould: as when the court, hall, lodgings, &c. are neither too large nor too small, but the court affords convenient light to the apartments about it; the hall is of fit capacity to receive company; and the bed-chamber, &c. of a proper size. When these divisions are either too great or too small, with respect to the whole, as where there is a large court to a little house, or a small hall to a magnificent palace, the fault is in the ordonnance. See ARCHITECTURE.

ORDONNANCE, in painting, is used for the disposition of the parts of a picture, either with regard to the whole piece, or to the several parts, as the groups, masses, contrasts, &c. See PAINTING.

ORDOVICES, ancient Britons, of whom we have the following account in Henry's History of Great Britain. They lived "in that country which is now called North Wales, and contains the counties of Montgomery, Merioneth, Caernarvon, Denbigh, and Flint. These Ordovices, or (as they are called by Tacitus) Ordeuices, are supposed to have been originally of the same tribe or nation with the Huicii of Warwickshire, who were under some kind of subjection to the Cornavii; but the Huicii of North Wales, being a free and independent people, were called Ordh Huici, or the free Huici. When they were invaded by the Romans, they showed a spirit worthy of their name, and fought with great bravery in defence of their freedom and independency. Though they received a great defeat from the Roman general Ostorius, in conjunction with the Silures, they maintained the war for a considerable time, until they were finally subdued with great slaughter, by the renowned Agricola. It was probably owing to the nature of the country, and to the vicinity of Diva, now Chester, where a whole legion was quartered, that the Romans had so few towns or stations in the territories of the Ordovices. Mediolanum, which is mentioned by Ptolemy, was the capital of the nation, and was probably situated at Maywood, in Montgomeryshire. It was a place of some consideration in the Roman times,

Ore  
||  
Orestes.

but afterwards quite demolished by Edwin, king of Northumberland. Besides this, the Romans had a few other towns in this country; at Segontium, now Caernarvon; Conovium, now Conway; and Varæ, now Bodvay, which are all mentioned in the eleventh journey of Antoninus. The country of the Ordovices was comprehended in the Roman province which was called *Britannia Secunda*."

ORE, in natural history, the compound mineral glebe, earth, stone, or other substance, which is sufficiently rich in metallic particles to be worth the while of purification, and by this means of separating the metal from it, whether gold, silver, copper, &c. See METALLURGY, Part ii. sect. 2, p. 427, &c.; and sect. 4, p. 431, &c.; and Part i. sect. 1. &c. p. 432, &c. See also MINERALOGY, Part i. sect. 2. p. 61, &c.

ORELLANA (Francis), the first European, as is commonly thought, who discovered the river of the Amazons. In 1539, he embarked near Quito, upon the river Coca, which farther down takes the name of Napo. From this he fell into another larger river; and, leaving himself entirely to the direction of the current, he arrived at Cape North, on the coast of Guiana, after sailing nearly 1800 leagues. Orellana perished ten years after, with three vessels which had been entrusted to him in Spain, without being able to find again the mouth of this river. In sailing down the river he met with some armed women, against whom an Indian cacique had told him to be on his guard, and he thence named it *the river of the Amazons*.

ORENSE, an ancient town of Spain, in the kingdom of Galicia, with a bishop's see. It is famous for its hot-baths; and is seated at the foot of a mountain, on the river Minho, over which there is a handsome bridge of one arch. W. Long. 7. 27. N. Lat. 42. 16.

ORESTES, in ancient history, a son of Agamemnon and Clytemnestra. When his father was cruelly murdered by Clytemnestra and Ægisthus, young Orestes was saved from his mother's dagger by means of his sister Electra, called by Homer *Laodicea*, having been privately conveyed to the house of Strophius, who was king of Phocis, and who had married a sister of Agamemnon. He was tenderly treated by Strophius, who carefully educated him with his son Pylades. The two young princes soon became acquainted, and from their familiarity arose the most inviolable attachment and friendship. When Orestes came to years of discretion, he visited Mycenæ, and avenged his father's death by assassinating his mother Clytemnestra and her adulterer Ægisthus. Various accounts are given of the way in which these murders were committed. After their commission, however, he was acknowledged king of Mycenæ; but being tormented by the furies, a punishment which the ancients always thought followed parricide, he exiled himself to Argos, where he was still pursued by the avengeful goddesses. Apollo, however, purified him, and he was acquitted by the unanimous opinion of the Areopagus, whom Minerva herself instituted on this occasion, according to the narration of the poet Æschylus, who flatters the Athenians in his tragical story, by representing them as passing judgment even upon the gods themselves. According to Pausanias, Orestes was purified of the murder, not at Delphi, but at Trœzene,

where still was seen a large stone at the entrance of Diana's temple, upon which the ceremonies of purification had been performed by nine of the principal citizens of the place. There was also at Megalopolis, in Arcadia, a temple dedicated to the furies near which Orestes cut off one of his fingers with his teeth in a fit of insanity. These different traditions are confuted by Euripides, who says that Orestes, after the murder of his mother, consulted the oracle of Apollo at Delphi, where he was informed that nothing could deliver him from the persecutions of the furies, if he did not bring into Greece Diana's statue, which was in the Taurica Chersonesus, and which as it is reported by some, had fallen down from heaven. This was an arduous enterprize. The king of Chersonesus always sacrificed on the altars of the goddesses all such as entered the borders of his country. Orestes and his friend were therefore both carried before Thoas the king of the place, and they were doomed to be sacrificed. Iphigenia, Orestes's sister, was then priestess of Diana's temple, and it was her office to immolate these strangers. The intelligence that they were Grecians delayed the preparations, and Iphigenia was anxious to learn something about a country which had given her birth. She even interested herself in their misfortunes, and offered to spare the life of one of them, provided he would convey letters to Greece from her hand. This was a difficult trial; never was friendship more truly displayed according to the words of Ovid, *ex Pont. 3. el. 2.*

Orestes.

*Ire jult Pylades curum moriturus Orestem,  
Hæc negat; inque vicem pugnat uterque mori.*

At last, however, Pylades gave way to the pressing intreaties of his friend, and consented to carry the letters of Iphigenia to Greece. These were addressed to Orestes himself; and therefore these circumstances soon led to a discovery of the connections of the priestess with the man whom she was going to immolate. Iphigenia was convinced that he was her brother Orestes; and when the cause of their journey had been explained, she herself resolved with the two friends to fly from Chersonesus, and to carry away the statue of Diana. Their flight was discovered, and Thoas prepared to pursue them; but Minerva interfered, and told him that all had been done by the will and with the approbation of the gods. Some imagine that Orestes came to Capadocia from Chersonesus, and that there he left the statue of Diana at Comana. Others contradict this tradition; and Pausanias thinks that the statue of Diana's Orthia was the same as that which had been carried away from the Chersonesus. Some again suppose that Orestes brought it to Aricia in Italy, where Diana's worship was established. It was after this that Orestes ascended the throne of Argos, where he reigned in perfect security, married Hermoine the daughter of Menelaus, and gave his sister to his friend Pylades. The marriage of Orestes with Hermione is also a matter of dispute among the ancients. All are agreed that she had been promised to the son of Agamemnon; but Menelaus had married her to Neoptolemus the son of Achille, who had shown himself to truly interested in his cause during the Trojan war. The marriage of Hermione with Neoptolemus displeased Orestes; he remembered that she

Orfa,  
Orford.

she had been early promised to him; he was therefore determined to recover her by force or artifice. This he did by procuring the assassination of Neoptolemus. According to Ovid's epistle of Hermione to Orestes, Hermione had always been faithful to her first lover, and even it was by her persuasions that Orestes removed her from the house of Neoptolemus, for she was dissatisfied with the partiality of Neoptolemus for Andromache, and her attachment for Orestes was increased. There are, indeed, various opinions likewise about this: he, however, certainly managed to secure her affections, and retired to his kingdom of Argos. His old age was crowned with peace and security, and he died in the 90th year of his age, leaving his throne to his son Tisamenes by Hermione. Three years after the Heraclidae recovered the Peloponnese, and banished the descendants of Menelaus from the throne of Argos. Orestes died in Arcadia, as to be say, by the bite of a serpent; and the Lacedemonians, who had become his subjects at the death of Menelaus, were directed by an oracle to bring his bones to Sparta. They were some time after discovered at Tegea, and his stature appeared to be seven cubits, according to the traditions mentioned by Herodotus and others. The friendship of Orestes and of Pylades became proverbial; and the two friends received divine honours among the Scythians, and were worshipped in temples.

ORFA, a considerable town of Diarbek in Asia, very pleasantly situated, pretty large, and well fortified. It formerly belonged to Persia; but is now in the Turkish dominions, and is a place of very good trade. It has a stately castle standing on a hill which makes a great show at a distance. They pretend to show the well where Rachel watered her father's camels when Jacob met her, and they call it *Abraham's well*. E. Long. 37. 45. N. Lat. 36. 20.

ORFORD, a town of Suffolk in England, 88 miles from London, situated between two channels where the river Ore, after having joined the Ald, falls into the sea. It was once a large populous town, with a castle: of which, and of a nunnery near the quay, there are still some ruins. The towers of the castle and its church are a sea-mark for colliers, coasters, and ships that come from Holland. There is a light-house at Orford-Nesse, which is also of great use to seamen, and is a shelter for them when the north-east wind blows hard upon the shore. The town was incorporated by Henry III, has a mayor, 18 portmen, 12 chief burghesses, a recorder, a town clerk, and two sergeants at mace. Though it sent members to parliament in the 26th of Edward I, yet it had no more elections till the reign of Edward IV. It still sends two members to parliament, and has the title of an *incorporated town*. There are still remaining the ruins of an holy house where the seamen's wives used to pray for the safety of their husbands. The town is now very mean, and no one contends for an interest in it, but such as want to make themselves a merit in the choice of the two members it returns to parliament. It has indeed, by the withdrawing of the sea, been deprived of its chief advantage, for it now deserves not the name of a harbour. It had the honour to give title of earl to the brave admiral Russell, which, after being many years extinct, was revived in the person

of Sir Robert Walpole, whose grandson now enjoys it. E. Long. 1. 33. N. Lat. 52. 15.

ORGAGNA (Andrea), an excellent Italian painter, was born at Florence in 1329. In his youth he learned sculpture; he was also a poet and an architect. He had a fruitful genius and his manner resembled that of the other painters of his time. Most of his works are at Pisa. The most admired of them is his picture of the Last Judgment, in which he painted his friends among the blessed, and his foes in hell. He died in 1389.

ORGAL, among dyers, denotes the lees of wine dried.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation in which sense the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called *organs*.

ORGAN, in music, denotes the largest and most harmonious of all wind instruments; on which account it is called the *organ opulentum*, the instrument by way of excellence; chiefly used for playing a thorough bass, with accompaniments.

That organs are the invention of remote antiquity has been argued and seems now to be generally allowed: but the particular time and country in which the discovery was made appears to be lost amidst the ruins of time. In ancient authors there are a variety of passages where mention is made of the organ, but it is at least possible that an instrument is meant very different from that which now goes by the same name. From St Augustine's commentary on the 4th verse of the 150th psalm we learn, that the Greeks had another name for these instruments in which bellows were employed; that the name *organ* was appropriated to this particular instrument merely from the usage of the Latin tongue; and that it was indifferently given to all instruments used to accompany the voice in concert. We mention this, not because we doubt of the antiquity of the organ, but merely to show that the time of its invention cannot be determined by the era of the authors where its name occurs. As the following observations, extracted from a periodical work

Gent. Mag.

which has long been in deserved esteem with the public, are intended to ascertain its early use, we submit them, without commentary, to the judgment of our readers. Cassiodorus has described our organ in a few words, lib. 1. Epist. 45. Praising that art, which makes *Organa extraneis modis insonare, et peregrini flatibus compleri, ut musica possit orare cantare*. And the emperor Julian has given an exact description of it in an epigram, which may be found in the *Anthologia* b. i. ch. 86. In his time these instruments were in such request, that Ammianus Marcellinus, b. xiv. ch. 6. complains that they occasioned the study of the sciences to be abandoned. However, those musical instruments whose melody is produced by wind, had been known at Rome long before. Witness that agreeable poem of Capa, which for its elegance has been ascribed to Virgil; where we find that the musician introduces the wind into her pipes by means of a pair of bellows, which he holds under her arm and blows. In the hydraulic organ, the water moves the air, instead of the bellows. Cornelius Severus, in his *Aena*, has given a most exact description.

Orgagna  
Organ.

**Organ.** description of it (A). And though there were two kinds of hydraulic and pneumatic instruments, the first of which played by the inspiration and action of bellows, and the others by the action of water, it is certain nevertheless, that both of them were pneumatic, being inspired by the wind. And Heron of Alexandria, in his Pneumatics, has treated of hydraulics as belonging to pneumatics. This Heron lived in the time of Ptolemy Euergetes, king of Egypt. When Suetonius says, that Nero *Organa hydraulica novi et ignoti generis circumduxit*, he did not mean that they were unknown at Rome before Nero, but that those of Nero were of a new construction. Those were the hydraulics of a new fabric, which he exhibited to the people at the public games, as Suetonius relates a little after. Heliogabalus, one of the worthy successors of Nero, like him was fond of these hydraulics; and Alexander Severus, his cousin and successor, had the same inclination. Claudian, who lived some time after, has left us this elegant description of them;

*Et qui magni levi detrudens murmura tactu  
Innumeras voces segetis modatur æne;  
Intonet erranti digito penitusque trabali  
Vestæ laborantes in carmina concitat undas.*

This very construction which is observed in the pipes of an organ, gradually decreasing in magnitude, has been represented in an epigram of Optatianus Porphyrius who lived in the time of Constantine. This epigram, which is quoted in Pithon's collection of ancient epigrams, is composed of verses of an unequal length, successively increasing. This corresponds with those words of the old scholiast on Juvenal, sat. 8. ver. 270. *Tunicæ Galli utuntur in sacris in modum organæ utrinque decrescentibus virgulis purpureis.*

On the whole, then, the antiquity of organs, or of instruments of a very similar nature, can scarcely be disputed; but nothing very particular respecting the time, place, or manner, of the invention can possibly be determined from those incidental observations which occur in the writings of the ancients (B). It appears indeed to have been borrowed by the Latins from the Greeks, but not to have been in general use till the eighth century: and it has been affirmed, that, in France, it was not known till the time of Louis the Debonair i. e. A. D. 815, when an Italian priest taught the use and construction of it, which he himself had learned at Constantinople. By some, however, it has been carried as far back as Charlemagne, and by others as far as Pepin. Bellarmine says that the organ began to be used in the service of the church about the year 660, as Plantina relates out of the Pontifical; for when Pope Vitalian reformed the singing of the Roman church, he added to it organs in order to support and embellish it. Ammonius thinks, however, that this happened after the year 820, in the time of Louis the Pious. Perhaps the learned Bingham is our surest guide in determining this point. He positively asserts † that there were no such things as organs in use in the ancient church; and that though church music was as old as the apostles, instrumental music was not so. He also says that it was the general opinion of the learned in his days, that organs were not introduced into churches till after the time of Thomas Aquinas, A. D. 1250; and for this opinion, as far as the authority of Aquinas will go, we have a positive proof; for in his sums we find these words. "Our church does not use musical instruments, as harps, and psalteries, to praise God withal, that she may not seem to Judaize (c)." From

**Organ.**

† ORIGENES SACRÆ.

(A) Which is thus translated by Mr Jabez Hughes:

As in an organ\*, first the rushing air  
A mass of waters does before it bear;  
And then the waters, in their turn we find  
Drive through the hollow pipes the vanquish'd wind;  
Which strongly from its strait confinement sent,  
Comes loudly rattling through the narrow vent:  
Still as the waters press, the spirits sound,  
And spread the building symphony around.  
So air and water meet, &c.

It is by no means certain that Cornelius Severus was the author of this poem, though it is published under his name by Le Clerc. Seneca's authority, on which the younger Scaliger founds his opinion, enforces no such conclusion. He only says, that "Severus was not discouraged from writing on this subject, by its having been already treated by Ovid and Virgil. Barthius, in his notes on Claudian, refers it to Manilius, and in his *Adversaria* to some Christian writer. By others it has been ascribed to Virgil, and by Scaliger, the father, to Quintilius Varus. But though it is less clear and methodical than Virgil; and though it has been much mutilated by time, it certainly was penned by a masterly and truly poetical hand.

(B) Vitruvius describes an organ in his 10th book, and St Jerome mentions one with 12 pair of bellows which might be heard a thousand paces, or a mile; and another at Jerusalem, which might be heard at the Mount of Olives.

(C) The lawfulness of using organs in churches, has, however, been ably defended by an appeal to the use which the Jews made of instruments of music in divine service; and with much reason; for were the use criminal in us, as was asserted by many well meaning men of the last century, and as it is still thought by some in this, it would unquestionably have been equally unlawful for the Jews. The Christians, in Aquinas's time, however, acted wisely in avoiding the use of them, if by so doing they would have given offence to their weaker

\* Organon  
Hydraulic.  
icon.

Organ.  
\* Bingham  
ubi supra.

From hence it has reasonably been concluded, particularly by the learned Gregory \*, that they were not used in churches in his time. Mr Wharton has also observed that *Marinus Sanutus* (who flourished A. D. 1290) first introduced wind organs into churches; from this circumstance he derived the name *Torcellus*, the name for organ in the Italian language. About this same time Durandus in his *Rationale* speaks of them as generally received in the church; and he, in Mr Gregory's opinion, is the first author who takes notice of it. These authorities are strong, and the opinions founded on them by the learned render them still more convincing; it appears, however, from the testimony of Gervas the monk of Canterbury, who flourished A. D. 1200, that organs were introduced upwards of 100 years even before that time; for in his descriptions of Lanfranc's church, as it was before the fire in 1174, he has these words, "*Crux astralis supra fornem organa gestare solebat.*" We do not say that this invalidates the reasoning of the learned Bingham; of that our readers are to judge, and in forming their judgments they will be determined by the credit of the testimonies which are here opposed to each other. If we suppose that of Gervas the strongest, and in opposition to the other conclude from it, that organs were introduced into England long before 13th century, it will give some countenance to an opinion which prevails pretty generally, viz. that in Italy, Germany, and England, they became frequent about the 10th century. See Music, n° 19. But however we are disposed to determine this matter (which in itself is but of little consequence), it is certain that the use of the organ was very common in the latter ages of the church, and the propriety of it was undisputed. In the last century, however, during the civil wars, organs were removed from the churches in England; and so generally reprobated, that at the Restoration, there could scarce be found either organists, organ builders, or fingers (D).

The organs in Germany (says Dr Burney in magnitude, and the organists in abilities, seem unrivalled in any other part of Europe, particularly in the use of pedals. In Marpurgh's Essays, vol. iii. there is a minute account of a variety of organs in Germany; of all which the longest pipe of the manuals is 16 feet long, and of the pedals 32. One of the largest organs in Germany, but which Marpurgh has omitted in his list, is at Gorlitz in Upper Lusatia. It would be to no purpose to enlarge our article with a more minute account of the state of organic music in different parts of the world: in various parts of the article Music, observations connected with this subject will be found, and to that we must refer. We may particularly mark, for the perusal of those who wish for further information on this subject, in addition to

n° 19. above referred to, several passages of the article Music, beginning at p. 492. We need scarcely refer to the life of Handel, which all ours readers who are fond of music of any kind, particularly sacred, have undoubtedly perused.

The church organ consists of two parts: the main-body, called the *great organ*; and the positive or *little organ*, which forms a small case or buffet, commonly placed before the great organ. The size of an organ is generally expressed by the length of its largest pipe: thus they say, an organ of 8, 16, 32, feet, &c. The organ in the cathedral church at Ulm in Germany is 93 feet high and 28 broad: its largest pipe is 13 inches diameter, and it has 16 pair of bellows.

The several parts of the church organ are as follow. HH is the sound-board: which is composed of two parts, the upper board or cover HHH, and the under board HI, which is much thicker than the other; each of these consists of several planks laid with their edges to each other, and joined very close together. In the under side of the lower board there are made several channels, which run in the direction LL, MM, &c. and are continued as far as there are stops in the organ, and come almost to the edge HK. These channels are covered over very close with parchment or leather all the way, except a hole that is commonly at the fore-end next HK, upon which a valve or puff is placed. These channels are called *partitions*. When this valve or flap is shut, it keeps out the air, and admits it when open. On the upper side of the lower board there are likewise cut several broad square channels, lying cross the former, but not so deep as to reach them; these lie in the direction LN, PQ, &c. To fit these channels, there are the same number of wooden sliders or registers *f, f, f*, &c. running the whole length; and these may be drawn out or thrust in at pleasure. The number of these is the same as that of the stops in the organ.

IKKK is the wind-chest, which is a square box fitted close to the under side of the lower board, and made air-tight, so that no air can get out but what, goes through the valves along the partitions.

VV are the valves or puffs which open into the wind-chest: they are all inclosed in it, and may be placed in any part of it, as occasion shall require. One of these valves, with the spring that shuts it, and the wire that opens it, is represented by fig. 2.

C, D, E, F, &c. are the keys on which the fingers are placed when the organ is played: these keys lie over the horizontal bar of wood W, in which are stuck an equal number of wire-pins *z, z*, on which keys are fixed; and the keys move up and down on the bar, as on a centre. There is another bar, against which the keys fall when put down, and which is here marked 3: on this also are several wires, which go through the keys, to guide them; and on this bar a lift is fastened

Organ.

fig. 1.

weaker brethren. For though they are highly ornamental, and in some churches may be productive of good effects, yet the use of them is far from being essential, and may be easily dispensed with.

(D) Organs have never yet been used in the establishment of Scotland, since that became Presbyterian; but they are used in Holland, where that form of church government also obtains. Bishop Horne, in a sermon, which he preached at the opening of the new organ at Canterbury in 1784, says that he believes some Presbyterian dissenters in England have adopted it in their places of worship. See his Sermon, page 8.

Organ. fastened to hinder the keys from knocking against the wood.

The keys are made to communicate with the valves several ways, as we shall now describe. First, *s, s, s*, are the key-rollers, moving on the pivots *t, t*: these rollers lie horizontally, one above another, and are of such a length as to reach from the valve to the key: *a, a, a*, are arms or levers fixed to the key-rollers: *w, w*, the valve-wires fixed to the arms *a, a*, and to the valves *V*, and go through the holes *b, b*, in the bottom of the wind-chest: *b, b, b*, are likewise arms fixed to the key-rollers: *d, d, d*, the key-wires, fixed to the arms *b, b*, and to the keys *C, D, E*. Now, when the end of any one of the keys *C, D, E*, is put down, it pulls down the arm *b*, by the wire *d*, which turns about the roller *s* with the arm *a*, that pulls down the wire *w*, which opens the valve that is shut by the spring as soon as the pressure is taken off the key. In this construction there must be a worm spring fastened to the key, and to the bar *W* on the further side, to keep down the end *s* of the key.

Another method of opening the valves is thus: *x, y*, *x, y*, are slender levers, moveable on the centres *1, 1*; *5 x, 5 x*, are wires going from the further ends of the keys to the ends *x* of the levers; *yV, yV*, are other wires, reaching from the ends *y* of the levers, through the holes *b*, to the valves *V*. So that putting down the key *C, D*, &c. raises the end *s*, which thrusts up the end *x* of the lever, by the wire *5 x*: this depresses the end *y* of the lever, which pulls down the wire *yV*, and opens the valve *V*.

A third way of opening the valves is this; At the end of the key *b*, is a lever *8, 9*, moving in the centre *7*. This makes, with the key a compound lever. From the end *9*, a wire goes to the valve. Now the putting down the end *6* of the key, raises the end *8*, which depresses the end *9*, of the lever *8, 9*, pulls down the wire, and opens the valve. There is only one of these drawn in the scheme, and but a few of the others, to avoid confusion.

*R, R*, are the rollers, to move the sliders, by help of the arms *cf, cf*, which are fixed horizontally in these rollers; *ke, ke*, are also levers fixed in the rollers; *le, le*, are the handles which lie horizontally, and pass through the holes *ll*; they are fastened to the lever *ke*, being moveable about a joint at *e*.

Now, any handle *lp*, being drawn out, pulls the end *e* towards *l*, which turns about *R, k*, along with the arm *cf*; and the end *f* pulls out the slider *fg*; and when *p* is thrust in, the arm *cf* likewise thrusts in the slider *fg*.

Upon the several rows of holes which appear on the top of the upper board, there are set up an equal number of rows of pipes. The pipes of an organ are of two kinds; the one has a mouth like a flute, the other with reeds. The first, called *pipes of mutation*, consist, (1.) of a foot *AABB* (fig. 3), which is a hollow cone, that receives the wind that is to sound the pipe: (2.) To this foot is fastened the body of the pipe *BBDD*. Between the foot and the body of the pipe is a diaphragm or partition *FEF*, that has a long out narrow aperture by which the wind comes out; over this aperture is the mouth *BBC*, whose upper lip *C*, being level, cuts the wind as it comes out.

The pipes are of pewter, of lead mixed with a twelfth part of tin, and of wood. Those of pewter are always open at their extremities; their diameter is very small, and their sound very clear and shrill. Those of lead mixed with tin are larger; the shortest are open, the longest quite stopped; those of a mean size are partly stopped, and have beside a little ear on each side of the mouth, to be drawn closer or set further asunder, in order to raise or lower the sound. The wooden pipes are square, and their extremity is stopped with a valve or tampion of leather. The found of the wooden and leaden pipes is very soft; the large ones stopped are commonly of wood, the small ones of lead. The longest pipes give the gravest sound, and the shortest the most acute: their lengths and widths are determined by a fixed proportion to their sounds; and their divisions are regulated by a rule, which is called the *diapason*. The longest has commonly 16 feet; but in very large organs it has 32 feet. The pedal tubes are always open though made of wood and of lead. Whatever note any open pipe sounds, when its mouth is stopped it will sound an octave lower; and a pipe of twice its capacity will like wise sound an octave lower.

A reed-pipe consists of a foot *AABB* (fig. 4.), that carries the wind into the shallot or reed *CD*, which is a hollow demi cylinder fitted at its extremity *D*, into a sort of mould, by a wooden tampion *G*. The shallot is covered with a plate of copper *KKLL*, fitted at its extremity *II*, into the mould, by the same wooden tampion. Its other extremity *KK* is at liberty: so that the air entering the shallot makes it tremble or shake against the reed; and the longer that part of the tongue *IL*, which is at liberty, is made, the deeper is the sound. The mould *II*, that serves to fix the shallot or reed, the tongue, tampion, &c. serves also to stop the foot of the pipe, and make the wind go out wholly at the reed. Lastly, in the mould is soldered the tube *HH*, whose inward opening is a continuation of that of the reed: the form of this tube is different in different ranks of pipes. The degree of acuteness or gravity in the sound of a reed pipe, depends on the length of the tongue, and that of the pipe *CK*, taken from the extremity of the shallot to the extremity of the tube. The quantity or intention of the sound depends on the width of the reed, the tongue, and the tube; as also on the thickness of the tongue, the figure of the tube, and the quantity of wind. To diversify the sounds of the pipes, a valve is added to the port vent, which makes the wind go out in fits or shakes. In fig. 1. *X* represents a flute-pipe of wood, *Z* a flute pipe of metal, *Y* a trumpet-pipe of metal. The pipes, to prevent them from falling, pass through holes made in boards, placed upon the upper board.

The pipes are made to communicate with the wind-chest in the following manner. There are holes bored that go through the upper and lower boards, and through the slider (when it is drawn out), into the partition below; so that any pipes placed upon those holes will then communicate with the partition, which by its valve communicates with the wind-chest. But when the slider is thrust in, its holes do not answer to those in the upper and lower boards; therefore, the

Organ.

Organ. communication is stopped, so that no wind can get to the pipe.

Plate  
CCCLXVII.

To every large organ there must be at least two pair of bellows, which are marked in fig. 1. by TU, TU, OO, are the handles, moving upon the axis *nn*, *nn*. Each of these bellows consists of two boards, the lowest of which is immovable; and in this there is a valve *r*, opening inwards, and a tube leading to it called the *conveying tube*. There is also a hole in this under board, from which a tube leads to the port-vent, which is a square tube marked 4, rising upward, and inserted into the under side of the wind-chest at 2. In the tube leading to the port-vent, there is a valve that opens towards the port-vent, and suffers the air to go up the port-vent, but not to return. Now the handle O being pulled down, raises the upper board T, and the air enters through the valve *r*; and when the handle is let go, the weight of the upper board, which carries three or four pound to every square foot, continually descending, drives the air through the port-vent to the sound-board: and as the bellows work alternately, one pair is constantly descending, which occasions a continual blast through the port-vent. In chamber-organs there is but one pair of bellows; but they are formed of three boards, in the manner of a smith's bellows, and so have a continual blast. All the internal structure of the organ is concealed from the sight by the front of the instrument, which stands upon the part between the numbers 3 and 6 (fig. 1.)

In every organ the number of partitions LL, MM, &c. there are in the sound-board (fig. 1.) that of the valves VV, that of the rollers *s s*, or of the levers *xy* or 8 *g* and their wires, and that of the keys ABC, &c. must be always equal. Large organs have commonly four or five set of keys, beside those that belong to the pedals or large pipes, the stops to which are played by the feet: said to be the invention of Bernhard, a German, about the year 1400. These command certain pipes, which, to increase the harmony, are turned below the diapason. The keys of an organ are usually divided into four octaves; which are, the first sub-octave, second sub-octave, middle octave, and first octave. Each octave is divided into 12 stops or frets, of which seven are black and five white; the former mark the natural notes, and the latter the artificial notes, that is, flats and sharps. The number of keys, therefore, when there are four octaves, must be 48. Some organists add one or more stops to the first and second sub-octave. The pedals have two or three octaves, at the option of the organist; so that the number of stops is indeterminate. The keys are placed between GG (fig. 1.), but the scheme could not contain them all. There are also as many handles *l*, *l*, &c. rollers RR, &c. sliders *f*, *f*, &c. as there are stops upon the organ; and it must be observed, that between the sliders *f*, *f*, &c. there are as many sliders on the right hand, and the same number of handles and rollers, and other rows of pipes placed between LN, PQ, which could not be expressed in the figure.

The least pipes and partitions are placed toward the middle of the organ, and the greatest on the outside. The stops of an organ have various denominations, according to the sounds they are to produce; some of

VOL. XIII.

which are diapason, principal, fifteenth, twelfth, tearce, cornet, trumpet, French horn, vox humana, flute, bassoon, cremona, &c. The foreign organs, especially those of Germany, have many more; particularly that in the abbey church of Weingarten, a town in the upper Palatine, which has 66 stops, and contains no fewer than 6666 pipes. The organ at Haerlem is said to have 60 stops, many of them but little known to the English workmen, and distinguished by names that express the sound which they produce.

When this magnificent instrument is played, the handle O of the bellows is first put down, which raises the upper board T, and gives room for the air to enter by the valve *r*. Then the other handle O is put down: in the mean time the board T, belonging to the first handle, descending, and shutting the valve *r* drives the air through the other valve, up the port-vent, and into the wind-chest. Then drawing out any handle, as that of the flute-stop *pl*, which draws out the slider *fg*, all the pipes in the set LN are ready to play, as soon as the keys C, D, E, &c. are put down: therefore if the key D be put down, it opens the corresponding valve *m V*, through which the air enters into the pipe X, and makes it sound. In the same manner any other pipe in the set LN, will sound when its key is put down; but no pipe, in any other set, will sound till the slider be drawn out by its corresponding handle.

Among the modern improvements of the organ, the most remarkable are the swell and the tremblant: the former, invented by an English artist, consists in a number of pipes placed in a remote part of the instrument, and inclosed in a kind of box, which, being gradually opened by the pressure of the foot, increases the sound as the wind does the sound of a peal of bells, or suppresses it in like manner by the contrary action. The tremblant is a contrivance by means of a valve in the port-vent or passage from the wind-chest, to check the wind, and admit it only by starts; so that the notes seem to stammer, and the whole instrument to sob, in a manner very offensive to the ear. There is a tremblant in the organ at the German chapel in the Savoy. See Hawkin's *History of Music*, and Burney.

*Hydraulic ORGAN*, denotes a musical machine that plays by water instead of wind. Of these there are several in Italy, in the grottoes of vineyards. Ctesibius of Alexandria, who lived in the time of Ptolemy Euergetes, is said to have invented organs that played by compressing the air with water, as is still practised. Archimedes and Vitruvius have left us descriptions of the hydraulic organ.

In the cabinet of Queen Christiana is a beautiful and large medallion of Valentinian, on the reverse whereof is seen one of these hydraulic organs; with two men, one on the right, the other on the left, seeming to pump the water which plays it, and to listen to its sound. It has only eight pipes, placed on a round pedestal. The inscription is *PLACEA SPETRI*, if it be not wrong copied, which we suspect to be the case.

*ORGASM* *οργασμος*, denoting violence or turbulence; formed from *οργαω*, *turgeo*, "I swell," an ecstasy or impetuous desire of coition, occasioned by a turbulence of the seminal vessels, which are no longer able to restrain their contents. The ancients also ex-

Organ,  
Orgasmos.

Orgia  
||  
Oribasius.

tend orgasm to the other humours, and even excrements, which being accumulated, and coming to ferment, demand excretion. Quincy uses orgasm for an impetuous or too quick motion of the blood or spirits; whereby the muscles are distended with an uncommon force.

ORGIA, feasts and sacrifices in honour of Bacchus held every third year, and chiefly celebrated by wild distracted women, called *Bacche*. The chief solemnities were performed in the night, to conceal, perhaps their shocking impurities; and a mountain was generally chosen as the place of celebration. They were instituted by Orpheus; and from him are sometimes called *Orphica*. Authors are not agreed as to the derivation of the word; but if we consider the frantic proceedings of the Bacchanalians, *οργη*, *furor* bids fair for the true etymology. See BACCHANALIA.

*Orgia*, according to Servius, was a common name for all kinds of sacrifices among the Greeks, as *cereemonia* was amongst the Romans.

ORGUES, in the military art, are thick long pieces of wood, pointed at one end, and shod with iron, clear one of another; hanging each by a particular rope or cord, over the gateway of a strong place, perpendicularly, to be let fall in case of the approach of an enemy.

Orgues are preferable to herbes, or portcullices, because these may be either broke by a petard, or they may be stopped in their falling down: but a petard is useless against an orgue; for if it break, one or two of the pieces, they immediately fall down again and fill up the vacancy; or if they stop one or two of the pieces from falling, it is no hinderance to the rest; for being all separate, they have no dependence upon one another.

ORGUES, is also used for a machine composed of several harquebuls or musket barrels bound together, by means whereof several explosions are made at the same time. It is used to defend breaches and other places attacked.

ORGYA, *οργυια*, an ancient Grecian measure containing six feet.

— ORIBASIA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 47th order, *Stellata*. The corolla is small, tubulated, and monopetalous. The pericarpium is a globular berry, grooved longitudinally; is quinquelocular, and contains one seed. Of this there are six species, all natives of the warmer parts of America, *viz.* 1. *Officinalis*: the natives of Guiana make infusions of the leaves, and give them in cases of spasmodic asthma, 2. *Racemosa*. 3. *Violacea*. 4. *Lutea*. 5. *Paniculata*. 6. *Longiflora*. The habit of all these plants resembles those of *Psychotria*.

ORIBASUS, a celebrated physician greatly esteemed by the emperor Julian, in whose reign he flourished. He abridged the words of Galen, and of all the most respectable writers on physic. This was done

at the request of the emperor. He accompanied Julian into the east, but his skill proved ineffectual in attempting to cure the fatal wound which his benefactor had received. After Julian's death he fell into the hands of the barbarians.

ORICHALCUM, or AURICHALCUM, a metallic substance resembling gold in colour, but very inferior in value. It was well known to the old Romans, who often took advantage of its resemblance to gold; for some sacrilegious characters, who could not resist the temptation of taking gold from temples and other public places, chose to conceal their guilt by replacing it with orichalcum. It was thus Julius Cæsar acted when he robbed the capital of 3000 pound weight of gold; in which he was followed by Titellius, who despoiled the temples of their gifts and ornaments, and replaced them with this inferior metal. It has been a matter of dispute with philosophers and others, what this metal could be, or how it was procured or made: it is probable at least that it was greatly analogous to our brass, if not wholly the same with it. (See BRASS) The value of our brass is much less than that of gold, and the resemblance of brass to gold, in colour, is obvious at first sight. Both brass and gold, indeed are susceptible of a variety of shades of yellow; and if very pale brass be compared with gold, mixed with much copper, such as the foreign goldsmiths, especially, use in their toys, a disparity may be seen; but the nearness of the resemblance is sufficiently ascertained in general, from observing that substances gilded with brass, or as it is commonly called *Dutch leaf*, are not easily distinguished from such as are gilded with gold leaf.

The Romans were not only in possession of a metallic substance, called by them *orichalcum*, and resembling gold in colour, but they knew also the manner of making it, and the materials from which they made it were the very same from which we make brass. There are, indeed, authors of great repute who think very differently; and who consider the art of making brass as an invention wholly modern. Thus M. Cronstedt does not think it just to conclude from old coins and other antiquities, that it is evidently proved that the making of brass was known in the most ancient times; \* and the authors of the French \* *Mineral Encyclopédie* assure us, that our brass is a very recent invention (A). It appears, however, from Pliny's Nat. Hist. lib. xxxiv. § 2. and from the concurring testimony of other writers, that orichalcum was not a pure or original metal: but that its basis was copper, which the Romans changed into orichalcum by means of *cadmia*, a species of earth which they threw upon the copper, and which is absorbed. It has indeed been contended that the *cadmia* of Pliny was native arsenic, an opinion which scarcely merits confutation, but which must appear extremely groundless, when we reflect that it is impossible to make either brass or copper from arsenic, and that Pliny expressly calls it a *stone* from which brass was made. The testimony of Ambrose

Orichalcum.

(A) Art Orichalque—"The vessels here called brazen, after ancient authors, cannot have been of the materials our present brass is composed of; the art of making it is a modern discovery." See *Laughton's Hist. of Ancient Egypt*, p. 58.

Orichalcum.

Orichalcum  
||  
Organum.

brose bishop of Milan, in the 4th century and of Primasius bishop of Adrumetum, in Africa, in the 6th, and of Isidorus bishop of Seville in the 7th, all seem to confirm Pliny's account. We may therefore safely conclude that the Romans knew the method of making brass by mixing *cadmia* or *calamine* with copper; yet it is probable they were not the inventors of this art, but that they borrowed it from some other country. It appears from a variety of testimonies that brass was made in Asia, in a manner very similar to that at Rome; and a variety of places are mentioned in that extensive country where it was commonly made: and it is supposed by some that in India, as well as in other parts of Asia, it was made in the remotest ages.

With respect to orichalcum, it is generally supposed that there were two sorts of it, one factitious, the other natural. The factitious, whether we consider its qualities or composition, appears to have been the same with our brass. As to the natural orichalcum, there is no impossibility in supposing, that copper ore may be so intimately blended with an ore of zinc, or of some other metallic substance, that the compound, when smelted, may yield a mixed metal of a paler hue than copper, and resembling the colour of either gold or silver. In Du Halde's history of China, we meet with the following account of the Chinese white copper. "The most extraordinary copper is called *de-onz*, or white copper: it is white when dug out of the mine, and still more white within than without. It appears by a vast number of experiments made at Peking, that its colour is owing to no mixture; on the contrary all mixtures diminish its beauty; for, when it is rightly managed, it looks exactly like silver: and were there not a necessity of mixing a little *tutenag*, or some such metal with it, to soften it and prevent its brittleness, it would be so much the more extraordinary, as this sort of copper is perhaps to be met with nowhere but in China, and that only in the province of *Tun naa*.\*" Notwithstanding what is here said of the colour of this copper being owing to no mixture, it is certain that the Chinese white copper, as brought to us, is a mixed metal; so that the ore from which it is extracted must consist of various metallic substances, and from some such ore it is possible that the natural orichalcum, if ever it existed, may have been made. But notwithstanding that the existence of natural orichalcum cannot be shown to be impossible, yet there is some reason to doubt whether it ever had a real existence or not.

We know of no country in which it is found at present; nor was it any where found in the age of Pliny; nor does he seem to have known the country where it ever had been found. He admits, indeed, its having been formerly dug out of the earth; but it is remarkable that in the very passage where he is mentioning by name the countries most celebrated for the production of different kinds of copper, he only says in general, concerning orichalcum, that it had been found in other countries, without specifying any particular country. Plato acknowledges, that orichalcum was a thing only talked of even in his time; it was nowhere then to be met with, though in the island of Atlantis it had been formerly extracted from its mine. The Greeks were in possession of a metallic

substance, called *orichalcum*, before the foundation of Rome; for it is mentioned by Homer and by Hesiod, and by both of them in such a manner as shows that it was then held in great esteem. Other ancient writers have expressed themselves in similar terms of commendation; and it is principally from the circumstance of the high reputed value of orichalcum that authors are induced to suppose the ancient orichalcum to have been a natural substance, and very different from the factitious one in use at Rome, and probably in Asia, and which it has been shown was nothing different from our brass.

But this conclusion cannot be validly drawn from their encomiums upon it; for at whatever time the method of making it was first discovered, both its novelty and scarceness, joined to its utility, would enhance its value; at least there can be no absurdity in supposing, that when first introduced it was greatly prized, even though it be granted that it possessed no other properties than such as appertain to brass.

Respecting the etymology of the word there is great diversity of opinions. Those who write it *aurichalcum* think it is composed of the latin word *aurum*, "gold," and the Greek *χαλκος*, "brass or copper." The most general opinion is, however, that it is composed of *ορος*, "a mountain" and *χαλκος*, alluding perhaps to its being found in mountains or mountainous countries. The above account is chiefly extracted from a paper in the second volume of memoirs of the Literary and Philosophical Society of Manchester, written by the present bishop of Landaff, Dr Watson, and communicated by Dr Percival. To this paper then we refer our readers who desire a more copious account of it. To the above two etymological meanings of the word we shall subjoin the following, mentioned by the learned bishop, and which, in our opinion is equally well founded, and certainly as ingenious as the other two.

The Hebrew word *Or*, *Aur*, signifies light, fire, flame: the Latin terms *uro* "to burn," and *aurum* "gold," are derived from it, inasmuch as gold resembles the colour of flame: and hence it is not improbable, that orichalcum may be composed of an Hebrew and a Greek term, and that it is rightly rendered, *flame-coloured copper*. In confirmation of this it may be observed, that the Latin epithet *lucidum*, and the Greek one *φαιρος*, are both applied to orichalcum, by the ancients.

ORIFICE, the mouth or aperture of a tube, pipe, or other cavity.

ORIGANUM, ORIGANY, or *Marjoram*: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order, *Verticillatæ*. There is a strobilus or cone collecting the calyces together. The principal species are, two hardy perennials and an annual for the open ground, and five perennials for the green house: viz. 1. The vulgare, or wild pot-marjoram; 2. The heracleoticum, or winter sweet-marjoram. These are finely scented aromatics, excellent for culinary purposes, particularly for broths, soups, &c. they have likewise merit for medical uses, and for giving fragrance to ointments; so that the plants are proper both for kitchen and physic gardens, and may also be employed in the pleasure ground as plants of variety. 3. The marjorana, or annual sweet-

Orient  
Origen.

majoram is an aromatic of the highest fragrance, is admirable for kitchen use, and excellent for nosegays; so is proper both for the kitchen and pleasure garden, but more particularly for the former. It is often called *knotted marjoram*, from the flowers growing in close knotted-like heads. The following mostly assume an undershrubby growth; frequently with abiding stalks, if they have shelter here in winter. 4. The dictamnus, or dittany of Crete. 5. The sipyleum or origanum of mount Sipylus. 6. The creticum, or Cretan origany. 7. The smyrnæum, or Smyrna origany. 8. The Egyptianum, or Egyptian origany. All these eight species of origanum flower in July and August; the flowers are small, monopetalous, ringent, universally hermaphrodite, and collected into verticilli round the stalks; succeeded by ripe seed in autumn; though in this country the annual marjoram and the three green-house sorts seldom perfect seed well unless the autumn proves remarkably fine and warm: in default, however, of seed, the propagation of all the perennial sorts, both hardy and green-house kinds, is easily affected by slips of the roots, &c. And the seed of the annual sort is imported plentifully from France or Italy by the seed dealers.

ORIENT, a harbour of France, in the province of Bretagne, in the bottom of the bay of St Lewis. Since the year 1720, a handsome town has been built here, where the East India company have large magazines. The English attempted to become masters of it in 1746, but miscarried. W. Long. 3. 22. N. Lat. 47. 45.

ORIENTAL PHILOSOPHY. See PHILOSOPHY.

ORIGEN, one of the most celebrated ecclesiastical writers, greatest geniuses, and most learned men of the primitive church during the third century, was born at Alexandria in the year 185; and was surnamed *Adamantus*, either from his indefatigable application to study, or from the firmness he discovered amidst the torments he suffered for the faith. Leonidas his father trained him at home with great care, and made him apply to the study of the Holy Scriptures from his infancy, in which he made surprising progress. The son's inclination and turn suited exactly with the father's design; for he pursued his studies with a most extraordinary zeal and ardour; and, being endued with a quick apprehension and a strong imagination, did not content himself, with that sense which at first presented itself; but farther endeavoured to dive into mysterious and allegorical explanations of the sacred books. He would sometimes even puzzle his father, by too much soliciting him for recondite meanings; which obliged the good man to reprehend him a little,

Origen.

and withal to advise him not to attempt to penetrate too far in the study of the holy scriptures, but to content himself with their most clear, obvious, and natural sense. Hence it appears, how early he was seized with that *furor allegoricus*, as a learned modern calls it, that rage of expounding the scriptures allegorically, which grew afterwards even to be a distemper, and carried him to excesses which can never be excused (A). He had afterwards in philosophy Ammonius the celebrated Christian philosopher, and St Clement of Alexandria for his master in divinity. At 18 years of age he succeeded that great man in the office of catechist; an important employment, which consisted in teaching divinity, and expounding the scriptures. Leonidas his father had suffered martyrdom the year before during the persecution of Severus in 202; and Origen had shown such eagerness to follow his father to martyrdom, that his mother was obliged to hide his clothes to prevent his going abroad. Origen had a great concourse of auditors who attended his school, some of whom were of the faithful, and the others pagans. He confirmed and strengthened the first in their faith, and converted most of the others; and there were such a number of martyrs amongst his disciples, that it might be said, that he kept rather a school of martyrdom than of divinity. He taught the doctrines of Christianity to the girls and women as well as to the men; and taking in a too literal sense what Christ says of becoming voluntary eunuchs, castrated himself, to prevent his deserving or suffering scandal. He took a voyage to Rome in 211, in the beginning of Caracalla's reign, and under the pontificate of Zepherinus. At his return he published many works, by which he acquired an extraordinary reputation, that drew to him a great number of auditors. But Demetrius, bishop of Alexandria, conceiving a jealousy of him, endeavoured by various pretences to injure him. At length Origen went to Antioch, whither the empress Mammæa had sent for him to bear him discourse on the Christian religion. He did not however stay long there, but returned to Alexandria, where he continued to teach till the year 228, when he left that city, and travelled into Achaia. In that journey he went into Palestine, and was ordained by the bishops of that province at 42 years of age. His being ordained by foreign bishops without the permission of Demetrius, renewed that prelate's resentment against him; on which Origen hastily returned to Alexandria, to endeavour to mollify him; but Demetrius drove him from thence in 231, and caused him to be excommunicated, and even deposed in a council held in Egypt. Origen then retired to Caesarea

(A) He is the first Christian (whose notions on this subject have come down to us) who believed in the restitution of all things. This is the sixth distinguishing tenet; to which is added this singular notion, that as Christ had been crucified in this world to save mankind, he is to be crucified in the next to save the devils. The other obnoxious tenets of Origen are these five; viz. 1. That in the Trinity the Father is greater than the Son, and the Son than the Holy Ghost. 2. The pre-existence of souls, which Origen considered as sent into mortal bodies for the punishment of sins committed in a former state of being. 3. That the soul of Christ was united to the world before the incarnation. 4. That the sun, moon, and stars, &c. were animated and endowed with rational souls. 5. That after the resurrection, all bodies will be of a round figure. It is probable that the mystic theology of the modern Quakers and other sects is derived from Origen. See *Masbriem. Eccl. Hist.* vol. 1st.

**Origen.** rea in Palestine, where he raised a celebrated school, and had St-Gregory Thaumaturgus, and a great number of other persons who were illustrious for their virtue and learning, for his disciples. He afterwards travelled to Athens; and then, at the desire of Firmilianus, staid some time at Cæsarea in Cappadocia; whence he was invited into Arabia, to convince and bring back to the truth Beryllus bishop of Bostra, who maintained that the Word had no existence before his incarnation. Origen had the happiness to make him sensible of his mistake; and some years after was sent for into Arabia by an assembly of bishops, to dispute against the Arabians, who maintained that the souls of the dead remained in a state of insensibility till the general resurrection. At length the seventh persecution of the Christians began in the reign of Decius, and none were used with greater severity than Origen. He supported with incredible constancy the dreadful torments which the persecutors of the Christians invented against them; torments that were the more insupportable, as they were made to continue a long time, and as they took the greatest care to prevent his expiring in the midst of his tortures: but in the midst of the most excruciating torments, he discovered an heroic courage, and suffered nothing to escape him that was unworthy a disciple of Jesus Christ. He died at Tyre, in 254, aged 69. He was the author of a great number of excellent works. The principal of those which have been handed down to us are, 1. A Treatise against Celsus, of which Spencer has given a good edition in Greek and Latin, with notes: this learned treatise has been translated into French by Elias Bouhereau, a protestant minister, born at Rochelle. 2. A great number of Homilies, with Commentaries on the Holy Scriptures. 3. *Philocalia*, and several other treatises. 4. Fragments of his Hexaples, collected by father Montfaucon, in two volumes folio. Of all Origen's books, the loss of the Hexaples is most to be regretted. This work was thus named from its containing six columns; in the first of which was the Hebrew text of the Bible; in the second, the same text in Greek Characters; in the third, the Greek version of the Septuagint; in the fourth, that of Aquina; in the fifth, that of Symmachus; and in the sixth, Theodosian's Greek version. This admirable work gave the first hint for our Polyglot Bibles. 5. The book of Principles; of which we have only an incorrect Latin version. In all his writings he discovers a surprising degree of modesty, candour, and humility; a noble and sublime genius, profound learning, and vast erudition. His manners were extremely pure, and he had a warm zeal for spreading the truths and morals of the gospel.

Much has been written both for and against this celebrated father, both by his cotemporaries and others: he has indeed suffered great abuse, which he did not deserve, and which we shall not retail; contenting ourselves with the following account of his character by Dupin, and some remarks on it by Dr Jortin. "Origen (says Dupin) had very quick parts, a very strong and enlarged imagination; but he relied too much on the vivacity of his genius, and often lost himself, out of too great earnestness to fathom and subtilise every thing. He had a very happy invention, and a more happy delivery of what he invented:

but he had not that exactness in his inventions, nor that gracefulness of delivery, as might be wished. He carried on his works with so great ease, that he is said to have dictated to seven or eight persons at a time; and he was so ready in expressing himself, that he made the greatest part of his homilies extempore: upon which account his style was not very correct or coherent. He had a vast memory, but often trusted too much to it. He was a person of most profound learning: he particularly studied Plato's philosophy, and indeed was too much addicted to it for a Christian. He understood likewise the doctrines of other philosophers. He applied himself mightily to the study of human learning. He was neither ignorant of history nor mythology; and he had as great a knowledge in all the profane sciences, as those who studied nothing else. But he particularly excelled in the knowledge of the Holy Scriptures, which he learned all by heart; and that he might neglect nothing for attaining a right understanding of the letter thereof, he carefully examined all the versions of the Bible, and compared them all together with the Hebrew text, subjoining a literal commentary upon the most difficult places. He was not very well skilled in the Hebrew; yet he knew enough of it to understand it, and to observe the difference of the text and the translations. Nevertheless, he did not adhere to the literal explication of the Bible, but thought it necessary, for the sake of gaining it credit with the heathens, who despised its plainness and simplicity, and of rendering it more useful to the world, to give mystical and allegorical interpretations of every thing in it."

Dr Jortin tells us, "That Origen was very learned and ingenious, and indefatigably industrious. His whole life from his early years was spent in examining, teaching, and explaining the Scriptures; to which he joined the study of philosophy and of all polite literature. He was humble, modest, and patient under great injuries and cruel treatment, which he received from Christians and Pagans: for though he ever had a considerable number of friends and admirers, on account of his amiable qualities and useful accomplishments, he was persecuted and calumniated by men, who had neither his learning nor his virtue, degraded from the order of presbyters, driven from his home, and excommunicated by one Demetrius bishop of Alexandria, who envied him, says Eusebius, for the reputation which he had gained. His inquisitive genius, and his mixing philosophy with Christianity, led him perhaps into some learned singularities and ingenious reveries; but he was by temper far from dogmatizing in such points, from fomenting schisms, and setting up himself for the head of a party. He lived in times when Christians were not so shackled with systems and determinations, as they were afterwards, nor so much exposed to disingenuous and illiberal objections; and had more liberty to pursue their inquiries and to speak their mind.—He was ever extremely sober and exemplary, practising what he preached to others; and he lived and died poor, and destitute even of common conveniences. The most complete edition of his works is that of Father Delarue, a Benedictine, in Greek and Latin. The celebrated Montfaucon likewise published, in 2 vols folio, some remains and fragments of his *Hexapla*."

**Origen.**

Jortin's  
Remarks,

P. 234, 238

Origenians  
||  
Oriolus.

He ought not to be confounded with another ORIGEN, a Platonic philosopher, and the disciple and friend of Porphyry, who studied philosophy under Ammonius: perhaps this Origen was the founder of the ORIGENIANS.

ORIGENIANS (*Origeniani*), ancient heretics, who even surpassed the abominations of the Gnostics.

Epiphanius speaks of them as subsisting in his time; but their numbers, he says, were inconsiderable. He seems to fix their rise about the time of the great *Origen*; but does not say that they derived their name from him. On the contrary, he distinguishes them from the *Origenists*, whom he derives from *Origen Adamantius*; adding, indeed, that they first took their name from one *Origen*; by which he intimates, that it was not the great *Origen*. And St Augustine expressly asserts, that it was another. Their doctrines were shameful: they rejected marriage; they used several apocryphal books, as the acts of St Andrew, &c. and endeavoured to excuse their open crimes, by saying, that the Catholics did the same in private.

ORIGENISTS, in church-history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The Origenists maintained, that the souls of men had a pre-existent state: that they were holy intelligences, and had sinned in heaven before the body was created: that Christ is only the son of God by adoption; that he has been successively united with all the angelical natures, and has been a cherub, a seraph, and all the celestial virtues one after another; that, in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men; and that their punishment, and that of the damned, will continue only for a certain limited time.

ORIGINAL, a first draught or design of any thing, which serves as a model to be imitated or copied.

ORIGINAL Sin, the crime of eating the forbidden fruit, of which, it is said, all mankind are guilty at their conception, by the imputation of Adam's transgression; which is accounted for by supposing, that Adam, as he was to be the father, was also the federal head and representative, of the whole human race: and that, on his sinning, all that were to spring from him partook of his crimes. See THEOLOGY, &c.

ORIGUELA, a town of Spain in Valentia. It is seated between the mountains on the banks of the river Segura, in a place fortified by nature, and in a fertile plain, abounding in all things, especially corn. It is surrounded with pleasant gardens, and has an university and a bishop's see. It is defended by an old castle; and is the capital of a government independent of Valentia, whose jurisdiction extends 30 miles in length and 15 in breadth. W. Long. o. 56. N. Lat. 38. 22.

ORILLON, in fortification, is a small rounding of earth, faced with a wall; raised on the shoulder of those bastions that have casemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See FORTIFICATION, p. 364.

ORIOLE, or ORIOLE, in ornithology, a genus belonging to the order of picæ. The bill in this genus is straight, conic, very sharp-pointed; edges cultrated, inclining inwards; mandibles of equal length. No-

trils small, placed at the base of the bill, and partly covered. Tongue divided at the end. Toes, three forward, one backward; the middle joined near the base to the outmost one—These birds are inhabitants of America, except in a few instances; are a noisy, gregarious, frugivorous, granivorous, and voracious race, very numerous, and often have pensile nests. The several species (which are very numerous, for Mr Latham enumerates and describes 45) seem to be principally distinguished by their colour. We have given engravings of two of them, the sharp-tailed and Baltimore oriole.

Oriolus.

Plate  
cccxlx.

1. The sharp-tailed oriole is about the size of a lark. The bill is dusky; the crown is brown and cinerous; the cheeks are brown, bounded above and below with deep dull yellow. The throat is white; the breast, sides, thighs, and vent, are a dull pale yellow, spotted with brown; the belly is white; the back is varied with ash-colour, black and white; the wing-coverts are dusky, with ferruginous edges. The quills are also dusky; the tail consists of narrow sharp-pointed feathers, of a dusky colour tinged with olive, and obscurely barred; and the legs are pale brown.

The other species which we shall describe, is called the *Baltimore* bird by Catesby and Latham, *le Baltimore* by Buffon, the *oriolus Baltimore* by Linnæus, and the *Baltimore oriole* by Pennant, and is an inhabitant of North America; which country it quits before winter, and probably retires to Mexico, the xochitotl of Fernandez seeming to be of the same species. The head, throat, neck, and upper part of the back of the male, is described to be black; the lesser coverts of the wings orange; the greater black, tipped with white; the breast, belly, lower part of the back, and coverts of the tail, of a bright orange; the primaries dusky, edged with white; the two middle feathers of the tail black; the lower part of the same colour, the remaining part orange; and the legs black. The head and back of the female is orange, edged with pale brown; the coverts of the wings of the same colour, marked with a single bar of white; the under side of the body and coverts of the tail yellow; the tail dusky, edged with yellow. The length both of the male and female is seven inches.—This bird suspends its nest to the horizontal forks of the tulip and poplar trees, formed of the filaments of some tough plants, curiously woven, mixed with wool, and lined with hairs. It is of a pear shape, open at top, with a hole on the side through which the young discharge their excrements, and are fed. In some parts of North America, this species, from its brilliant colour, is called the *fiery hanging-nest*. It is named the *Baltimore bird* from its colours, resembling those in the arms of the late lord Baltimore, whose family were proprietors of Maryland.

There are several other species of the oriole, all inhabitants of North America. These, according to Mr Pennant's enumeration, are the white-backed, the bastard, the black, the brown-headed, the rusty, the white-headed, the Hudonian white-headed, the olive, the yellow-throated, the unalaschka, the sharp-tailed, and the red-wing. This last species is known in America by the name of the *red-winged starling* and the *swamp black-bird*. Although they appear at New York only from April to October, they probably continue through the whole year in the southern parts; at least,

Catesby

**Oriolus.** Catesby and Latham make no mention of their departure. They are seen at times in such prodigious flocks, as even to obscure the sky. They were esteemed the pest of the colonies, making most dreadful havock among the maize and other grain, both when new sown and when ripe. They are very bold, and not to be terrified by a gun; for notwithstanding the sportsman makes slaughter in a flock, the remainder will take a short flight, and settle again in the same field. The farmers sometimes attempt their destruction, by steeping the maize before they saw it in a decoction of white hellebore. The birds that eat this prepared corn, are seized with a vertigo, and fall down; which sometimes drives the rest away. This potion is particularly aimed at the purple grackles or purple jackdaw, which comforts in myriads with this species, as if in conspiracy against the labours of the husbandman. The fowler seldom fires among the flocks without killing some of each. They appear in greatest numbers in autumn, when they receive additions from the retired parts of the country, in order to prey on the ripened maize. Some of the colonies established a reward of three-pence a dozen for the extirpation of the jackdaws: and in New England, the intent was almost effected at the cost of the inhabitants; who discovered, at length, that Providence had not formed these seemingly destructive birds in vain. Notwithstanding they caused such havock among the grain, they made ample recompense, by clearing the ground of the noxious worms\* with which it abounds. As soon as the birds were destroyed, the reptiles had full leave to multiply: and the consequence was the total loss of the grass in 1749, when the New Englanders, too late repentants, were obliged to get their hay from Pennsylvania, and even from Great Britain.

\* The Caterpillar of the Bruchus Pisi, or Pease Beetle, in particular.

There is besides another oriole of this species, called the *Baylard Baltimore*: Its size is that of the true Baltimore, but it measures somewhat less in length; the bill is lead-coloured; the forehead and cheeks black mixed with yellow; the hind head and nape are olive grey, marked with a few spots of black; the upper part of the back is the same, but somewhat duller; the lower part of the back, the rump, fore part of the neck, breast, belly, sides, thighs, upper and lower tail-coverts, and under the wings, are orange-yellow, but brightest on the breast and tail coverts; the lesser wing-coverts are deep brown; the greater are the same, tipped with dirty yellowish white; the quills are brown, bordered on both edges with white; the two middle tail-feathers are olive, then blackish, marked at the end with a longitudinal yellowish spot; the next on each side are olive and black, confusedly mixed: and the four outer ones are of a yellowish olive: the legs and claws are bluish. They inhabit North America.

There seems to be great confusion and uncertainty in the true and bastard Baltimores and their females; most likely at last they may, the whole of them, turn out mere varieties of one single species, all of them perhaps referable to one or other sex of the true Baltimore, in the different stages of life.

It would be absurd and indeed impossible, without enlarging the article beyond all bounds, to describe each particular variety: we shall therefore refer those of our readers who wish for a more copious account,

to Mr Latham's *Synopsis of Birds*, where the whole genus is more minutely and more accurately described than any where else that we know.

**ORION**, in fabulous history, was the son of Jupiter, Neptune, and Mercury. For as these gods were visiting the earth, they entered the house of Hyrieus, a native of Tanagra, in Boeotia, under the character of benighted travellers, on account of his being famed for hospitality to strangers. Hyrieus treated them in the best manner in his power; and even killed an ox, the only one he had, for their entertainment. At which the gods were so pleased, that they offered the old man whatever he would ask; who letting them know that he desired nothing so much as a son, they, to gratify his wish, caused the ox's hide to be brought before them, in which, having deposited their urine, they bad him keep it under ground for nine months. He then dug for the skin, and found in it a beautiful child, whom he called *Orion ab urina*. The name was afterwards changed into Orion by the corruption of one letter, as Ovid observes; *Perdidi antiquum litera prima sonum*. Orion soon became conspicuous; and Diana took him among her attendants, and even became deeply enamoured of him. His gigantic stature, however, displeased CEnopion king of Chios, whose daughter Hero or Merope he requested in marriage: The king, not willing to deny him openly, promised to make him his son-in-law as soon as he delivered his island from wild-beasts. This task, which CEnopion supposed to be impracticable, was soon performed by Orion, who eagerly demanded his reward. CEnopion, on pretence of complying, intoxicated his illustrious guest, and put out his eyes on the sea-shore, where he had laid himself down to sleep. Orion found himself blind when he awoke. He went, directed by the sound to a neighbouring forge, where he placed one of the workmen on his back, and by his directions went to a place where the rising sun was seen with the greatest advantage. Here he turned his face towards the luminary; and, according to report, he immediately recovered his eye-sight, and hastened to punish the perfidious cruelty of CEnopion. Orion was reported to be an excellent workman in iron, and to have fabricated a subterraneous palace for Vulcan.

Aurora, whom Venus had inspired with love, carried him away into the island of Delos, that she might enjoy his company with greater security: but Diana, who was jealous of this, destroyed him with her arrows. Some say that Orion had provoked Diana's resentment, by offering violence to Opis, one of her female attendants: or, as others say, because he had attempted the virtue of the goddess herself. According to Ovid, Orion died of the bite of a scorpion, which the earth produced to punish his vanity, in boasting that no animal on earth could conquer him. Some say that Orion was son of Neptune and Euryale, and that he had received from his father the privilege and power of walking over the sea without wetting his feet. Others assert that he was a son of Terra, like the rest of the giants. He had married a nymph called *Sida*, before his connection with the family of CEnopion, but Sida was the cause of her own death, by boasting herself fairer than Juno. Diodorus says, that Orion was a celebrated hunter, superior to the rest of mankind, by his strength and uncommon stature.

He

Orion.

Orion.

He built the port of Zancle, and fortified the coast of Sicily against the frequent inundations of the sea by heaping a mound of earth called *Pelorum*, on which he built a temple to the gods of the sea. After death Orion was placed in heaven, where one of the constellations still bears his name. The constellation of Orion was placed near the feet of the bull. It was composed of 17 stars in the form of a man holding a sword; for which reason the poets often speak of Orion's sword. As the constellation of Orion, which rises about the 9th day of March, and sets about the 21st of June, is generally supposed to be accompanied at its rising with great rains and storms, it has acquired the epithet of *aquosus* given it by Virgil. Orion was buried in the island of Deles; and the monument which the people of Tanagra in Boeotia showed as containing his remains was nothing but a Cenotaph. The daughters of Orion distinguished themselves as much as their father; and when the oracle had declared that Boeotia should not be delivered from a dreadful pestilence before two of Jupiter's children were immolated on the altars, they joyfully accepted the offer, and voluntarily sacrificed themselves for the good of their country. Their names were Menippe and Metioche. They had been carefully educated by Diana; and Venus and Minerva had made them very rich and valuable presents. The deities of hell were struck with the patriotism of these two females; and instantly two stars were observed to arise from the earth, which still smoked with their blood, and they were placed in the heavens in the form of a crown. According to Ovid, their bodies were burned by the Thebans, and from their ashes arose two persons, whom the gods soon after changed into constellations.

ORION, in astronomy, one of the constellations of the southern hemisphere. The word is formed from

the Greek *ὄρεω*, "to make water;" the ancients supposing that it raised tempests at its rising and setting. The stars in the constellation Orion, in Ptolemy's catalogue are 37, in Tycho's 62, in the Britannic catalogue 80.

ORISTAGNI, an ancient town of the island of Sardinia, with an archbishop's see. It is pretty large and well fortified; but thinly inhabited, on account of the unhealthy air; it is seated on the western coast, in a bay of the same name, in E. Long. 8. 58. N. Lat. 39. 55.

ORIXA, a kingdom of Indostan, lying on the Gulph of Bengal. It is divided from the ancient kingdom of Golconda, by a ridge of mountains, the end of which runs a little way into the Sea. It is fertile in corn and cattle, and they have several good towns and harbours on the coast; there are also manufactures of different kinds carried on throughout the kingdom. The prince is a Gentoo, who pays to the Great Mogul a tribute to the amount of about 12,000l. yearly.

ORIXA, in botany: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking with those that are doubtful. The calyx is quadripartite: the petals are four, plain and lanceolated; the stigma lobular: the capsule and seeds unknown. Of this there are two species, *v. z.* 1. The frutescens; 2. Japonica, both natives of Japan.

ORKNEY ISLANDS, called *Orcades* by the ancients, certain islands on the north of Scotland (A), from which they are separated by a frith 20 miles in length and 20 in breadth.

As writing seems to have been unknown in the northern islands, during those periods which the antiquarian would call the most curious and important, the

Oristagni

Orkney.

(A) The northern isles of Scotland have been often mentioned by ancient authors, and called by different names from those they now go by; so that it is sometimes difficult to know which of them are meant. The ancient name, however, of the islands, which are the subject of this article, has never been disputed. The *Ebudæ*, it is agreed, are the modern Hebrides; and there is no doubt of the ancient *Orcades* being the same with the Orkneys. Of Thule, however, we are not so certain: and whether it means the Shetland isles, or Iceland, remains undetermined. Pythias, a Massilian, pretends to have visited these islands, and particularly Thule; But he does not mention the *Orcades*. The geographer Mela, who was contemporary with the emperor Claudius, is the next writer who describes the northern islands. Of the Orkneys he gives a remarkably just account, and says there were thirty in number, with narrow channels between them; but he is less accurate with respect to the rest. Pliny the Elder is the third who mentions the northern islands. He makes the number of the Orkneys to be forty, and of the Hebrides to be thirty. Solinus, the supposed contemporary with Agricola, is the next after Pliny. In his time, and according to his account, these islands had not a single inhabitant, and were overgrown with rushy grafs. It seems on the whole to be pretty generally allowed, that Julius Agricola, who first sailed round Britain, discovered the *Orcades* till then unknown, and subdued them\*. Claudius was so far from reducing them (as is asserted by Jerom in his Chronicle), that Juvenal has these lines in Hadrian's time:

*Arma quid ultra  
Littora Juvæne promovimus et modo captas  
Orcades, et minima contentos nocte Briannos.* SAT. II. 160.

In vain, O Rome, thou dost this conquest boast  
Beyond the *Orcades*' short-nighted coast. DRYDEN.

Facitus informs us, that, before the completion of the first century the Roman fleets sailed round Scotland, and landed in the *Orcades* to refresh.

\* The Romans; never that we know, visited these islands again but once, which was probably after Honorius had defeated the Saxons in the seas of Orkney.

**Orkney.** the chief part of our information respecting the ancient state of the Orkneys must be derived from tradition and conjecture. Their mountainous situation, and natural jealousy of strangers, obstructed the progress both of knowledge and religion: for instead of receiving either from their southern neighbours, we are certain that they derived their knowledge of Christianity from Norway, during the expeditions undertaken by that nation (in the end of the 10th or beginning of the 11th century) to make settlements in the Orkneys, and on the coast of Caithness (A). The best (because it is in all probability the most authentic) account that we have of this early part of the history of the Orkneys, seems to be in Torfæus. See *TORFÆUS*. His history must, doubtless, have been compiled chiefly from tradition, which is far from being the surest mode of information. During the time of Gregory the Great, when by his policy the Picts were driven from other parts of Scotland, they came to the Orkades as an asylum; but it does not appear, and is far from being probable, that they received a favourable reception, for many of them migrated to Shetland, and from thence to the opposite coasts of Norway. A particular history of these islands during those early ages would afford little entertainment, because its authenticity is at least doubtful. These islands were at various times harassed and plundered by adventurers from Scandinavia; and the Norwegian princes frequently laid the inhabitants under tribute.

We have said that the Christian religion was transported to the Orkneys from Norway, and that this happened in the beginning of the 11th century. About which time Sigurdus possessed the entire dominion of those isles, and for many years exercised all the powers of a monarch in the north. At the same time

VOL. XIII.

Christianity had dawned on Scandinavia, and had become the established religion in the seat of government in Norway. Its doctrines interwove themselves with the policy of the nation: its principles, so nearly interesting to human happiness, made their farther publication an object of much moment to the adventurous princes, and gave a new law to their enterprises. While the power of these principles was acting with original force upon the minds of the people, and their zeal rendered them ambitious of any exploit, whereby they could diffuse their influence; Olaus prince of Norway equipped a squadron destined to carry the knowledge of the gospel to other shores. On this pious adventure he was accompanied not only by numbers of all ranks, whom, as usual, a love of enterprise invited; but by many persons of distinguished knowledge and abilities, men of sincere piety, who had become particularly well acquainted with the Christian doctrines, and entertained a deep sense of their infinite importance. These entered into the fleet, joyful in the prospect of spreading the truths which they revered through yet unenlightened countries; and the squadron soon appeared off the Orkades. Olaus got Sigurdus on board of his fleet, with his son, and but a few attendants, and, as the heir of Harold, he claimed all the provinces over which Sigurdus reigned; and at the same time he ordered him to renounce and abjure the religion of his fathers, and to embrace Christianity. Delay was not permitted; Christianity was forced upon him and his subjects; and, on the departure of Olaus, he carried the son of Sigurdus as an hostage for what he had engaged; which was to give honourable protection to all those holy men who might choose to reside in those parts for the purpose of instructing the people in the nature of the Christian doctrines; for many of the more intelli-

**Orkney.**

gent

(A) It has been asserted, that the Orkneys, as well as the hills of Shetland, were originally peopled from Norway, in the ninth, tenth, or eleventh century. Others again imagine, with as much probability, that the Picts were the original inhabitants, and call Orkney the ancient kingdom of the Picts. Certain singular houses, now overgrown with earth, are called *Picts houses*; and the Pentland frith (formerly *Pightland* or *Pitland*) is supposed to retain their name. Claudian's lines, cited by Mr Hamden, prove, that the Picts, with some other German colony, particularly the Saxons, were at that time in possession of these isles; and so Ninnius expressly says. Many of the present inhabitants use the Norse language, which differs but little from the Teutonic or Pictish language, and was in general use to the last century; but except in Foula, where a few words are still known by the aged people, it is quite lost. The English tongue, with a Norwegian accent, is that of these islands; but the appearance of the people, in their manners and genius, evidently show their northern origin. Ninnius, c. 5. puts their arrival at Orkney not less than 900 years after the coming of Brutus into Britain, which he says was in the time of Eli the Jewish high-priest. The ancient surnames are of German original. Some date the first settlement of the Picts here A. M. 4867; when, emigrating from their native country, they planted a colony in Orkney, and thence crossing Pitland frith, and traversing Caithness, Ross, Murray, Marr, and Angus, settled in Fife and Lothian; thence called by writers *Pitlandia*. Others think they did not settle here till the time of Reuther king of Scotland, when the Picts, joining with a party of the Scots, were repulsed, with the loss of their king Gethus, and many of the Picts and Scottish nobility, with great slaughter: but the invasions of the Britons, at the same time, constrained the Picts to fly to Orkney, where they chose for king Gothus their deceased sovereign's brother, till they were able to return to Lothian, and drive out the Britons. After this they flourished here, and were governed by kings of their own. There still remains a place called Cunningsgar, the dwelling place of the minister of Sandwich, whose name and form bespeak it the residence of some of them. But no traces of their history remain, except the name of Belus, in ancient characters, on a stone in the church of Birsa, where still is to be seen one of the principal palaces. This government probably subsisted till the subversion of the Pictish kingdom in Scotland, A. D. 839, by Kenneth II. king of Scotland. On the whole, however, the time of the discovery and population of the Orkneys is certainly unknown. Probably it was very early; for we are told that they owe their name to the Greeks:

*Orkades has memorant dictas a nomine Græco.*

CLAUDIAN.

Orkney.

gent and religious men who had come from Norway with Olaus, remained in the Orkades and in the north of Scotland, to fulfil their pious resolution of spreading the light of the gospel there. Olaus, with the rest of his followers, failed on another expedition towards the frith of Moray. The death of Kindius his son, which happened soon after Olaus's return to Norway, released Sigurdus from his engagements with him; and he entered into one with Malcolm II. one of whose daughters he had in marriage, and by whom he had a son, Torphinus. Torphinus's bravery, magnificence, generosity, and hospitality, endeared him to the inhabitants; and he ruled without controul for many years, till Ronald, a grandson of Sigurdus, who had lived in Norway, and who was esteemed the rightful heir of the earldom of Orkney, made a successful descent upon it. Torphinus wished to give him battle; and in a sea-fight, with the assistance of some ships from Arminius, a man who had filled some of the first places in Norway, he totally defeated him. By courting the friendship of that court, his dominions remained quiet for the greater part of his life; the latter part of which was no less eminent for establishing salutary laws, and encouraging the arts of industry, than the former had been distinguished for military fame and success in the exploits of war. He lived to an advanced age, until after Malcolm III. had ascended the throne of Scotland. Torphinus had built a sumptuous church in Byrfa, where the first bishops of Orkney resided. In the decline of life he retired to that island, and, finishing his days with exemplary piety, was with much solemnity interred in the temple which he had raised. His country long lamented the loss of so celebrated a ruler, who had established security in it, through the influence of his laws, and had taught it to enjoy the arts and blessings of peace. He left two sons, Paul and Erland, who through the whole of their lives amicably shared both in the honours and administration of their father's extensive domain. During this period, the northern counties are said to have arrived at a very superior degree of cultivation and improvement, which became equally conspicuous in the richness of their lands, and in the mildness of their dispositions. Their sons, however, did not both inherit their father's virtues. Magnus, the son of Erland, was pious and peaceable; a great promoter of religion, and anxious in patronising the Romish missionaries, and in protecting the establishments of Christianity: but Hacon, the heir of Paul, was vehement, wild, and impatient of restraint. He saw how Magnus was revered, and envy drove him to revenge; for, by the most deliberate and deceitful villainy, he got Magnus into his power, and murdered him without mercy. The latter part of his life was spent in penance, and in improving his dominions.

Magnus's singular piety, and the manner of his unfortunate death, were so well represented at the court of Rome, that he was canonized. Hacon left two sons, Paul the Silent, and Harold the Orator. Caithness came to Harold, and the Orkneys were governed by Paul.

Ronald, a descendant of St Magnus, an elegant and accomplished youth, appeared at the court of Norway, and was supported in a claim upon the Orkneys, as the heir of the canonized martyr. He sent

messengers to Paul, and offered to share the government with him; but this proposal was refused, and the ambassadors were treated with great contempt. They, however, found persons of power disposed to second their master's views; who soon after their return set out, and vowed, if he succeeded, to build a magnificent church, and to dedicate it to St Magnus. All seemed satisfied with the enterprise; and, full of hope, the fleet set sail. Paul in the mean time put himself in a state of defence. By very artful manœuvres, however, Ronald obtained his purpose, and willingly shared his sovereignty with Harold, the legal heir of Paul. They lived amicably together; and on the assassination of Ronald, which was accomplished by a proud chieftain, who thought himself insulted, he was buried with great pomp. Harold now fully possessed the unrivalled sovereignty of the north, and lived long to enjoy it. We find that in 1196 he was able to bring 7000 men to the field, and a body of cavalry, against the army of William king of Scotland, but was immediately defeated. In the next year, the Caithnessians rebelled again, headed by one Roderick, and Torphinus, son to Harold. The king met and defeated them near Inverness. Roderick was slain; and William, seizing on Harold in the extremity of Caithness, detained him till Torphinus surrendered himself as an hostage; but on some new treasons of the father, the king, according to the barbarity of the times, caused the eyes of the unhappy youth to be put out; and had him emasculated, of which he soon perished in prison. Harold died in the 73d year of his age; and with him ended, in its earls, the independent sovereignty of the north of Scotland. The Norwegians seem to have been in possession of these isles as late as 1266; for then Magnus IV. king of Norway, being worsted in war with the Scots, yielded them to Alexander III. king of Scotland by treaty, and Haquin king of Norway confirmed the possession of them to king Robert Bruce in the year 1312. Lastly, in 1464, Christian I. king of Norway and Denmark, when he gave his daughter in marriage to James III. king of Scotland, transferred all his right to them to his son-in-law and his successors; to make which more binding the Pope's confirmation was obtained. We are told by some that Magnus sold them to Alexander for the sum of 4000 merks Sterling, and a yearly acknowledgment of 100 merks.

They are about 30 in number; but many of them are uninhabited, the greater part being small, and producing only pasturage for cattle. The principal islands are denominated by the names of *Mainland*, *South Ronaldsha*, *Swinna*, *Flatto*, *Copinsba*, *Strusen-sha*, *Stronja*, *Sanda*, &c. the terminations in *a*, or *ba*, being generally given in the Teutonic to such places as are surrounded by water. The currents and tides flowing between the islands are extremely rapid and dangerous. Near an island called *Swinna* are two great whirlpools, called the *wells of Swinna*, which are counted dangerous by mariners, especially in a calm. When sailors find themselves sucked into the vortex, it is said they throw out a barrel, or some bulky substance, which smooths the water till it is sucked down and thrown up at a considerable distance, during which time the ship passes over in safety. But when there is a breeze of wind, these whirlpools may

Orkney.

Orkney. may be crossed without any danger. The largest of these islands is called *Pomona*, in length 33, and in breadth 9 miles, containing 9 parish-churches, and 4 excellent harbours.

The air of these islands is moist, on account of the neighbourhood of the sea; and frost and snow do not continue long. In some places the soil is bare and mountainous, and in others sandy and barren; however, many of the islands produce large crops of barley and oats, but no wheat or other grain excepting what is inclosed in gardens. These, when duly cultivated, produce all kinds of kitchen herbs and roots, bringing even fruit-trees to maturity; but out of them, in the open country, there is scarce a tree or shrub to be seen, except juniper, wild myrtle, heath, and the cyur-hodon: yet this deficiency cannot be imputed to the poverty of the soil, or the nature of the climate; for the trunks of large oaks are frequently dug up in the marshes. This is likewise the case in the most barren parts of the Highlands of Scotland, where not a shrub is to be seen above the surface of the earth: nay, the inhabitants frequently find, deep in the earth, the roots of large trees, evidently exhibiting marks of the ax by which they were felled; so that these northern parts must have undergone some strange revolutions. The Orkneys produce great variety of herbs and berries, grafs and corn, which last is exported as far as Edinburgh. In some of the islands, the natives have discovered mines of tin, lead, and silver, though none of them are wrought to any advantage; in others, we find abundance of marl, grey and red slate, quarries of freestone, and even of marble and alabaster. When the wind rages to any violence, the sea throws in plenty of timber, torn from other countries; and, not unfrequently, the people find large pieces of ambergrease. The fresh water in these islands is very pure and limpid; and, though there are no large rivers in the Orkneys, the ground is well watered with lakes and pleasant rivulets, that not only serve to turn their mills, but also abound with trout of the most delicate flavour.

Besides the abundance of little horses, black cattle, sheep, swine, and rabbits, the inhabitants of the Orkneys rear all sorts of domestic animals and tame poultry. Their heaths and commons yield plenty of red deer, and all sorts of game; partridges, grouse, heath-cocks, plover, duck, teal, and widgeon: the sea-coast teems with seals and otters; and are visited by whales, cod, ling, tusk, herrings, and all manner of fish: on the shore they find spermaceti, or sepia, and a great variety of shells and corallines, with a multitude of oysters, remarkably large muscles, crabs, and cockles. The rocks are covered with sea-fowl, wild geese, solan geese, barnacles, eagles, hawks, and kites. With respect to the barnacles, or, as the natives call them, the *cleck geese*, they are said to be found in shells sticking by the bills to trees, in several islands. Martin affirms he has seen them in this situation, but could not perceive them alive; and indeed the whole account of their generation and production, exhibited by the northern naturalists, is absurd and unphilosophical. The Orkney eagles are so strong, that, according to the reports of the country, they have been known to carry away young children in their talons. Certain it is, they make such havoc among

the lambs, that he who kills an eagle is intitled by law to a hen from every house in the parish where it was killed. The king's falconer visits these islands every year, in order to fetch away the young hawks and falcons from their nests among the precipices: he enjoys a yearly salary of twenty pounds, and may claim a hen or a dog from every house in the country, except those that are expressly exempted from this imposition.

The gentry of the Orkneys are civilized, polite, and hospitable; and live like those of Scotland, from whom they are chiefly descended. They live comfortably, are remarkably courteous to strangers, and drink a great quantity of wine, with which their cellars are generally well stored. Indeed the inhabitants of the Orkneys may be now justly deemed a Scotch colony. They speak the language, profess the religion, follow the fashions, and are subject to the laws, of that people. They are frugal, sagacious, circumspect, religious, and hospitable. Their mariners are remarkably bold, active, dexterous, and hardy. Many surprising instances of longevity occur here, as well as in Shetland, of persons living to the age of 140. The Orkney women are generally handsome and well shaped, and bring forth children at a very advanced age. In the Orkneys, some particular lands are held by a tenure called *Udal Right*, from Ulcius, or Olaus, king of Norway, who farmed the lands, on condition of receiving one-third of the produce; and this right devolved in succession, without any charter granted by the sovereign. The inhabitants of Orkney, instead of measuring their corn, weigh it in pismores or pundlers. Their least denomination is a mark, consisting of 18 ounces, and 24 marks make a lipound, which is a Danish quantity. The poorer sort of people in the Orkneys appear very meanly habited, with a piece of seal skin instead of shoes; and living chiefly on salt-fish, are subject to the scurvy. They are much addicted to superstitious rites; in particular, interpreting dreams and omens, and believing in the force of idle charms. The islands of Orkney, we have already observed, produce very bold, able, and hardy mariners. The common people, in general, are inured to fatigue, and remarkably adventurous, both in fishing during rough weather, and in climbing the rocks for the flesh, eggs, and down of sea-fowl. Formerly, while they were exposed to the invasions of the Norwegians, or western islanders, every village was obliged to equip a large boat well manned; and all the fencible men appeared in arms, when alarm was given by the beacons lighted on the tops of the rocks and highest mountains. These beacons, known by the name of *ward-bills*, are still to be seen in every island. Their corn land they inclose with mud or stone walls, to preserve it from the ravages of their sheep, swine, and cattle, which wander about at random, without being attended by herdsmen: their ordinary manure, especially near the sea-coast, is sea-weed, which they carefully gather and divide into equal portions. Their sheep are marked on the ears and nose; but so wild, that when they have occasion to shear them in the month of May, they are obliged to hunt every individual, with dogs trained for that purpose. Their manner of catching sea-fowl is curious and particular.

Orkney.

Under the rock where these fowls build, they row their boat, provided with a large net, to the upper corners of which are fastened two ropes, lowered down from the top of the mountain by men placed in that station. These hoisting up the net, until it be spread opposite to the cliffs in which the fowls are sitting, the boatmen below make a noise with a rattle, by which the fowls being frightened, fly forwards into the bottom of the net, in which they are immediately enclosed and lowered down into the boat; others practise the method used in Iceland and Norway, and are lowered down by a single rope from the summit of the mountain; this is the constant way of robbing the hawk's nest. See *BIRD-catching*. In these islands some strange effects are produced by thunder and lightning. In the year 1680, the lightning entered a cow-house, in which 12 cows stood in a row, and killed every second beast as she stood, and left the rest untouched. The distempers that prevail mostly in the Orkneys are agues, consumptions, scurvy, and itch. The agues, which abound in the spring, the natives cure with a diet drink of bitters and antiscorbutics infused in ale: for phthical complaints they use the plant arby, and the caryophyllus marinus boiled with sweet milk.

The isles of Orkney and Shetland compose one stewartry, and send one member to the British parliament. The right of superiority to the Orkneys was dismembered from the crown by the union parliament, and granted for a certain yearly consideration to the earl of Morton, by Queen Anne, who appointed him hereditary steward and justiciary. This nobleman possesses the power of creating certain judges, called *bailiffs*. There is one of these established in every island and parish, with power to superintend the manners of the inhabitants, to hold courts and determine civil causes, according to the laws of Scotland, to the value of ten pounds Scots money, amounting to 16s. 8d: but all contests of higher import are referred to the decision of the steward or his deputy, who resides at Kirkwall, which is the seat of justice. Subservient to the bailiffs are six or seven of the most reputable and intelligent inhabitants, who oversee the conduct of their fellows, acting as constables, and make report of all enormities to the bailiff; who causes the delinquent to be apprehended and punished, if the crime be within the extent of his judicial power; otherwise he transmits him to Kirkwall, where he is tried by the steward. The Protestant religion prevails in the isles of Orkney, according to the rites and discipline of the kirk; these, and the isles of Shetland, constituting one presbytery, which assembles at Kirkwall. The country is divided into 18 parishes, containing 31 churches, and above 100 chapels.

The trade of the Orkneys is not at present very considerable, though it might be extended to great advantage. They supply with fresh provisions, for ready money, the ships and vessels that touch upon the coast in the course of northern voyages, or in their passage from the East Indies, when they go north about Ireland and Scotland, in time of war, to avoid the privateers of the enemy. They are also visited by those engaged in the herring-fishery, though there is not such a resort on this account to these islands as to the isles of Shetland. Nevertheless, a good number of

Orkney.

boats from the western parts of Scotland, as well as from Londonderry, Belfast, and other parts of Ireland, fish for herring as far north as the Leuze, and supply the Orkneys with tobacco, wine, brandy and other spiritous liquors, cloths, and divers manufactures. These they exchange for fish, and oil extracted from porpoises, seals, and other sea-animals. The people of Orkney export annually great numbers of black cattle, swine, and sheep; together with large quantities of corn, butter, tallow, salt, and stuffs made in the country, over and above the skins of seals, otters, lambs, and rabbits, down, feathers, writing-quills, hams, and wool; yet all these articles would, in point of profit fall infinitely short of their herring-fishery, were it prosecuted with industry, economy, and vigour. As there are no merchants in the Orkneys at present who export fish on their own account, what herrings are taken, they sell to the Dutch or Scotch dealers in and about Inverness. They generally fish for herring on the west side of the Orkneys; and are therefore more remote from markets than those who are employed in the same manner on the coast of Shetland. In the Orkney islands they see to read at midnight in June and July; and during four of the summer months they have frequent communications, both for business and curiosity, with each other, and with the continent: the rest of the year, however, they are almost inaccessible, through fogs, darkness, and storms. It is a certain fact, that a Scotch fisherman was imprisoned in May, for publishing the account of the prince and princess of Orange being raised to the throne of England the preceding November; and he would probably have been hanged, had not the news been confirmed by the arrival of a ship.

We may reckon among the curiosities of the Orkneys, the *Phaseoli*, commonly known by the name of *Molucca beans*, and sometimes they are called *Orkney beans*. They are a sort of fruit found on the shore of the Orkney islands, being thrown on them by storms of westerly wind. They are of several distinct species, and are none of them the produce of those islands, nor of any places thereabout, but are probably of American origin, many of them being plainly natives of Jamaica, and other islands of the Indies.

They are found principally on those coasts which are most exposed to the waves of the great ocean, and are on these so plentiful, that they might be gathered in large quantities, if of any value; but the only use they are put to, is the making of snuff-boxes out of them. Sir Robert Sibbald, and Mr Wallace, in their accounts of Scotland, have both named them *Molucca BEANS*. Many strange fishes and curious shells are also frequently cast up by the ocean; of these last a vast variety are preserved for adorning the cabinets of modern naturalists. Sometimes exotic fowls are driven upon the Orkneys by tempestuous weather: fish, as large as whittings, have been thrown ashore to a considerable distance within the land. At Cantick head, in the island Waes, and some other places, huge stones are often heaved up by the violence of the sea and wind, and cast over high rocks upon the land. A single Laplander has been seen more than once on this coast, in his slender canoe, covered with skins, being driven hither by adverse winds and storms. The Orkneys are

Orkney. are not altogether destitute of ancient monuments and curiosities of art. In Hoy we find an entire stone, 36 feet long, 18 in breadth, and 9 in thickness lying between two hills, and known by the name of *dwarfie stone*. It is hollowed within by the tools of a mason, the marks of which are still apparent. The entrance is a square hole about two feet high, with a stone, by way of door standing before it. Within we find a bed with a pillow cut out of the stone; at the other end is a couch of the same kind; and in the middle a hearth, above which there is a hole or vent for the exit of the smoke. This curiosity is found in the midst of a desolate heath, and is supposed to have been the residence of a hermit: in the very neighbourhood of this stone there is a very high and steep mountain, called the *wart hill of Hoy*, near the summit of which in the months of May, June, and July, something at noon-day is seen to shine and sparkle with a remarkable lustre, supposed by the common people to be an enchanted carbuncle: many persons have clambered up the hill in quest of it, but found nothing. Perhaps this splendour is produced by the reflection of the sun on a small stream of water sliding over the face of a smooth rock. At Stennis, in the main land, there is a causeway of stones over a loch or lake, at the south end of which we observe a circle of stones rising about 20 feet above ground, each being six feet in breadth, and from one to two feet in thickness: between this circle and the causeway two stones of the same dimensions stand by themselves, and one of them is perforated in the middle. At the distance of half a mile from the other end of the causeway appears a larger circle of the same kind of stones, the diameter of which may amount to 110 paces; some of these stones are fallen; and to the east and west of the larger circle are two artificial green mounts. Both rounds are surrounded with a ditch; and one cannot view them without admiration, considering the art that must have been used to bring such unwieldy masses together in this order. They were probably temples and places of sacrifice used in times of pagan superstition; and seem to bear a great affinity with the celebrated monument called *Stonehenge*, on Salisbury Plain in England. In one of the mounts, at the north end of the causeway, the natives found nine *fibule*, or clasps of silver, formed into a circle, and resembling a horse-shoe. In many different places of the Orkneys we find rude obelisks or single stones of a great height, set up either as memorials of battles, treaties, or the decease of remarkable personages. In Rousay, between two high mountains, there is a place which the natives distinguish by the appellation of the *camp of Jupiter Fring*: but the meaning of this name, handed down by tradition, is not known. At the west end of the main land, near Skeal, we find a surprising causeway, above a quarter of a mile in length, on the summit of high hills, composed of reddish stones of different magnitudes impressed with various figures both on the upper and under surface. Some gentlemen in the neighbourhood have carried off the most beautiful of these stones, to be set in their chimneys by way of ornament, like the painted tiles of Holland. This country produces many sepulchres of different nations. In the plains or links of Skeal, the sand being blown away

from the surface of the ground, several square catacombs appear built of stones well cemented together, containing some parcels of black earth, and each secured by a large stone at the mouth. Sepulchres of the same kind are found at Rousum in Stronfa; which is likewise remarkable for a different kind of monument, consisting of one entire stone cylinder hollowed, with a bottom like that of a barrel, and a round stone to fill up the entrance: above, the stone was sharpened into an edge; within were found some burned bones and red clay; and over it was placed a large flat stone for the preservation of the whole. These in all probability, were Roman catacombs. In Westra divers Danish graves have been discovered: in one of these appeared the skeleton of a man, with a sword on one side and a Danish ax on the other. Some have been found buried with dogs, combs, knives, and other utensils. In many places of the country we find round hillocks or barrows, here known by the name of *brogh*, signifying in the Teutonic language, burying-place, supposed to have been the cimetaries of the ancient Saxons. In different parts of these islands we see the remains of great buildings, believed to have been fortresses erected by the Danes or Norwegians when they possessed the country. One of these in the isle of Wyre, called the *castle of Caphi-row*, signifying a town of security, is surrounded by a fosse, and the first floor still remains above ground, a perfect square of stone wall, very thick, strongly built, and cemented with lime, the area within not exceeding ten feet in length. Of this coppirow the common people relate many idle fables. In the chapel of Clet, in the isle of Sanda, there is a grave 19 feet long, in which was found part of a man's back bone, larger than that of a horse. Human bones, of nearly the same size, have been dug up in Westra; and indeed this country is remarkable for producing men of a gigantic stature. Within the ancient fabric of Lady Kirk in South Ronaldshaw, there is a stone four feet long and two feet broad, on which the print of two feet are engraven, supposed to be the place where, in times of popery, penitents stood to do public penance. The cathedral of Kirkwall, the capital of the Orkneys, is a fine Gothic building, dedicated to St Magnus, but now converted into a parish church. Its roof is supported by 14 pillars on each side; and its steeple in which there is a good ring of bells, by four large pillars. The three gates of the church are chequered with red and white polished stones, embossed and elegantly flowered.

Campbell, in his Political Survey, suggests two improvements in the Orkneys: 1. The erecting an university; of which he recapitulates the probable advantages, arising from their central situation: And, 2. Allowing the East India company to erect a spacious magazine in one of these islands; where also a collector, and a sufficient number of king's officers, should reside, to receive the duties of such East India commodities as might be taken off by British subjects. These he proposes for the Orkneys in particular, and in addition to improvements proposed for the whole islands in general. We are told that the Orkneys contain 30,000 inhabitants, and are equal in extent to the county of Huntingdon.

ORLE, ORLET, or *Orlo*, in architecture, a fillet under

Orkney,  
Orle.

Orle  
||  
Orleans.

under the ovolo, or quarter round of a capital. When it is at the top or bottom of a shaft, it is called *cincture*. Palladio uses the word *orlo* for the plenith of the basis of the columns.

ORLE, in heraldry. See HERALDRY, p. 454.

ORLEANOIS, a province of France, including the several districts of Orleanois-Propre, Beauce-Propre, or Charttrain, Dunois, Vendomois, Blafois, the greatest part of Gatinois, and Perche-Gouet. The principal rivers of it are the Loire, the Loiret, the Cher, the Laconie, the Aigle, the Hyere, the Yonne, and the Eyre. There are also some remarkable canals, particularly those of Briare and Orleans. The river Loire, and the canals drawn from thence, greatly facilitate and promote the inland trade of the kingdom, and particularly of this government, which lies entirely within the jurisdiction of the parliament of Paris; and besides the chief governor, has several subordinate ones.

Orleanois, in Latin *Aurelianensis Ager*, is bounded on the south by Sologne, on the north by Upper-Beauce, on the east by Gatinois, and on the west by Dunois and Vendomois. The Loire divides it into Upper and Lower; the former lying to the north, and the latter to the south of that river. It yields plenty of grain, wine, wood, and fruit, and abounds in cattle, game, and fish.

ORLEANS, the capital of the government of Orleanois. It was anciently called *Genabum*, or *Cenabum*; and afterwards denominated *Aurelia*, *Aurelia*, and *Aurelianum*, by the emperor Aurelian, who considerably enlarged it. In Julius Cæsar's time it was the capital of the Carnutes. It stands about 20 leagues south of Paris, on the northern bank of the Loire; across which Mr Wraxall says there is an elegant bridge of nine arches, the entrance by which is exceedingly noble and striking, the street which leads from it being composed of most elegant modern buildings. In general, however, excepting this street it is very meanly built; the streets are narrow, and the inhabitants in general poor. It is surrounded with walls, and fortified with 40 towers. The streets almost all terminate at the quay for the convenience of trade. It is a place of considerable magnitude; and before the revolution had several inferior courts of justice, and an university of no great repute. It was also a bishop's see; and the cathedral is a most superb Gothic structure, and had the finest steeple in France till it was damaged in the time of the civil wars. There were 22 parishes in it, and a great number of churches, some of which were collegiate, and religious houses. There is also a public walk, planted with several rows of trees; and there used to be some sugar bakers; a manufacture of stockings and sheep skins; a seminary in which divinity was taught; a great trade in brandy, wine, spices, and several manufactures, which, with many other commodities, used to be conveyed to Paris by means of the Loire, and the canal which takes its name from the city. The canal begins about two miles above the city; is near 18 leagues in length; and terminates on the Loing, which falls into the Seine. The environs of Orleans, more especially in the province of Sologne, to the south of the Loire, are very agreeable. It is in general a level country, covered with corn and vines. To the north of the city is a

Orleans.

forest, the largest in the whole kingdom. Before the revolution it belonged to the duke of Orleans; to whom the timber felled in it, one year with another, brought about 100,000 livres. Ever since the year 1344 this city has been a dukedom and peerage, and usually an appendage of some prince of the blood. The late duke, who took the name of *Egalité* and who has since been executed, seems to have been one of the most detestable monsters which ever disgraced humanity. Louis XIV. gave the dukedom to his own brother Philip, who began and finished the canal; which, by the duties paid by vessels going up and down, brought in, one year with another, 150,000 livres. The bishop was suffragan to the archbishop of Paris, and had a revenue of 24,000 livres, out of which his tax to Rome was 2000 florins. A new bishop it is said, on the first day of his entering, had the privilege of releasing all the prisoners in it, except those committed for treason. In the street leading from the bridge stands the celebrated monument where Charles VII. and Joan of Arc the Maid of Orleans, are represented on their knees before the body of our Saviour, who lies extended on the lap of the Virgin. It was erected by order of that monarch in 1458, to perpetuate his victories over the English, and their expulsion from his dominions. All the figures are in iron. The king appears bareheaded, and by him lies his helmet surmounted with a crown. Opposite to him is the Maid herself, in the same attitude of grateful devotion to Heaven. It is a most precious and invaluable historical monument.

"In the Hotel de Ville (says Wraxall) is a portrait of the same immortal woman, which I studied long and attentively. Though it was not done till 1581, which was near 130 years after her decease, it is yet the oldest and best picture of her now existing. The painter seems undoubtedly to have drawn a flattering resemblance of her, and to have given his heroine imaginary charms. Her face, though long, is of exceeding beauty, heightened by an expression of intelligence and grandeur rarely united. Her hair falls loosely down her back, and she wears on her head a sort of bonnet enriched with pearls, and shaded with white plumes, tied under her chin with a string. About her neck is a little collar, and lower down, upon her bosom, a necklace composed of small links. Her dress, which is that of a woman, I find it difficult exactly to describe. It fits close to the body, and is cut or slashed at the arms and elbows. Round her waist is an embroidered girdle, and in her right hand she holds the sword with which she expelled the enemies of her sovereign and her country. I am not surprised at the animated and enthusiastic attachment which the French still cherish for her memory. The critical and desperate emergency in which she appeared; her sex, youth, and even the obscurity of her birth; the unparalleled success which crowned her enterprize; the cruel and detestable sentence by which she was put to death; the air of the marvellous spread over the whole narration, increased and strengthened by that veneration which time affixes to every great event—all these united causes conspire to place her above mortality. Rome and Athens would undoubtedly have ranked her among their tutelary deities, and have erected temples to her honour; nor can I help being amazed, that amidst the almost infinite number

Orleans  
||  
Ormskirk.

number of modern saints who croud and disgrace their churches, no altar has yet been dedicated to the Maid of Orleans." See FRANCE, n<sup>o</sup> 101.

The bridge was new built this century, and opened in 1760; and the French esteem it the finest in the world. E. Long. 1. 59. N. Lat. 47. 54.

ORLEANS (Peter Joseph), a French Jesuit, whom it is proper to mention, because he wrote an *Histoire des Révolutions d'Angleterre*, was born at Bourges in 1641. He taught the belles lettres for some time in his society, but afterwards devoted himself to the writing of history. This pursuit he continued till his death, which happened in 1698. He wrote also A History of the Revolutions of Spain: A History of two conquering Tartars, Chunchi and Camhi; The Life of Father Coten, &c. His History of the Revolutions in England, under the Family of the Stuarts, from the Year 1603 to 1690, was translated into English, and published at London, 1711, in one vol. 8vo: to which is prefixed an Introduction, by Laurence Echard, M. A. who says, that "the great varieties and wonderful changes in these reigns are here judiciously comprised in a moderate volume with no less perspicuity than strictness; and with a beautiful mixture of short characters, nice reflections, and noble sentences, which render the whole agreeable and instructive. But while the reader is entertained with so much skill and fineness, we ought to caution him with relation to the education and religion of the author; for though he has great marks of a generous candour, and a laudable deference to all superiors; yet he is to be considered, in all places, as one in favour with the French king, and not only a true papist, but a complete jesuit."

ORLOPE, in the sea language, the uppermost space or deck in a great ship, reaching from the main to the mizen mast. In three deck ships, the second and lowest decks are sometimes called *orlopes*.

ORMOND, the northern division of the county of Tipperary, in the province of Munster in Ireland. For a long time it gave the title of *earl*, and afterwards of *marquis* and *duke*, to the noble family of Butler, descended from a sister of Thomas a Becket archbishop of Canterbury; till, at the accession of George I. the last duke was attainted of high treason, and died abroad. In that part of the country the family had great prerogatives and privileges granted by Edward III.

ORMSIDE, a town of England, near Appleby, in Westmoreland, with a church and parish, but small. A great number of vessels of brass, some of which seemed to have been gilt, were discovered near the manor-house, by the water washing away the soil. The manor-house is built castleways.

ORMSKIRK, in Lancashire, in England, is a handsome town, with a good inland-trade. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Stafford, Warwick, Leicester, Oxford, Worcester, &c. There is a bituminous earth about this place, from which oil of amber is extracted, that preserves raw flesh, and serves the poor people instead of candles.

There is nothing remarkable at Ormskirk, but the monuments of some of the ancient family of the Stan-

leys before they were ennobled. Not far from it is Latham House; to which belongs a large estate, and a fine park. It is remarkable only because it was gallantly defended in the civil wars by lady Charlotte countess of Derby, who held it to the last extremity against the parliament forces, which could never oblige her to capitulate. She held out gloriously till she was relieved by Prince Rupert. It was, however, ruined in a second siege; and sold by the family to the late Sir Thomas Bootle, who built a very magnificent house upon it.

ORMUS, a small island of Asia, at the bottom of the gulph of the same name, at the entrance of the Gulph of Persia. It is about two leagues from the main land, and about six leagues in circuit. They catch excellent oysters about the island; and it yields plenty of fine white salt; also a kind of shining black sand, which is used for dusting writings, and is transported in considerable quantity to Europe. There is neither sweet water nor grass upon it, the soil being of a salt sulphureous nature. It was taken by the Portuguese in 1507, who fortified it; and it was afterwards frequented by a vast number of merchants, who were extremely rich. In 1622 the Persians, by the assistance of the English, conquered this place, and demolished the houses, which were 4000 in number, containing 40,000 inhabitants. Some time after, the Persians rebuilt the fort, and placed a garrison in it; but they could never bring it to be a place of trade as before: however, it is the key of the Persian Gulph, as well on account of the importance of the place, as the commodiousness of the harbour. It is now almost deserted, for it produces nothing but salt, which sometimes is two inches deep upon the surface of the earth. E. Long. 56. 25. N. Lat. 27. 20.

ORNICUS LAPIS, a name given by some authors to the sapphire of the ancients, which is a peculiar species of the lapis lazuli, in which the gold-coloured matter is not disposed in veins, but in separate spots, of the form of a star. It was first called *oriniscus* and *orinus*, by corruption from *aurinus*, "golden;" and thence came at length the word *ornicus*.

ORNITHIÆ, a name given by the ancients to certain winds, which usually blew in the spring, at the time when the birds of passage came over to them. Pliny says, that these winds blew from the west, and that by some the Etesian winds were called by this name. Others suppose that they blew from the north, or north-west.

ORNITHOGALLUM, STAR OF BETHLEHEM: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronariæ*. The corolla is hexapetalous, erect, persisting, and patent above the middle; the filaments altered dilated at the base. There are seven species; all of them herbaceous perennials, rising from six inches to three feet high, having stalks terminated with long spikes of hexapetalous, star-shaped, white, and yellow flowers. Six of the species are very hardy, and will prosper in any situation; but one, named the *capensis*, a native of the Cape of Good Hope, requires the assistance of artificial warmth to preserve it in this country. They are all easily propagated by offsets from the roots. The bulbous roots of all the species are nutritious and wholesome.

## O R N I T H O L O G Y.

**O**RNITHOLOGY is a science which treats of birds; describes their form, external and internal; and teaches their œconomy and their uses.

A bird is an animal covered with feathers; furnished with a bill; having two wings, and only two legs; with the faculty, except in a very few instances, of removing itself from place to place through the air.—But before proceeding to analyse the characteristic parts of birds, it will be proper to premise an explanation of the terms used by naturalists in describing them.

**EXPLANATION** of some Technical Terms in Ornithology used by PENNANT and LINNÆUS.

Fig.

- |  |  |   |   |
|--|--|---|---|
| 1. <i>Cere. Cera</i>                                   | THE naked skin that covers the base of the bill in the hawk kind.  | 12. <i>Coverts of the tail Uropygium.</i>               | Those that cover the base of the tail.  |
| 2. <i>Capistrum</i>                                    | A word used by Linnæus to express the short feathers on the forehead just above the bill. In crows these fall forwards over the nostrils.          | 13. <i>Vent-feathers</i>                                | Those that lie from the vent to the tail. <i>Crissum Linnæi,</i>  |
| 3. <i>Lorum</i>  | The space between the bill and the eye, generally covered with feathers; but in some birds naked, as in the black and white grebe.                 | 14. <i>The tail. Rectrices</i>                          | That rise from the shoulders, and cover the sides of the back.  |
| 4. <i>Orbis. Orbita</i>                                | The skin that furrounds the eye, which is generally bare; particularly in the heron and parrot.  | 15. <i>Scapular feathers</i>                            | The hind part of the head.  |
| 5. <i>Emarginatum</i>                                  | A bill is called <i>rostrum emarginatum</i> when there is a small notch near the end: this is conspicuous in that of butcher-birds and thrushes.   | 16. <i>Nucha</i>  | A term Linnæus uses for a straight and slender bill.  |
| 6. <i>Vibresæ</i>                                      | <i>Vibresæ pectinata</i> , stiff hairs that grow on each side the mouth, formed like a double comb, to be seen in the goatfucker, fly-catcher, &c. | 17. <i>Rostrum subulatum</i>                            | All the toes divided to the bottom.   |
| 7. <i>Basard wing Alula spuria</i>                     | A small joint rising at the end of the middle part of the wing, or the <i>cubitus</i> ; on which are three or five feathers.                       | 18. <i>Pes ambulatorius</i>                             | The outer toe more or less united to the middle one, particularly conspicuous in the feet of the kingfisher.  |
| 8. <i>Lesser coverts of the wings. Rectrices primæ</i> | The small feathers that lie in several rows on the bones of the wings. The under coverts are those that line the inside of the wings.              | 19. <i>Pes grassarius</i>                               | The foot of the woodpecker formed for climbing. Climbing feet.  |
| 9. <i>Greater coverts Rectrices secundæ</i>            | The feathers that lie immediately over the quill feathers and secondary feathers.  | 20. <i>Pes scanforius</i>                               | Such as those of the grebes.  |
| 10. <i>Quill feathers Primores</i>                     | The largest feathers of the wings, or those that rise from the first bone.   | 21. <i>Finned foot. Pes cobatus</i>                     | The webs indented in the sides, as in the coots and scoloped-toed sandpipers.   |
| 11. <i>Secondary feathers Secundariæ</i>               | Those that rise from the second.   | 22. <i>Scoloped foot. Pes pinnatus</i>                  | Such as want the back toe.  |
|  |  | 23. <i>Pes trydactylus curjorius</i>                    | In which the foot is composed of two toes, observed only in the ostrich.  |
|  |  | 24. <i>Pes didactylus</i>                               | When the webs reach only half way of the toes.  |
|  |  | 25. <i>Semipalmated. Pes semipalmatus</i>               | When the hind-claw adheres to the leg without any toe, as in the petrels.   |
|  |  | 26. <i>Ungue postico sessile</i>                        | All the four toes connected by webs, as in the corvorants.  |
|  |  | 27. <i>Digitis 4 omnibus palmatis Rostrum cultratum</i> | When the edges of the bill are very sharp, such as in that of the crow.   |
|  |  | 28. <i>Unguiculatum</i>                                 | A bill with a nail at the end; as in those of the gooseanders and ducks.  |
|  |  | 29. <i>Lingua ciliata</i>                               | When the tongue is edged with fine bristles, as in ducks.   |
|  |  | 30. <i>Integra</i>                                      | When plain or even.   |
|  |  | 31. <i>Lumbriciformis Pedes compedes</i>                | When the tongue is long, round and slender like a worm, as that of the woodpecker.  |
|  |  | 32. <i>Nares Lineares</i>                               | When the legs are placed so far behind as to make the bird walk with difficulty, or as if in fetters; as is the case with the auks, grebes, and divers. |
|  |  | 33. <i>Emarginate</i>                                   | When the nostrils are very narrow, as in sea-gulls.   |
|  |  |   | With a rim round the nostrils, as in the stare.   |

SECT.

A BIRD may be divided into *head, body, and limbs.*

I. H E A D.

1. BILL (*rostrum*), is a hard horny substance, consisting of an upper and under part, extending from the head, and answering to the mandibles in quadrupeds. Its edges generally plain and sharp, like the edge of a knife, *cultrated*, as are the bills of crows; but sometimes *ferrated*, as in the toucan; or *jagged*, as in the gannet and some herons; or *peñinated*, as in the duck; or *denticulated*, as in the mergansers; but always destitute of real teeth immersed in sockets.

The base in falcons is covered with a naked skin or cere (*cera*); in some birds with a carneous appendage, as the turkey; or a callous, as the curaffo.

In birds of prey, the bill is hooked at the end, and fit for tearing: in crows, straight and strong for picking: In water-fowl; either long and pointed, for striking; or slender and blunt, for searching in the mire; or flat and broad for gobbling. Its other uses are for building nests; feeding the young; climbing, as in parrots; or, lastly, as an instrument of defence or offence.

2. NOSTRILS, (*nares*), the nice instruments of discerning their food, are placed either in the middle of the upper mandible, or near the base, or at the base, as in parrots; or behind the base, as in toucans and hornbills: but some birds, as the gannet, are destitute of nostrils. The nostrils are generally naked; but sometimes covered with bristles reflected over them, as in crows, or hid in the feathers, as in parrots, &c.

The fore-part of the head is called the *front* (*capistrum*); the summit (*vertex*), or the *crown*: the hind part, with the next joint of the neck (*nucha*), the *nape*: the space between the bill and the eyes, which in herons, grebes, &c. is naked (*lora*), the *straps*: the space beneath the eyes (*genæ*), the *cheeks*.

3. ORBITS (*orbitæ*), the eye-lids; in some birds naked, in others covered with short soft feathers.

Birds have no eye-brows; but the grouse kind have in lieu a scarlet naked skin above, which are called *super-cilia*; the same word is also applied to any line of a different colour that passes from the bill over the eyes.

4. EARS. Birds are destitute of auricles or external ears, having an orifice for admission of sound; open in all but owls, whose ears are furnished with valves.

5. The CHIN, the space between the parts of the lower mandible and the neck, is generally covered with feathers; but, in the cock and some others, has carneous appendages called *wattles* (*palæaria*); in others, is naked, and furnished with a pouch, capable of great dilatation (*sacculus*), as in the pelican and corvorants.

6. NECK (*collum*), the part that connects the head to the body; is longer in birds than in any other animals; and longer in such as have long legs than in those that have short, either for gathering up their meat from the ground, or striking their prey in the water, except in web-footed fowl, which are, by reversing their bodies, destined to search for food at the bottom of waters, as swans, and the like. Birds, especially those that have a long neck, have the power of retracting, bending, or

VOL. XIII.

stretching it out, in order to change their centre of gravity from their legs to their wings.

II. B O D Y.

1. Consists of the BACK (*dorsum*), which is flat, straight, and inclines; terminated by the

2. RUMP (*uropygium*), furnished with two glands, secreting a fattish liquor from an orifice each has, which the birds express with their bills to oil or anoint the decomposed parts of their feathers. These glands are particularly large in most web-footed water-fowl; but in the grebes, which want tails, they are smaller.

2. BREAST (*pectus*), is ridged and very muscular, defended by a forked bone (*clavicula*), the merry-thought.

The short winged birds, such as grouse, &c. have their breasts most fleshy or muscular; as they require greater powers in flying than the long-winged birds, such as gulls and herons, which are specifically lighter and have greater extent of sail.

4. BELLY (*abdomen*), is covered with a strong skin, and contains the entrails.

5. The VENT, or vent-feathers (*crissum*), which lies between the thighs and the tail. The anus lies hid in those feathers.

III. L I M B S.

1. WINGS, (*alæ*), adapted for flight in all birds except the dodo, ostriches, cassowary, great auk, and the pinguins, whose wings are too short for the use of flying; but in the dodo and ostrich, when extended, serve to accelerate their motion in running; and in the pinguins perform the office of fins, in swimming or diving.

The wings have near their end an appendage covered with four or five feathers, called the *bastard wing*, (*ala notha*), and *alula spuria*.

The lesser coverts (*teñrices*), are the feathers which lie in the bones of the wings.

The greater coverts are those which lie beneath the former, and cover the quill-feathers and the secondaries.

The quill-feathers (*primores*), spring from the first bones (*digiti* and *metacarpi*) of the wings, and are 10 in number.

Quill-feathers are broader on their inner than exterior sides.

The secondaries (*secundariæ*), are those that rise from the second part (*cubitus*), and are about 18 in number, are equally broad on both sides. The primary and secondary wing-feathers are called *remiges*.

A tuft of feathers placed beyond the secondaries near the junction of the wings with the body. This in water-fowl is generally longer than the secondaries, cuneiform, and may not unaptly be called the *tertials*.

The scapulars are a tuft of long feathers arising near the junction of the wings (*brachia*) with the body, and lie along the sides of the back, but may be easily distinguished, and raised with one's finger.

The inner coverts are those that clothe the under side of the wing.

The subaxillary are peculiar to the greater Paradise. The wings of some birds are instruments of offence. The anhima of Marcgrave has two strong spines in the front of each wing. A species of plover, Edw. tab. 47.

External  
Parts.

and 280. has a single one in each; the whole tribe of jacana, and the gambo, or spur-winged goose of Mr Willoughby, the same.

2. The TAIL is the director or rudder of birds in their flight; they rise, sink, or turn by its means; for when the head points one way, the tail inclines to the other side: it is, besides, an equilibrium or counterpoise to the other parts; the use is very evident in the kite and swallows.

The tail consists of strong feathers (*rectrices*), 10 in number, as in the woodpeckers, &c.; 12 in the hawk tribe, and many others; in the gallinaceous, the *méranganfers*, and the duck kind, of more.

It is either even at the end, as in most birds, or forked, as in swallows; or cuneated, as in magpies, &c.; or rounded, as in the purple jackdaw of Catesby. The grebe is destitute of a tail, the rump being covered with down; and that of the cassowary with the feathers of the back.

Immediately over the tail are certain feathers that spring from the lower part of the back, and are called the *coverts of the tail* (*uropygium*.)

3. THIGHS (*femora*), are covered entirely with feathers in all land-birds, except the bustards and the ostriches; the lower part of those of all waders, or cloven-footed water-fowl, are naked; that of all webbed-footed fowl the same, but in a less degree; in rapacious birds, are very muscular.

4. LEGS (*crura*); those of rapacious fowls very strong, furnished with large tendons, and fitted for tearing and a firm gripe. The legs of some of this genus are covered with feathers down to the toes, such as the golden eagle; others to the very nails; but those of most other birds are covered with scales, or with a skin divided into segments, or continuous. In some of the pies, and in all the passerine tribe, the skin is thin and membranous: in those of web-footed water-fowl, strong.

The legs of most birds are placed near the centre of gravity: in land-birds, or in waders that want the back toe, exactly so, for they want that appendage to keep them erect. Auks, grebes, divers, and pinguins, have their legs placed quite behind, so are necessitated to sit erect: their pace is awkward and difficult, walking like men in fetters: hence Linnæus styles their feet *pedes compedes*.

The legs of all cloven-footed water-fowl are long, as they must wade in search of food: of the palmated, short, except those of the flamingo, the avocet, and the courier.

5. FEET (*pedes*), in all land-birds that perch, have a large back toe: most of them have three toes forward, and one backward. Woodpeckers, parrots, and other birds that climb much, have two forward, two backward; but parrots have the power of bringing one of their hind toes forward while they are feeding themselves. Owls have also the power of turning one of their fore toes backward. All the toes of the *swift* turn forwards, which is peculiar among land-birds: the tridactylous woodpecker is also anomalous, having only two toes forward, one backward: the ostrich is another having but two toes.

6. TOES (*digiti*). The toes of all waders are divided; but, between the exterior and middle toe, is

generally a small web, reaching as far as the first joint.

The toes of birds that swim are either plain, as in the single instance of the common water-hen or gallinule; or pinnated, as in the coots and grebes; or entirely webbed or palmated, as in all other swimmers.

All the plover tribe, or *charadrii*, want the back-toe. In the swimmers the same want prevails among the albatrosses and auks. No water fowl perch, except certain herons, the corvorant and the shag.

7. CLAWS (*ungues*). Rapacious birds have very strong, hooked, and sharp claws, vultures excepted. Those of all land-birds that roost on trees have also hooked claws, to enable them to perch in safety while asleep.

The gallinaceous tribe have broad concave claws for scraping up the ground.

Grebes have flat nails like the human.

Among water-fowl, only the skua, *Br. Zool.* II. p. 529. No 243. and the black-toed gull, *Br. Zool.* II. p. 532. No 244. have strong hooked or aquiline claws. All land-birds perch on trees, except the fruthious and some of the gallinaceous tribes. Parrots climb; woodpeckers creep up the bodies and boughs of trees; swallows cling.

All water-fowl rest on the ground, except certain herons, and one species of ibis, the spoonbill, one or two species of ducks and of corvorants.

#### IV. FEATHERS.

FEATHERS are designed for two uses; as coverings from the inclemency of the weather, and instruments of motion through the air. They are placed in such a manner as to fall over one another (*tegulatum*), so as to permit the wet to run off, and to exclude the cold; and those on the body are placed in a quincuncial form; most apparent in the thick-skinned water-fowl, particularly in the divers.

1. The parts of a feather are, the shafts; corneous, strong, light, rounded, and hollow at the lower part; at the upper, convex above, concave beneath, and chiefly composed of a pith.

2. On each side the shafts are the vanes, broad on one side, narrow on the other; each vane consists of a multitude of thin laminæ, stiff, and of the nature of a split quill. These laminæ are closely braced together by the elegant contrivance of a multitude of small bristles; those on one side hooked, the other straight, which lock into each other, and keep the vanes smooth, compact, and strong.

The vanes near the bottom of the shafts are soft, unconnected, and downy.

3. Feathers are of three kinds: (1.) Such as compose instruments of flight; as the pen feathers, or those which form the wings and tail, and have a large shaft. The vanes of the exterior side bending downward, of the interior upward, lying close on each other, so that when spread not a feather misses its impulse on the air. The component parts of these feathers are described before.

(2.) The feathers that cover the body, which may be properly called the *plumage*, have little shaft, and much vane; and never are exerted or relaxed unless in anger, fright, or illness.

(3.)

External  
Parts.

Flight.

(3.) The **DOWN** (*plume*), which is dispersed over the whole body amidst the plumage, is short, soft, unconnected, consists of lanuginous vanes, and is intended for excluding that air or water which may penetrate or escape through the former. This is particularly apparent in aquatic birds, and remarkably so in the anserine tribe. There are exceptions to the forms of feathers. The vanes of the subaxillary feathers of the Paradise are unconnected, and the laminæ distant, looking like herring-bone. Those of the tail of the ostrich, and head of a species of curassó, curled. Those of the cassowary consist of two shafts, arising from a common stem at the bottom: as do at the approach of winter (after moulting) those of the ptarmigans of arctic countries. The feathers of the penguins, particularly those of the wings, consist chiefly of thin flat shafts, and more resemble scales than feathers; those of the tail, like split whale bone.

## SECT. II. *Flight of Birds.*

THE flight of birds is various; for, had all the same, none could elude that of rapacious birds. Those which are much on wing, or flit from place to place, often owe their preservation to that cause: those in the water, to diving.

Kites, and many of the falcon tribe, glide smoothly through the air, with scarce any apparent motion of the wings.

Most of the order of pies fly quick, with a frequent repetition of the motion of the wings. The Paradise floats on the air. Woodpeckers fly awkwardly, and by jerks, and have a propensity to sink in their progress.

The gallinaceous tribe, in general, fly very strong and swiftly; but their course is seldom long, by reason of the weight of their bodies.

The columbine race is of singular swiftness; witness the flight of the carrier-pigeon. See *CARRIER Pigeon*.

The passerine fly with a quick repetition of strokes; their flight, except in migration, is seldom distant.

Among them, the swallow tribe is remarkably agile, their evolutions sudden, and their continuance on wing long.

Nature hath denied flight to the struthious; but still, in running, their short wings are of use, when erect, to collect the wind, and like sails to accelerate their motion.

Many of the greater cloven-footed water-fowl, or waders, have a slow and flagging flight; but most of the lesser fly swiftly, and most of them with extended legs, to compensate the shortness of their tails. Rails and gallinules fly with their legs hanging down.

Coots and grebes with difficulty are forced from the water; but when they rise, fly swiftly. Grebes and also divers fly with their hind parts downwards, by reason of the forwardness of their wings.

Web-footed fowl are various in their flight. Several have a sailing or flagging wing, such as gulls. Fingguins, and a single auk, are denied the power of flight. Wild geese, in their migrations, do not fly pell-mell, but in a regular figure, in order to cut the air with greater ease; for example, in long lines, in the figure of a  $\triangleright$ , or some pointed form or letter, as the ancients

report that the cranes assumed in their annual migrations, till their order was broken by storms.

*Strymona, sic gelidum, bruma pollente, relinquunt,  
Potura te, Nile, GRUES, primoque voatu  
Effingunt varios, casu mæstrante, figuras.  
Mox ubi percussit tensus NOTUS altior alas,  
Confusos tenere in mistæ glomerantur in orbes,  
Et turbata perit dispersis litera pennis.*

Lucan. lib. v. l. 711.

\* TΔΔ.

From observation it appears, that the flight of birds is much assisted by their being endowed with the peculiar faculty of enlarging their bulk at will; and from this circumstance the animal is enabled to buoy itself up the easier in the air, its specific gravity being lessened in proportion as the bulk is increased.

This arises from certain air vessels communicating with the lungs, and dispersed over various parts of the body, even to the bones; whereby the bird, by filling or emptying these vessels, has the power of contracting or dilating itself according to the occasion it may have for the change. See *COMPARATIVE Anatomy*, n<sup>o</sup> 121—123.

## SECT. III. *Of the Nuptials, Nidification, and Eggs of Birds.*

1. MOST birds are monogamous, or pair; in spring fixing on a mate, and keeping constant till the cares of incubation and educating the young brood is past. This is the case, as far as we know, with all the birds of the first, second, fourth, and fifth orders.

Birds that lose their mates early, associate with others; and birds that lose their first eggs will pair and lay again. The male, as well as the female, of several, join alternately in the trouble of incubation, and always in that of nutrition; when the young are hatched, both are busied in looking out for and bringing food to the nestlings; and, at that period, the mates of the melodious tribes, who, before were perched on some sprig, and by their warbling alleviated the care of the females confined to the nest, now join in the common duty.

Of the gallinaceous tribe, the greatest part are polygamous, at least in a tame state; the pheasant, many of the grouse, the partridges, and bustards, are monogamous; of the grouse, the cock of the wood, and the black game, assemble the females during the season of love, by their cries,

*Et venerem incertam rapiunt.*

The males of polygamous birds neglect their young; and in some cases, would destroy them, if they met with them. The œconomy of the struthious order, in this respect, is obscure. It is probable that the birds which compose it are polygamous, like the common poultry, for they lay many eggs; the dodo, however, is said to lay but one.

All waders or cloven-footed fowl are monogamous; and all with pinnated feet are also monogamous, except the ruffs.

The swimmers or web-footed fowl observe the same order, as far as can be remarked with any certainty; but many of the auks assemble in the rocks in such numbers, and each individual so contiguous, that it is

Nidifi-  
cation.

not possible to determine their method in this article.

It may be remarked, that the affection of birds to their young is very violent during the whole time of nutrition, or as long as they continue in a helpless state; but as soon as the brood can fly and shift for itself, the parents neglect, and even drive it from their haunts, the affection ceasing with the necessity of it: but during that period,

The mothers nurse it, and the fires defend.  
The young dismiss'd, to wander earth, or air,  
There stops the instinct, and there ends the care:  
The link dissolves; each seeks a fresh embrace;  
Another love succeeds, another race.

2. The Nest of a bird is one of those daily miracles that from its familiarity, is passed over without regard. We stare with wonder at things that rarely happen, and neglect the daily operations of nature that ought first to excite our admiration and claim our attention.

Each bird, after nuptials, prepares a place suited to its species, for the depositing its eggs and sheltering its little brood: different genera, and different species, set about the task in a manner suitable to their several natures; yet, every individual of the same species collects the very same materials, puts them together in the same form, and chooses the same sort of situation for placing this temporary habitation. The young bird of the last year, which never saw the building of a nest, directed by a heaven-taught sagacity, pursues the same plan in the structure of it, and selects the same materials as its parent did before. Birds of the same species, of different and remote countries, do the same. The swallows of Britain, and of the remoter parts of Germany, observe the same order of architecture; and in many instances have been known to return to the same places in which they had reared their young the year before.

The nests of the larger rapacious birds are rude, made of sticks and bents, but often lined with something soft; they generally build in high rocks, ruined towers, and in desolate places: enemies to the whole feathered creation, they seem conscious of attacks, and seek solitude. A few build upon the ground.

Shrikes, allied to the rapacious birds, build their nests in bushes, with moss, wool, &c.

The order of pies is very irregular in the structure of their nests. Parrots, and in fact all birds with two toes forward and two backward, lay their eggs in the hollows of trees. And most of this order creep along the bodies of trees, and lodge their eggs also within them.

Crows build in trees: among them, the nest of the magpie, composed of rude materials, is made with much art, quite covered with thorns, and only a hole left for admittance.

The nests of the orioles are contrived with wonderful sagacity, and are hung at the end of some bough, or between the forks of extreme branches. In Europe, only three birds have penile nests; the common oriole, the parus pendulinus or hang-nest titmouse, and one more. But in the torrid zone, where the birds fear the search of the gliding serpent and inquisitive monkey, the instances are very frequent; a mar-

vellous instinct implanted in them for the preservation of their young. See ORIOLES.

All of the gallinaceous and struthious orders lay their eggs on the ground. The ostrich is the only exception, among birds, of the want of natural affection: "Which leaveth her eggs in the earth, and warmeth them in the dust, and forgetteth that the foot may crush them, or the wild beast may break them."

The columbine race makes a most artless nest, a few sticks laid across may suffice.

Most of the passerine order build their nests in shrubs or bushes, and some in holes of walls or banks. Several in the torrid zone are penile from the boughs of high trees; that of the taylor-bird, a wondrous instance\*. Some of this order, such as larks, and the \* See Me-  
goatfucker, on the ground. Some swallows make a taccia, n<sup>o</sup>  
curious plaster-nest beneath the roofs of houses; and 5.  
an Indian species, nests of a certain glutinous matter, which are collected as delicate ingredients for soups of Chinese epicures. See the article *BIRDS Nests*.

Most of the cloven-footed water-fowl, or waders, lay upon the ground. Spoonbills and the common heron build in trees, and make up large nests with sticks, &c. Storks build on churches, or the tops of houses.

Coots make a great nest near the water side.

Grebes, in the water, a floating nest, perhaps adhering to some neighbouring reeds.

Web footed fowl breed on the ground, as the avoet, terns, some of the gulls, mergansers, and ducks: the last pull the down from their breasts, to make a softer and warmer bed for their young. Auks and guillemots lay their eggs on the naked shelves of high rocks; pinguins, in holes under ground: among the pelicans, that which gives name to the genus, makes its nest in the desert, on the ground. Shags, sometimes on trees; corvorants and gannets, on high rocks, with sticks, dried algæ, and other coarse materials.

3. Rapacious birds, in general, lay few eggs; eagles and the larger kinds, fewer than the lesser. The eggs of falcons and owls are rounder than those of most other birds; they lay more than six.

The order of pies vary greatly in the number of their eggs.

Parrots lay only two or three white eggs.

Crows lay six eggs, greenish, mottled with dusky.

Cuckoos, as far as we can learn, two.

Woodpeckers, wryneck, and kingsfisher, lay eggs of a clear white and semi-transparent colour. The woodpeckers, lay six, the others more.

The nuthatch lays often in the year, eight at a time, white, spotted with brown.

The hoopoe lays but two cinerous eggs.

The creeper lays a great number of eggs.

The honeyfucker, the least and most defenceless of birds, lays but two: but Providence wisely prevents the extinction of the genus, by a swiftness of flight that eludes every pursuit.

The gallinaceous order, the most useful of any to mankind, lay the most eggs, from 8 to 20. *Benigna circa hoc natura, innocua et esculenta animalia fecunda generavit*, is a fine observation of Pliny. With exception to the bustard, a bird that hangs between the

Nidifi-  
cation.

Eggs. the gallinaceous and the waders, which lay only two.

The columbine order lays but two white eggs; but the domestic kind breeding almost every month, supports the remark of the Roman naturalist.

All of the passerine order lay from four to six eggs; except the titmouse and the wren, which lay 15 or 18, and the goatfucker, which lays only two.

The struthious order disagrees much in the number of eggs: the ostrich laying many, as far as 50; the dodo but one.

The cloven-footed water-fowl, or waders, lay, in general, four eggs: The crane and the Norfolk plover seldom more than two. All those of the snipe and plover genus are of a dirty white, or olive spotted with black, and scarce to be distinguished in the holes they lay in. The bird called the Land Rail (an ambiguous species), lays from 15 to 20. Of birds with pinnated feet, the coot lays seven or eight eggs, and sometimes more. Grebes, from four to eight, and those white.

The web-footed, or swimmers, differ in the number of their eggs. Those which border on the order of waders, lay few eggs; the avocet two; the flamingo three; the albatross, the auks, and guillemots, lay only one egg a-piece: the eggs of the two last are of a size strangely large in proportion to the bulk of the birds. They are commonly of a pale green colour, spotted, and striped so variously, that not two are alike; which gives every individual the means of distinguishing its own on the naked rock where such multitudes assemble.

Divers only two.

Terns and gulls lay about three eggs, of a dirty olive, spotted with black.

Ducks lay from eight to twenty eggs; the eggs of all the genus are of a pale green, or white, and unspotted.

Penguins probably lay but one egg.

Of the pelican genus, the gannet lays but one egg; the shags or corvorants, six or seven, all white; the last, the most oblong of eggs.

A minute account of the eggs of birds might occupy a treatise of itself. This is only meant to shew the great conformity nature observes in the shape and colours of the eggs of congenerous birds; and also, that she keeps the same uniformity of colour in the eggs as in the plumage of the birds they belong to.

Zinnani published, at Venice, in 1737, *A Treatise on Eggs*, illustrated with accurate figures of 106 eggs. Mr Reyger of Dantzick published, in 1766, a posthumous work by Klein, with 21 plates, elegantly coloured: but much remains for future writers.

#### SECT. IV. *System.*

CONSIDERING the many systems that have been offered to the public of late years, Mr Pennant gives the preference to that composed by Mr Ray in 1667, and afterwards published in 1678; but observes, at the same time, that it would be unfair to conceal the writer, from whom our great countryman took the original hint of forming that system which has proved

the foundation of all that has been composed since that period.

He was a Frenchman, Balon of Mans, who first attempted to range birds according to their natures; and performed great matters, considering the unenlightened age he lived in; for his book was published in 1555. His arrangement of rapacious birds is as judicious as that of the latest writers. For his second chapter treats of vultures, falcons, shrikes, and owls: in the two next, he passes over to the web-footed water fowl, and to the cloven-footed: in the fifth, he includes the gallinaceous and struthious; but mixes with them the plovers, bunting and larks: in the sixth are the pies, pigeons, and thrushes; and the seventh takes in the rest of the passerine order.

Notwithstanding the great defects that every naturalist will at once see in the arrangement of the lesser birds of this writer, yet he will observe a rectitude of intention in general, and a fine notion of system, which was left to the following age to mature and bring to perfection. Accordingly Mr Ray, and his illustrious pupil the honourable Francis Willoughby, assumed the plan: but with great judgment flung into their proper stations and proper genera those which Belon had confusedly mixed together. They formed the great division of terrestrial and aquatic birds; they made every species occupy their proper place, consulting at once exterior form and natural habit. They could not bear the affected intervention of aquatic birds in the midst of terrestrial birds. They placed the last by themselves; clear and distinct from those whose haunts and œconomy were so different.

The subjoined scheme of arrangement by Mr Pennant, is introduced with the following observations.

"Mr Ray's general plan is so judicious, that to me it seems scarce possible to make any change in it for the better: yet, notwithstanding he was in a manner the founder of systematic zoology, later discoveries have made a few improvements on his labours. My candid friend Linnæus did not take it amiss, that I, in part, neglect his example: for I permit the land-fowl to follow one another, undivided by the water-fowl, the grallæ, and anseres of his system†; but, in my generical arrangement, I most punctually attend to the order he has given in his several divisions, except in those of his anseres, and a few of his grallæ. For, after the manner of Mr Brisson, I make a distinct order of water-fowl with pinnated feet, placing them between the waders or cloven-footed water-fowl and the web-footed. The ostrich, and land-birds with wings useless for flight, I place as a distinct order. The trumpeter (*psophia Linnei*), and the bustards, I place at the end of the gallinaceous tribe. All are land-birds. The first multiparous, like the generality of the gallinaceous tribe; the last granivorous, swift runners, avoiders of wet places; and both have bills somewhat arched. It must be confessed, that both have legs naked above the knees; and the last, like the waders, lay but few eggs. They seem ambiguous birds that have affinity with each order; and it is hoped, that each naturalist may be indulged the toleration of placing them as suits his own opinion."

To the above, we have thought it necessary to subjoin an extract of the orders and genera as they stand in the *Index Ornithologicus* and General Synopsis of birds as published by Mr Latham; as from the copious manner in which he has treated the subject, and from a very great addition he has been enabled to make to this branch of natural history, some deviations from the plan of preceding authors, as well as the formation of some new genera, have necessarily arisen.

In the latter arrangements of birds, although it cannot be said that the authors have lost sight of their great predecessor Linnæus, yet the necessity of deviating from him must seem obvious, when the very great number of species which have come to our knowledge of late years, sufficient to justify such alteration, and satisfy the most scrupulous advocates of this great man, is considered. In his last edition of the *Systema Naturæ*, Linnæus enumerates about 930 birds only; but in

Arrange-  
ment.

in the Index and Synopses of Mr Latham, they have been increased to very near 4000, a number never imagined by former writers on the subject to exist in nature.

M. Biberg, in his excellent treatise *Oeconomia Naturæ amen. acad.* vol. 2. calculates the probability of the vegetable kingdom furnishing as far as 10,000 species; that of the vermes 2000; insects 10,000; amphibia 300; fishes 2000; birds 2000; quadrupeds 200.

How far we have already exceeded this number in every department the naturalist can testify; but how much farther the list may be increased, no one will pretend to foretel, whilst the ardour and indefatigable industry of the present race of naturalists, added to the taste for possessing new acquisitions, and exploring new countries, shall continue.

For *Linneus's Arrangement*. See ZOOLOGY.

ment.

## O R O

Ornitho-  
mancy  
||  
Orobio.

ORNITHOMANCY, a species of divination performed by means of birds; being the same with augury. See DIVINATION and AUGURY.

ORNITHOPUS, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The legumen is articulated, cylindrical, and bent in the form of a bow.

ORNUS FRAXINUS, is that species of the ash tree, in the Linnæan system, which, according to Dr Cirillo of Naples, produces the manna. It is the ash-tree, whose smaller leaves are sawed, with flowers having petals. In order to obtain the manna, those whose business it is, in July and August, make an oblong incision, and take off from the bark of the tree about three inches in length and two in breadth: they leave the wound open, and by degrees the manna runs out, and is almost suddenly thickened to its proper consistence, and is found adhering to the bark of the tree. This is collected in baskets, and called *manna grassa*. When they want fine manna, they apply to the incision of the bark thin straw, or small bits of shrubs; so that the manna in coming out runs upon these bodies, and is collected in a sort of regular tubes, which gave it the name of *manna in cannoli*.

OROBANCHE, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personatæ*. The calyx is bilid; the corolla ringent; the capsule unilocular, bivalved, and polyspermous; there is a glandule under the base of the germen.

OROBIO (Don Belthasar), a celebrated Jew of Spain. He was carefully educated in Judaism by his parents who were Jews, though they outwardly professed themselves Roman Catholics; abstaining from the practice of their religion in every thing, except only the observation of the fast of expiation, in the month Tisri or September. Orobio studied the scholastic philosophy usual in Spain, and became so skilled in it, that he was made professor of metaphysics in the university of Salamanca. Afterwards, however, applying himself to the study of physic, he practised that art at Seville with success, till, accused of Judaism, he was thrown into the inquisition, and suffered the most dreadful cruelties, in order to force a confession. He himself tells us, that he was put into a dark dungeon, so strait that he could scarce turn himself in it; and suffered so many hardships, that his brain began to be disturbed. He talked to himself often in this way: "Am I indeed that Don Balthasar Orobio who walked freely about in Seville, who was entirely at ease,

## O R O

Orobio.

and had the blessings of a wife and children?" Sometimes, supposing that his past life was but a dream, and that the dungeon where he then lay was his true birth-place, and which to all appearance would also prove the place of his death. At other times, as he had a very metaphysical head, he first formed arguments of that kind, and then resolved them; performing thus the three different parts of opponent, respondent, and moderator, at the same time. In this whimsical way he amused himself from time to time, and constantly denied that he was a Jew. After having appeared twice or thrice before the inquisitors, he was used as follows: At the bottom of a subterraneous vault, lighted by two or three small torches, he appeared before two persons, one of whom was judge of the inquisition, and the other secretary; who, asking him whether he would confess the truth? protested, that in case of a criminal's denial, the holy office would not be deemed the cause of his death if he should expire under the torments, but that it must be imputed entirely to his own obstinacy. Then the executioner stripped off his clothes, tied his feet and hands with a strong cord, and set him upon a little stool, while he passed the cord through some iron buckles which were fixed in the wall; then drawing away the stool, he remained hanging by the cord, which the executioner still drew harder and harder, to make him confess, till a surgeon assured the court of examiners, that he could not possibly bear more without expiring. These cords put him to exquisite tortures, by cutting into the flesh, and making the blood burst from under his nails. As there was certainly danger that the cords would tear of his flesh, to prevent the worst, care was taken to gird him with some bands about the breast, which however were drawn so very tight, that he would have run the risk of not being able to breathe, if he had not held his breath in while the executioner put the bands round him; by which device his lungs had room enough to perform their functions. In the severest extremity of his sufferings he was told that this was but the beginning of his torments, and that he would better confess before they proceeded to extremities. Orobio added further, that the executioner, being on a small ladder, in order to frighten him, frequently let it fall against the shin-bones of his legs; so that the staves being sharp, created exquisite pain. At last, after three years confinement, finding themselves baffled by his perseverance in denying his religion, they ordered his wounds to be cured, and discharged him. As soon as he had got liberty, he resolved to quit the Spanish dominions; and, going to France, was made professor of physic at Thoulouse,

Orobis,  
Orodes.

Thouloufe. The theses which he made as candidate for this place were upon putrefaction; and he maintained them with so much metaphysical subtilty, as embarrassed all his competitors. He continued in this city for some time, still outwardly professing popery: but at last, weary of dissembling, he repaired to Amsterdam, where he was circumcised, took the name of Isaac, and professed Judaism; still continuing, however, to practise physic, in which he was much esteemed. Upon the publication of Spinoza's book, he despised a system the falleness of which he quickly discovered; and when Bredenbourg's answer to it came to his hands; Orobio, being persuaded that the writer, in refuting Spinoza, had also admitted some principles which tended to Atheism, took up his pen against them both, and published a piece to that purpose, intitled, *Certamen philosophicum adversus J. B. Principia*. But the dispute which he held with the celebrated Philip Limborch against the Christian religion made the greatest noise. Here he exerted the utmost force of his metaphysical genius, and carried himself with great temper. The three papers which he wrote on the occasion were afterwards printed by his antagonist, in an account which he published of the controversy, under the title of *Amica Collatio cum Judao*. Orobio died in 1687.

OROBUS, BITTER VETCH: A genus of the decandria order, belonging to the diadelphica class of plants; and in the natural method ranking under the 32d order, *Papilionaceae*. The style is linear; the calyx obtuse at the base, with the upper segments deeper and shorter than the rest. There are nine species. All of them have fibrated roots, which are perennial, but are annual in stalk, rising early in spring and decaying in autumn. They are very hardy plants, and prosper in any common soil of a garden. Most of the sorts are very floriferous, and the flowers conspicuous and ornamental for adorning the flower compartments. The flowers are universally of the papilionaceous or butterfly kind, consisting each of four irregular petals, *i. e.* a standard, two wings, and a keel; and are all succeeded by long taper seed-pods, furnishing plenty of ripe seed in autumn; by which the plants may be propagated abundantly, as also by parting the roots.

The Scotch-Highlanders have a great esteem for the tubercles of the roots of the tuberous, or species sometimes called *word-pea*. They dry and chew them in general to give a better relish to their liquor; they also affirm that they are good against most disorders of the breast, and that by the use of them they are enabled to resist hunger and thirst for a long time. In Bread-albane and Roisshine, they sometimes bruise and steep them in water, and make an agreeable fermented liquor with them. They have a sweet taste, something like the roots of liquorice; and, when boiled, we are told, they are nutritious and well flavoured; and in times of scarcity they have served as a substitute for bread.

ORODES, a prince of Parthia, who murdered his brother Mithridates, and ascended his throne. He defeated Crassus the Roman triumvir, and poured melted gold down the throat of his fallen enemy, to reproach him for his avarice and ambition. He followed the interest of Cassius and Brutus at Philippi. It is said, that when Orodes became old and infirm, his 30 children applied to him, and disputed in his

presence their right to the succession. Phraates, the eldest of them, obtained the crown from his father; and, to hasten him out of the world, he attempted to poison him. The poison had no effect; and Phraates, still determined on his father's death, strangled him with his own hands, about 35 years before the Christian era. Orodes had then reigned about 50 years.

ORONTIUM, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the second order, *Piperitae*. The spadix is cylindrical covered with florets; the corolla hexapetalous and naked; there is no style; the follicles are monospermous.

OROONOKO, a great river of terra firma, in South America, which rises in Popayan, and falls into the sea with 16 mouths.

ORPHAN, a fatherless child or minor; or one that is deprived both of father and mother.

ORPHEUS, a celebrated poet and musician of antiquity. His reputation was established as early as the time of the Argonautic expedition, in which he was himself an adventurer; and is said by Apollonius Rhodius not only to have incited the Argonauts to row by the sound of his lyre, but to have vanquished and put to silence the sirens by the superiority of his strains. Yet, notwithstanding the great celebrity he had so long enjoyed, there is a passage in Cicero, which says, that Aristotle, in the third book of his *Poetics*, which is now lost, *doubted if such a person as Orpheus ever existed*. But as the work of Cicero, in which this passage occurs, is in dialogue, it is not easy to discover what was his own opinion upon the subject, the words cited being put into the mouth of Caius Cotta. And Cicero, in other parts of his writings, mentions Orpheus as a person of whose existence he had no doubts. There are several ancient authors, among whom is Suidas, who enumerate five persons of the name of *Orpheus*, and relate some particulars of each. And it is very probable that it has fared with Orpheus as with Hercules, and that writers have attributed to *one* the actions of *many*. But, however that may have been, we shall not attempt to collect all the fables that poets and mythologists have invented concerning him; they are too well known to need insertion here. We shall, therefore, in speaking of him, make use only of such materials as the best ancient historians, and the most respectable writers among the moderns, have furnished towards his history.

Dr Cudworth, in his *Intellectual System*\*, after examining and confuting the objections that have been made to the being of an Orpheus, and with his usual learning and abilities clearly establishing his existence, proceeds, in a very ample manner, to speak of the opinions and writings of our bard, whom he regards not only as the first musician and poet of antiquity, but as a great mythologist, from whom the Greeks derived the Thracian religious rites and mysteries. \* Book I. Sect. 17.

"It is the opinion (says he) of some eminent philologists of later times, that there never was any such person as Orpheus, except in Fairy-land; and that his whole history was nothing but a mere romantic allegory, utterly devoid of truth and reality. But there

Orpheus. is nothing alleged for this opinion from antiquity, except the one passage of Cicero concerning Aristotle; who seems to have meant no more than this, that there was no such poet as Orpheus anterior to Homer, or that the verses vulgarly called *Orphical* were not written by Orpheus. However, if it should be granted that Aristotle had denied the existence of such a man, there seems to be no reason why his single testimony should preponderate against the universal consent of all antiquity: which agrees, that Orpheus was the son of *Æger*, by birth a Thracian, the father or chief founder of the mythological and allegorical theology amongst the Greeks, and of all their most sacred religious rites and mysteries; who is commonly supposed to have lived before the Trojan war, that is, in the time of the Israelitish judges, or at least to have been senior both to Hesiod and Homer; and to have died a violent death, most affirming that he was torn in pieces by women, because their husbands deserted them in order to follow him. For which reason, in the vision of Herus Pamphilus, in Plato, Orpheus's soul passing into another body, is said to have chosen that of a swan, a reputed musical animal, on account of the great hatred he had conceived for all women, from the death which they had inflicted on him. And the historic truth of Orpheus was not only acknowledged by Plato, but also by Isocrates, who lived before Aristotle, in his oration in praise of Busiris; and confirmed by the grave historian Diodorus Siculus, who says, that Orpheus diligently applied himself to literature, and when he had learned *τα μυθολογούμενα*, or the mythological part of theology, he travelled into Egypt, where he soon became the greatest proficient among the Greeks in the mysteries of religion, theology, and poetry. Neither was his history of Orpheus contradicted by Origen, when so justly provoked by Celsus, who had preferred him to our Saviour; and, according to Suidas, Orpheus the Thracian was the first inventor of the religious mysteries of the Greeks, and that religion was thence called *Ὀρφεύς* *Threskeia*, as if a Thracian invention. On account of the great antiquity of Orpheus, there have been numberless fables intermingled with his history; yet there appears no reason that we should disbelieve the existence of such a man."

Cudworth is also of opinion, that the poems ascribed to Orpheus were either written by him, or that they were very ancient, and contained his doctrines. He farther argues, that though Orpheus was a polytheist, and asserted a multiplicity of gods, he nevertheless acknowledged one supreme unmade deity, as the original of all things; and that the Pythagoreans and Platonists not only had Orpheus in great esteem, being commonly called by them the *Theologer*, but were also thought in great measure to have owed their theology and philosophy to him, deriving it from his principles and traditions.

The bishop of Gloucester\* speaks no more doubtfully of the existence of Orpheus than of Homer and Hesiod, with whom he ranks him, not only as a poet, but also as a theologian, and founder of religion.

The family of Orpheus is traced by Sir Isaac Newton for several generations: "Seiæc passing over the Hellespont, conquers Thrace; kills Lycurgus, king

of that country; and gives his kingdom and one of his singing-women to *Ægerus*, the son of *Tharops*, and father of Orpheus; hence Orpheus is said to have had the muse *Calliope* for his mother."

He is allowed by most ancient authors to have excelled in poetry and music, particularly the latter: and that to such a degree, that he is represented as taming the most ferocious animals, changing the course of the winds by his melody, and as causing the trees of the forest to dance in concert with his lyre. This account, though we must suppose it fabulous, yet proves his excellence to have been great before it could have given rise to such fictions. He is said to have early cultivated the lyre, in preference to every other instrument: so that all those who came after him were contented to be his imitators; whereas, according to Plutarch, he adopted no model; for before his time no other music was known, except a few airs for the flute. Music was so closely connected in ancient times with the most sublime sciences, that Orpheus united it not only with philosophy, but with theology and legislation. He abstained from eating animal food; and held eggs in abhorrence as aliment, being persuaded that the egg subsisted before the chicken, and was the principle of all existence: both his knowledge and prejudices, it is probable, were acquired in Egypt, as well as those of Pythagoras many ages after.

With respect to his abstaining from the flesh of oxen, Gesner supposes it may have proceeded from the veneration shown to that animal so useful in tillage, in the Eleusinian mysteries instituted in honour of Ceres, the goddess of agriculture. He might have added, that, as these mysteries were instituted in imitation of those established in Egypt in honour of Osiris and Isis, this abstinence from animal food was of the like origin, and a particular compliment to Apis. But Abbé Fraguier, in an ingenious dissertation upon the *Orphic Life*, gives still more importance to the prohibition; for as Orpheus was the legislator and humanizer of the wild and savage Thracians, who were cannibals, a total abolition of eating human flesh could only be established by obliging his countrymen to abstain from every thing that had life.

With respect to theology, Diodorus Siculus tells us, that his father *Ægerus* gave him his first instructions in religion, imparting to him the mysteries of Bacchus, as they were then practised in Thrace. He became afterwards a disciple of the *Idæi Dactyli* in Crete, and there acquired new ideas concerning religious ceremonies. But nothing contributed so much to his skill in theological matters, as his journey into Egypt; where being initiated into the mysteries of Isis and Osiris, or of Ceres and Bacchus, he acquired a knowledge concerning initiations, expiations, funeral rites, and other points of religious worship, far superior to any one of his age and country. And being much connected with the descendants of Cadmus, the founder of Thebes in Bœotia, he resolved, in order to honour their origin, to transport into Greece the whole fable of Osiris, and apply it to the family of Cadmus. The credulous people easily received this tale, and were much flattered by the institution of the ceremonies in honour of Osiris. Thus Orpheus, who was held in great veneration at the Grecian Thebes, of which he was become a citizen, admirably adapted this

\* Warbur-  
ton.

*Orpheus.* this fable, and rendered it respectable, not only by his beautiful verses and manner of singing them, but by the reputation he had acquired of being profoundly skilled in all religious concerns. Diodorus Siculus also says that he was a most attentive student in all kinds of literature, whether sacred or profane.

At his return into Greece, according to Pausanias, he was held in the highest veneration by the people, as they imagined he had discovered the secret of expiating crimes, purifying criminals, curing diseases, and appeasing the angry gods. He formed and promulgated an idea of a hell, from the funeral ceremonies of the Egyptians, which was received throughout all Greece. He instituted the mysteries and worship of Hecate among the Eginites, and that of Ceres at Sparta.

Justin Martyr says, that he introduced among the Greeks near 360 gods; Hesiod and Homer pursued his labours, and followed the same clue, agreeing in the like doctrines, having all drank at the same Egyptian fountain.

Profane authors look upon Orpheus as the inventor of that species of magic called *evocation of the manes*, or raising ghosts; and indeed the hymns which are attributed to him are mostly pieces of incantation, and real conjuration. By all accounts he was an admirable musician: he is said to have received a lyre from Apollo, or according to some from Mercury, upon which he played with such a masterly hand, that even the most rapid rivers ceased to flow, the savage beasts of the forest forgot their wildness, and the mountains came to listen to his song. All nature seemed charmed and animated, and the nymphs were his constant companions. Eurydice was the only one who made a deep impression on the melodious musician, and their nuptials were celebrated. Their happiness, however, was but short: for Aristæus became enamoured of her; and as she fled from her pursuer, a serpent that was lurking in the grass bit her foot, and she died of the poisoned wound. Her loss was severely felt by Orpheus, and he resolved to recover her or perish in the attempt. With his lyre in his hand, he entered the infernal regions, and gained an easy admission to the palace of Pluto. The king of hell was charmed with the melody of his strains; and according to the beautiful expressions of the poets, the wheel of Ixion stopped, the stone of Sisyphus stood still, Tantalus forgot his perpetual thirst, and even the Furies relented. Pluto and Proserpine were moved with his sorrow, and consented to restore him Eurydice, provided he forbore looking behind him till he had come to the extreme borders of hell. The conditions were gladly accepted, and Orpheus was already in sight of the upper regions of the air, when he forgot his promises, and turned back to look at his long lost Eurydice.

All dangers past, at length the lovely bride  
In safety goes, with her melodious guide;  
Longing the common light again to share,  
And draw the vital breath of upper air:  
He first, and close behind him followed she;  
For such was Proserpine's severe decree.  
When strong desires th' impatient youth invade;  
By little caution, and much love betrayed:

A fault which easy pardon might receive,  
Were lovers judges, or could hell forgive.  
For near the confines of ethereal light,  
And longing for the glimmering of a sight,  
Th' unwary lover cast a look behind,  
Forgetful of the law, nor master of his mind.  
Straight all his hopes exhal'd in empty smoke;  
And his long toils were forfeit for a look.

DRYDEN'S *Virgil*.

He saw her, but she instantly vanished from his eyes; He attempted to follow her, but he was refused admission; and the only comfort he could find was to soothe his grief at the sound of his musical instrument in grottoes or on the mountains. He totally separated himself from the society of mankind; and the Thracian women whom he had offended by his coldness to their amorous passion, or according to others, by his unnatural gratifications and impure indulgencies, attacked him while they celebrated the origins of Bacchus; and after they had torn his body to pieces, they threw his head into the Hebrus, which still articulated the words Eurydice! Eurydice! as it was carried down the stream into the Ægean sea. Others think, that as he attempted to conjure his wife from the dead, which they understood by the story of his going down to hell, he thought he saw her, and when afterwards, on looking back he missed her, he died of grief. There is certainly some reason for supposing this to be the case: for there were persons and temples publicly appointed for the purpose; and Pausanias really speaks of that temple which was in Theſprotia, and where Orpheus went to call up the ghost of Eurydice. Poets often mention this subject; and instances of it occur in history both sacred and profane. The witch of Endor is well known to those who read the historical part of the Bible. But to particularise instances, whether sacred or profane, would be endless. Some maintain that he was killed by a thunder-bolt. He was buried at Pieria in Macedonia, according to Apollodorus. The inhabitants of Dion boasted that his tomb was in their city, and the people of Mount Libethrus in Thrace claimed the same honour; and farther observed that the nightingales which built their nests near his tomb, sang with greater melody than all other birds. Orpheus, as some report, after death received divine honours; the muses gave an honourable burial to his remains, and his lyre became one of the constellations in the heavens.

Tzetzes explains the fable of his drawing his wife Eurydice from hell, by his great skill in medicine, with which he prolonged her life, or, in other words, snatched her from the grave. Æsculapius, and other physicians, have been said to have raised from the dead those whom they had recovered from dangerous diseases.

The bishop of Gloucester, in his learned, ample, and admirable account of the Eleusinian mysteries, says, "While these mysteries were confined to Egypt their native country, and while the Grecian lawgivers went thither to be initiated, as a kind of designation to their office, the ceremony would be naturally described in terms highly allegorical. The way of

Orpheus. speaking was used by Orpheus, Bacchus, and others: and continued, even after the mysteries were introduced into Greece as appears by the fables of Hercules, Castor, Pollux, and Theseus's descent into hell; but the allegory was so circumstanced, as to discover the truth concealed under it. So Orpheus is said to get to hell by the power of his harp:

*Thracia fretus cithara, fidibusque canoris.*

VIRG. ÆN. vi. ver. 119.

That is, in quality of lawgiver; the harp being the known symbol of his laws, by which he humanized a rude and barbarous people.—Had an old poem, under the name of *Orpheus*, intitled *A descent into Hell*, been now extant, it would perhaps have shown us, that no more was meant than Orpheus's *initiation*.\* See MYSTERIES.

Many ancient writers, in speaking of his death, relate, that the Thracian women, as hinted at above, enraged at being abandoned by their husbands, who were disciples of Orpheus, concealed themselves in the woods, in order to satiate their vengeance; and, notwithstanding they postponed the perpetration of their design, some time through fear, at length, by drinking to a degree of intoxication, they so far fortified their courage as to put him to death. And Plutarch assures us, that the Thracians stigmatized their women, even in his time, for the barbarity of this action.

Our venerable bard is defended by the author\* of the *Divine Legation*, from some insinuations to his disadvantage in Diogenes Laertius. "It is true (says he), if uncertain report was to be believed, the mysteries were corrupted very early; for Orpheus himself is said to have abused them. But this was an art the debauched mystæ of later times employed to varnish their enormities; as the detested pæderasts of after-ages scandalized the blameless Socrates. Besides, the story is so ill laid, that it is detected by the surest records of antiquity: for in consequence of what they fabled of Orpheus in the mysteries, they pretended he was torn in pieces by the women; whereas it appeared from the inscription on his monument at Dium in Macedonia, that he was struck dead with lightning, the envied death of the reputed favourites of the gods."

This monument at Dium, consisting of a marble urn on a pillar, was still to be seen in the time of Pausanias. It is said, however, that his sepulchre was removed from Libethra, upon Mount Olympus, where Orpheus was born, and from whence it was transferred to Dium by the Macedonians, after the ruin of Libethra by a sudden inundation which a dreadful storm had occasioned. This event is very minutely related by Pausanias.

Virgil bestows the first place in his Elysium upon the legislators, and *these who brought mankind from a state of nature into society.*

*Magnanimi hercæ, nati melioribus annis.*

At the head of these is Orpheus, the most renowned of the European lawgivers, but better known under the character of a poet: for the first laws being written in measure, to allure men to learn them, and, when learnt, to retain them, the fable would have it, that by the force of harmony Orpheus softened the savage inhabitants of Thrace:

*Thracicus longa cum veste sacerdos  
Oblequitur numeris septem discrimina vocum:  
Jamque eadem digitis, jam pectine pulsat eburno.*

ÆN. lib. vi. ver. 645.

The seven strings given by the poet in this passage to the lyre of Orpheus, is a circumstance somewhat historical. The first Mercurian lyre had, at most, but four strings. Others were afterwards added to it by the second Mercury, or Amphion: but, according to several traditions preserved by Greek historians, it was Orpheus who completed the second tetrachord, which extended the scale to a heptachord, or *seven sounds*, implied by the *septem discrimina vocum*. For the assertion of many writers, that Orpheus added two new strings to the lyre, which before had seven, clashes with the claims of Pythagoras to the invention of the octachord, or addition of the sound *proslambanomenos* to the heptachord, of which almost all antiquity allows him to have been the inventor. And it is not easy to suppose, that the lyre should have been represented in ancient sculpture with four or five strings only, if it had had nine so early as the time of Orpheus, who flourished long before sculpture was known in Greece. See the article LYRE.

With respect to the writings of Orpheus, he is mentioned by Pindar as author of the *Argonautics*, and Herodotus speaks of his *Orphics*. His hymns, says Pausanias, were very short, and but few in number: the Lycomides, an Athenian family, knew them by heart, and had an exclusive privilege of singing them, and those of their old poets, Musæus, Onomacritus, Pamphus, and Olen, at the celebration of the Eleusinian mysteries; that is, the priesthood was hereditary in this family.

Jamblicus tells us, that the poems under the name of *Orpheus* were written in the Doric dialect, but have since been transdialected, or modernised. It was the common opinion in antiquity that they were genuine; but even those who doubted of it, gave them to the earliest Pythagoreans, and some of them to Pythagoras himself, who has frequently been called the *follower of Orpheus*, and has been supposed to have adopted many of his opinions.

Of the poems that are still subsisting under the name of *Orpheus*, which were collected and published at Nuremberg 1702, by And. Christ, Eschenbach, and which have been since reprinted at Leipzig 1764, under the title of *ORPHICÆ ANANTA*, several have been attributed to Onomacritus, an Athenian, who flourished under the Pylistratide, about 500 years before Christ. Their titles are, 1. The *Argonautics*, an epic poem. 2. Eighty-six hymns; which are so full of incantations and magical evocation, that Daniel Heinsius has called them *veram Satanae liturgiam*, "the true liturgy of the devil." Pausanias, who made no doubt that the hymns subsisting in his time were composed by Orpheus, tells us, that though less elegant, they had been preferred for religious purposes to those of Homer. 3. *De lapidibus*, a poem on precious stones. 4. Fragments, collected by Henry Stevens. Orpheus has been called the *inventor*, or at least the *propagator*, of many arts and doctrines among the Greeks. 1. The combination of letters, or the art of writing. 2. Music, the

Orpheus

\* Warturton.

**Orpheus**, the lyre, or *cithara*, of seven strings, adding three to that of Mercury. 3. *Hexameter verse*. 4. *Mysteries and theology*. 5. *Medicine*. 6. *Magic and divination*. 7. *Astrology*. Servius upon the sixth *Æneid*, p. 450, says Orpheus first instituted the harmony of the spheres. 8. He is said likewise to have been the first who imagined a plurality of worlds, or that the moon and planets were inhabited.

**ORPHEUS**, in ichthyology, the name of a fish caught in the Archipelago. It is of a broad and flat figure, and of a fine purple colour; its eyes are large and prominent, and its teeth serrated; it has only one fin on the back, and the anterior rays of that are prickly, the others soft to the touch; its anus is small, and is said to have no passage for the semen.

This was the fish called *orpheus* by the ancients, but the modern Greeks call another fish by that name. It is a species of the sparus, of a flat figure, but very thick, has a small mouth, and is covered with small but very rough scales, which adhere very firmly to the flesh; the tail is not forked; it has fleshy lips, and very small teeth; its back and sides are black; its belly white; it has a large black spot at the root of the tail; its head is reddish, and its fins are very elegantly diversified with various colours; it has only one back-fin, and that has the anterior ray prickly, the hinder ones not at all so. It grows sometimes to 20 pounds weight, and is much esteemed among the modern Greeks.

**ORPIMENT**, *auripigmentum*, in natural history, a bituminous mineral composed of sulphur and arsenic, sometimes artificially produced, but found also native in the earth, and constituting one of the ores of arsenic. It is of two kinds, red and yellow, the former generally found in an indurated state; though Cronstedt supposes that it may also be met with in loose scaly powder, as it is sometimes met with in the shops. It is commonly found in shapeless masses, very seldom crystallised; though Baron Borne once found it in a polyhedral form on a blue clay in Hungary. The name *red orpiment* has been given by the more judicious to sandarach, and by the vulgar to red arsenic; but it is to be restrained only to this fossil, which is of a fine bright red, and of the regular texture of the orpiments, and answering all their characters. It is a very beautiful substance of a fine bright red, very glossy, and a little transparent, and is found in the Turkish dominions, in the islands of the Archipelago, and even in Great Britain, Dr Hill having received some of it from Cornwall, under the name of *red mundic*. The yellow kind is met with commonly of shining flexible lamellæ like mica, the specific gravity about 5.15. It burns with a blue flame, and contains about one tenth of its weight of sulphur. It is found native in Hungary, and in many parts of Germany and the Turkish dominions; it is the common orpiment of the shops. Some are of opinion, that the noxious qualities of the arsenic are so much counteracted by the sulphur with which this substance is mixed, that it may be swallowed with safety; but Macquer positively asserts the contrary, and very seriously cautions against its use, even though we be certain that the orpiment is native. There is besides a broad-flaked, gold-coloured kind, well known among the ancients, as is plain from the description

of it left us by Dioscorides, and much esteemed at present by our painters. This is found in several places, as in the islands of the Archipelago, in the mines of Gossiaer in Saxony, in some parts of Turkey, and the East Indies, and in its utmost purity about Smyrna; this makes the finest of all yellows in painting. The small-flaked, yellow kind, which is the common orpiment of the shops, is also a fine colour, though greatly inferior to the former. The Indians use orpiment, corrected with juice of lemons, with good success against fevers.

The red arsenic, or *realgar*, is likewise found in an indurated state, and in regular or stalactitical masses. It is either opaque or semitransparent; sometimes it is found quite transparent, and regularly crystallised in octohedral prisms or pyramids; in which last form it is called *ruby of arsenic*. Its specific gravity is about 3.225; it contains 16 per cent. of sulphur; and its red colour is easily destroyed by the nitrous acid. In order to analyse these two kinds of orpiment, they ought to be digested in marine acid, adding the nitrous by degrees to assist the solution. The sulphur is then left on the filter, while the arsenic remains in the solution, from which it may be precipitated in its metallic form by zinc, adding spirit of wine to the solution.

**ORPINE**, in botany. See **SEDUM**.

**ORRERY**, a curious machine for representing the motions or phases of the heavenly bodies. See **ASTRONOMY**, n° 13, 487, 488, and 490.

The reason of its being called an *Orrery*, was this: Mr Rowley, a mathematical instrument-maker, having got one from Mr George Graham, the original inventor, to be sent abroad with some of his own instruments, he copied it, and made the first for the earl of Orrery. Sir Richard Steel, who knew nothing of Mr Graham's machine, thinking to do justice to the first encourager, as well as to the inventor, of such a curious instrument, called it an *Orrery*, and gave Mr Rowley the praise due to Mr Graham.

It would be too great an undertaking here to give an account of the mechanism of the larger sort of orreries, which represent the movements of all the heavenly bodies; nor indeed can it be done either by diagram or description, to render it intelligible to the most discerning reader: but, instead of that, we shall exhibit an idea of the theory and structure of an useful, concise, and portable planetarium, which any gentleman may have made for a small expence, and will exhibit very justly the motions of all the primary planets about the sun, by wheel-work; and those that have secondaries, or moons, may have them placed about their primaries moveable by the hand, so that the whole shall be a just representation of the solar system, or true state of the heavens, for any given time of the year.

In order to this, we must compare, and find out the proportion, which the periodical times, or revolutions of the primary planets, bear to that of the earth: which, with respect to the *Georgium Sidus*, are not as yet sufficiently ascertained; but those of the other planets are such as are expressed in the table below, where the first column is the time of the earth's period in days and decimal parts; the second, that of the planets; the third and fourth are numbers in the same proportion to each other: as,

**Orpiment**  
**Orrery**

Ortery	365,25 : 33	♂ :: 83 : 20, for Mercury.
	365,25 : 224,7	♀ :: 52 : 32, for Venus.
Orrus.	365,25 : 686,9	♂ :: 40 : 75, for Mars.
	365,25 : 4332,5	♂ :: 7 : 83, for Jupiter.
	365,25 : 10759,3	♂ :: 5 : 148, for Saturn.

Plate  
CCCLXIX.

If we now suppose a spindle or arbor with fix wheels fixed upon it in an horizontal position, having the number of teeth in each corresponding to the numbers in the third column, viz. the wheel AM of 83 teeth, BL of 52, CK of 50 (for the earth), DI of 40, EH of 7, and FG of 5; and another set of wheels moving freely about an arbor, having the number of teeth in the fourth column, viz. AN of 20, BO of 32, CP of 50 (for the earth), DQ of 75, ER of 83, and FS of 148; then, if those two arbors of fixed and moveable wheels are made of the size, and fixed at the distance from each other, as here represented in the scheme, the teeth of the former will take those of the latter, and turn them very freely when the machine is in motion.

These arbors, with their wheel, are to be placed in a box, of an adequate size, in a perpendicular position; the arbor of fixed wheels to move in pivots at the top and bottom of the box; and the arbor of moveable wheels to go through the top of the box, to a proper height, on the top of which is to be placed a round ball gilt with gold to represent the sun. On each of the moveable wheels is to be fixed a socket, or tube, ascending above the top of the box, and having on the top a wire fixed, and bent at a proper distance into a right angle upwards, bearing on the top a small round ball, representing its proper planets.

If then on the lower part of the arbor of fixed wheels be placed a pinion of screw-teeth, a winch turning a spindle with an endless screw, playing in the teeth of the arbor, will turn it with all its wheels; and these wheels will move the others about, with their planets, in their proper and respective periods of time, very exactly. For while the fixed wheel CK moves its equal CP once round, the wheel AM will move AN a little more than four times round, and so will nearly exhibit the motion of Mercury; and the wheel FG will turn the wheel FS about  $\frac{1}{29.5}$  round, and so

will truly represent the motion of Saturn: and the same is to be observed of all the rest.

ORERY (Earls of). See BOYLE.

ORRICE. See IRIS.

ORRUS, in botany, a name by which many of the ancients called the cultivated pine-tree, from its being remarkably full of juice.

The first person who has given us the name is Theophrastus; but he is followed in it not only by the other Greeks, but also by the Latins, who have called the same tree for the same reason *sapinus*, a contraction or abbreviation of the word *sapapinus*, the juicy pine. Pliny tells us, that this last was the name of the manured pitch-tree; but in this he errs; for Vitruvius, and others, tell us, that the pine-nuts, *nuces pineæ*, which were eaten and used in medicine, were the fruit of the *sapapinus*, or *sapinus*; and it is evident, that these must be the produce of a pine-tree, not of a pitch-tree, or any thing of the fir kind.

ORSATO (Sertorio), a celebrated antiquarian, historian, and poet, was born at Padua in 1617, and early discovered a taste for literature and the sciences. He applied himself to searching out antiquities and ancient inscriptions; for which purpose he travelled through all the different parts of Italy, and in the mean time poetry was his amusement. When advanced in age, he taught natural philosophy in the university of Padua. He was also a member of the academy of the Ricovrati. Having presented to the doge and senate of Venice the history of Padua, which he had dedicated to them, he made a long speech, during which he struggled with a natural want, and died of suppression of urine, on the 3d of July 1678. He wrote a great number of books which are esteemed, some in Latin, and others in Italian.

He ought not to be confounded with John Baptist ORSATO, an able physician and antiquary, who was born at Padua in 1673, and wrote, 1. *Dissertatio epistolaris de Lucernis antiquis*. 2. A Dissertation *De patera antiquorum*. 3. A small treatise *De sternis veterum*; and some other works.

ORSI (John Joseph), an ingenious philologer and poet, was born at Bologna in the year 1652; and studied polite literature, philosophy, the civil law, and mathematics. His house was a kind of academy, where many persons of literature regularly assembled. He wrote many ingenious sonnets, pastorals, and other works in Italian, and died in 1733.

ORTEGAL CAPE, the most northern promontory of Spain, where there is also a castle of the same name. W. Long. 8. 20. N. Lat. 44. 0.

ORTELIUS (Abraham), a celebrated geographer, born at Antwerp, in 1527, was well skilled in the languages and the mathematics, and acquired such reputation by his skill in geography, that he was surnamed the *Ptolomy of his time*. Justus Lipsius, and most of the great men of the 16th century, were Ortelius's friends. He resided at Oxford in the reign of Edward VI. and came a second time into England in 1577. His *Theatrum Orbis* was the completest work of the kind that had ever been published, and gained him a reputation equal to his immense labour in compiling it. He also wrote several other excellent geographical works; the principal of which are his *Theſaurus*, and his *Synonyma Geographica*. The world is likewise obliged to him for the *Britannia*, which he persuaded Camden to undertake. He died at Antwerp in 1598.

ORTHEZ, a city in the province of Bearn, and perhaps the meanest in all France. It was, however, till the Revolution, a bishop's see. The cathedral is a wretched edifice, very ancient, built in a barbarous style, and almost in ruins. The remains of the castle of Orthez are very noble, and its situation is fine, on a hill, which commands the town and a great extent of country. The people call it *Le Chateau de la Reine Jeanne*, because that queen resided in it during many years, in preference to the castle of Pau. Some of the apartments, though in ruins, may yet be entered. The princess Blanche, daughter to John king of Arragon and Navarre, was shut up, and died here, in 1464. Her brother being dead, she became heiress to the crown of Navarre; but her father having delivered her into the hands of her younger sister Leonora countess

Orfato  
||  
Orthez.

Orthodox  
Ortygia.

of Foix, she confined the unhappy Blanche in the castle of Orthez, and, after an imprisonment of two years, caused her to be poisoned.

ORTHODOX, in church history, an appellation given to those who are found in all the articles of the Christian faith.

ORTHOGRAPHIC PROJECTION of the SPHERE, that wherein the eye is supposed to be at an infinite distance; so called, because the perpendiculars from any point of the sphere will all fall in the common intersection of the sphere with the plane of the projection. See GEOGRAPHY, n° 63, &c. and PROJECTION.

ORTHOGRAPHY, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing words, with all the proper and necessary letters, making one of the four great divisions or branches of grammar. See GRAMMAR.

ORTHOGRAPHY, in geometry, the art of drawing or delineating the fore right plan of any object, and of expressing the heights or elevations of each part. It is called *Orthography*, for its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in architecture, the elevation of a building.

ORTHOGRAPHY, in perspective, is the fore-right side of any plane, *i. e.* the side or plane that lies parallel to a straight line, that may be imagined to pass through the outward convex points of the eyes, continued to a convenient length.

ORTHOPNOEA, a species or degree of asthma, where there is such a difficulty of respiration that the patient is obliged to sit or stand upright in order to be able to breathe. See MEDICINE, n° 291.

ORTIVE, in astronomy, the same with *easfern*. The ortive or eastern amplitude, is an arch of the horizon intercepted between the place where a star rises, and the east point of the horizon, or point where the horizon and equator intersect.

ORTOLAN, in ornithology. See EMBERIZA.

ORTNAU, a county of Germany, in the circle of Suabia, lying along the Rhine, and separating it from Alsace. It is bounded on the south by Bressan, on the north by the margravate of Baden, and on the east by the duchy of Wirtemberg. It contains three imperial towns; namely, Oßenburg, Gegenbach, and Zell. It belongs partly to the house of Austria, partly to the bishopric of Spire, and partly to the county of Hannau.

ORTYGIA, the birth-place of Diana, was a beautiful grove of trees of various kinds, chiefly cypresses, near Ephesus; on the coast, a little up from the sea. This place was filled with shrines and images. The priests of the goddess were eunuchs, and exceedingly respected by the people. A general assembly was held there yearly, and splendid entertainments were provided, and mystic sacrifices solemnized. The Cenchrius, probably a crooked river, ran through it; and above it was a mountain Solmissus, on which, it was fabled, the Curetes stood, and rattled on their shields, to divert the attention of Juno. The improved face of a country is perishable like human beauty. Not only the birth-place of Diana and its sanctity are forgotten, but the grove and buildings which adorned it appear no more; and perhaps, says Dr Chandler,

the land has encroached on the sea, and the valley, in which Arvisia is, was once Ortygia. See EPHEBUS and DIANA, &c.

Orvieto,  
Oryza.

ORVIETO, a town of Italy, in the patrimony of St Peter, with a bishop's see, and a magnificent palace. It is the capital of the province of Orvietano, in the ecclesiastic state, in E. Long. 13. Lat. 43. It is a large strong town, situated at the conflux of the Tiber and the Chiane, on a steep hill, surrounded on every side with rocks and precipices. To this situation it is owing that it has no springs; but there is a very surprising well cut into the rock, to supply it with fresh water. The mules which bring up the water on their backs, go down by a staircase of 150 steps, and 60 windows, and come up by another, without meeting. The architect of this singular building was the famous Antonio da San Gallo, employed by Clement VII. At the entrance is this inscription, *Quod natura munimento inviderat, industria adjecit*. This city, called *Herbanum* by Pliny, and *Urbevetanum* by Procopius, is the see of a bishop suffragan of Rome. The cathedral, which is of Gothic architecture, is a handsome building, which was begun in 1260 by Nicolo Pisano. The front is adorned with fine statues, among the rest the Virgin Mary and the four Evangelists, with a basso relievo of the last judgment, by the said Nicolo Pisano, and others representing some histories of the old testament. The other half of the front is a surprising work in Mosaic, by Scalzi, expressing the history of the new testament. In the church there is a very fine organ, and a basso-relievo of Raphael da Monte Lupo. Here is also a chapel, which was begun to be painted by F. Angelo, a dominican, and finished by Luke Signorelli, where you see a very beautiful representation of the last judgment. Orvieto was once a potent and populous city, but is now much upon the decline.

ORYZA, RICE, in botany: A genus of the digynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx is a bivalved uniflorous glume; the corolla bivalved, nearly equal, and adhering to the seed. There is but one species, namely the sativa or common rice. This plant is greatly cultivated in most of the eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into England and other European countries every year, where it is much esteemed for puddings, &c. it being too tender to be produced in these northern countries without the assistance of artificial heat; but from some seeds which were formerly sent to Carolina there have been great quantities produced, and it is found to succeed as well there as in the eastern countries.

This plant grows upon moist soils, where the ground can be flowed over with water after it is come up. So that whoever would cultivate it in this country should sow the seeds upon a hot-bed; and when the plants are come up, they should be removed into pots filled with light rich earth, and placed in pans of water, which should be plunged into a hot bed; and, as the water wastes, it must from time to time be renewed again. In July these plants may be set abroad in a warm situation, still preserving the water in the pans, otherwise they will not thrive; and, toward the latter end

*Oryza.* of August, they will produce their grain, which will ripen tolerably well, provided the autumn proves favourable. The leaves of rice are long, like the reed, and fleshy; the flowers blow on the top like barley; but the seed which follows is disposed in clusters, each of which is inclosed in a yellow husk, ending in a spiral thread. The seed is oblong, or rather oval, and white.

Rice is the chief commodity and riches of Damietta in Egypt. Dr Hasselquist gives the following description of the manner in which they dress and separate it from the husks. "It is pounded by hollow iron pestles of a cylindrical form, lifted up by a wheel worked by oxen. A person sitting between the two pestles, pushes forward the rice when the pestles are rising; another lifts, winnows, and lays it under the pestles. In this manner they continue working it until it is entirely free from chaff and husks. When clean, they add a 30th part of salt, and pound them together; by which the rice, formerly grey, becomes white. After this purification, it is passed through a fine sieve to part the salt from the rice; and then it is ready for sale." Damietta sells every year 60,800 sacks of rice, the greatest part of which goes to Turkey, some to Leghorn, Marseilles, and Venice.

Rice, according to Dr Cullen, is preferable to all other kinds of grain, both for largeness of produce, quantity of nourishment, and goodness. This, he says, is plain from macerating the different grains in water; for, as the rice swells to the largest size, so its parts are more intimately divided. Rice is said to affect the eyes; but this is purely prejudice. Thus it is alleged a particular people of Asia, who live on this grain, are blind-eyed; but if the soil be sandy, and not much covered with herbage, and as these people are much employed in the field, this affection of their eyes may be owing to the strong reflection of the rays of light from this sandy soil; and our author is the more inclined to this opinion, because no such effect is observed in Carolina, where rice is very commonly used.

Dr Percival informs us, that as a wholesome nourishment rice is much inferior to salep. He digested several alimentary mixtures prepared of mutton and water, beat up with bread, sea-biscuit, salep, rice flour, sago powder, potato, old cheese, &c. in a heat equal to that of the human body. In 48 hours they had all acquired a vinous smell, and were in brisk fermentation, except the mixture with rice, which did not emit many air-bubbles, and was but little changed. The third day several of the mixtures were sweet, and continued to ferment; others had lost their intestine motion, and were sour; but the one which contained the rice was become putrid. From this experiment it appears that rice, as an aliment, is slow of fermentation, and a very weak corrector of putrefaction. It is therefore an improper diet for hospital patients, but more particularly for sailors, in long voyages, because it is incapable of preventing, and will not contribute much to check the progress of, that fatal disease the sea scurvy. Under certain circumstances, rice seems disposed of itself, without mixture, to become putrid. For by long keeping it sometimes acquires an offensive fætor. Nor, according to our author, can it be considered as a very nutritive kind of food, on account of its difficult solubili-

ty in the stomach. Experience confirms the truth of *Oryzivera*, this conclusion; for it is observed by the planters in the West Indies, that the negroes grow thin, and are less able to work, whilst they subsist upon rice.

*ORYZIVERA*, called the rice-bird of Catesby.

It is about the size of a sparrow, being six inches three quarters long, with the head, and whole under side of the body, black; hind part of the neck in some pale yellow, in others white; coverts of the wings and primaries black; the last edged with white; part of the scapulars, lesser coverts of the wings, and rump, white; back black, edged with dull yellow; tail of the same colours, and each feather sharply pointed; the legs are red. The head, upper part of the neck, and back, of the female is yellowish brown, spotted with black; under part of a dull yellow; sides thinly streaked with black. These birds inhabit in vast numbers the island of Cuba, where they commit great ravages among the early crops of rice, which precede those of Carolina. As soon as the crops of that province are to their palate, they quit Cuba, and pass over the sea, in numerous flights, directly north, and are very often heard in their passage by sailors frequenting that course. Their appearance is in September, while the rice is yet milky; and they commit such devastations, that forty acres of that grain have been totally ruined by them in a small time. They arrive very lean, but soon grow so fat as to fly with difficulty; and when shot often burst with the fall. They continue in Carolina not much above three weeks, and retire by the time the rice begins to harden, going on to other parts, and staying in each only so long as the rice continues green. They come into Rhode Island and New York at the end of April, or the second week in May, frequenting the borders of fields, and live on insects, &c. till the maize is fit for their palate, when they begin by pecking holes in the sides of the husks, and after satiating themselves go on to another, which leaves room for the rain to get in, and effectually spoils the plants. They continue there during the summer, and breed, returning as autumn approaches to the southward. The males and females do not arrive together; the females come first. They are esteemed to be the most delicate birds of those parts, and the male is said to have a fine note. This species is known in the country by the names of *Bab Lincoln* and *Conquaddle*; likewise called by some the *White-backed Maize-thief*.

OSBORN (Francis), an eminent English writer in the 17th century. He was educated in a private manner; and at ripe years frequented the court, and was master of the horse to William earl of Pembroke. Upon the breaking out of the civil wars, he adhered to the parliament party, and had several public employments conferred upon him. In the latter part of his life he lived at Oxford, in order to print several books, and to look after his son, for whom, by the favour of the parliament, he procured a fellowship in All-soul's college. His Advice to a son, so soon as it was published, being complained of to Dr John Tenant, vice chancellor of Oxford, as of irreligious tendency, there was a proposal made to have it publicly burnt; but that taking no effect, it was ordered that no bookseller or others should sell it, which only made it sell the faster. He wrote also historical Memoirs of the reigns

Ofchopho-  
ria,  
Ofilla.

reigns of queen Elizabeth and king James I.; A Discourse on the greatness and corruption of the church of Rome; a Discourse upon Machiavel, &c. He died in 1659.

OSCHOPHORIA, a festival observed by the Athenians. It receives its name *απο του φερειντας οχας*, "from carrying boughs hung up with grapes," called *οχας*. Its original institution is thus mentioned by *Plut. in Thef.* Theseus, on returning from Crete, forgot to hang out the white sail, by which his father was to be apprized of his success. This neglect proved fatal to *Ægeus*, for he threw himself into the sea, and perished. Theseus no sooner reached the land, than he sent a herald to inform his father of his safe return, and in the mean time he began to make the sacrifices which he had vowed to make when he first set sail from Crete. The herald, on his entrance into the city, found the people in great agitation. Some lamented the king's death, while others, elated at the sudden news of the victory of Theseus, crowned the herald with garlands in token of their joy. The herald carried back the garlands on his staff to the sea shore; and, after waiting till Theseus had finished his sacrifice, he related the melancholy account of the king's death. Upon this the people ran in crowds to the city, showing their grief by cries and lamentations.—From this circumstance, therefore, at the feast of Ofchophoria, not the herald but his staff is crowned with garlands, and all the people that are present always exclaim *ελεειν, ιε, ιε*, the first of which expresses haste, and the others a consternation or depression of spirits. The historian further mentions, that Theseus, when he went to Crete, did not take with him the usual number of virgins, but that in the place of two of them, he took two youths of his acquaintance, whom he caused to pass for women, by disguising their dress, and by accustoming them to the ointments and perfumes of women, as well as by a long and successful imitation of their voice. The imposition succeeded; their sex was not discovered in Crete; and when Theseus had triumphed over the Minotaur, he with these two young men led a procession, with branches in their hands, in the same habit, which is still used at the celebration of the festival. The branches which were carried were in honour of Bacchus or Ariadne, or because they returned in Autumn, when the grapes were ripe. Besides this procession, there was also a race, in which young men only whose parents were both alive were permitted to engage. It was customary for them to run from the temple of Bacchus to that of Minerva, which was on the sea-shore. The place where they stopped was called *οχοφοριον*, because the boughs which they carried in their hands were deposited there. The rewards of the conqueror was a cup called *πενταπλοα* "five-fold," because it contained a mixture of five different things, wine, honey, cheese, meal, and oil.

OSCILLA, small images of wax or clay made in the shape of men or women, and consecrated to Saturn, to render him propitious. The word is sometimes used to signify a kind of masks scooped from the bark of trees, and worn by the performers of comedy in the ruder ages of Rome. In this sense we find it in *Virg. Geo. ii. 386*. It also signifies little heads or images of Bacchus, which the countrymen of old hung upon trees, that the face might turn every way,

VOL. XIII.

out of a notion that the countenance of this god gave felicity to themselves, and fertility to their vineyards. An allusion to this opinion and custom is also found in *Virgil, Geo. ii. 388*.

OSENEY-ISLAND, in England, is formed by the river Isis in the meadows near Oxford, where a magnificent abbey was erected, at the instigation of a concubine of King Henry I. to atone for her sins; and the said king built a palace there, wherein King Richard I. was born, which Edward II. converted into a monastery.

OSIRIS, in mythology, one of the gods of ancient Egypt, and very generally believed to have been the sun, or at least the mind actuating that luminary.

The Egyptians derived all things from two principles, an *active* and a *passive*. Their active principle, according to the learned Jablonski\*, was an infinite and eternal *spirit*; and their passive principle was *night*. This spirit they considered sometimes as a *male*, sometimes as a *female*, divinity, and occasionally they attributed to it *both sexes*; but it does not appear to have been the object of their worship. It shall be shown elsewhere (see *POLYTHEISM*), that the earliest objects of pagan adoration were the sun, moon, and planets; and that the philosophers and priests of ancient Egypt worshipped the sun by the name of *Osiris*, may be proved by numberless testimonies from the most authentic records of antiquity. Diogenes Laertius affirms, that they held the sun and moon for divinities, and that they called the latter *Isis*; and Macrobius says expressly, "*Nec in occulto est, neque aliud esse Osirin quam Solem, nec Isin aliud esse quam terram.*" The same writer informs us, that in the hieroglyphic writings of ancient Egypt, "Osiris was represented by a sceptre and an eye," to denote that this god was the *sun* looking down from heaven on all things upon earth.

It must not, however, be concealed, that some of the ancients, and a few of the most learned moderns, have contended, that by *Osiris* the Egyptians understood the Nile or spirit of the Nile, whilst others have confounded him with the Grecian Bacchus. Scaliger and Selden have adopted the former of these opinions, and Servius on Virgil has given his countenance to the latter. But that they are all mistaken, has been evinced by Jablonski in such a manner as to enforce the fullest conviction: "When the Egyptians, in their sacred books, sometimes give the name of *Osiris* to the Nile and its wonderful increase during the heat of summer, they mean nothing more (says he) but to attribute to their god Osiris the gift which fertilizes their country." This they would the more readily do that they believed the Nile to have its source in heaven.

Hence Eusebius tells us†, *Οσιρις εστιν ο Νειλος, ον εχ ουρα† Prepar. του καταφερειναι οινεται, Osiris is the Nile, because they think it is sent down from heaven.*—In one sense Osiris might be Bacchus, because the original Bacchus was himself the sun (see *MYSTERIES* n° 12); but that the Egyptian god could not be worshipped as the inventor of wine is indeed undeniable, if, as Jablonski labours to prove, the primitive religion of the country inculcated upon its votaries, that wine was the gift, not of a benevolent god, but of an evil genius, the enemy of the human race. In support of this opinion our learned author quotes a passage from Plutarch, from which it appears, that, before the era of Prometheus, the

Osiris.

Egyptians neither drank wine themselves nor offered it in libations to the gods; because they believed that the first vine sprung from the earth that was impregnated by the blood of those giants who perished in the war with the gods. It is indeed true, that the Greeks, who borrowed their religion as well as the first principles of science from Egypt, attributed to their Bacchus many of the actions of Osiris; but it is likewise true, that they gave him other attributes, which the Egyptian god could not possess consistently with the known superstitions of that country. Salmassius, however, attempts to prove, from the import of the name, that the *Osiris* of Egypt must have been the Bacchus of Greece. Σαρ, or Σαρρ, he says, signifies a *son* in the Egyptian language; and hence he concludes, that the god was by that people called *Osiris*, for the same reason that by the Greeks he was called *Κορρος*, and by the Romans *Liber*. But this seems all to be a mistake. *Siris* makes a part of many Egyptian proper names, as *Bu-siris*, *Terne-siris*, *Tapo-siris*, &c. and is in all probability derived from the Hebrew word *Sar*, *Sur*, or *Sir*, which signifies a *prince*, *potentate*, or *grandee*. As the name of the god was in Egypt not *Osiris*, but *Isiris* or *Ysiris*, it was probably made up of *Sir* or *Si-is*, and the Hebrew prefix *I* or *Isb*, denoting *strength*; so that the whole word will signify the *strong* or *mighty prince*. If so, we cannot doubt, as Diodorus Siculus, Eusebius, Sextus Empiricus, &c. all affirm, that the Egyptians worshipped the sun by the name of *Osiri*, but that by this name they meant the *power* or *governing mind* of the sun, as the Greeks and Romans seem to have done by their *Phæbus* and *Apollo*.

But though the original Osiris was undoubtedly the sun, or the intelligence actuating the sun, yet there is reason to believe that there was a *secondary Osiris*, who at a very early period reigned in Egypt; and was deified after his death for the benefits he had rendered to his country (see POLYTHEISM). This is indeed so generally admitted, as to have occasioned great controversies among the learned respecting the time when he flourished, and whether he was the civilizer of rude barbarians or the victorious sovereign of a polished nation. The illustrious Newton, it is well known, has adopted the latter opinion; and with much plausibility endeavoured to prove, that *Osiris* was the same with *Sesostris* or *Sesac*: but it must be confessed, that his conclusion is contrary to all the most authentic records of antiquity; and that it would be easy, by the same mode of arguing, to give a shew of identity to two persons universally known to have flourished in very distant ages (A). The annals of Egypt, as may be seen in the writings of Herodotus, Diodorus Siculus, Strabo, Plutarch, and others, who copied from those annals, expressly asserted the distinct personality of Osiris and Sesostris, and placed them in æras vastly distant from each other. Osiris, if any credit be due to those historians, was the founder of the Egyptian monarchy; and, as was customary in those days, having either received the name of the sun, or communicated

his own to that luminary, was after his death deified for the benefits which he had rendered to his country: and being at first worshipped only as a demigod, was in process of time advanced to full divinity, and confounded with his heavenly godfather. The Greeks, who, though original in nothing, were always prompted by their vanity to hold themselves out as the first of the nations, claimed this Osiris as their own, and pretended that he was the son of Jupiter and Niobe. He reigned, say they, over the Argives; but afterwards delivered his kingdom to his brother Algialeu, and took a voyage into Egypt, of which he made himself master, and married Io or Isis. He established good laws there; and they were both after their deaths worshipped as gods. That this is a ridiculous fiction needs no proof; since every one knows, that good laws were established in Egypt long before the Argives had any king, or indeed existed either as a tribe or nation.

**OSMUNDA, MOONWORT;** a genus of the order of filices, belonging to the cryptogamia class of plants. There are several species; the most remarkable of which is the regalis, osmund-royal, or flowering fern. This is a native of Britain, growing in putrid marshes. Its leaf is doubly winged, bearing bunches of flowers at the ends. The root boiled in water is very slimy; and is used in the north to stiffen linen instead of starch. Some of the leaves only bear flowers.

**OSNABURG,** a bishopric of Germany, situated in the centre of the circle of Westphalia, between the Weser and the Em., having Minden on the east, Munster on the west, Diepholt on the north east, and Ravensburg on the south-west. It is about 45 miles long and 25 broad, producing some rye, several sorts of turf, coals, marble, and good pasturage. The inhabitants, who are a mixture of Protestants and Roman Catholics, breed a considerable number of cattle, especially hogs of which they make excellent bacon and hams; but a great part of the country consists of heaths. By the treaty concluded here in 1648, the bishopric was to be an alternative between the Roman Catholics and Lutherans; and the Lutheran bishop was to be a younger prince of the house of Brunswick Lunenburg, or, on failure thereof of Brunswick Wolfenbuttle. In consequence of this settlement, it has been twice held by a British prince since the accession of the family of Hanover. The bishop is able to raise 25000 men, his revenue being between 20,000 and 30,000*l*. The chief manufactures of the country are a coarse kind of linen cloth and yarn, which are said to bring into it annually about 1,000,000 of rix-dollars. There are also some woollen manufactures in Osnaburg and Bramsche. The land-estates of the bishopric are, the chapter, the knights, and the four towns. The diets are held at Osnaburg, when called together by the bishop. The count of Bar is hereditary seneschal or steward, and president of the college of knights. The bishop is a prince of the empire; and in the matricula is rated at 6 horse and 36 foot, or 216 florins monthly, in lieu of The

Osmunda,  
Osnaburg.

(A) This has been in fact done by Warburton; who employs Newton's mode of reasoning with equal plausibility, and perhaps superior force, to prove the identity of King Arthur and William the Conqueror. See *Divine Legation of Moses*, Vol. III. Book iv. Sect. 3.

Osnaburg. them. To the chamber of the empire he contributes each term 81 rix dollars, 14 kruitzers and a half. The capital of this bishopric is

OSNABURG, or *Osnabruck*. It was formerly an imperial city, and one of the Hanse towns; but is now subject to the bishop, though it still enjoys many privileges, and a revenue of about 8000 or 9000 rix-dollars. It has its name from a bridge over the river Hase, or Ose, which divides it into the Old and New Town, and stands 75 miles west of Hanover, and 30 north east of Munster, being surrounded with walls and ditches, but commanded by a mountain within cannon shot. It stands in a fine plain, and is adorned with several good buildings, and on the mountain there is an abbey. The magistracy of this city, which is rechosen yearly on the 2d of January, is Lutheran; and the churches belong, some to the Lutherans, and some to the Papists. Both parties have the full and free exercise of their religion, whether the bishop be Protestant or Papist. The bishop's palace, called *Petersburg*, was built by Bishop Ernest-Augustus, brother to King George I. It is well fortified, and separated from the town by a bridge. It is a hexagon, with a court in the middle, and at each corner a turret. In the town-house are still preserved the pictures of the plenipotentiaries that assisted at the conferences there for the famous treaty of Westphalia. In the treasure of the cathedral are still to be seen some ornaments given by Charlemagne, as also his crown, which is only of silver gilt, and his comb and baton, six feet in length, both of ivory; together with other curiosities. Charlemagne is said to have erected here a school for Latin and Greek, which the Jesuits in 1625 converted into an academy. They have the best bread and beer that is to be met with in all Westphalia, and have a pretty good trade in bacon and linen; as also by brewing a palatable thick sort of beer called *buse*. This city is noted for a treaty betwixt the emperor and the king of Sweden in 1648, wherein the affairs of the Protestants were regulated, which was a branch of the treaty of Westphalia. The town, with the rest of the principality, is subject to its bishop, who is a count of the empire, and by the treaty of Westphalia must be alternately a Protestant and Papist. The Popish bishop is suffragan to the archbishop of Cologne; but the Protestant bishop is indeed a temporal prince, and always of the house of Brunswic, in consideration of the principality of Halberstadt, which was taken from this house, and conferred upon the elector of Brandenburg. Frederick duke of York, second son of his majesty George III. is the present bishop. The cathedral is in the hands of the Roman Catholics, with the church and monastery of the Dominicans in the old city, and the collegiate church of St John in the new. The Protestants are masters of the great parochial church of St Mary in the old city; and both religions have a voice in the election of the magistrates. Of 25 canons belonging to the cathedral, 18 are Roman Catholics, and the Revenues of 4 more are enjoyed by the Jesuits for the support of the college; so that there are but 3 Protestant canons, who have no voice in the election of the Roman Catholic bishop, when it is his turn to succeed. The bishop's palace is fortified like a castle: here it was that George I. was born on the 28th of May 1660, his father Ernest-Augustus being

then bishop and prince of the place; and here also he died in the night of the 10th of June 1727, and, as some say, in the very room in which he was born. The bishopric is situated in the centre of the circle; the north part of it is marshy, but at the south extremity of it are some mountains. The inhabitants have considerable manufactures of linen, and a good breed of cattle; and of their hogs, for which they are remarkable, is made the best Westphalia bacon. Not far from this city are to be seen the ruins of an old church and castle, called *Beulem*, which some say was built by King Wittekind upon his conversion; and about two miles from it lies the monastery of Rulle, on the bank of a lake so deep, that report says it could never yet be fathomed. This was the first town in Westphalia which received the Lutheran doctrine.

*OSNABURG Island*, one of the Islands in the South Sea, discovered by Captain Wallis in 1767. It is a high, round island, not above a league in circuit; in some parts covered with trees, in others a naked rock. S. Lat. 22. W. Long. 141. 34.

OSORIUS (Jerom), was born of a noble family at Lisbon, 1500. He was educated at the university of Salamanca, and afterwards studied at Paris and Bologna. On his return to Portugal he gradually rose to the bishopric of Sylves, to which he was appointed by Catherine of Austria, regent of the kingdom in the minority of Sebastian. At the request of cardinal Henry of Portugal, he wrote his history of King Emanuel, and the expedition of Gama; which his great contemporary Camoens made at the same time the subject of his immortal *Lusiad*; a poem which has at length appeared with due lustre in our language, being translated with great spirit and elegance by Mr Mickle. It is remarkable that the history of Osorius, and the epic poem of Camoens, were published in the same year, 1572: but the fate of these two great authors were very different; the poet was suffered to perish in poverty, under the reign of that Henry who patronized the historian: yet allowing for the difference of their professions, they possessed a similarity of mind. There appear many traces of that high heroic spirit even in the priest Osorius, which animated the soldier Camoens: particularly in the pleasure with which he seems to describe the martial manners of his countrymen under the reign of Emanuel. "In that age (says the historian in the close of his manly work), poverty and sadness were banished from Portugal. Complaints were never heard; but every place, from the court to the cottage, resounded with mirth and music. Illicit love was unknown; nor would the ladies listen to the most honourable addresses of such youths as had not signalized themselves in war. No young man about court, however noble by birth, was permitted to wear the dress of manhood till he had passed over into Africa, and thence brought back with him some animal esteemed for its rarity; and such was the hardy education of the nobility in that age, that many of them travelled every where in quest of adventures." This is a striking picture of the manners of chivalry, to which Portugal owed much of its glory in that splendid period. There is one particular in the character of Osorius, which, considering his age and country, deserves the highest encomium; and that is his tolerating spirit. In the first book of his history, he

Oforius

Offat.

speaks of Emanuel's cruel persecution of the Jews in the following generous and exalted language: "This (says he) was authorised neither by law nor by religion. Can men be compelled to believe what they reject with abhorrence? Do you take upon you to restrain the liberty of the will, or to fetter the understanding? Such an attempt must be unsuccessful; and is not acceptable to Christ, who expects from man the devotion of the heart, and not that formal worship which is the offspring of pains and penalties. He wishes them to study his religion, and adopt it from conviction, not from terror: for who does not see that forced belief is mere hypocrisy?" Oforius is said to have used many arguments to dissuade Sebastian from his unfortunate expedition into Africa, and to have felt so deeply the miseries which befel the Portuguese after that fatal event, that his grief was supposed to accelerate his death. He expired in 1580, happy, says De Thou (who celebrates him as a model of Christian virtue), that he died just before the Spanish army entered Portugal, and thus escaped being a witness to the desolation of his country.—His various works were published at Rome in 1592, by his nephew Oforius, in four volumes folio, with a life of their author. Among these are two remarkable productions; the first, An Admonition to Queen Elizabeth, exhorting her to return into the Church of Rome; the second, An Essay on Glory, written with such classical purity, as to give birth to a report, that it was not the composition of Oforius, but the last work of Cicero on that subject.

OSPREY. See FALCO, sp. 17.

OSSA, a lofty mountain of Thessaly, near the Peneus, which runs between this mountain and Olympus; famous in the fabulous story of the giants (Homer, Virgil, Horace, Seneca, Ovid). The bending and unbending of its pines, on the blowing of a strong north wind, formed a clashing sound like thunder (Lucan). It was once the residence of the Centaurs, and was formerly joined to mount Olympus; but Hercules, as some report, separated them, and made between them the celebrated valley of Tempe. This separation of the two mountains was more probably effected by an earthquake which happened about 1885 years before the Christian era. Its greatest celebrity arises from its being one of those mountains which the giants in their wars against the gods heaped up one on the other to scale the heavens with more facility. A town of Macedonia.

OSSAT (Arnauld de), born in the diocese of Auch in 1536, of mean parentage, was taken notice of by a gentleman in the diocese, who made him study with his ward the Lord of Castlenau de Magnoac. He studied the law at Dijon under Cujace, and applied himself to the bar at Paris. He was secretary at

Rome to M. de Feix, archbishop of Thoulouse; to cardinal Este; and afterwards to cardinal de Joyeuse, by the French king's express command. After rising to the highest dignities both in church and state, in 1599 he was created a cardinal by pope Clement VIII. He died in 1604. An eminent French writer gives him the following character: "He was a man of prodigious penetration; applied himself so closely to affairs, and especially was so judicious in forming his resolutions, that it is almost impossible to find out one false step in the many negotiations in which he was concerned." His works, and especially his letters, have been much esteemed in the learned world.

OSSIAN, the son of Fingal, a celebrated Celtic poet, who flourished about the end of the second and beginning of the third century. Several incidents in his poems point out this as his æra: particularly the engagement of Fingal with Carcul, or Caracalla, the son of the emperor Severus, styled by Ossian, *The Son of the King of the World*. M. Tellemont fixes the elevation of Caracalla to a share in the government to the year 198, and the association of his brother Geta to 208. About which time Gibbon fixes the Caledonian war, and speaks thus upon the subject: "This Caledonian war, neither marked by decisive events, nor attended with any important consequences, would ill deserve our attention; but it is supposed, not without a considerable degree of probability, that the invasion of Severus is connected with the most shining period of the British history or fable. Fingal, whose fame, with that of his heroes and bards, has been revived in our language by a recent publication, is said to have commanded the Caledonians in that memorable juncture, to have eluded the power of Severus, and to have obtained a signal victory on the banks of the Carun, in which the son of *the King of the World*, Caracul, fled from his arms along the fields of his pride\*." \* Ossian's Poems, vol. i. p. 175. Something of a doubtful mist still hangs over these Highland traditions; nor can it be entirely dispelled by the most ingenious researches of modern criticism (A): but if we could with safety indulge the pleasing supposition, that Fingal lived and that Ossian sung, the striking contrast of the situation and manners of the contending nations might amuse a philosophic mind. The parallel would be little to the advantage of the more civilized people, if we compared the unrelenting revenge of Severus with the generous clemency of Fingal; the timid and brutal cruelty of Caracalla, with the bravery, the tenderness, the elegant genius of Ossian; the mercenary chiefs who, from motives of fear or interest, served under the Imperial standard, with the free-born warriors who started to arms at the voice of the king of Morven: if, in a word we contemplated the untutored Caledonians glowing

(A) "That the *Caracul* of Ossian is the *Caracalla* of the Roman history, is perhaps the only point of British antiquity in which Mr Macpherson and Mr Whitaker are of the same opinion; and yet the opinion is not without difficulty. In the Caledonian war, the son of Severus was known only by the appellation of *Antoninus*; and it may seem strange, that the Highland bard should describe him by a nick name, invented four years afterwards, scarcely used by the Romans till after the death of that emperor, and seldom employed by the most ancient historians. See Dion. l. lxxvii. p. 1317. Hist. August. p. 89. Aurel. Victor. Euseb. in Chron. ad ann. 214.

Ossian.

glowing with the warm virtues of nature, and the degenerate Romans polluted with the mean vices of wealth and slavery."

The date of this action, if the poems be true, is rather confounding: for the next expedition, which is produced to fix the time in which Ossian flourished, was conducted by Oscar (against the usurper Caran-fius, the Car of Ossian), who did not assume the purple till so late as the year 287. This account indeed corresponds pretty well with the account given by Irish histories, which place the death of Fingal in the year 283, and that of Oscar, (who died many years before his father Ossian) in the year 296. These hints are not thrown out because we think they militate against the authenticity of the poems; for distant though these dates be, it is yet possible to reconcile them. Old age was and is very common in those regions; and Ossian himself, we are told, was an instance of great longevity. Indeed at such a distance of time it cannot be expected that we should give either a very particular or a very exact account of Ossian and his heroes. Were there no doubts remaining of the truth of the facts, it is still natural to suppose that they must have suffered obscurity through the rust of time, and above all through the neglect of the poems, which lately were unknown.

The first expedition on which Ossian's father sent him was, to raise a stone on the banks of Crona, to perpetuate the memory of a victory which the king of Morven had obtained at that place. The Highlanders talk of this as being emblematical of that immortality which heroes were to receive from his future compositions. In this expedition he was accompanied by Toscar, father of the beautiful Malvina, the amiable companion of his grief, after the death of her beloved Oscar, his son. It appears from his poems, that, in one of his early expeditions to Ireland, he had fallen in love with and married Eivirallin, daughter to Branno, petty king of Lego. "I went in suit of the maid of Lego's fable surge; twelve of my people were there, the sons of streamy Morven. We came to Branno, friend of strangers; Branno of the sounding mail.—'From whence (he said) are the arms of steel? Not easy to win is the maid that has denied the blue-eyed sons of Erin. But blest be thou, O son of Fingal! happy is the maid that waits thee. Though twelve daughters were mine, thine were the choice, thou son of fame.'—Then he opened the hall of the maid; the dark haired Eivirallin\*." This Eivirallin was the mother of his son Oscar, whose exploits he celebrates in many of his poems, and whose death he laments in the first book of Temora. Eivirallin died some time before Oscar (FINGAL, B. iv.); who seems to have been her only child; and Ossian did not marry afterwards: so that his posterity ended in the death of Oscar; who seems to have died as he was about to be married to Malvina, the daughter of Toscar. Several of her lamentations for her lover are recorded by Ossian, which paint her grief in the strongest and most beautiful colours. "It is the voice of my love! few are his visits to my dreams.—But thou dwellest in the soul of Malvina, son of mighty Ossian. My sighs arise with the beams of the east; my tears descend with the drops of night. I was a lovely tree in thy presence, Oscar, with all my branches round me: but

thy death came like a blast from the desert, and laid my green head low; the spring returned with its flowers, but no green leaf of mine arose." *Poem of CROMA.*

The principal residence of Ossian was in the vale of Cona, now Glerco, in Argyleshire. See FINGAL.

His poems relate many of his expeditions to Ireland, Scandinavia, Clyde, and Tweed or Teutha. His exploits on these occasions, after making a large allowance for poetical exaggeration, show him to have been no less a warrior than a poet: (See OSSIAN'S WORKS, in the poems *Callion and Colmal, Lathmor, Berrathon*, &c. By these expeditions, which were always undertaken for the relief of the distressed, the mind of Ossian seems to have been cultivated and enlarged beyond what is usually to be met with in so rude a period of society as that in which he lived. His poems breathe, throughout, such a spirit of generosity and tenderness, especially towards the fair sex, as is seldom or never to be met with in the compositions of other poets who lived in a more advanced state of civilisation. He lived to an extreme old age; having survived all his family and friends, many of whom perished by a fatal accident, recorded in one of his poems called the *fall of Tura* \*. Malvina, alone, the love of his son Oscar, remained with him till within a few years of his death, and paid him every attention that could be expected from the tender relation in which she stood to him. To her he addresses many of his poems, which seem to have been composed for the most part in his old age. Her death is pathetically lamented by him in the poem of *Berrathon*: towards the close of which, he, gives the presages of his own departure; an event which he often wishes for, under the blindness and other calamities of his declining years. "Roll on, ye dark-brown years, for ye bring no joy on your course. Let the tomb open to Ossian, for his strength has failed. The sons of the song are gone to rest: my voice remains, like a blast, that roars lonely on the sea surrounded rock, after the winds are laid. The dark moss whistles there, and the distant mariner sees the waving trees †.—"But Ossian is a tree that is withered. Its branches are blasted and bare; no green leaf covers its boughs. From its trunk no young shoot is seen to spring. The breeze whistles in its grey moss: the blast shakes its head of age.—The storm will soon overturn it, and strew all its dry branches with thee, O Dermid! and with all the rest of the mighty dead, in the green winding vale of Cona ‡."

It is not certain at what age Ossian died; but from his having been long blind with years, and from the many contrasts between his present and past situations, in poems composed, as it would appear, at a considerable distance of time from each other, it is most likely he lived to an extreme old age. The current tradition is, that he died in the house of a Culdee, called the *Son of Alpin*, with whom he is said to have held several conferences about the doctrines of Christianity. One of these dialogues is still preserved, and bears the genuine marks of a very remote antiquity; (*Dissertation* prefixed to *Ossian's Works*). Several of Ossian's poems are addressed to this son of Alpin, who was probably one of those Christians whom the persecution under Dioclesian had driven beyond the pale of the Roman empire.

The

Ossian.

The poems of Ossian, though always held in the highest esteem by those who knew them, were allowed to remain in the obscurity of their original Gaelic, till Mr Macpherson, about 30 years ago, translated a collection of them into English, which immediately attracted the attention of every person who had a true taste for poetry. Dr Blair, in particular, introduced these poems into the world with those critical remarks which do no less honour to himself than to the poet. According to that eminent critic, the two great characteristics of Ossian's poetry are tenderness and sublimity. Ossian is, perhaps, the only poet who never relaxes, or lets himself down into the light and amusing strain. He moves perpetually in the high region of the grand and pathetic. The events which he records are all serious and grave; the scenery wild and romantic. We find not in him an imagination that sports itself, and dresses out gay trifles to please the fancy. His poetry, more perhaps than that of any other, deserves to be styled the *Poetry of the heart*. It is a heart penetrated with noble sentiments, with sublime and tender passions; a heart that glows and kindles the fancy; a heart that is full, and pours itself forth. Of all the great poets, Homer is the one whose manner and whose times come the nearest to Ossian's. Homer's ideas were more enlarged, and his characters more diversified. Ossian's ideas fewer, but of the kind fittest for poetry; the bravery and generosity of heroes, the tenderness of lovers, and the attachment of friends. Homer is diffuse; Ossian abrupt and concise. His images are a blaze of lightning, which flash and vanish. Homer has more of impetuosity and fire; Ossian of a solemn and awful grandeur. In the pathetic, Homer has a great power; but Ossian exerts that power much oftner, and has the character of tenderness more deeply imprinted on his works. No poet knew better how to seize and melt the heart. With regard to dignity of sentiment, we must be surprised to find that the pre-eminence must clearly be given to the Celtic bard. This appears nowhere more remarkable than in the sentiments which he expresses towards his enemies. "Uthal fell beneath my sword, and the sons of Berrathon fled.—It was then I saw him in his beauty, and the tear hung in my eye. Thou art fallen, young tree, I said, with all thy beauty round thee. Thou art fallen on thy plains, and the field is bare. The winds come from the desert, and there is no sound in thy leaves! Lovely art thou in death, son of car-borne Lathmore †." His supposition, that all the little feuds and differences of this life should be forgot in a future state, and that those who had once been foes would "stretch their arms to the same shell in Loda," gives us the highest idea of the man as well as of the poet. "Daughter of beauty, thou art low! A strange shore receives thy corse. But the ghosts of Morven will open their halls when they see thee coming. Heroes around the feast of dim shells, in the midst of clouds, shall admire thee; and virgins shall touch the harp of mist ‡."—"The feuds of other years by the mighty dead are forgotten. The warriors now meet in peace, and ride together on the tempest's wing. No clang of the shield, no noise of the spear, is heard in their peaceful dwellings. Side by side they sit, who once mixed in battle their steel. There, Lochlin and Morven meet at the

† Ossian's Works, poem of Berrathon.

‡ Gaelic Antiquities, poem of Trachal.

mutual feast, and listen together to the song of their bards §."

But the sublimity of moral sentiments, if they wanted the softening of the tender, would be in hazard of giving a stiff air to poetry. It is not enough that we admire. Admiration is a cold feeling in comparison of that deep interest the heart takes in tender and pathetic scenes. With scenes of this kind Ossian abounds; and his high merit in these is incontestable. He may be blamed for drawing tears too often from our eyes; but that he has the power of commanding them, no man who has the least sensibility can question. His poems awake the tenderest sympathies, and inspire the most generous emotions. No reader can rise from him without being warmed with the sentiments of humanity, virtue, and honour.

But the excellency of these poems occasioned in many persons a doubt of their authenticity. Their genuineness, however, has been very ably defended by Dr Blair and Lord Kames, and warmly supported by the author of the *Gaelic Antiquities*, who has given the public some more remains of Ossian's poetry.

As the nature of our work will not allow us to treat this matter at full length, we shall only give a brief view of the arguments offered in support of the authenticity of these poems, referring our readers to the authors just now mentioned and others, for fuller satisfaction.

"In every period of society (says Dr Blair), human manners are a curious spectacle; and the most natural pictures of ancient manners are exhibited in the ancient poems of nations. These make us acquainted with the notions and feelings of our fellow-creatures in the most artless ages; discovering what objects they admired, and what pleasures they pursued, before those refinements of society had taken place, which enlarge indeed, and diversify the transactions, but disguise the manners of mankind.

"Besides this, ancient poems have another merit with persons of taste. They promise some of the highest beauties of poetical writing. That state, in which human nature shoots wild and free, though unfit for other improvements, certainly encourages the high exertions of fancy and passion.

"In the infancy of societies the passions of men have nothing to restrain them: their imagination has nothing to check it. And as their feelings are strong, so their language of itself assumes a poetical turn. Men never have used so many figures of style, as in those rude ages, when, besides a warm imagination to suggest lively images, the want of proper and precise terms for the ideas they would express, obliged them to have recourse to circumlocution, metaphor, comparison, and all those substituted forms of expression, which gave a poetical air to language. An American chief, at this day, harangues at the head of his tribe in a more bold metaphorical style than a modern European would adventure to use in an epic poem.

"Poetry has been said to be more ancient than prose, which, in a qualified sense, is true. Music or song has been found coeval with society among the most barbarous nations; and the only subjects which could prompt men, in their first rude state, to utter their thoughts in compositions of any length, were such as naturally

Ossian.

§ 1b. poem of Dargo.

Offian.

naturally assumed the tone of poetry; praises of their gods, or of their ancestors; commemorations of their own warlike exploits; or lamentations over their misfortunes. And before writing was invented, no other compositions, except songs or poems, could take such hold of the imagination and memory, as to be preserved by oral tradition, and handed down from one race to another.

"Hence we may expect to find poems among the antiquities of all nations. It is probable, too, that an extensive search would discover a certain degree of resemblance among all the most ancient poetical productions, from whatever country they have proceeded. In a similar state of manners, similar objects and passions operating upon the imaginations of men will stamp their productions with the same general character. Some diversity will, no doubt, be occasioned by climate and genius. But mankind never bear such resembling features as they do in the beginnings of society. What we call the *oriental vein* of poetry, because the earliest poetical productions have come to us from the east, is probably no more *oriental* than *occidental*; it is characteristic of an age rather than a country; and belongs, in some measure, to all nations at a certain period. Of this the works of Offian seem to furnish a remarkable proof.

"He appears clearly to have lived in a period which enjoyed all the benefit I have just now mentioned of traditionary poetry. The exploits of Trathal, Trenmor, and the other ancestors of Fingal, are spoken of as familiarly known. Ancient bards are frequently alluded to. In one remarkable passage, Offian describes himself as living in a sort of classical age, enlightened by the memorials of former times, conveyed in the songs of bards, and points at a period of ignorance which lay beyond the reach of tradition. Offian himself appears to have been endowed by nature with exquisite sensibility; prone to that tender melancholy which is so often an attendant on great genius; and susceptible equally of strong and of soft emotions. He was not only a professed bard, but a warrior also, and the son of the most renowned hero and prince of his age. This formed a conjunction of circumstances uncommonly favourable towards exalting the imagination of a poet.

"The manners of Offian's age were favourable to a poetical genius. Covetousness and effeminacy were unknown. The cares of men were few. The great object pursued by heroic spirits, was, 'to receive their fame,' that is, to become worthy of being celebrated in the songs of bards; and 'to have their names on the four grey stones.' To die unlamented by a bard, was deemed so great a misfortune as even to disturb their ghosts in another state. In such times as these, in a country where poetry had been so long cultivated, and so highly honoured, is it any wonder that among the race and succession of bards, one Homer should arise: a man who, endowed with a natural happy genius favoured by peculiar advantages of birth and condition: and meeting in the course of his life, with a variety of incidents proper to fire his imagination, and to touch his heart, should attain a degree of eminence in poetry, worthy to draw the admiration of more refined ages?"

Offian.

Besides, his compositions, when viewed in themselves, have, we are told, all the internal marks of antiquity so strongly impressed upon them, that no reader of taste and judgment can deny their claim to it. They exhibit so lively picture of customs which have disappeared for ages, as could be drawn only from nature and real life. The features are so distinct, that few portraits of the life continually passing before us are found to be drawn with so much likeness. The manners uniformly relate to a very early stage of society; and no hint, no allusion to the arts, customs, or manners, of a more advanced period, appears throughout the poems. To that distinction of ranks, which is always found in adult societies, the poet appears to have been a perfect stranger. The first heroes prepare their own repasts, and indiscriminately condescend to the most menial services. Their quarrels arise from causes generally slight, but in such a period extremely natural. A rivalry in love, an omission at a feast, or an affront at a tournament, are often the foundation of a quarrel among single heroes. And the wars in which whole tribes are engaged, are carried on with a view, not to enlarge their territory, but to revenge perhaps the killing of a few deer on their mountains, or the taking forcibly away one of their women. Their occupation was war and hunting; and their chief ambition was to have their fame in the songs of the bards.

The notions of a future state, exhibited in these poems, are likewise strongly marked with the character of antiquity. A creed so uncommon that the imagination of a modern could not be supposed to grasp so strong an idea of it from mere fancy, is uniformly supported throughout. This creed is extremely simple, but admirably suited to the times.

The language too, and the structure, of these poems, bear the most striking characters of antiquity. The language is bold, animated, and metaphorical, such as it is found to be in all infant states; where the words, as well as the ideas and objects, must be few; and where the language, like the imagination, is strong and undisciplined. No abstract, and few general, terms appear in the poems of Offian. If objects are but introduced in a simile, they are always particularized. It is "the young pine of Inishuna;" it is "the bow of the showery Lena." This character, so conspicuous in the poems of Offian, is a striking feature in the language of all early states; whose objects and ideas are few and particular, and whose ordinary conversation is of course highly figurative and poetical. A picture, therefore, marked with such striking features, could not be drawn without an original.

The whole texture of the composition is also, like the language, bold, nervous, and concise; yet always plain and artless; without any thing of that modern refinement, or elaborate decoration, which attend the advancement of literature. No foreign ornaments are hunted after. The wild and grand nature which lay within the poet's view, is the only source from which he draws his ornaments. Beyond this circle, his imagination, though quick and rapid, seldom made any excursion. We perceive his language always to be that of a person who saw and felt what he describes; who bore a part in the expeditions which he celebrates,

Ossian

brates, and who fought in the battles which he sings. Such is the nature of the internal proof adduced in the present case, which, unquestionably has weight, and that not inconsiderable; but unsupported by external proof, or contrary to facts, however forcible it may be in itself, when considered in this connection, and found wanting, it will neither silence the querulous sceptic, nor, in all probability, will it ever convince those who have truth for their object, and who wish to investigate, and, if possible, discover it on surer grounds. Internal proof is of the greatest service in a variety of excellent causes; but it comes in rather as a succedaneum than as direct evidence; and without something more to the purpose, it may excite admiration, but will seldom enforce belief. Of the customs and manners of ancient times, we know but little, and of that little we have often but a confused notion. There is therefore room for genius and ability to exert itself in deceiving; and in proportion to the darkness in which the subject is involved, the deception will generally be the more complete, and the secret windings of error less easy to be developed.

Destitute of external proofs, authenticity may appear to be probable, but cannot be certain; and in such circumstances, on many occasions, and especially with respect to ancient writings, we may, without any offence to truth or to sound reasoning, give them up as spurious. In the present instance, therefore, it is just and proper to add to what has been already said, the more external and positive proofs of the authenticity of the poems in question, by the strength or weakness of which the subject must be finally determined. It is observed, therefore, That there have been in the Highlands of Scotland, for some ages back, a vast many poems ascribed to Ossian: That these poems have been held in the highest veneration, repeated by almost all persons, and on all occasions. These are facts so well known, that nobody as yet has been hardy enough to deny them. There is not an old man in the Highlands, who will not declare, that he heard such poems repeated by his father and grandfather, as pieces of the most remote antiquity. There is not a district in the Highlands where there are not many places, waters, isles, caves, and mountains, which from time immemorial are called after the names of Ossian's heroes—There is not a lover of ancient tale or poetry, however illiterate, who is not well acquainted with almost every single name, character, and incident, mentioned in those translations of Ossian's poems, which he may have never heard of.—Bards, who are themselves several centuries old, quote those poems, imitate them, and refer to them.—The ordinary conversation and comparisons of the Highlanders frequently allude to the customs and characters mentioned in them;—and many of their most common proverbs, established by the most ancient use, are lines borrowed from the poems of Ossian.\*—The most ancient of the clans boast of deriving their pedigree, each from some one of Ossian's heroes;—and many of the signs armorial assumed by them, are drawn from the feats ascribed to their predecessors in those poems†.—Manuscripts are mentioned, in which some of those have been preserved for several centuries‡; and a list of living names, in different parts of the

Highlands, is appended to, as persons who still repeat a part of these poems ||.—Whilst Mr Macpherson was engaged in the translation, many respectable persons, gentlemen and clergymen, avowed to the public, that these were Ossian's poems, with which they had long been acquainted, and that the translation was literal §. This appears also from the large specimens of the originals published and compared by proper judges. The originals lay a considerable time in the hands of the bookseller, for the inspection of the curious; they have been afterwards shown frequently to many of the best judges, and offered for publication if the editor had been favoured with subscriptions. The editor of the pamphlet, in which their authenticity is attested by many respectable names of undoubted veracity, observes, by way of conclusion, "that more testimonies might have been produced by a more enlarged correspondence with the Highland counties: But I apprehend, if any apology is necessary, it is for producing so many names in a question where the consenting silence of a whole country was, to every unprejudiced person, the strongest proof that spurious compositions, in the name of that country, had not been obtruded upon the world." It is likewise argued in support of the authenticity of these poems, that candid sceptics, on hearing some of them repeated by illiterate persons, who had never seen the translation, caused them to give the meaning of what they repeated, by an extempore translation into English, and by this means had all their doubts of the authenticity of Ossian removed\*. They urge further, that such passages of Ossian's works as are still repeated by some old men, are among the most beautiful parts of Ossian's poems; such as the battle of Lora, the most affecting parts of Carthon, Berrathon, the death of Osear, and Darthula, or the children of Ufnoth, &c.": which gives a credibility to his being equal to the other parts of the collection, none of it being superior to these in merit.

To these and the like arguments advanced in support of the authenticity of the poems ascribed to Ossian, many objections have been urged. Those of Johnson and his friend Shaw are universally known. A later writer objects to them in the following manner: No fragments of British poetry in Scotland are to be found. Many specimens of Irish poetry in Scotland have been published: but none older than a century or two. Translations have also appeared; but in general, of no fidelity. Those of the poems ascribed to Ossian, in particular have deservedly drawn much of the public attention; but they will only mislead any reader who wishes to form an idea of Celtic poetry. He that believes Ossian to have flourished about the year 300, and his writings preserved by oral tradition for 1460 years, large is his faith, and he might move mountains! Gentlemen of the Highlands of Scotland, with whom our author conversed on the subject, assured him, that they looked upon nine-tenths of Mr Macpherson's work as his own; and upon the other tenth, as so much changed by him, that all might be regarded as his own composition. There are positive evidences, he says, which convince him that not one of the poems given to Ossian, and probably not one passage of them, is older than the 15th century.

‡ Kames's *Sketches*. B. i.

*Ossian* century. The very first author we know who mentions Fingal is Barbour, a Scotch poet, who wrote in 1375. Fingal was an Irish hero : and one Good, a schoolmaster, of Limeric, sent some account of Ireland to Camden, in 1566, in which mention is made of some strange fables, that the people amuse themselves with, about the "giants *Fin Mac Huyle*, and *Otter Mac Oshin*," of which we shall speak more largely presently. In the mean time, to these, and such like objections, it has been answered, That poetry has been cultivated with most success in the earliest stages of society ; that in Greece, Orpheus, Linus, Hesiod, and Homer, wrote their admiral poems some ages before any thing had been written in prose in the Greek language ; that the book of Job, written in a very early period of society, is highly poetical ; that among the tribes of Lapland and America, there have been found, in the earliest state, some excellent pieces of poetry. That the Caledonians, in particular, had some peculiar institutions, which tended to improve their poetry : their druids were among the most learned philosophers which perhaps any age or country produced ; their bards or poets were the disciples of those druids, and were always a standing order, to which none but the most promising geniuses were admitted. This standing college of poets was furnished, not only with the fruits of their own long study and observation, but also with as much as merited to be preserved of the compositions of their predecessors in office, since the "light of the song" first dawned. They had the advantage of one another's conversation ; which would excite their emulation, and make them aspire to eminence : They were always present, and generally engaged, in every grand operation that was transacted ; which could not fail to inspire their muse with the truest poetic fire.

The case of Ossian was particularly favourable. He lived in an age when manners came to a considerable degree of refinement under the care of the bards and druids. Poetry in his day was considerably advanced ; and the language, though strong and figurative, had undergone some degree of cultivation, and learned to flow in regular numbers, adapted to the harp, the favourite instrument of the times. As a prince and a warrior, his mind must have been expanded and much enlarged by his excursions to other countries. At home he had Ullin, Alpin, Carril, and Ryno, to converse with ; all of them poets of eminence, who would have advanced him greatly by their example and conversation. All these advantages, meeting with a native fire and enthusiasm of genius, as in the case of Ossian, may well be supposed to have produced poems that might challenge the veneration of ages.

But it is not to their merit alone that we owe the preservation of these poems so long by oral tradition. Other circumstances concurred ; of which, the institution of the BARDS deserves particular notice. In a country, the only one perhaps in the world in which there was always, from the earliest period almost to the present age, a standing order of poets, we cannot reasonably be surpris'd, either at finding excellent poems, compos'd, or, after being compos'd, carefully preserv'd from oblivion. A great part of the business of this order was to watch over the poems of Ossian. In every family of distinction there was

*Ossian* always one principal bard, and a number of disciples, who vied with each other in having these poems in the greatest perfection. Should the institution of the bards last for ever, the poems of Ossian could never perish.

Nor were they only the bards of great families who took an interest in these poems ; the vassal, equally fond of the song with his superior, entertained himself in the same manner. This, with a life free from care, a spirit unbroken by labour, and a space of time unoccupied by any other employment or diversion, contributed to render the Highlanders a nation of fingers and poets. From such a people, the superior merit of Ossian's poems would naturally procure every encouragement, which they always retained as long as the manners of the people remained unchanged.

Many other reasons conspired to preserve the poems of Ossian. The martial and intrepid spirit which they breathed, made it the interest of the chieftains to preserve them : the strain of justice, generosity, and humanity, which runs through them, recommended them to the superintendants of religion, who well knew how much the morals of a people must be tinctured with those songs which they are continually repeating, and which have all the advantages of poetry and of music. In superstitious ages, the people revered these poems, from their being address'd generally to some, "son of the rock," supposed to be the tutelar saint of the place, or the great Irish apostle St Patrick. Besides, every hill and dale which the natives of the Highlands walked over, was classic ground. Every mountain, rock, and river, was immortalis'd in the song. This song would naturally be suggest'd by the sight of these objects, and every body would hum it as he walked along. All the proverbs and customs to which these poems gave rise, would operate in the same manner. The son would ask what they meant, and the father would repeat the song from which they were taken. The distinct and unsubdu'd state in which the Highlanders remained for so long a course of ages, every clan, one generation after another, inhabiting the same valley, till towards the present century, contributed much to preserve their traditions and their poems ; and the constant and general custom of repeating these in the winter-nights, kept them always alive in their remembrance.

To these causes and customs the preservation of Ossian's poems, for so many ages, has been ascribed. But these causes and customs have ceased to exist ; and the poems of Ossian, of course, have ceased to be repeated.—Within a century back, the Highlands of Scotland have undergone a greater revolution than it had done for ten before that period. With a quicker pace the feudal system vanished ; property fluctuated ; new laws and new customs step'd in, and supplanted the old ; and all this with such sudden and such violent convulsions, as may well account for the shaking of a fabric which had stood so many ages, that it seem'd to have bidden defiance to all the injuries of time. Even since Mr Macpherson gathered the poems in his collection, the amusements, employments, and taste of the Highlanders are much altered. A greater attention to commerce, agriculture, and pasturage, has quite engross'd that partial attention which was paid,

Ossian.

even then, to the song of the bard. In twenty years hence, if manners continue to change so fast as they do at present, the faintest traces will scarce be found of those tales and poems. "Ossian himself is the last of his race; and he too shall soon be no more, for his grey branches are already strewed on all the winds."

Among the causes which make these poems vanish so rapidly, poverty and the iron rod should come in for a large share. From the baneful shade of those murderers of the muse, the light of the song must fast retire. No other reason needs be given why the present Highlanders neglect so much the songs of their fathers.—Once, the humble, but happy vassal, sat at his ease, at the foot of his grey rock or green tree. Few were his wants, and fewer still his cares; for he beheld his herds sporting around him, on his then unmeasured mountain. He hummed the careless song, and tuned his harp with joy, while his soul in silence blessed his children.—Now, we were going to draw the comparison:

—fed Cynthius aurem  
Velut et admonuit.

It is more agreeable to remark, as another cause for the neglect of ancient poems and traditions, the growth of industry, which fills up all the blanks of time to more advantage, and especially the increase of more useful knowledge.—But above all, the extinction of the order of the bards hastened the catastrophe of Ossian's poems. By a happy coincidence Macpherson overtook the very last that remained of this order, (Macvurich, bard to Clanronald), and got his treasure. This fact (with the red book furnished by Mr Macdonald of Croidart, and some other MSS.) accounts for Mr Macpherson's having found these poems in greater number and perfection than they could ever since be met with. The fragments, however, which have since been gathered, give a credibility to every thing that has been said of the original grandeur of the building.

Although this disquisition has already extended to a length which readers not partial to Scottish antiquities will perhaps think too great, we cannot dismiss it without observing, that Fingal and Ossian have been claimed by the Irish as well as by the Caledonians. On this double claim, as well as on the controversy concerning the authenticity of the poems, there is so much candour and good sense in the following remarks of T. F. Hill, published in the 53d volume of the Gentleman's Magazine, that we cannot deny ourselves the pleasure of making them conclude the article.

Mr Hill travelled through the Highlands of Scotland during the summer months of 1780. He seems to have been very ardent in his inquiries concerning Ossian, and to have conducted those inquiries with great judgement. The consequence was, that he received different accounts in different places, and picked up various songs relating to Fingal and his heroes.

"From this collection, it is evident (he says) that there are many traditional songs preserved in the Highlands relating to Fingal and his heroes, as well as to several other subjects. It is also evident, that these

songs contain portions of the very poems published by Mr Macpherson and Mr Smith, under the name of *Ossian*. We may therefore justly conclude, that those poems are not wholly the forgery of their editors, but compiled at least from original songs. I by no means think it worth my while to notice the various concessions in favour of this conclusion, which the minor antagonists of Ossian have of late been forced to make. I myself have given proofs of it, which need, I hope, no external confirmation. To these proofs might be added, that I met with many traditional preservers of these songs, in every different part of the Highlands; some of whom, especially in Argyleshire, Lochabar, and on the rest of the western coast, were said to possess various poems attributed to Ossian, although I had neither leisure nor opportunity to collect copies from them.—But enough has already been said on this subject, if my testimony deserves regard.

"These principles being established, it remains to be considered how far the poems published by Macpherson and Smith deserve to be considered as the works of Ossian.

"The songs attributed to that bard, which contain passages of the Ossian of Macpherson and Smith, are by no means uniformly consistent with the poems in which the parallel passages are found, but frequently relate to different events, and even contain different circumstances. From hence it seems most probable, that Mr Macpherson and Mr Smith compiled their publications from those parts of the Highland songs which they most approved, combining them into such forms as according to their ideas were most excellent, and preserving the old names and the leading events. In this process they were supported and encouraged by the variety of songs preserved in the Highlands upon the same subject, and by the various modes in which the same event is related. Mr Macpherson may indeed have MSS. of all the poems he has published; which MSS. may either have been compiled by himself, or by some former collector; or they may possibly contain entire poems really ancient. But Mr Smith has honestly acknowledged, that he himself compiled his Ossian in the manner above described. 'After the materials were collected (says he), the next labour was to compare the different editions; to strike off several parts that were manifestly spurious; to bring together some episodes that appeared to have a relation to one another, though repeated separately; and restore to their proper places some incidents that seemed to have run from one poem into another:—and hence it was unavoidably necessary to throw in sometimes a few lines or sentences to join some of the episodes together.—I am sensible that the form of these poems is considerable altered from what is found in any one of the editions from which they are compiled. They have assumed somewhat more of the appearance of regularity and art—than that bold and irregular manner in which they are originally delivered.'

"Mr Smith also speaks of the Ossian of Mr Macpherson in a somewhat similar manner: 'That we have not the whole of the poems of Ossian, or even of the collection translated by Mr Macpherson, we allow: yet still we have many of them, and of almost all a part.

Ossian.

Ossian.

part. The building is not entire, but we have still the grand ruins of it.

"What portion, therefore, of the Ossian of Macpherson and Smith is original, no man can determine except themselves. Smith indeed says, that he has mentioned all his *material* alterations, transpositions, and additions, in his notes; and that, *for the most part*, he was guided in them by the Sgeulachds, or traditional tales accompanying the songs; but there are few such notes in his book, and perhaps as few Sgeulachds in the mouths of the Highlanders. In Macpherson and Smith also we see these poems divested of their idiomatic peculiarities and fabulous ornaments; which renders it impossible to discover what manners and opinions are really ancient, and what are of modern invention. Yet it is remarkable, that in spite of all the objections to their authenticity, necessarily produced by such a treatment of them, they still possess an internal evidence of originality which has enabled them hitherto to withstand all the torrent of opposition.

"The Ossian of Macpherson and Smith appears therefore to be a mutilated work, even though we should suppose that the songs they originally compiled from were the undoubted works of that celebrated bard. But this is far from being the case; for even allowing that an Ossian ever existed and wrote, yet time must have introduced such material changes in his works, if preserved merely by tradition during so long a period, that their own author would hardly know them again. I think it however doubtful, whether such a being as Ossian ever appeared in the world.

"All the songs which I met with in the Highlands relative to the Feinne or Fingalians were attributed to Ossian: his name seems merely a common title, which is ascribed to all the poetic annals of his race.

"From these considerations, we seem authorized finally to conclude, that the Ossian of Macpherson and Smith is a mutilated compilation from Highland songs, ascribed indeed to that bard, yet very little likely to be his composition. Out of these they selected the best parts, and rejected such as they thought might discredit the character of Highland antiquity; attributing them to later times, and the ignorant bards of the fifteenth century. Perhaps even the works of Homer himself, which had so many different editions, very considerably varying from each other, were compiled by a somewhat similar process from the ancient Greek songs.

"Another question remains to be considered: Whether these songs are the compositions of the Highlands or of Ireland? and, Whether Ossian was an Irish or a Caledonian Scot? It is my opinion, that the songs in this collection evidently manifest a connection with Ireland, though their traditional preservation in Scotland has sometimes introduced the name of Scotland in its stead. One of their principal personages is St Patrick, the peculiar apostle of Ireland, which alone seems sufficient to mark their origin (A). If there-

fore we may reason from a part to the whole, it is just to conclude, that all the other songs preserved in the Highlands relative to the Fingalians are also Irish. They are wholly confined to the western coast of the Highlands, opposite Ireland; and the very traditions of the country themselves acknowledge the Fingalians to be originally Irish. The genealogy of Fingal was there given me as follows: Fion Mac Coul, Mac Trathal, Mac Arslat Riogh Erin, or king of Ireland; thus attributing the origin of his race to the Irish. I am inclined to believe that these notions about Fingal were common to the Scots in the most ancient times, and brought by them from Ireland to Scotland, the hereditary superstition of both races; for, notwithstanding it may appear most probable that Ireland should receive colonies from Scotland than the contrary, we have direct historic evidences that Scotland received them from Ireland; and no bare theoretic probability deserves to be opposed to the positive assertions of history.

"With regard to the Erse manuscripts, about which so much has been said, it becomes me to acknowledge, that I have never seen enough of them to give any decided opinion: those which I have seen induce me to think they principally owe their existence to Ireland.

"I shall not repeat what others have said to prove the Fingalians Irish; though the connection of Fingal with Ireland has been already warmly asserted.

"But an unnoticed though curious passage in Camden affords us the most remarkable, and perhaps the most convincing, proof that Fingal is an Irish hero, which demonstrates at least that he was indisputably claimed by the Irish 200 years ago. It is contained in an extract (already mentioned) made by Camden, from an account of the manners of the native Irish, written by one Good, a schoolmaster at Limerick, in 1566. 'They think,' says he, speaking of Ireland and its inhabitants, 'the souls of the deceased are in communion with famous men of those places, of whom they retain many stories and sonnets; as of the giants Fin-Mac-Huyle, Osker-Mac-Ofshin, or Ofshin-Mac-Owim; and they say, through illusion, that they often see them.'

"The very material importance of this curious passage, with relation to the present subject, it is unnecessary to urge; for every eye must see it. We also obtain from it new information in respect to the last part of the history of Fingal and his heroes; as it enables us to determine who they were, with a precision which must otherwise have been wanting, to complete these remarks on the Highland songs.

"The singular agreement of this passage with the accounts of Ossian which were taught me in Scotland is worthy particular remark; it confirms them even in the most novel and peculiar instances. The Fingalians were generally represented as giants; but the most remarkable concurrence is in the mythologic character attributed by both to Fingal, Osker, and Ossian.

3 X 2

In

(A) "The Scots indeed lay claim to the birth of St Patrick, and boast also his burial place. Camden, edit. Gibson, 1695, pp. 921, 1014. And so also do the Britons, *ib.* p. 631, 1014; but his life and miracles all agree to attribute to Ireland. In Gough's edition of Camden, the account of St Patrick is in vol. iii. p. 612, 618. See PATRICK (St).

*Offian.* In proof of this, I have to observe, that Mac Nab described Fingal as the Odin of the Scots, and that a song called *Urnigh Offian* evidently speaks of him as such. This curious passage represents him exactly in the same character; a hero with whom the spirits of the deceased are in communion, who is their chieftain, and the lord of their feasts. The gods of all the northern nations seem to have been of this class; mighty heroes, esteemed once to have been invincible on earth, though perhaps not ever strictly men, nor yet constantly regarded as giants. Such are Odin, Thor, and the other Teutonic gods; such are Fingal, Oscar, and the rest of the Fingalians among the ancient Scots; such also are Hercules, Bacchus, and even Jupiter himself, with all his sons and daughters, among the original Greeks, a people who agreed in many particulars with our own ancestors in northern Europe. The notions entertained about ghosts, as an intermediate order of beings between men and divinities, endowed with some share of power to do evil, is also remarkably congruous with this mythology.

"As Fingal was a divine hero, so Offian seems to have been a divine bard. Some of the gods of the Teutons were bards in like manner: the god Niord and his wife Skada quarrelled in elegant verse of their own composition; and Odin is the relator of his own Edda. Apollo, the poetic deity of Greece, likewise sung the history of his fellow-deities to men on earth, as well as Orpheus his son. The bards and traditional preservers of songs in Scotland and Ireland have ever been fond of ascribing all ancient poems to this Offian, and especially those relating to his own race; and from this cause the poems ascribed to Offian are become so voluminous. The ancient Egyptians had a similar custom of ascribing their works to Hermes: *οι ημετεροι προβουνοι τα αυτων της σοφιας επιματα αυτοι ανεπιστησειν ερχουσαντα τα οικεια συγγραμματα επονομαζοντες*, says Jamblichus, S. I. c. 1. which rendered the Hermetic writings equally voluminous. The Egyptians, who possessed the art of writing, deposited their works in the adyta of their temples; as the Arabians deposited their poems of old in the temple of Mecca: but because the Egyptians affixed to them no author's name, except that of Hermes, to him, as to the Scottish Offian, almost all the national literature was attributed by religious flattery.

"I sincerely wish, that some gentleman possessed of adequate abilities and acquaintance with the Erse language, would undertake to collect these Offianic songs in their simple original state; as they undoubtedly contain much curious knowledge, accumulated in the various ages through which they have descended to us, and would probably afford much new information on subjects at present very ill understood. I own, however, that I should rather choose to seek for them in Ireland than in Scotland; but neither country should be unexplored.

"After having thus freely, though I hope not uncandidly, delivered my sentiments on the Offian of Mr Macpherson, it becomes me to acknowledge myself deeply indebted to it for the pleasure in perusal it has frequently afforded me. I am willing, and indeed happy, thus publicly to declare myself a warm admirer of it as a literary composition. The novelty of its manner, of its ideas, and of the objects it describes,

added to the strength and brilliancy of genius which frequently appear in it, have enabled me to read it with more delight, and to return to it more frequently, than almost any other work of modern times. And let it be regarded in what light it may, the praise of elegant selection and composition certainly belongs to its editor. If I had not entertained these opinions of its merit, I should never have taken so much pains to investigate its authenticity; nor indeed can I believe, if the general opinion had not concurred with mine, that the world would ever have wasted so much time in disputing about it."

**OSSIFICATION**, in the animal œconomy, the formation of the bones, but more particularly the conversion of parts naturally soft to the hardness and consistency of bones. Bones, Dr Drake contends, are formed out of the most comminute or broken parts of the blood; since we see that the blood of old men, which by a long course of circulation becomes in a manner unfit for the common office of nutrition, will however ossify, and convert into bones, many of the tendons and ligaments, and even the coats of the vessels themselves, whose substance being next to the bones the most compact, admits only of the smallest particles of the blood, which therefore soonest become osseous, as they are frequently found. Dr Nesbit's opinion of ossification is, that in the blood, or a fluid secreted from it, there is an ossifying juice, having particles which are not apparent; that whenever nature designs an ossification between membranes, or within a cartilage, she occasions a more than usual afflux of this fluid; which so much distends the vessels which were before invisible, as to make them capable of receiving the red globules of blood, which is always to be seen near to the place where ossification is begun. In this blood, gritty bony particles may be felt by the point of a knife, which have been formed by the attraction and cohesion of the particles of the ossifying juice obstructed, along with the other grosser fluids, in the beginning of the vessels prepared to receive reffluent juices. The blood being capable of forming fine membranes, the membranous parts of a bone, which act as a gluten to keep these particles and fibres together, if there be any such, that do not arise from the coats of its vessels, are produced by a cohesion round the cretaceous particles of a part of the fluid, in which they were generated and contained. Thus the membranes of cartilages serve as a bed between or within which the bony particles are deposited, or shoot; but without any intermixture of the particles of the bone and cartilage, or continuation of the fibres of the one substance to those of the other; as is evident in cartilages containing bones kept long enough in water, and then slit; for the bone will, as soon as the large vessels that enter its substance are divided, slip as easily, and perhaps easier, from it than an acorn does out of its cup: and there is a smoothness and polish of the parts of both cartilage and bone, which show there is no conjunction of the fibres of the two substances. While the bones are increasing within cartilages, the cartilages are extended and spread out; by which, with the pressure which they suffer, and the great influx of various fluids, and the nutritious matter being hindered to flow freely into them, they decrease continually, and at last may truly be said to be entirely destroyed. Dr Buddeus endeavours to

prove,

**Ossifragum** prove, that the preternatural ossifications, which are commonly said to be formed in different parts of the body, do not deserve that name; for that these hard substances have scarce any other properties of bone except whiteness and hardness.

**OSSIFRAGUM**, in botany, a name given by Bartholinus, and some other writers, to a kind of grass which grows in some parts of Norway. It comes up early in the spring, before any other grass, and the cattle are tempted to eat it; but it emaciates them, and renders them sickly: their back bones become protuberant if they feed on it for any time; and their legs so weak that they can hardly go. The remedy among the country people, which is a very curious one, is this: They collect the bones of different animals, and break them into small pieces. The cattle greedily devour this sort of food when offered them in this disease, and there follows a sort of drivelling at the mouth for a considerable time, after which they become perfectly well. It is possible there may be much absurdity in this story. The kingdom of Norway is full of mines, and the effluvia of these may be the occasion of the cattle's illness, and the ceasing of these effluvia their cure; for it is not probable that either of these effects should be owing to the grass or the bones.

**OSSORY**, the west division of Queen's-county in Ireland.

**Ossory** (Bale bishop of). See **BALE**.

**OSSUNA**, an ancient and considerable town of Andalusia in Spain, with an university, an hospital, and the title of a duchy. N. Latitude 37. 8. W. Long. 4. 18.

**OSTADE** (Adrian Van), an eminent Dutch painter born at Lubec in 1610. He was a disciple of Francis Hals, in whose school Brouwer was cotemporary with him, where they contracted an intimate friendship. The subjects of his pencil were always of a low kind, he having nearly the same ideas as Teniers; diverting himself with clowns and drunkards in stables, ale-houses, and kitchens. His pictures are so transparent and highly finished, that they have the polish and lustre of enamel: they have frequently a force superior to Teniers; yet it were to be wished that he had not designed his figures so short. He is perhaps one of the Dutch masters who best understood the *chiaro oscuro*; and he was often employed to paint figures for the best landscape-painters of his countrymen. He died in 1685. His works, especially those of his best time and manner, are very scarce; so that when they are to be purchased, no price is thought too much for them. His prints etched by himself, large and small, consist of 54 pieces.

**OSTALRIC**, a town of Spain, in Catalonia. It had a strong castle, but was taken by the French and demolished in 1695. It is seated on the river Tordera, in E. Long. 2. 45. N. Lat. 24. 44.

**OSTEND**, a very strong sea port town of the Netherlands, in Austrian Flanders, with a good harbour and a magnificent town-house. It is not very large, but it is well fortified. It was much more considerable before the long siege of the Spaniards, which continued from 1601 to 1604, when it was almost entirely reduced to ashes. The Dutch lost 50,000 men, and the Spaniards 80,000. Isabella Eugenia, gover-

nante of the Netherlands, made a vow she would not shift her smock before Ostend surrendered; but before the town was taken it had greatly changed its colour. However, the ladies of the court, to keep her in countenance, had theirs dyed, that they might be like that of their mistress. This place was taken by the Dutch in 1706, but restored to the emperor in 1724, when an East India company was established here, but entirely suppressed by treaty in 1731. It was taken by the French in August 1745, after ten days siege, but rendered back by the treaty of Aix-la-Chapelle. It was lately over-run by the French Republicans, with Dumourier at their head, but was quickly recovered by the junction of the allies; it is now again in the hands of the French; and what may be its fate in the issue of the present war cannot as yet be determined. It is ten miles W. of Bruges, eight N. E. of Newport, 22 N. E. of Dunkirk, and 60 N. W. of Brussels. E. Long. 3. 1. N. Lat. 51. 14.

**OSTEOCOLLA**, *οστεοκολλα*, in natural history, a white or ash-coloured sparry substance, in shape like a bone, and by some supposed to have the quality of uniting broken bones, on which account it is ordered in some plasters; a supposition we fear which is not warranted by experience. It is found in long, thick, and irregularly cylindric pieces, which are in general hollow, but are sometimes filled up with a marly earth, and sometimes contain within them the remains of a stick, round which the osteocolla had been formed; but though it is plain from thence that many pieces of osteocolla have been formed by incrustations round sticks, yet the greater number are not so, but are irregularly tubular, and appear to be formed of a flat cake, rolled up in a cylindric shape. The crusts of which these are composed do not form regular concentric circles round the internal cavity, as must have been the case had they been formed by incrustation. On the other hand, they plainly show that they were once so many thin strata, composing a flat surface, which has afterwards been rolled up, as one might do a paper three or four times doubled, into two, three, or more spiral lines; in which case, each single edge of the paper would be everywhere a regular point of a continued spiral line drawn from a given point; but they would by no means be so many detached concentric circles. The osteocolla is found of different sizes, from that of a crow-quill to the thickness of a man's arm. It is composed of sand and earth, which may be separated by washing the powdered osteocolla with water, and is found, both in digging and in several brooks, in many parts of Germany, and elsewhere. It is called *hammolteus* in many parts of Germany. It has this name in these places from its always growing in sand, never in clay, or any solid soil, nor even in gravel. Where a piece of it any where appears on the surface, they dig down for it, and find the branches run ten or twelve feet deep. They usually run straight down, but sometimes they are found spreading into many parts near the surface, as if it were a subterraneous tree, whose main stem began at 12 feet depth, and thence grew up in a branched manner till met by the open air. The main trunk is usually as thick as a man's leg, and the branches that grow out from it are thickest near the trunk, and thinner as they

**Osteocolla** they separate from it. The thinnest are about the size of a man's finger. The people employed to collect it, when they cannot find any mark of it on the surface, search after the specks of white or little lumps of whitish soft matter, which they find lying in various parts on the top of the sand. These always lead them either to a bed of perfect osteocolla, or to some in the formation. If they miss of it, they still find a substance, like rotten wood; which, when traced in its course, is found to proceed from a main trunk, at the depth of that of the osteocolla, and to spread itself into branches in the same manner. The diggers call this substance the flower of osteocolla or hammotheus.

The osteocolla found in the earth is at first soft and ductile; but in half an hour's time, if exposed to the air, it becomes as hard as we find it in the shops. The method to take up a perfect piece for a specimen is to open the ground, clear away the sand, and leave it so for an hour or thereabouts: in this time it will harden, and may be taken out whole. It is certain, that the osteocolla is produced at this time; for if a pit be cleared of it, there will more grow there in a year or two, only it will be softer, and will not harden so easily in the air as the other. What the rotten substance resembling the decayed branches of trees is, we cannot determine, unless it really be such; but the opinion of the common people, that it is the root of something, is absurd, because its thickest part always lies at the greatest depth, and the branches all run upwards. The osteocolla is a marly spar, which concretes round this matter; but what it is that determines it to concrete nowhere on the same ground but about these branches, it is difficult to say. The rottenness of this substance, which forms the basis of the osteocolla, renders it very liable to moulder and fall away; and hence it is that we usually see the osteocolla hollow. Sometimes it is found solid; but in this case there will be found to have been a vegetable matter serving as its basis, and instead of one branch, it will be found in this case to have concreted about a number of fibres, the remains of which will be found in it on a close examination. See *Philos. Trans.* n° 39.

**OSTEOLOGY**, that part of anatomy which treats of the bones. See *ANATOMY*, Part I.

**OSTERVALD** (John Frederick), a famous Protestant divine, was born at Neuschattel in 1663; and made such rapid progress in his studies, that he became master of arts at Saumur before he was 16 years of age. He afterwards studied at Orleans and at Paris. At his return to Neuschattel in 1699, he became pastor of the church there; and contracted a strict friendship with the celebrated John Alphonse Turretin of Geneva, and the illustrious Samuel Werenfels of Basil. The union of these three divines, which was called the *Triumvirate of the divines of Switzerland*, lasted till his death. Mr Osterwald acquired the highest reputation by his virtues, his zeal in instructing his disciples, and restoring ecclesiastical discipline. He wrote many books in French; the principal of which are, 1. A Treatise concerning the Sources of Corruption, which is a good moral piece. 2. A Catechism, or Instruction in the Christian Religion; which has been translated into German, Dutch, and English; and the Abridgment of the Sacred Hi-

story, which he prefixed to it, was translated and printed in Arabic, in order to be sent to the East Indies, by the care of the Society for the Propagation of the Gospel; and that Society, established in London, paid him a high compliment, by admitting him an honorary member. 3. A treatise against Impurity. 4. An edition of the French Bible of Geneva, with Arguments and Reflections, in folio. 5. *Ethica Christiana*. 6. *Theologia Compendium*, &c. He died in 1747, regretted by all who knew him.

**OSTIA** is a borough situated at the mouth of the Tiber, about 12 miles to the westward of Rome. It was built by Ancus Martius, the fourth king of Rome, and was called *Ostia Tiberina*, in the plural number, i. e. the two mouths of the Tyber, which were separated by the Holy Island, an equilateral triangle, whose sides were each of them computed at about two miles. The colony of Ostia was founded immediately beyond the left or southern, and the port immediately beyond the right or northern, branch of the river; and the distance between their remains measures something more than two miles on Cingolani's map. In the time of Strabo, the sand and mud deposited by the Tyber had choaked the harbour of Ostia; the progress of the same cause has added much to the size of the Holy Island, and gradually left both Ostia and the port at a considerable distance from the shore. The dry channels (*fiumi morti*), and the large estuaries (*lagno di Ponente, de Levante*), mark the changes of the river, and the efforts of sea. Its port was one of the most stupendous works of Roman magnificence, and it was a long time one of the best towns on the coast; but having been destroyed by the Saracens, and the harbour choaked up, as mentioned above, it has not been able since to recover itself. Though it be an inconsiderable place, and but poorly inhabited by reason of the badness of the air, yet it is the see of a bishop, who is always deacon of the cardinals, and crowns the Pope. The old Ostia, where you see the ruins of the ancient harbour, is beyond New Ostia, towards the sea; the latter is but a little cluster of houses, with a small castle. It is 12 miles S. W. of Rome. E. Long. 12. 24. N. Lat. 41. 44. There were salt-works in Ostia, called *Saline Ostienses*, as early as the times of Ancus Martius (Livy; from which the *Via Salaria*, which led to the Sabines, took its name, (Varro). It gave name to one of the gates of Rome, which was called *Ostiensis* (Ammian).

**OSTIACKS**, a people of Siberia in Asia. They live upon the banks of the rivers Oby and Jenisay, and on those of some other rivers which fall into these. These people are very poor, and very lazy, and in the summer-time live mostly upon fish. They are of a middle size, with broad faces and noses, and yellowish or red hair. All their garments from top to toe are made of fish skins, for they have neither linen nor woollen; and indeed they might almost as well go naked. Their greatest diversion is hunting; and they go together in crowds, with a weapon like a large knife fastened in a stick. In summer they take and dry the fish which serves them in winter; and when that season begins, they go into the woods, with their bows and arrows, their dogs and nets, to kill sables, ermines, bears, rein-deer, elks, martens, and foxes. Part of the furs of these is paid as a tax to the empress of

**Ostia,  
Ostiacks.**

Ostiacks.

of Russia, and the rest are sold at a state price to the Russian governors, but sometimes they are allowed to dispose of them to private persons.

They chiefly live upon venison, wild-fowl, fish, and roots, for they have neither rice nor bread. They drink for the most part water, and it is said they can very well relish a draught of train oil. They are immoderately fond of tobacco, and of swallowing the smoke, which soon intoxicates them. In the winter they build their huts in woods and forests, where they find the greatest plenty of game, and dig deep in the earth to secure themselves from the cold, laying a roof of bark or rushes over their huts, which are soon covered with snow. In summer they build above ground on the banks of the rivers, to enjoy the convenience of fishing, and make no difficulty of forsaking their habitations. They have a sort of princes among them, in one of whose houses some European travellers found four wives (A). One of these had a red cloth coat on, and was set off with all sorts of glass beads. There was no other furniture than cradles and chests, made of the bark of trees sewed together. Their beds consisted of wood-shavings, almost as soft as feathers, and their children lie naked upon them in cradles. They can neither read nor write, nor do they cultivate the land; and seem totally ignorant of times past. They have neither temples nor priests; and their boats are only made of the bark of trees sewed together. Their religion is Pagan; and they have some little brazen idols, tolerably well cast, representing men and animals, made of wood and earth, all of which are dressed in silks, in the manner of Russian ladies. In general, however, they are ill made, every man being his own carver. They place them on the tops of hills, in groves, and in the pleasantest places their country affords, and sometimes before their huts; yet they have no set time for performing religious worship, but apply to their gods for success in all their undertakings. As they have no regular priests, every old man may devote himself to that service, and the office is frequently performed by the masters and heads of families. Strahlenberg says, that when he was among them he saw one of their temples, which was built of wood in an oblong form like a great barn, covered at the top with birch-bark. At the end of the wall supporting the gable was a kind of altar, made of timber, on which were placed two idols, representing a man and women dressed in all sorts of rags; and round these were other small figures, as deer, foxes, and hares, all which were roughly carved in wood, and also clothed in rags. They did not appear to have much devotion, nor any great reverence for their idols. When they offer sacrifices, they present the beast to the idol; and having bound it, an old man puts up the petitions of those who brought the offering; he then lets fly an arrow at the beast, and the people assist in killing it. It is then drawn three times round

the idol; and the blood being received into a vessel, they sprinkle it on their houses; they afterwards dress the flesh and eat it, rejoicing and singing their country songs: they also besmear the idol with the blood of the sacrifice, and grease their mouths with the fat. What they cannot eat they carry home to their families, and make presents of it to their neighbours: they as often sacrifice a fish as a beast. At the conclusion of the feast they shout, to show their gratitude to the idol for his attending and accepting their devotions; for they are persuaded that the saint or hero represented by the image always attends their sacrifices, which when over, he returns to his abode in the air. There is nothing more surprising, nor, if properly improved, is there any thing more instructing, than the history of superstition. It is with this view that we have given so enlarged a view of the Ostiacks, longer, some may imagine, than their importance demands. It would, however, in our opinion, be improper to let such an opportunity slip of exhibiting the extreme weakness of unassisted reason, and the consequent necessity of a divine revelation. That the religion of these ignorant and misguided Pagans is the corruption of a primitive revelation, we think at least probable; nor do we see any way of so satisfactorily accounting for the universal use of sacrifices. The Ostiacks are obliged to take an oath of fidelity to the Russian government; and on these occasions they use the following ceremony. After laying down a bear skin and an axe, and holding over it a piece of bread on a knife, they say, "In case I do not to my life's end prove true and faithful to the supreme government of the country, or if I knowingly and willingly break through my allegiance, or be wanting in the duty I owe to the said supreme government, may the bear tear me to pieces in the wood; may the bread I eat stick in my throat, and choke me; may the knife stab me, and the ax cut off my head." The like ceremony is used among them in the deposition of a witness.

OSTRACION, in zoology, a genus of the amphibia nantes class. It has ten long cylindrical obtuse teeth in each jaw; the aperture is linear; the body is covered with a bony substance, and it has no belly-fins. There are nine species; principally distinguished by the angles of their bodies, and number of fins near their tail.

OSTRACISM, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, lest they should attempt any thing against the public liberty. This punishment was called *ostracism*, from the Greek word *οστρακον*, which properly signifies a "shell;" but when applied to this object, it is used for the billet on which the Athenians wrote the names of the citizens whom they intended to banish. The learned are divided with regard to the substance of which this billet was formed: some insist that it was a small stone, or a piece of brick;

Ostiacks  
||  
Ostracism.

(A) They may have as many wives as they please, and make no scruple of marrying their nearest relations. They purchase a wife of her relations for three or four rein-deer, and take as many as they please, returning them again if they do not like them, only losing what they gave for the purchase. Upon the birth of their children, some give them the name of the first creature they happen to see afterward. Thus the child has frequently the name of an animal, and you hear a man call his son perhaps *Sabatki*, or my little dog; others call their children according to the order of their birth as *First*, *Second*, *Third*, &c.

Ostracism. brick; some that it was a piece of bark; and others assert, that it was a shell. The word admits most of these interpretations. But what determines its true sense, is the epithet given it by ancient authors, of *ceramitè mastix*; which words signify, "The punishment of potter's clay;" and this expression seems to us a proof, that the word *οστρακισμός*, when applied on this occasion, signifies a "piece of baked earth, in the form of a shell;" and undoubtedly the Latin authors had this idea of the word here, for they translated it by *testula*.

The ancients are likewise divided with regard to the time when ostracism was instituted. But they all agree, that the person who moved the law was its first victim. But as to the name of its patron, and the time of its establishment, they differ extremely. Many are of opinion, that ostracism owes its origin to very remote times.

However that be, the punishment of ostracism was inflicted by the Athenians when their liberty was in danger. If, for instance, jealousy or ambition had sowed discord among the chiefs of the republic; and if different parties were formed, which threatened some revolution in the state; the people assembled to propose measures proper to be taken in order to prevent the consequences of a division which in the end might be fatal to freedom. Ostracism was the remedy to which they usually had recourse on these occasions; and the consultations of the people generally terminated with a decree, in which a day was fixed for a particular assembly, when they were to proceed to the sentence of ostracism. Then they who were threatened with banishment, omitted no assiduity or art which might gain them the favour of the people. They made harangues to evince their innocence, and the great injustice that would be done them if they were banished. They solicited, in person, the interest of every citizen; all their party exerted themselves in their behalf; they procured informers to vilify the chiefs of the opposite faction. Some time before the meeting of the assembly, a wooden inclosure was raised in the forum, with ten doors, *i. e.* with as many as there were tribes in the republic; and when the appointed day was come, the citizens of each tribe entered at their respective door, and threw into the middle of the inclosure the small brick on which the citizen's name was written whose banishment they voted. The archons and the senate presided at this assembly, and counted the ballots. He who was condemned by 6000 of his fellow-citizens, was obliged to quit the city within ten days; for 6000 voices, at least, were requisite to banish an Athenian by ostracism.

The Athenians, without doubt, foresaw the inconveniences to which this law was subject; but they chose rather, as Cornelius Nepos hath remarked, sometimes to expose the innocent to an unjust censure, than to live in continual alarms. Yet as they were sensible that the injustice of confounding virtue and vice would have been too flagrant, they softened, as much as they could, the rigour of ostracism. It was not aggravated with the circumstances which were most dishonourable and shocking in the ordinary mode of exile. They did not confiscate the goods of those who were banished by ostracism. They enjoyed the produce of their effects in the places into which they

were banished; and they were banished only for a certain time. But in the common banishment, the goods of the exiles were always confiscated, and no hopes were given them of ever returning to Athens.

The scholiast of Aristophanes informs us of a third difference betwixt ostracism, and the common banishment. He says, that a particular place of retirement was assigned to those who were banished by ostracism, which was not appointed to the other exiles. We suspect, however, the truth of this observation; for Themistocles was certainly not limited in his banishment. That great man as we are told by Thucydides, tho' his chief residence was at Argi, travelled over all the Peloponnesus.

This punishment, far from conveying the idea of infamy, became at Athens, a proof of merit, by the objects on which it was inflicted; as Aristides the sophist justly observes, in his second declamation against the Gorgias of Plato, where he says, that ostracism was not an effect of the vindictive spirit of the people against those whom it condemned; that the law, whether good or bad (for he enters not into an examination of the question), was only meant to prune the luxuriant growth of transcendent merit; that it condemned to an exile of ten years, only those illustrious men who were accused of being exalted far above other citizens by their conspicuous virtue; and that none of that public indignation was shown to the exiles by ostracism, which commonly breaks out against criminals.

Such were the mitigations with which this law was introduced among the Athenians: and by them we see that they were sensible of all the inconveniences to which it was subject. They were indeed too enlightened a people not to foresee the many instances of injustice which it might produce; that if in some respects it would be favourable to liberty, in others it would be its enemy, by condemning citizens without allowing them a previous defence, and by making a capricious and envious people arbiters of the fate of great men; that it might even become pernicious to the state, by depriving it of its best subjects, and by rendering the administration of public affairs an odious employment to men of capital talents and virtue.

However great the inconveniences of ostracism were, it would not have been impossible to avoid them; and we may add, that this law would have been of service to the state, if the people by whom it was instituted had always had discernment enough only to give it force on such occasions as endangered liberty. But its fate was like that of almost all other laws which the wisest legislators have planned for the good of communities. Destined by their institution to maintain order, to repress injustice, and to protect innocence, men have found ways to pervert their application, and have made them instruments to gratify their private passions. Thus ostracism was established to prevent the dangerous enterprises of the great, and to preserve the vigour of the democracy; but the people of Athens, naturally jealous and envious, exerted that law, to remove men of eminent merit from the state, by whose presence they were reproved and intimidated. The fear of tyranny was commonly but a specious pretext with which they veiled their malignity. The repeated

*Ostrocites*, repeated victories which they had gained over the Persians, had rendered them, says Plutarch, proud and insolent. Intoxicated with their prosperity, they arrogated all its glory to themselves; they were jealous of those citizens whose political and military talents were the subjects of public eulogium. They thought the glory acquired by great men diminished their own reputation. An Athenian no sooner distinguished himself by a splendid action, than he was marked out as a victim by public envy. His reputation was a sufficient reason for his banishment.

*OSTRACITES*, in natural history, a name used for the fossil oysters, common in many parts of England. They are of various shapes and kinds; and the name is by some authors made to signify the shell itself, when preserved in its native state and condition; as is the case with those about Woolwich and Blackheath; and by others the stones cast or formed in those shells, or in cavities from whence they have been washed away and dissolved: in both these cases the stone carries the exact resemblance of the shell, even in its nicest lineaments; in the first case, bearing every mark of the inside, in the other of the outer surface. This stone is in great plenty in many parts of England; and it is very famous, in some places, for its virtues in cases of the gravel, and the like complaints.

*OSTREA*, the *OYSTER*, in zoology, a genus belonging to the order of vermes testacea. The shell has two unequal valves; the cardo has no teeth, but a small hollowed one with transverse lateral streaks. There are 31 species, principally distinguished by peculiarities in their shells. The common oyster is reckoned an excellent food; and is eaten both raw and variously prepared. The character of the genus, in the words of Barbut, is, "The animal a tethys; the shell bivalve, unequivalve, with something like ears; the hinge void of teeth, with a deep oval hole, and transverse streaks on the sides. There is no womb nor anus." The genus is divided into four families, of which *ostrea* is the last. See *PECTENS*. The same author gives us the following enlarged account of the oyster.

"This sea-fish occupies in the scale of nature one of the degrees the most remote from perfection; destitute of defensive weapons and progressive motion, without art or industry, it is reduced to mere vegetation in perpetual imprisonment, though it every day opens regularly to enjoy the element necessary to its preservation. The animal figure, and the springs of its organization, are scarce discernible through the course and shapeless mass; a ligament placed at the summit of the shell serves as an arm to its operations. Oysters are reputed to be hermaphrodites; the spawn which they cast in May adheres to the rocks and other matters at the bottom of the sea; and in the space of 24 hours is provided with shells, in which are contained other oysters, that never leave the spot on which they were fixed, till the greedy fisherman tears them from the element. The green oysters eaten at Paris are commonly brought from Dieppe. Their colour is owing to the care taken to bed them in creeks, encompassed with verdure, whence they acquire their delicacy. Common oysters should be fresh, tender, and moist. The most esteemed are those caught at the mouth of rivers, and in clear water.

Vol. XIII.

Great account is made of oysters from Brittany, but still greater of those that come from Marennes in Saintonge. Preference is given to those that are edged with small brown fringe, or beard, which epicures call fecundated oysters; but that those are females is a mistake. The want of fresh water renders oysters hard, bitter, and unpalatable. Mud and sea-weed destroy them in their very birth; galangal root, mussels, scollops, sea-stars, and crabs, are formidable enemies to the oyster. There are found in Spain red and russet coloured oysters; in Illyria, brown coloured, with the flesh black; and in the Red Sea, of the colour of the Iris. Oysters of the mangle-tree are of two sorts; those of St Domingo are delicate, adhering to the stumps of the trees that dip in the water. The negro divers cut them off with a bill, and they are served upon table with the roots."

Britain has been noted for oysters from the time of Juvenal; who, satyrizing Montanus an epicure, says,

*Circais nata forent, an  
Lucrinum ad saxum, Resupinove, edita fundo,  
Ostrea, callebat primo deprendere morsu.*

He, whether Circe's rock his oysters bore,  
Or Lucrine lake, or distant Richborough's shore,  
Knew at first taste.

The luxurious Romans were very fond of this fish, and had their layers or stews for oysters as we have at present. Sergius Orata was the first inventor, as early as the time of L. Crassus the orator. He did not make them for the sake of indulging his appetite, but through avarice, and made great profits from them. Orata got great credit for his Lucrine oysters; for, says Pliny, the British were not then known.

The ancients eat them raw, having them carried up unopened, and generally eating them at the beginning of the entertainment, but sometimes roasted. They had also a custom of stewing them with mallows and ducks, or with fish, and esteemed them very nourishing.

Britain still keeps its superiority in oysters over other countries. Most of the coasts produce them naturally; and in such places they are taken by dredging, and are become an article of commerce, both raw and pickled. The very shells, calcined, become an useful medicine as an absorbent. In common with other shells, they prove an excellent manure.

Stews or layers of oysters are formed in places which nature never allotted as habitations for them. Those near Colchester have been long famous; at present there are others that at least rival the former, near the mouth of the Thames. The oysters, or their spats, are brought to convenient places, where they improve in taste and size. It is an error to suppose, that the fine green observed in oysters taken from artificial beds, is owing to copperas; it being notorious how destructive the substance of the solution of it is to all fish. We cannot give a better account of the cause, or of the whole treatment of oysters, than what is preserved in the learned bishop Sprat's history of the Royal Society, from p. 307 to 309.

"In the month of May, the oysters cast their spawn, (which the dredgers call their *spats*); it is like to a drop of candle, and about the bigness of a half-

3 Y

penny

Ostrea.

penny. The spat cleaves to stones, old oyster-shells, pieces of wood, and such like things, at the bottom of the sea, which they call *cultch*. It is probably conjectured, that the spat in 24 hours begins to have a shell. In the month of May, the dredgers (by the law of the admiralty court) have liberty to catch all manner of oysters, of what size soever. When they have taken them, with a knife they gently raise the small brood from the cultch, and then they throw the cultch in again, to preserve the ground for the future, unless they be so newly spat, that they cannot be safely severed from the cultch; in that case they are permitted to take the stone or shell, &c. that the spat is upon, one shell having many times 20 spats. After the month of May, it is felony to carry away the clutch, and punishable to take any other oysters, unless it be those of size, (that is to say) about the bigness of an half-crown piece, or when, the two shells being shut, a fair shilling will rattle between them.

"The places where these oysters are chiefly caught, are called the *Pent-Burnham, Malden, and Colne-waters*; the latter taking its name from the river of Colne, which passeth by Colchester, gives name to that town, and runs into a creek of the sea, at a place called the *Hythe*, being the suburbs of the town. This brood and other oysters they carry to the creeks of the sea, at Brickelsea, Merfy, Langno, Fingrego, Wivenho, Tolesbury, and Saltcoase, and there throw them into the channel, which they call their *beds* or *layers*, where they grow and fatten; and in two or three years the smallest brood will be oysters of the size aforesaid. Those oysters which they would have green, they put into pits about three feet deep in the salt marshes, which are overflowed only at spring tides, to which they have sluices, and let out the salt-water until it is about a foot and a half deep. These pits, from some quality in the soil co-operating with the heat of the sun, will become green, and communicate their colour to the oysters that are put into them in four or five days, though they commonly let them continue there six weeks or two months, in which time they will be of a dark green. To prove that the sun operates in the greening, Tolesbury pits will green only in summer; but that the earth hath the greater power, Brickelsea pits green both winter and summer; and for a further proof, a pit within a foot of a greening-pit will not green; and those that did green very well, will in time lose their quality. The oysters, when the tide comes in, lie with their hollow shell downwards; and when it goes out, they turn on the other side: they remove not from their place, unless in cold weather, to cover themselves in the ouse. The reason of the scarcity of oysters, and consequently of their dearth, is, because they are of late years bought up by the Dutch.

"There are great penalties by the admiralty court laid upon those that fish out of those grounds which the court appoints, or that destroy the cultch, or that take any oysters that are not of size, or that do not tread under their feet, or throw upon the shore, a fish which they call a *five finger*, resembling a spur-rowl, because that fish gets into the oysters when they gape, and sucks them out.

"The reason that such a penalty is set upon any

that shall destroy the cultch, is, because they find that if that be taken away, the ouse will increase, and the muscles and cockles will breed there, and destroy the oysters, they having not whereon to stick their spat.

"The oysters are sick after they have spat; but in June and July they begin to mend, and in August they are perfectly well; the male oyster is black-lick, having a black substance in the fin; the female white-lick (as they term it), having a milky substance in the fin. They are salt in the pits, saltier in the layers, but saltest at sea."

The oyster affords the curious in microscopic observations a very pleasing entertainment. In the clear liquor many little round living animalcules have been found, whose bodies being conjoined, form spherical figures, with tails, not changing their place otherwise than by sinking to the bottom, as being heavier than the fluid; these have been seen frequently separating, and then coming together again. In other oysters, animalcules of the same kind were found, not conjoined, but swimming by one another, whence they seemed in a more perfect state, and were judged by Mr Leeuwenhoek to be the animalcules in the roe or semen of the oyster.

A female oyster being opened, incredible multitudes of small embryo oysters were seen, covered with little shells, perfectly transparent, and swimming along slowly in the liquor; and in another female, the young ones were found of a browner colour, and without any appearance of life or motion.

Monsieur Joblot also kept the water running from oysters three days, and it appeared full of young oysters swimming about nimbly in it; these increased in size daily; but a mixture of wine, or the vapour of vinegar, killed them.

In the month of August oysters are supposed to breed, because young ones are then found in them. Mr Leeuwenhoek, on the 4th of August, opened an oyster, and took out of it a prodigious number of minute oysters, all alive, and swimming nimbly about in the liquor, by means of certain exceeding small organs extending a little way beyond their shells; and these he calls their beards. In these little oysters, he could discover the joinings of the shells; and perceived that there were some dead ones, with their shells gaping. These, tho' so extremely minute, are seen to be as like the large oysters in form as one egg is to another.

As to the size of them he computes, that 120 of them in a row would extend an inch; and consequently that a globular body, whose diameter is an inch, would, if they were also round, be equal to 1,728,000 of them. He reckons 3000 or 4000 are in one oyster, and found many of the embryo oysters among the bairds; some fastened thereto by slender filaments, and others lying loose: he likewise found animalcules in the liquor 500 times less than the embryo oysters.

It is not very uncommon to see on oyster-shells, when in a dark place, a shining matter or bluish light, like a flame of brimstone, which sticks to the fingers when touched, and continues shining and giving light for a considerable time, though without any sensible heat. This shining matter being examined with a microscope, was found to consist of three sorts of animalcules;

Ostrea.

Ostrich  
||  
Oswestry.

cules; the first whitish, and having 24 or 25 legs on a side, forked, a black speck on one part of the head, the back like an eel with the skin stripped off. The second fort, red, resembling the common glow-worm, with folds on its back, but legs like the former; a nose like a dog's, and one eye in the head. The third fort, speckled, with a head like a sole, with many tufts of whitish hairs on the sides of it. Some much larger and greyish might be seen, having great heads, two horns like a snail's, and six or eight whitish feet; but these did not seem to shine.

OSTRICH, in zoology. See STRUTHIO.

OSTROVIZZA, in Dalmatia (see DALMATIA), which some would have the same as Arauzona, and others the Silupi of the ancients, though probably it has no connection with either the one or the other. It was purchased in 1410 by the republic of Venice, for 5000 ducats, and some pieces of land besides. Its fortifications, which was seated on a rock, perpendicularly cut all round, and deservedly reckoned impregnable before the use of artillery, was taken by Soliman in 1524, but soon after returned under the dominion of Venice. At present, no traces of its fortification remain, and it is only a bare and isolated mass. There are some natural curiosities about the place.

OSTUNI, a town of Italy, in the kingdom of Naples, and in the Terra di Otranto, with a bishop's see. Its territory is well cultivated, and abounds with olives and almonds. It is seated on a mountain near the Gulph of Venice, in E. Long. 17. 49. N. Lat. 49. 59.

OSWEGO, a fort of North America, seated on the south side of the lake Ontario, in W. Long. 70. 35. N. Lat. 45. 15.

OSWEIZEN, a town of Poland, in the palatinate of Cracovia, with the title of a duchy. It carries on a great trade in salt, and is seated on the river Vistula. E. Long. 19. 47. N. Lat. 50. 1.

OSWESTRY, in the county of Salop, in England, 172 miles from London, is a very old town, with a castle, a wall, and a ditch, and was anciently a borough. It is a place celebrated in Saxon history and legendary piety. On this spot, August 5. 642, was fought the battle between the Christian Oswald king of the Northumbrians and the pagan Penda king of the Mercians, in which Oswald was defeated, and lost his life. The barbarian victor cut the body of the slain prince in pieces, and stuck them on stakes dispersed over the field as so many trophies; but, according to others, his head and hands only were thus exposed. A prince so dear to the church as Oswald, and so attached to the professors of the monastic life, received every posthumous honour they could bestow. He was raised to the rank of a saint, and his sanctity confirmed by numberless miracles, which are too numerous and too trifling to admit of particular description. Its church, which is of no great antiquity, was formerly a monastery, and was called Blancminster. It is, however, spacious, and has a handsome plain tower. In the years 1542 and 1567, this town suffered much by fire. It is governed by two bailiffs, burgessees, &c. and once drove a great trade in Welsh cottons and flannels, which is now very much decayed. There is now scarce a tolerable house for travellers. But besides a good grammar school, it is noted for an excel-

lent charity-school for 40 boys, besides girls, which has the best methods for exciting the emulation of the children in their learning; for 20 of the boys are set to strive against 20 others for shoes, and the 20 who perform their task best have shoes first; then 10 of the boys are set against 10 others for the like premium, and so on till they are all shod: so in the girls school a shift is put up for the best spinner, a head-dress for the best sempstress, a pair of stockings for the best knitter, a bible for the best reader, and a copy-book for the best writer. In the wall with which the town was fortified there were four gates. That called the *Block-gate* is demolished; the *New-gate*, *Willow-gate*, and the *Beatrice-gate*, still remain. The last is a handsome building, with a guard-room on both sides. There are only two fragments of the castle remaining. It stood on an artificial mount, surrounded by a fosse, extending to the *Willow-gate*.

OSYMANDES, a famous king of Egypt, was, according to some authors, the first monarch who collected a great number of books for the purpose of forming a library. To this curious collection he gave the title of *Pharmacy of the Soul*. Of all the monuments of the kings of Thebes, that of Osymandes is one of the most magnificent. "He appears (says an elegant author) to have been a prince of great elegance and taste in this day. Diodorus Siculus describes many sumptuous edifices erected by him; among those edifices his palace or mausoleum, whichever it was, has been eminently distinguished for the paintings and sculptures with which it was adorned. When we look to the subjects of those works, we shall have reason to think that no man in any age could discover a fairer and more enlightened judgment than he did in the employment of the genius around him, which was not tamely devoted to dull or contracted objects, nor lavished on scenes of savage life, nor wholly engrossed in allusions to himself, but sensibly enlarged to a variety of contemplation which might become a great sovereign; and in each of those parts the subject was characteristically great.

"\* In one place was represented, in a multitude of sculptures, his expedition against the Bactrians, a people of Asia, whom he had invaded with 400,000 foot, and 20,000 horse, and whom he conquered. In another part was displayed the variety of fruits and productions, with which Pan, the great source of all things, had enriched the fertile land over which Osymandes reigned. A third group of figures represented the monarch himself, as the high-priest of the country, offering to the gods the gold and silver which he drew every year from the mines of Egypt. In another part of the edifice was exhibited, in an infinite number of figures, an assembly of judges, in the midst of a great audience attentive to their decisions; the president, or chief of those judges, surrounded by many books, wore on his breast a picture of truth with her eyes shut—those emphatic emblems, beyond which no age could go for the impression of that wisdom and impartiality which ought to prevail in administrative justice."

In short, we cannot without astonishment read the account which Diodorus Siculus gives of the almost incredible magnificence of this prince, and of the immense sums which he spent upon those grand works.

Osyman-  
des  
Otaheitee.

Amongst a variety of other surprising curiosities, was to be seen a statue in the attitude of sitting, which was the largest in all Egypt, the length of one of the feet being seven cubits. Not only the art of the sculptor, but also the beauty of the stone which was perfect in its kind, contributed to render this a masterpiece of sculpture. It bore the following inscription: *I am OSYMANDES, king of kings; whoever will dispute with me this title, let him surpass me in any of my works.*

Indeed (to use the words of the same elegant author quoted above) "the palace or mausoleum of this accomplished prince must give us a striking assurance of the progress which had been made in the arts at that time; whether he was, as some have thought†, the immediate successor of the first Buisir, which was somewhat later than the period of Semiramis; or, as others have conceived‡, subsequent to Sesostris, which would be 400 years later. Diodorus Siculus, who describes that edifice, says nothing of the age in which Osymandes lived; every opinion therefore on that point must be conjecture. We shall only remark, that there is nothing in the works of art in that edifice which should appear too much for the earliest age in which that monarch has been placed, when we look back to what was done in those works in a period full as early by Semiramis in Assyria."

OTACOUSTIC INSTRUMENT, or *Auricular Tube*, an instrument to facilitate the hearing. See ACOUSTICS, n° 25.

OTAHEITEE, a celebrated island of the South Sea, situated in W. Long. 149. 13. S. Lat. 17. 46. It was discovered by Captain Wallis in 1767; afterwards Mr Bougainville touched here; and it was visited by Captain Cook in 1773 and 1774, who had in 1769 failed round the island in a boat to observe the transit of Venus.

The island consists of two distinct kingdoms, which are united by a narrow neck of land; the larger being called by the natives *Tiarrahou*, or *O-Taheitee Nue*; the smaller one *Opoureonou*, or *O-Taheitee-Ete*. The circumference of both islands is about 40 leagues; the larger kingdom being divided into 43 districts. The country has a delightful romantic appearance. The coast, viewed from the sea, presents a most beautiful prospect, being elevated like an amphitheatre. The island is skirted with a reef of rocks, and towards the sea is level, being covered with fruit-trees of various kinds, particularly the cocoa-nut. At the distance of about three miles from the shore, the country rises into lofty hills that are covered with wood, and terminate in peaks, from which large rivers are precipitated into the sea. The stones every where appear to have been burnt, not one being found which did not give manifest signs of fire; so that there is great reason for supposing that this and the neighbouring islands are either the shattered remains of a continent, or were torn from rocks, which from the creation of the world have been the bed of the sea, and thrown up in heaps to a height which the waters never reach. What is further extraordinary, the water does not gradually grow shallow as we approach the shore, but is of immense depth close by the land; and the islands in this neighbourhood are almost everywhere surrounded by reefs, which appear to be rude and broken in the

manner that some violent concussion would naturally leave the solid substance of the earth; and Mr Forster saw a rock with projecting longitudinal angles of black compact basalt. The exterior ranges of hills are sometimes entirely barren, and contain a great quantity of yellowish clay, mixed with iron ochre; but others are covered with mould and wood like the mountains in the internal parts of the country. Pieces of quartz are sometimes met with here; but no indications of precious minerals or metals of any kind have been observed, iron only excepted.

The air is extremely healthy and pleasant; the heat is not troublesome; and fresh meat will keep very well for two days, and fish one day. The winds do not blow constantly from the east, but generally a little breeze from east to south south-east. The tide rises very little; and, being governed by the winds, is very uncertain. "The climate," says M. Bougainville, "is so healthy, that notwithstanding the hard labour of the ships companies while on shore, though the men were continually in the water, and exposed to the meridian sun, though they slept upon the bare soil, and in the open air, none of them fell sick; those who were afflicted with the scurvy, and were sent on shore, regained their strength: although they were obliged to assist in the erecting of a fort, and had scarce one uninterrupted night, yet they were so far recovered in the short space of time they continued there, that they were afterwards perfectly cured on board."

Notwithstanding the great height of the inland mountains of Otaheitee, none of their rocks have the appearance of barrenness, every one of them being covered with woods. "We hardly believed our eyes," says M. de Bougainville, "when he saw a peak covered with woods up to its highest summit, which rises above the level of the mountains in the interior parts of the southern quarter of this island. Its apparent size seemed to be more than 30 toises in diameter, and grew less in breadth as it rose higher. At a distance it might have been taken for a pyramid of immense height, which the hand of an able sculptor had adorned with garlands and foliage." One of the mates of the Dolphin, with a party of marines and seamen, penetrated into the interior parts of the island; and having ascended, with great difficulty, a mountain which they supposed to be a mile high, they discovered mountains before them so much higher, that with respect to them they seemed to be in a valley: towards the sea the view was enchanting, the sides of the hills were beautifully clothed with wood, villages were everywhere interspersed, and the valleys between them afforded a still richer prospect; the houses stood thicker, and the verdure was more luxuriant; and Mr Forster, with other gentlemen, ascended to the summit of one of the highest mountains in the island, from whence they had a prospect of the island of Huahine, and some others lying at the distance of 40 leagues; from which we may form some judgment of the prodigious height of that mountain. The view of the fertile plain below them, and of a river making innumerable meanders, was delightful in the highest degree. The vegetation on the upper part of the mountains was luxuriant, and the woods consisted of many unknown sorts of trees and plants.

The soil of this island is a rich fat earth, of a black- Soil and  
ish produce.

Appear-  
ance of the  
country.

Otaheitee. ish colour. It produces spontaneously, or with the slightest culture imaginable, a great variety of the most excellent fruits; such as bread-fruit, cocoa-nuts, bananas of 13 sorts, plantains, potatoes, yams, a fruit known here by the name of *jambu*, and reckoned most delicious; sugar-canes, which the inhabitants eat raw; ginger; turmeric; a root of the salep kind, called by the inhabitants *pea*; a plant called *ethee*, of which the root only is eaten; a fruit that grows in a pod like that of a large kidney bean, by the natives called *abee*; a tree called *wharra*, which produces fruit something like the pine-apple, and which is known in the East Indies by the name of *pandanus*: a shrub called *nono*; the *morinda*, which also produces fruit; a species of fern; a plant called *theve*; and the Chinese paper-mulberry, of the bark of which they make their cloth; an herb which the inhabitants eat raw, its flavour somewhat resembling that of the West India spinach called *calletoon*, but its leaf very different; a plant which the natives call *ava* or *cava*, from the root of which they express a liquor, which, if drank to excess, intoxicates like wine or distilled spirits. Here are a sort of shady trees covered with a dark-green foliage, bearing golden-coloured apples, which, in juiciness and flavour, resemble the ananas or pine-apple. One of the most beautiful trees in the world received here the name of *Barringtonia*; it had a great abundance of flowers larger than lilies, and perfectly white, excepting the tips of their numerous chives, which were of a deep crimson. Such a quantity of these flowers were seen dropped off, that the ground underneath the tree was entirely covered with them. The natives called the tree *buddow*; and said, that the fruit, which is a large nut, when bruised and mixed up with some shell-fish, and thrown into the sea, intoxicates the fish for some time, so that they come to the surface of the water, and suffer themselves to be taken with people's hands. Several other maritime plants in tropical climates are found to have the same quality. Mr Dalrymple describes the method of catching fish with these plants as follows: The plant is thrust under the coral rocks or hollows where the fish haunt; the effect is most sensible in still water, though it is effectual in the open sea; for the same gentleman says, he has seen fish soon after float on the surface of the water half dead, and some totally without life; and where the effect is less violent, the fish will be seen under the water to have lost their poise, without coming up to the surface. Fish caught in this manner are not in the least noxious or ill tasted.

5  
Animals.

In this island they have domestic poultry exactly resembling those of Europe: besides which there are wild ducks; also beautiful green turtle-doves; large pigeons of a deep blue plumage and excellent taste; a small sort of paroquets, very singular on account of the various mixture of red and blue in their feathers; also another sort of a greenish colour, with a few red spots; the latter are frequently tamed, and are valued on account of their red feathers. Here is a king-fisher of a dark green, with a collar of the same hue round his white throat; a large cuckoo, and a blue heron. Small birds of various kinds dwell in the shady trees; and, contrary to the generally received opinion, that birds in warm climates are not remarkable for their song, have a very agreeable note. There were

no quadrupeds but dogs, hogs, and rats; and for these last the natives were said to have a scrupulous regard, inasmuch that they would by no means kill them; however, Captain Cook, in 1773, turned about 14 cats on the island, which have probably reduced the number of these vermin. No frogs, toads, scorpions, centipedes, or any kind of serpent, have been found here: the ants, however, are troublesome, but not very numerous. When the Endeavour first arrived here in 1769, the flies were found excessively troublesome; but musketto nets and fly-flaps in some measure removed the inconvenience. Sydney Parkinson, in his journal, says, that notwithstanding these flies are so great a nuisance, the natives, from a religious principle, will not kill them. But there is a strange disagreement in the accounts of different voyagers concerning this matter. For M. Bougainville says, "this island is not infested by those myriads of troublesome insects that are the plague of other tropical countries." And Mr Forster says, "not a gnat or musketto hummed unpleasantly about us, or made us apprehensive of its bite." This inconvenience must therefore be felt at certain seasons of the year, and in certain districts of the country, more sensibly than at other times and places. There is great variety of excellent fish; and, according to Aitourou, a native who embarked with M. de Bougainville, there are sea-snakes on the shore of Otaheitee, whose bite is mortal.

6  
Description of the inhabitants, &c.

The inhabitants of Otaheitee are a stout, well-made, active, and comely people. The stature of the men, in general, is from five feet seven to five feet ten inches; the tallest man seen by Captain Wallis measured six feet three inches and a half; and Captain Cook, in his second voyage, describes O-Too, the king of Otaheitee, to be of that height. "In order to paint an Hercules or a Mars," says M. de Bougainville, "one could nowhere find such beautiful models." They are of a pale brown complexion; in general their hair is black, and finely frizzled; they have black eyes, flat noses, large mouths, and fine white teeth; the men wear their beards in many fashions, all of them plucking out a great part, and have prominent bellies. Most of them smell strong of the cocoa nut oil. The women in general are much smaller, especially those of the lower rank or tawtows, which is attributed to their early and promiscuous intercourse with the men; whilst the better sort, who do not gratify their passions in the same unbridled manner, are above the middle stature of Europeans. Their skin is most delicately smooth and soft; they have no colour in their cheeks; their nose is generally somewhat flat, but their eyes are full of expression, and their teeth beautifully even and white. "The women," says M. de Bougainville, "have features not less agreeable than the generality of Europeans, and a symmetry of body and beautiful proportion of limbs which might vie with any of them. The complexion of the men is tawny; but those who go upon the water are much more red than those who live on shore. Some have their hair brown, red, or flaxen, in which they are exceptions to all the natives of Asia, Africa, and America, who have their hair black universally; here, in the children of both sexes, it is generally flaxen. The strongest expression is painted in the countenance of these people; their walk is graceful, and all their motions are performed,

Otaheitee performed with great vigour and ease." "I never beheld statelier men, (says Sidney Parkinson.) The men of consequence on the island wear the nails of their fingers long, which they consider as a very honourable badge of distinction, since only such people as have no occasion to work can suffer them to grow to that length. This custom they have in common with the Chinese; but the nail of the middle finger on the right hand is always kept short, the meaning for which peculiarity could not be learned. Only the single cripple was met with among them, and he appeared to have been maimed by a fall. The women always cut their hair short round their heads. Both sexes have a custom of staining their bodies, which they call *tattooing*; both men and women have the hinder part of their thighs and loins marked very thick with black lines in various forms; these marks are made by striking the teeth of an instrument somewhat like a comb just through the skin, and rubbing into the punctures a kind of paste made of foot and oil, which leaves an indelible stain. The boys and girls under twelve years of age are not marked; a few of the men, whose legs were marked in chequers by the same method, appeared to be persons of superior rank and authority. Mr Banks saw the operation of tattooing performed upon the backside of a girl about thirteen years old. The instrument used upon this occasion had thirty teeth: and every stroke, of which at least a hundred were made in a minute, drew an ichor or serum a little tinged with blood. The girl bore it with most stoical resolution for about a quarter of an hour; but the pain of so many hundred punctures as she had received in that time, then became intolerable. She first complained in murmurs, then wept, and at last burst into loud lamentations, earnestly imploring the operator to desist. He was, however, inexorable; and when she began to struggle, she was held down by two women, who sometimes soothed and sometimes chid her; and now and then, when she was most unruly, gave her a smart blow. Mr Banks staid in a neighbouring house an hour, and the operation was not over when he went away; yet it was but performed upon one side, the other having been done some time before; and the arches upon the loins, in which they most pride themselves, and which give more pain than all the rest, were still to be done. Both men and women are not only decently but gracefully clothed, in a kind of white cloth that is made of the bark of a shrub, and very much resembles coarse China paper. Their dress consists of two pieces of this cloth; one of them, having a hole made in the middle to put the head through, hangs from the shoulders to the mid leg before and behind: another piece, which is between four and five yards long, and about one yard broad, they wrap round the body in a very easy manner: This cloth is not woven; but is made like paper, of the macerated fibres of the inner bark spread out and beaten together. Their ornaments are feathers, flowers, pieces of shell, and pearls; the pearls are worn chiefly by the women. In wet weather they wear matting of different kinds, as their cloth will not bear wetting. The dress of the better sort of women consists of three or four pieces: one piece, about two yards wide and eleven long, they wrap several times round their waist, so as to hang down like a petticoat as low as the

middle of the leg; and this they call *parou*. This simple drapery affords the sex an opportunity of displaying an elegant figure to the greatest advantage, according to the talents and taste of the wearer: no general fashions force them to disfigure instead of adorning themselves, but an innate gracefulness is the companion of simplicity. To this cloth they give a very strong perfume.

The chief use which they make of their houses is to sleep in them; for unless it rains, they eat in the open air under the shade of a tree. These houses are no other than sheds, all built in the wood between the sea and the mountains; they are erected on an oblong square; their width is nearly half of their length; they are nothing more than a roof, not quite four feet from the ground, raised on three rows of pillars, one row on each side, and one in the middle. The roof resembles the thatched houses in England, and consists of two flat sides inclining to each other. Their thatch consists of palm-leaves. The floor of their dwelling is covered with hay, over which they spread mats. Some of these erections are furnished with a stool, which is appropriated solely to the use of the master of the family: they consist of no other furniture except a few blocks of wood, which being square, one side is hollowed into a curve; and these they use as pillows, and with their apparel they cover themselves. In these open dwellings the whole family repose themselves at night. The size of the house is proportioned to the number that constitutes the family. The established order in these dormitories is, for the master and his wife to sleep in the middle; round them the married people; in the next circle the unmarried women; and in the next, at the same distance, the unmarried men; and the servants at the extremity of the shed; but in fair weather the latter sleep in the open air. Some few dwellings, however, constructed for greater privacy, are entirely inclosed with walls of reeds, connected together with transverse pieces of wood, so as to appear somewhat like large bird cages closely lined; in these houses there is commonly a hole left for the entrance, which can be closed up with a board.

Their candles are made of the kernels of a kind of oily nut, which they stick one above another on a skewer that is thrust through the middle of them; the upper one being lighted burns to the second, at the same time consuming that part of the skewer that goes through it; the second taking fire burns in the same manner down to the third, and so to the last; they burn a considerable time, and afford a pretty good light. The natives generally retire to rest about an hour after it is dark.

The food of the common people entirely consists of Food, me-  
vegetables. These are, the bread-fruit, with bananas, thod of  
plantains, yams, apples, and a four fruit, which, though <sup>8</sup>cooking,  
not pleasant by itself, gives an agreeable relish to &c.  
roasted bread-fruit, with which it is frequently beaten  
up: (See the article *BREAD-TREE*). The flesh, which  
is reserved for the tables of the great, is either poultry,  
hogs, or dogs; the flesh of their fowls is not well-  
tasted, but that of dogs is esteemed by the natives be-  
yond pork. The smaller fish are generally eaten raw,  
as we eat oysters: every thing that can be procured  
from the sea is made an article of their food; for they  
will eat not only sea-insects, but what the seamen call  
blubbers,

*Otaheitee.* *Ulubbers*, though some of them are so tough that they are obliged to suffer them to become putrid before they can be chewed. A very large shark being caught by the Dolphin's people was given to the natives; who soon cut it to pieces, and carried it away with great satisfaction.

They kill the animals they intend for food by suffocating them, which is done by stopping the mouth and nose with their hands; they then singe off the hair, by holding the animal over a fire, and scraping him with a shell: with this instrument they cut him up, and take out the entrails; which are washed, and put into cocoa-nut-shells, together with the blood. Dogs are eaten that are fed wholly upon bread-fruit, cocoa-nuts, yams, and other vegetables, and are never suffered to taste any animal food; and those who have tasted the flesh of a dog thus fed, have declared it to be little inferior to English lamb. In order to dress their food, they kindle a fire, by rubbing the end of one piece of dry wood upon the side of another, in the manner as a carpenter with us whets a chisel. They then dig a pit about half a foot deep, and two or three yards in circumference; they pave the bottom with large pebble stones, which they lay down very smooth and even, and then kindle a fire in it with dry wood, leaves, and the husks of cocoa-nuts. When the stones are sufficiently heated, they take out the embers, and rake up the ashes on every side; they then cover the stones with a layer of green cocoa-nut leaves, and wrap up the animal that is to be dressed in the leaves of the plantain. If it is a small hog, they wrap it up whole; if a large one, they split it. When it is placed in the pit, they cover it with the hot embers, and lay upon them bread-fruit and yams, which are also wrapped up in the leaves of plantain. Over these they spread the remainder of the embers, mixing among them some of the hot stones, with more cocoa-nut-tree leaves upon them, and then close up all with earth, so that the heat is kept in; the oven is kept thus closed a longer or shorter time according to the size of the meat that is dressed. The meat, when taken out, is said to be better dressed than any other way. They use shells for knives; and carve very dexterously with them, always cutting from themselves. One of the principal attendants on Oberea, attempting the use of the knife and fork, could not feed himself therewith; but, by the mere force of habit, his hand came to his mouth, and the victuals at the end of his fork went away to his ear.

They are quite unacquainted with the method of boiling water, as they have no vessels among them that will bear the fire. Whilst the noble Oberea was one morning at breakfast with Captain Wallis on board the Dolphin, the surgeon filled the tea-pot by turning the cock of a vase that stood upon the table. One of the lady's attendants observed this practice very attentively, and soon after turning the cock himself, received the water upon his hand; he no sooner felt himself scalded, than he roared and danced about in an extravagant manner. The other Indians, unapprised of the cause of these emotions, stood gazing at him in amazement, and not without some mixture of terror: but the gentlemen in company, who soon perceived the cause of the outcry, dispelled the apprehensions of their visitants; and some ointment being applied to

the scald, good humour and confidence were again restored. The gunner of the ship, who was appointed comptroller of the market which was established on shore with the natives, used to dine on the spot; the astonishment of these people was very great to see him dress his pork and poultry in a pot; at length an old man, who was extremely serviceable in bringing down provisions to be exchanged, was put into possession of an iron pot, and from that time he and his friends ate boiled meat every day. Several iron pots were likewise given to Oberea and some of the chiefs; which were in constant use, and drew every body to see them; but although the particulars of two successive voyages of Captain Cook to this island are circumstantially related, we hear no more of this improvement in the culinary art, or of the further assistance which has been rendered those people in supplying them with pots for boiling; but however desirous the natives might be to eat boiled meat, it was not advisable to have such an article of barter as iron kettles, when a few spike nails, or a common hatchet, would procure one of the largest hogs.

Salt water is the usual sauce to their food; those who live near the sea have it furnished as it is wanted, others at a distance keep it in large bamboos. The kernels of the cocoa-nuts furnish them with another sauce: these made into a paste something of the consistence of butter, are beat up with salt water, which has a very strong flavour; but though at first it seemed very nauseous, yet when the taste became familiar, it was much relished.

Their general drink is water, or the milk of the cocoa-nut. They showed in general an aversion to strong liquors; and whenever any one of them happened to drink so freely with any of the ship's company as to be intoxicated, he resolutely refused to taste any thing that was like to produce the same effect again; but they have a plant which they call *ava ava*, from the root of which they procure a liquor which has an inebriating quality. Their manner of preparing this strong drink is as simple as it is disgusting to an European. Several of the people take some of the root, and chew it till it is soft and pulpy; they then spit it out into a platter or other vessel, every one into the same: into this general receptacle water is poured according to the quantity prepared. The juice thus diluted, is strained through some fibrous stuff like fine shavings, after which it is fit for drinking, and it is always prepared for present use: it has a pepperish taste; drinks flat, and rather insipid; and though it intoxicates, yet Captain Cook saw but one instance where it had that effect, as the natives generally drink it with great moderation, and but little at a time. Sometimes they chew this root as Europeans do tobacco, and sometimes they will eat it wholly.

They eat alone, or at least only in company with a guest that happens to call in; and the men and women never sit down together to a meal: the shade of a spreading tree serves them for a parlour; broad leaves spread in great abundance serve for a table-cloth; and if a person of rank, he is attended by a number of servants who seat themselves round him: before he begins his meal, he washes his mouth and hands very clean, and repeats this several times whilst he is eating. The quantity

Otaheitee.

quantity of food which these people eat at a meal is prodigious. Captain Cook says, he has seen one man devour two or three fishes as big as a peach; three bread-fruits, each bigger than two fists; 14 or 15 plantains, or bananas, each six or seven inches long and four or five round, and near a quart of the pounded bread-fruit. Men of rank are constantly fed by their women; and one of the chiefs who dined on board the ships in 1769, showed such reluctance to feed himself, that one of the servants was obliged to feed him to prevent his returning without his meal. In one of the excursions which the gentlemen of the ships made into the country in 1773, they arrived at a neat house, where a very fat man, who seemed to be a chief of the district, was lolling on his wooden pillow; before him two servants were preparing his desert by beating up with water some bread-fruit and bananas in a large wooden bowl, and mixing with it a quantity of fermented four paste called *mahie*. While this was doing, a woman, who sat down near him, crammed down his throat by handfuls the remains of a large baked fish, and several bread-fruits, which he swallowed with a voracious appetite; his countenance was the picture of phlegmatic insensibility, and seemed to testify that all his thoughts centered in the gratification of his appetite. He scarce deigned to look at the strangers; and a few monosyllables which he uttered were extorted from him to remind his feeders of their duty, when by gazing at them they grew less attentive to him.

That these people, who are remarkably fond of society, and particularly that of their women, should exclude its pleasures from the table, where, among all other nations, whether civil or savage, they have been principally enjoyed, is truly inexplicable. How a meal, which every where else brings families and friends together, comes to separate them here, was a singularity much inquired about, but never accounted for. "They ate alone (they said), because it was right;" but why it was right to eat alone, they never attempted to explain. Such, however, was the force of habit in this instance, as it is in every other, that they expressed the strongest dislike, and even disgust, at their visitants eating in society, especially with women, and of the same victuals. "At first (says Captain Cook) we thought this strange singularity arose from some superstitious opinion; but they constantly affirmed the contrary. We observed also some caprices in the custom; for which we could as little account as the custom itself. We could never prevail with any of the women to partake of the victuals at our table, when we were dining in company; yet they would go five or six together in the servants apartments, and there eat very heartily of whatever they could find: nor were they in the least disconcerted if we came in while they were doing it. When any of us have been alone with a woman, she has sometimes eaten in our company; but then she has expressed great unwillingness that it should be known, and always extorted the strongest promises of secrecy. Among themselves, even two brothers and two sisters have each their separate baskets of provisions, and the apparatus of their meal. When they first visited us at our tents, each brought his basket with him; and when we sat down to table, they would go out, sit down upon the ground, at two or three yards distance from each other, and turning

their faces different ways take their repast without exchanging a single word. The women not only abstain from eating with the men, and of the same victuals, but even have their victuals separately prepared by boys kept for that purpose, who deposit it in a separate shed, and attend them with it at their meals. But though they would not eat with us, or with each other, they have often asked us to eat with them, when we have visited those with whom we were particularly acquainted at their houses; and we have often upon such occasions eaten out of the same basket, and drank out of the same cup. The elder women, however, always appeared offended at this liberty; and if we happened to touch their victuals, or even the basket that contained it, they would throw it away."

After meals, and in the heat of the day, the middle-aged people of the better sort generally sleep. They are indeed extremely indolent; and sleeping and eating are almost all that they do. Those that are older are less drowsy, and the boys and girls are kept awake by the natural activity and sprightliness of their age.

These islanders, who inhabit huts exposed to all the winds, and hardly cover the earth, which serves them for a bed, with a layer of leaves, are remarkably healthy and vigorous, and live to an old age without enduring any of its infirmities; their senses are acute, and they retain their beautiful teeth to the last. M. de Bougainville describes an old man, whom they saw on their landing, who had no other character of old age, than that respectable one which is imprinted on a fine figure. His head was adorned with white hair, and a long white beard; all his body was nervous and fleshy; he had neither wrinkles, nor showed any other tokens of decrepitude. This venerable man seemed displeased at the arrival of these strangers; he even retired without making any returns to the courtesies they paid to him; but he gave no signs either of fear, astonishment, or curiosity: very far from taking any part in the raptures which the multitude expressed, his thoughtful and suspicious air seemed to indicate, that he feared the arrival of a new race of men would interrupt the happiness he had so long enjoyed. From whence it may be inferred, that his mind was not a whit more impaired than his body. There are, however, several sorts of leprous complaints on this island, which appear in cutaneous eruptions of the scaly kind; some were seen that had ulcers upon different parts of their bodies: yet they seemed little regarded by those who were afflicted with them, and no application whatever was used to them, not so much as to keep off the flies. But instances of them are rare, as the excellency of their climate, and the simplicity of their vegetable food, prevent almost all dangerous and deadly disorders. They are sometimes afflicted with the cholera, and coughs are not unknown among them; and the chiefs, who fare more sumptuously, are sometimes attacked with a disorder similar to the gout, in which the legs are swelled and excessively painful. M. de Bougainville's surgeon assured him, that he had seen many with marks of the small-pox.

The usual method employed here to restore the sick to health, is by pronouncing a set form of words; after which

Otaheitee. which the exorcist applies the leaves of the cocoa-tree plaited to the fingers and toes of the sick; so that nature is left to conflict with the disease, without being assisted with any salutary application of art. But tho' they seem utterly destitute of medical knowledge, they appear to be no inconsiderable proficient in surgery, which they had an opportunity of proving while the Dolphin lay here. One of the seamen, when on shore, ran a large splinter into his foot; and the surgeon not being at hand, one of his comrades endeavoured to take it out with a penknife; but after putting the poor fellow to a great deal of pain, he was obliged to give it over: an old native, who had been very active and successful in establishing a good understanding between the ship's company and his countrymen, happening to be present, called a man from the other side of the river, who having examined the lacerated foot, fetched a shell from the beach, which he broke to a point with his teeth; with which instrument he laid open the wound, and extracted the splinter. Whilst this operation was performing, the old man went a little way into the wood, and returned with some gum, which he applied to the wound upon a piece of the cloth that was wrapped round him, and in two days time it was perfectly healed. This gum was produced by the apple-tree; the surgeon of the ship procured some of it, and used it as a vulnerary balsam with great success. Captain Cook, in 1769, saw many of the natives with dreadful scars; one man, in particular, whose face was almost entirely destroyed: his nose, including bone, was perfectly flat; and one cheek and one eye were so beaten in, that the hollow would almost receive a man's fist; yet no one ulcer remained.

The venereal disease is said to have been entailed upon these people by the crew of M. de Bougainville's ships, who visited this island a short time after Captain Wallis had left it. In 1769, more than one half of the crew in Captain Cook's ship had contracted it, during a month's stay here. The natives distinguished it by a name of the same import with rottenness, but of a more extensive signification. They described, in the most pathetic terms, the sufferings which the first victims to its rage endured; and told him that it caused the hair and the nails to fall off, and the flesh to rot from the bones; that it spread an universal terror and consternation among the inhabitants, so that the sick were abandoned by their nearest relations, lest the calamity should spread by contagion, and were left to perish alone in such misery as till then had never been known among them. But there seems to be some reason to hope that they had found out a specific cure for it, as none were seen on whom it had made a great progress; and one who went from the ship infected, returned, after a short time, in perfect health. Both Captain Cook and Mr Forster, in their relations of their voyage in the Resolution, endeavour to establish the opinion, that this scourge of licentiousness was felt in the South Sea islands, previous to any of the modern voyages that have been made thither, and that it was an indigenous disease there. But if that conclusion is well-founded, how comes it that at all the places where the Resolution touched in 1773, which had been before visited by the Endeavour in 1769, such as New Zealand for instance, the crew, more or less, be-

VOL. XIII.

came infected by their commerce with the women, and not at all so at places which they visited, for the first time, in the Resolution?

The principal manufacture among the Otaheiteans is their cloth. This is made of the bark of trees, which are of three kinds, viz. the Chinese mulberry-tree, or *auta*; the bread-fruit tree, or *ooroo*; and one that is described by Dr Hawkesworth as resembling the wild fig-tree of the West-Indies. Of all these the paper mulberry affords the best cloth; what is made from that being both finer, softer, whiter, and better suited to take a colour; the *ooroo* produces cloth much inferior in contexture; and the last is very coarse, in colour resembling the darkest brown paper; but this last is the only kind that withstands water: (See the article BARK.)—They likewise prepare a red dye; which is made by mixing the yellow juice of a small species of fig, which the natives call *mattee*, with the greenish juice of a sort of fern or bindweed, or of several other plants, which produce a bright crimson: and this the women rub with their hands, if the piece is to be uniformly of a colour; or they make use of a bamboo reed if the piece is to be marked or sprinkled into different patterns. The colour fades very soon, and becomes of a dirty red; but notwithstanding this defect, and its being liable to be spoiled by rain, the cloth thus stained is highly valued, and is worn only by the principal inhabitants of the country. The inhabitants perfume their clothes with certain plants; concerning which, Mr Forster made all possible inquiry. Tahea, a friendly native, showed him several plants which are sometimes used as substitutes; but the most precious sort he either could not, or would not, point out: and from the account of Omai it appears, that there are no less than 14 different sorts of plants employed for this purpose.

Matting is another Otaheitean manufacture: and in this they are so dexterous, that they produce finer mats than any made in Europe. Rushes, grass, the bark of trees, and the leaves of a plant called *uharrou*, are the materials which they work up for this purpose. Their matting is applied to various uses: the coarser kind is employed for sleeping on in the night, or sitting on through the day; the finer sort is converted into garments in rainy weather, their cloth being soon penetrated by wet. They are very dexterous in making basket and wicker-work: their baskets are of a vast number of different patterns, many of them exceedingly neat; and the making them is an art practised by every one, both men and women.

Instead of hemp, they make ropes and lines of the bark of a tree; and thus they are provided with fishing nets; the fibres of the cocoa-nut furnish them with thread, with which they fasten the different parts of their canoes, &c. The bark of a nettle which grows in the mountains, and is called *orawa*, supplies them with excellent fishing-lines, capable of holding any kind of fish; and their hooks are made of mother-of-pearl, to which they fix a tuft of hair, made to resemble the tail of a fish. Instead of making them bearded, the point is turned inwards. They make also a kind of seine of a coarse broad grass, the blades of which are like flags. These they twist and tie together in a loose manner, till the net, which is about as wide as a large sack, is from 60 to 80 fathoms long.

Manufac-  
tures.

**Otaheitee.** This they haul in smooth shoal water; and its own weight keeps it so close to the ground, that scarcely a single fish can escape. They make harpoons of cane, and point them with hard wood; with which they can strike fish more effectually than an European can with one headed with iron.

**11**  
Working  
tools.

The tools used by the Otaheiteans for all their purposes are, an adze made of stone; a chisel or gouge made of bone, generally the bone of a man's arm between the wrist and elbow; a rasp of coral, and the skin of a sting-ray; also coral and sand, as a file or polisher; and with these they fell timber, cleave and polish it, and hew stone. The stone which makes the blade of their adzes is a kind of basalt, of a grey or blackish colour, not very hard, but of considerable toughness: they are formed of different sizes; some that are intended for felling, weigh from six to eight pounds; others that are used for carving, not more than as many ounces; but it is necessary to sharpen these rude tools almost every minute; for which purpose a cocoa-nut shell full of water and a stone are always at hand. With such tools they generally take up several days in felling a tree; but after it is down, and split into planks, they smooth them very dexterously and expeditiously with their adzes, and can take off a thin coat from a whole plank without missing a stroke.

**12**  
Weapons.

Their weapons are slings, which they use with great dexterity; pikes headed with the skins of sting-rays; and clubs of about six or seven feet long, made of a very hard wood. Thus armed, they are said to fight with great obstinacy; and to give no quarter to man, woman, or child, who happens to fall into their hands during the battle, nor for some time afterwards, till their passion subsides. They have likewise bows and arrows; but the arrows are good for nothing except to bring down a bird, being headed only with stone, and none of them pointed. They have targets of a semi-circular form, made of wicker-work, and plaited strings of the cocoa-nut fibres, covered with glossy, bluish-green feathers belonging to a kind of pigeon, and ornamented with many shark's-teeth, arranged in three concentric circles.

**13**  
Canoes.

Their boats or canoes are of three different sorts. Some are made out of a single tree, and hold from two to six men. These are principally employed in fishing; the others are constructed of planks very dexterously sewed together; they are of different sizes, and will hold from 10 to 40 men: they generally lash two of these together, and set up two masts between them; or if they are single, they have an on-trigger on one side, and only one mast in the middle; and in these vessels they will sail far beyond the sight of land. The third sort seems to be principally designed for pleasure or shew. These are very large, but have no sail; and in shape resemble the gondolas of Venice. The middle is covered with a large awning; and some of the people sit upon it, and some under it. The plank of which these vessels are constructed, is made by splitting a tree, with the grain, into as many thin pieces as possible. The boards are brought to the thickness of about an inch, and are afterwards fitted to the boat with the same exactness that might be expected from an expert joiner. To fasten these planks together, holes are bored with a piece of bone, fixed

into a stick for that purpose. Through these holes a kind of plaited cordage is passed, so as to hold the planks strongly together. The seams are caulked with dry rushes; and the whole outside of the vessel is painted over with a kind of gummy juice, which supplies the place of pitch.

The Otaheiteans are a very industrious people, and friendly in their dispositions; but like all other nations not fully civilized, their passions are extremely violent and they are very fickle. The manner of singling out a man here for a chosen friend is by taking off a part of your clothing and putting it upon him. Their usual manner of expressing their respect to strangers, or to their superiors, at a first meeting, is by uncovering themselves to the middle. They have a custom of saluting those who sneeze, by saying *evavocia-t-eatoua*, "May the good eatoua awaken you," or "May not the evil eatoua lull you asleep!"

**14**  
Character,  
manners,  
&c.

Their propensity to theft is very great, inasmuch, that M. Bougainville says, "even in Europe itself one cannot see more expert filchers than the people of this country;" and indeed, in all the voyages made by Captain Cook and others, they had abundant experience of this disposition of the natives, which often produced quarrels, and sometimes even fatal effects. In their behaviour they are extremely lascivious, almost beyond credibility. A woman of distinction who visited Mr Banks used the following ceremony on her first approach to the stranger. After laying down several young plantain-leaves, a man brought a large bundle of cloth; which having opened, he spread it piece by piece on the ground, in the space between Mr Banks and his visitants. There were in all nine pieces: having spread three pieces one upon another, the lady came forward, and, stepping upon them, took up her garments all around her to her waist; she then turned three times round, after which she dropped the veil: when other three pieces were spread, she practised the same ceremony; and so the third time, when the last three pieces were laid out; after which the cloth was again rolled up, and delivered to Mr Banks as a present from the lady, who with her attending friend came up and saluted him. From the unbridled licentiousness of these people, the French gave this island the name of the *New Cythera*. Nay, to such a degree do they carry their libidinous excesses, that a number of the principal people, it is related, have formed themselves into a society, in which every woman is common to every man. This society is distinguished by the name of *Arreoy*, the members of which have meetings from which all others are excluded. At these meetings the passions are excited by a studied course of sensuality, and the coarsest and most brutal pleasures are enjoyed by the whole company. If, however, notwithstanding these excesses, any of the female members of this community should prove with child, unless she can procure some man to adopt the child as his own, not all the strong affections of a mother, if such are not entirely eradicated by a course of life subversive of the feelings, as well as the modesty of nature, can save the life of the precondemned innocent; but the child as soon as born is smothered, and the mother is left at liberty to renew her former course of execrable prostitution. Should any man be found to cooperate with a woman in saving the life of a child, they are

Otaheitee. are both excluded for ever from the *arreoy*, and are considered as man and wife. The woman from that time is distinguished by the term *whannow-now*, "the bearer of children;" which in this part of the world only is considered as a term of reproach; and so depraved are those people, that being a member of such a society is boasted of as being a privilege, instead of being stigmatized as the foulest crime. The *arreoy*s enjoy several privileges, and are greatly respected throughout the Society Islands, as well as at Otaheitee; nay, they claim a great share of honour from the circumstance of being childless. Tupia, one of the most intelligent natives, when he heard that the king of England, had a numerous offspring, declared, that he thought himself much greater, because he belonged to the *arreoy*s. That this society indulge themselves in promiscuous embraces, and that every women is common to every man, is contradicted by Mr Forster. He says, that these *arreoy*s choose their wives and mistresses from among the prostitutes; and from this circumstance, as well as their extreme voluptuousness, they have seldom any reason to dread the intrusion of children. He had the following circumstances related to him by Omai or Omiah, one of the natives, who was brought to England. He said that the pre-eminence and advantages which a man enjoyed as *arreoy* were so valuable as to urge him against his own feelings to destroy his child; that the mother was never willing to consent to the murder; but that her husband and other *arreoy*s persuaded her to yield up the child; and that where entreaties were not sufficient, force was sometimes made use of. But, above all, he added, that this action was always perpetrated in secret; inasmuch, that not even the *towtow*s or attendants of the house were present; because, if it were seen, the murderers would be put to death.

Both men and women constantly wash their whole bodies three times a-day in running water, and are remarkably cleanly in their clothes. They are most expert swimmers, being accustomed to the water from their infancy. Captain Cook relates the following remarkable instance of their expertness. On a part of the shore where a tremendously high surf broke, inasmuch that no European boat could live in it, and the best European swimmer he was persuaded would have been drowned, as the shore was covered with pebbles and large stones, yet here were 10 or 12 Indians swimming for their amusement. Whenever a surf broke near them, they dived under it, and rose again on the other side. The stern of an old canoe added much to their sport. This they took out before them, and swam with it as far as the outermost breach; when two or three getting into it, and turning the square end to the breaking wave, were driven in towards the shore with incredible rapidity, sometimes almost to the beach; but generally the wave broke over them before they got half way; in which case they dived, and rose to the other side with the canoe in their hands, and swimming out with it again, were again driven back. This amazing expertness drew the Captain's attention for more than half an hour; during which time none of the swimmers attempted to come ashore, but seemed to enjoy the sport in the highest degree. At another time, one of the officers of the quarter-deck intending to drop a bead into a canoe for a little boy of six years

of age, it accidentally missed the boat, and fell into the sea; but the child immediately leaped overboard, dived after it, and recovered it. To reward him for this feat, some more beads were dropped to him; which excited a number of men and women to amuse the officers with their amazing feats of agility in the water, and not only fetched up several beads scattered at once, but likewise large nails, which, from their weight, descended quickly to a considerable depth. Some of these people continued a considerable time under water; and the velocity with which they were seen to go down, the water being extremely clear, was very surprising. Here a green branch of a tree is used as an emblem of peace, in exact conformity to the custom of the ancient nations. We shall add an extract here from Captain Cook's last voyage to the Pacific Ocean.

"Nothing could make a stronger impression at first sight, on our arrival here, than the remarkable contrast between the robust make and dark colour of the people of Tongataboo\*, and a sort of delicacy and whiteness which distinguish the inhabitants of Otaheitee. It was even some time before that difference could preponderate in favour of the Otaheiteans; and then only, perhaps, because we became accustomed to them, the marks which had recommended the others began to be forgotten. Their women, however, struck us as superior in every respect: and as possessing all those delicate characteristics which distinguish them from the other sex in many countries. The beard which the men here wear long, and the hair, which is not cut so short as is the fashion at Tongataboo, made also a great difference; and we could not help thinking that on every occasion they shewed a greater degree of timidity and fickleness. The muscular appearance, so common amongst the Friendly Islanders, and which seems a consequence of their being accustomed to much action, is lost here, where the superior fertility of their country enables the inhabitants to lead a more indolent life; and its place is supplied by a plumpness and smoothness of the skin; which though perhaps more consonant with our ideas of beauty, is no real advantage, as it seems attended with a kind of languor in all their motions, not observable in the others. This observation is fully verified in their boxing and wrestling, which may be called little better than the feeble efforts of children, if compared to the vigour with which these exercises are performed at the Friendly Islands.

"Personal endowments being in great esteem amongst them, they have recourse to several methods of improving them, according to their notions of beauty. In particular, it is a practice, especially amongst the *Arreoy*, or unmarried men of some consequence, to undergo a kind of physical operation to render them fair. This is done by remaining a month or two in the house; during which time they wear a great quantity of clothes, eat nothing but bread fruit, to which they ascribe a remarkable property in whitening them. They also speak, as if their corpulence and colour, at other times, depended upon their food; as they are obliged, from the change of seasons, to use different foods at different times.

"The graceful air and firm step with which these people walk are not the least obvious proof of their personal accomplishments. They consider this as a thing

Otaheitee.

\* One of the Friendly Islands.

Otaheitee. thing so natural, or so necessary to be acquired, that nothing used to excite their laughter sooner, than to see us frequently stumbling upon the roots of trees, or other inequalities of the ground.

"Their countenances very remarkably express the abundant mildness or good nature which they possess, and are entirely free from that savage keenness which marks nations in a barbarous state. One would, indeed, be apt to fancy that they had been bred up under the severest restrictions to acquire an aspect so settled, and such a command of their passions, as well as steadiness in conduct. But they are at the same time frank, cheerful, and good-humoured; though sometimes, in the presence of their chiefs, they put on a degree of gravity, and such a serious air, as becomes stiff and awkward, and has an appearance of reserve.

"Their peaceable disposition is sufficiently evinced from the friendly reception all strangers have met with who have visited them. Instead of offering to attack them openly or clandestinely, as has been the case with most of the inhabitants of these seas, they have never appeared in the smallest degree hostile, but on the contrary, like the most civilized people, have courted an intercourse with their visitors by bartering, which is the only medium that unites all nations in a sort of friendship. They understand barter (which they call *fukkatou*) so perfectly, that at first we imagined they might have acquired this knowledge of it by commercial intercourse with the neighbouring islands; but we were afterwards assured, that they had little or no traffic except with Feejee, from which they get the red feathers, and some few other articles which they esteem. Perhaps no nation in the world traffic with more honesty, and less distrust. We could always safely permit them to examine our goods, and to hand them about one to another; and they put the same confidence in us. If either party repented of the bargain, the goods were re-exchanged with mutual consent and good humour. Upon the whole, they seem possessed of many of the most excellent qualities that adorn the human mind, such as industry, ingenuity, perseverance, affability, and perhaps other virtues which our short stay with them might prevent our observing.

"The only defect fullying their character, that we know of, is their propensity to thieving, to which we found those of all ages and both sexes addicted, and to an uncommon degree. It should, however, be considered, that this exceptionable part of their conduct seemed to exist merely with respect to us; for in their general intercourse with one another, I had reason to be of opinion, that thefts do not happen more frequently (perhaps less so) than in other countries, the dishonest practices of whose worthless individuals are not supposed to authorize any indiscriminate censure on the whole body of the people. Great allowances should be made for the foibles of these poor natives of the Pacific Ocean, whose minds we overpowered with the glare of objects, equally new to them as they were captivating. Stealing, amongst the civilized and enlightened nations of the world, may well be considered as denoting a character deeply stained with moral turpitude, with avarice unrestrained by the known rules of right, and with profligacy producing extreme indigence, and neglecting the means of relieving it.

But at the Friendly and other islands which we visited, the thefts so frequently committed by the natives, of what we had brought along with us, may be fairly traced to less culpable motives. They seemed to arise solely from an intense curiosity or desire to possess something which they had not been accustomed to before, and belonging to a sort of people so different from themselves. And perhaps, if it were possible that a set of beings seemingly as superior in our judgment as we are in theirs should appear amongst us, it might be doubted, whether our natural regard to justice would be able to restrain many from falling into the same error. That I have assigned the true motive for their propensity to this practice, appears from their stealing every thing indiscriminately at first sight, before they could have the least conception of converting their prize to any one useful purpose. But I believe, with us, no person would forfeit his reputation, or expose himself to punishment, without knowing before-hand how to employ the stolen goods. Upon the whole, the pilfering disposition of these islanders, though certainly disagreeable and troublesome to strangers, was the means of affording us some information as to the quickness of their intellects. For their small thefts were committed with much dexterity; and those of greater consequence with a plan or scheme suited to the importance of the objects. An extraordinary instance of the last sort was, in their attempts to carry away one of the Discovery's anchors at mid-day.

"Their common diet is made up of at least nine-tenths of vegetable food; and I believe more particularly the *mabee*, or fermented bread-fruit, which makes part almost of every meal, has a remarkable effect upon them, preventing a costive habit, and producing a very sensible coolness about them, which could not be perceived in us who fed on animal food. And it is, perhaps, owing to this temperate course of life that they have so few diseases among them. See n° 8.

"They only reckon five or six which might be called chronic, or national disorders; amongst which are the dropsy, and the *sesai*, or indolent swellings before mentioned, as frequent at Tongataboo. But this was before the arrival of the Europeans; for we have added to this short catalogue a disease which abundantly supplies the place of all the others, and is now almost universal. For this they seem to have no effectual remedy. The priests, indeed, sometimes give them a medley of simples, but they own that it never cures them. And yet they allow that in a few cases nature, without the assistance of a physician, exterminates the poison of this fatal disease, and a perfect recovery is produced. They say, that if a man is infected with it he will often communicate it to others in the same house, by feeding out of the same utensils, or handling them, and that, in this case, they frequently die, while he recovers; though we see no reason why this should happen. See n° 9.

"Their behaviour on all occasions seems to indicate a great openness and generosity of disposition. Omai, indeed, who, as their countryman, should be supposed rather willing to conceal any of their defects, has often said that they are sometimes cruel in punishing their enemies. According to his representation, they torment them very deliberately; at one time tearing out  
small.

Otaheitee. small pieces of flesh from different parts; at another taking out the eyes; then cutting off the nose; and lastly, killing them by opening the belly. But this only happens on particular occasions. It cheerfulness argues a conscious innocence, one would suppose that their life is seldom sullied by crimes. This, however, I rather impute to their feelings, which, though lively, seem in no case permanent; for I never saw them in any misfortune labour under the appearance of anxiety after the critical moment was past. Neither does care ever seem to wrinkle their brow. On the contrary, even the approach of death does not appear to alter their usual vivacity. I have seen them when brought to the brink of the grave by disease, and when preparing to go to battle; but in neither case ever observed their countenances overclouded with melancholy or ferocious reflection. Such a disposition leads them to direct all their aims only to what can give them pleasure and ease. Their amusements all tend to excite and continue their amorous passions; and their songs, of which they are immoderately fond, answer the same purpose. But as a constant succession of sensual enjoyments must cloy, we found that they frequently varied them to more refined subjects, and had much pleasure in chanting their triumphs in war, and their occupations in peace; their travels to other islands and adventures there; and the peculiar beauties, and superior advantages of their own island over the rest, or of different parts of it over other less favourite districts. This marks that they receive great delight from music; and though they rather expressed a dislike to our complicated compositions, yet were they always delighted with the more melodious sounds produced singly on our instruments, as approaching nearer to the simplicity of their own. Neither are they strangers to the soothing effect produced by particular sorts of motion, which in some cases seem to allay any perturbation of mind with as much success as music. Of this I met with a remarkable instance. For, on walking one day about Matavai Point, where our tents were erected, I saw a man paddling in a small canoe so quickly, and looking about with such eagerness on each side, as to command all my attention. At first I imagined that he had stolen something from one of the ships, and was pursued; but on waiting patiently saw him repeat his amusement. He went out from the shore till he was near the place where the swell begins to take its rise; and, watching its first motion very attentively, paddled before it with great quickness till he found that it overtook him, and had acquired sufficient force to carry his canoe before it, without passing underneath. He then sat motionless, and was carried along at the same swift rate as the wave, till it landed him upon the beach. Then he started out, emptied his canoe, and went in search of another swell. I could not help concluding, that this man felt the most supreme pleasure, while he was driven on so fast and so smoothly by the sea; especially as, though the tents and ships were so near, he did not seem in the least to

envy, or even to take any notice of, the crowds of his countrymen collected to view them as objects which were rare and curious. During my stay, two or three of the natives came up, who seemed to share his felicity, and always called out when there was an appearance of a favourable swell, as he sometimes missed it, by his back being turned, and looking about for it. By them I understood that this exercise, which is called *choroo*, was frequent amongst them; and they have probably more amusements of this sort, which afford them at least as much pleasure as skating, which is the only one of ours with whose effects I could compare it."

The language of these islanders is soft and melodious: it abounds with vowels, and the pronunciation of it is easily acquired: but it was found excessively difficult to teach the natives to pronounce a single English word; probably not only from its abounding with consonants, but from some peculiarity in its structure; for Spanish and Italian words, if ending in a vowel, they pronounced with the greatest ease. A sufficient acquaintance has not been formed with it to determine whether it is copious or not; but it is certainly very imperfect, being totally without inflection either of nouns or verbs. Few of the nouns have more than one case, and few of the verbs more than one tense. It was impossible to teach the islanders to pronounce the names of their guests. They called Captain Cook *Toote*; Mr Hicks, the first lieutenant, *Hete*, &c. and in this manner they formed names for almost every man in the ship. In some, however, it was not easy to find any traces of the original; and they were perhaps not mere arbitrary sounds formed upon the occasion, but signified words in their own language; and it seems that they could perfectly remember these appellations at the distance of four years, by their inquiries after such gentlemen as were absent on the second voyage by name. Mr Monkhouse, a midshipman, they called *Matte*, which in their language signifies *dead*; because he commanded a party that killed a man for stealing a musket. The nearest imitation they could reach of king George, was by calling him *Kihirgo*. We have the following observations on this subject, in vol. ii. of Cook's last voyage to the Pacific Ocean: "The language of Otaheitee, though doubtless radically the same with that of New Zealand and the Friendly Islands, is destitute of that guttural pronunciation, and of some consonants, with which those latter dialects abound. The specimens we have already given are sufficient to mark wherein the variation chiefly consists, and to show, that, like the manners of the inhabitants, it has become soft and soothing. During the former voyage, I had collected a copious vocabulary, which enabled me the better to compare this dialect with that of the other islands; and during this voyage I took every opportunity of improving my acquaintance with it, by conversing with Omai before we arrived, and by my daily intercourse with the natives while we now remained there (A). It

Otaheitee.

15  
Language,  
&c.

(A) See this vocabulary at the end of the second volume of Captain Cook's second voyage. Many corrections and additions to it were now made by this indefatigable inquirer; but the specimens of the language of Otaheitee, already in the hands of the public, seem sufficient for every useful purpose,

Otaheitee.

abounds with beautiful and figurative expressions, which, were it perfectly known, would I have no doubt put it upon a level with many of the languages that are most in esteem for their warm and bold images. For instance, the Otaheiteans express their notions of death very emphatically, by saying, "that the soul goes into darkness; or rather into night." And, if you seem to entertain any doubt, in asking the question, "if such a person is their mother?" they immediately reply with surprise, "Yes, the mother that bore me." They have one expression that corresponds exactly with the phraseology of the scriptures, where we read of the "yearning of the bowels."—They use it on all occasions, when the passions give them uneasiness, as they constantly refer pain from grief, anxious desire, and other affections, to the bowels, as its seat; where they likewise suppose all operations of the mind are performed. Their language admits of that inverted arrangement of words which so much distinguishes the Latin and Greek from most of our modern European tongues, whose imperfections require a more orderly construction, to prevent ambiguities. It is so copious, that for the bread-fruit alone, in its different states, they have above 20 names; as many for the taro root; and about 10 for the coconut. Add to this, that, besides the common dialect, they often expostulate in a kind of stanza or recitative, which is answered in the same manner."

A map of Otaheitee, engraved for Captain Cook's first voyage, was taken out, and laid before Tuahoa the high admiral, without informing him of what it was; however, he immediately found it out, and was overjoyed to see a representation of his own country. He pointed out all the districts of it, naming every one of them in their order.

These people have a remarkable sagacity in foretelling the weather, particularly the quarter from whence the wind will blow. In their long voyages they steer by the sun in the day, and in the night by the stars; all of which they distinguish by different names, and know in what part of the heavens they will appear in any of the months during which they are visible in their horizon. They also know the times of their annual appearing and disappearing, with more precision than would easily be believed by an European astronomer. Their time they seem to reckon by moons, 13 of which make a year. The day they divide into six parts, and the night into an equal number. They judge of the time of the day by the height of the sun, but they cannot ascertain the time of the night by the stars. In numeration, the greatest length they can go is 200; that is, when they have counted each of their fingers and toes ten times over. When they take the distance from one place to another, they express it by the time which is required to pass it.

The government of the Otaheiteans seems greatly to resemble the early state of the European nations under the feudal system. Their orders of dignity are *earree-rabie*, which answers to king; *earree*, baron; *manahouni*, vassal; and *totoutou*, vassal. There are two kings in the island, one being the sovereign of each of the peninsulas of which it consists. Each of them is treated with great respect by all ranks, but does not appear to be invested with so much power as is exercised by the *earrees* in their own districts. When

the king, whom they called *O-Too*, made a visit to Captain Cook, the chiefs who happened to be there before him, immediately stripped themselves in great haste. Captain Cook took notice of it; upon which they said *earree, earree*, signifying, that it was on account of O-too being present; but this was the only outward token of respect they paid him, for they never rose from their seats, or made any other obeisance.

The *earrees* are lords of one or more of the districts into which each of the peninsulas is divided, and of which there are 43 in the larger one. These parcel out their territories to the *manahounis*, who superintend the cultivation of the ground. The lowest class, called *totoutous*, seem to be nearly under the same circumstances with the villeins in feudal governments. They do all the laborious work, cultivate the land, catch fish, fetch wood and water, &c. Each of the *earrees* keeps a kind of court, and has a great number of attendants, chiefly the younger brothers of their own tribe; and among these some hold particular offices, but of which little more is known than some of their names.

In this country a child succeeds to his father's titles and authority as soon as he is born; and thus the king no sooner has a son born, than his sovereignty ceases. A regent is then chosen; and the father generally retains his power under that title, until his child becomes of age. The child of the baron succeeds to the titles and honors of his father as soon as it is born, as well as the son of the king; so that a baron who was yesterday called *earree*, and was approached with the ceremony of lowering their garments, so as to uncover the upper part of the body, is to-day, if his wife happens to be delivered of a child, reduced to the rank of a private man; all marks of respect being transferred to the child if it is suffered to live, though the father still continues possessor and administrator of his estate. But the acquiescence which the lower class of people, or *totoutous*, yield to the command of their chiefs, is very remarkable. They are not suffered to taste any animal food, although they are employed in feeding it for their lords. They endure patiently very severe blows, if, when collected into a large body, they in any manner press upon or annoy the king or a chief in his progress; and all this passive spirit is preserved without any power being lodged in the hands of the king to exact it; for he uses no military force, nor is even attended with body-guards.

There are but few actions which are reckoned crimes among the Otaheiteans. Adultery, however, is sometimes punished with death: but in general, the woman escapes with a severe beating, and the gallant passes unnoticed. The regulation of public justice is not confined to the magistrate; for the injured party redresses his own wrong by inflicting whatever punishment he can upon the offender: but in matters of notorious wrong, the chiefs sometimes interpose. The nobility have livery for their servants; and in proportion as the master's rank is more or less elevated, these fashes are worn higher or lower, being fastened close under the arms of the servants belonging to the chiefs, and going round the loins of those belonging to the lowest class of nobility. Several parts of the island seem to be private property, which descend to the heir

Otaheitee.

**Otaheitee.** of the possessor on his death, and the descent seems to fall indifferently on man or woman. Captain Cook was of opinion, that the number of inhabitants on the whole island amounted to 204,000, including women and children.

17  
Religion.

The religious language of the Otaheiteans, like that of the Gento Bramins, is different from what is used in common discourse; but, according to the accounts we have of their notions concerning the origin of the world, nothing can be more ridiculous. They imagine that the Supreme Deity, besides a great many female descendants, has one son named *Tane*; and to him they direct their worship, though they do not believe that the good or bad conduct of mankind here on earth makes them more or less acceptable to this divinity. They believe the existence of the soul after death, and of a greater or lesser degree of happiness to be then enjoyed; but they seem to have no conception of a state of punishment or of suffering hereafter. The share of happiness which they imagine every individual will enjoy in this future state, will be assigned to him according to the rank he holds on earth. We are not, however, told wherein they suppose the happiness of this future state to consist; but it is most probably a pretty exact imitation of a Mohammedan paradise, for these voluptuaries can hardly be supposed capable of imagining any pleasure independent of the intercourse of the sexes.

The priesthood seems to be hereditary in one family or tribe; and as it is said to be numerous, probably those of that order are restrained from becoming members of the *Arreoy*: but whether or not any peculiar decorum is necessary to be observed, hath not yet appeared. These priests are professedly the men of science; but their knowledge is altogether frivolous and useless, for it consists in being conversant with the names of their different divinities, and such absurd traditions as have been handed down among them from one generation to another. Their religious notions being deposited in an unknown tongue, they are respected because they are not understood; and as the cure of the soul is no object of regard, the most important concern to these people, the cure of their bodies, is committed to the priests, and much parade is used in their attempts to recover the sick, though their remedies consist of ridiculous ceremonies and enchantments rather than any thing else.

The marriages of these people are merely secular contracts; but no one has a right to perform the operation of tattooing except the priests; and this being a custom universally adopted by the natives, it may be supposed that the performing it is a very lucrative employment. The males in general undergo a kind of circumcision, which it is disgraceful not to comply with, and which is likewise the exclusive privilege of the priests to perform. But what most establishes the credit of this order of men is their skill in astronomy and navigation.

Captain Cook, who had some reason to believe that, among the religious customs of this people, human sacrifices were sometimes offered up to their deities, went to the morai, or place of worship, accompanied by Captain Furneaux, having with them a sailor who spoke the language tolerably well, and several of the natives. In the morai was a tupapow, a kind of bier,

with a shed erected over it, on which lay a corpse and some provisions. Captain Cook then asked if the plantain were for the *Eatua*? If they sacrificed to the *Eatua* hogs, dogs, fowls, &c.? To all of which an intelligent native answered in the affirmative. He then asked if they sacrificed men to the *Eatua*? He was answered, *taata eno*, "bad men they did; first *tiparraby*, beating them till they were dead." He then asked if good men were put to death in this manner? His answer was no, only *taato eno*. The Captain then asked if any *Earees* were? The native replied, they had hogs to give the *Eatua*, and again repeated *taato eno*. He was then asked if tow-tows, who had no hogs, dogs, or fowls, but yet were good men, were ever sacrificed to the *Eatua*? The answer still was no, only bad men. Many other questions were put to him; all his answers to which seemed to confirm the ideas that men for certain crimes were condemned to be sacrificed to the gods, provided they did not possess any property which they might give for their redemption. However, in pursuing such inquiries as these, no certain information could be obtained, on account of the slight knowledge which had been acquired of the language of the country: but according to further accounts which Captain Cook received from Omai, it seems to rest with the high-priest to single out the victims for sacrifice; who, when the people are assembled on any solemn occasion, retires alone into the house of God, and stays there for some time; when he comes out, he informs the assembly that he has seen and conversed with the great god (the high priest alone having that privilege, and that he has asked for a human sacrifice; and tells them he has desired such a person, naming a man present, who has most probably, on some account or other, rendered himself obnoxious to this ghostly father. The words are no sooner gone out of his mouth, than the devoted wretch is put to death; but his guilt cannot be doubted, after the oracle has pronounced his doom.

On this island was seen the figure of a man constructed of basket-work, rudely made, but not ill designed: it was something more than seven feet high, and rather too bulky in proportion to its height. This wicker skeleton was completely covered with feathers, which were white where the skin was to appear, and black in the parts which it is their custom to paint or stain, as well upon the head, which was designed to represent hair. Upon the head also were four protuberances; three in front, and one behind, which the Indians called *tate etc*, little men. The image was called *Manioe*; it was a representation of *Mauve*, one of their *Eatuas*, or gods of the second class, and was said to be the only one of the kind on Otaheitee.

These people pray at sun-rise and sun-set. They have also a number of superstitious practices, in order to conciliate the influence of evil genii. E-Tee, a chief, who seemed to be the king's prime minister in 1774, very seriously asked Mr Forster whether they had a god (*Eatua*), in their country, and whether they prayed to him (*epoore*?) When he told them that they acknowledged a Divinity who had made every thing, and was invisible, and that they were accustomed to address their petitions to him, he seemed to be highly pleased, and repeated his words with comments of his own, to several persons who sat round

Otaheitee. round him; seeming thereby to intimate, that the ideas of his countrymen corresponded with theirs in this respect.

Their morais are used both as burying-grounds and places of worship; they are approached with the most wonderful expressions of reverence and humility; and this, it should seem, not because any thing there is esteemed sacred, but because they there worship an invisible being, for whom they entertain the most reverential respect, although not excited by the hope of reward or the dread of punishment. Though they do not appear to have any visible object of worship, yet, says Captain Cook, this island, and indeed the rest that lie near it, have a particular bird, some a heron, and others a kingfisher, to which they pay a particular regard, and concerning which they have some superstitious notions, respecting good or bad fortune, as we have of the swallow and robin redbreast, and will on no account molest or kill them. One of these cemeteries, or places of worship, was known to Captain Cook, on his first voyage, by the name of Tootahah's morai, then the regent; but when on his second voyage, after the death of that chief, he called it by that name, Maratata, a chief that accompanied the party, interrupted him, intimating, that it was no longer Tootahah's after his death, but was then known as O-Too's morai, the then reigning prince. A fine moral for princes! daily reminding them of mortality whilst they live, and teaching them, that after death they cannot call even that ground their own which their dead corpse occupies! The chief and his wife, on passing by it, took their upper garments from their shoulders. From hence it should seem that the royal family have a particular morai, and that it always bears the name of the reigning prince.

18  
Funerals.

An Indian, who had snatched away a musket from a centry whilst on duty, was, by the inhumanity of a midshipman who commanded the guard, pursued and shot. The unhappy fate of this poor fellow gave an opportunity for seeing the manner in which these people treat their dead. They placed the corpse in the open air till the bones became quite dry: a shed was erected close by the house where the deceased had resided; it was about 15 feet long, and eleven broad; one end was left quite open; the other end, and the two sides, were partly inclosed with a sort of wicker-work. The bier was a frame of wood, like that on which the sea-beds, called *cots*, are placed, with a matted bottom, and supported by four posts, at the height of about four feet from the ground. The body was covered first with a mat, and then with white cloth; by the side of it lay a wooden mace, one of their weapons of war; and near the head of it, which lay next to the close end of the shed, lay two cocoa-nut shells: at the other end a bunch of green leaves, with some dried twigs, all tied together, were stuck in the ground, by which lay a stone about as big as a cocoa-nut. Near these lay one of the young plantain-leaves, that are used for emblems of peace, and close by it a stone ax. At the open end of the shed also hung, in several strings, a great number of palm-nuts; and without the shed was stuck up in the ground a stem of a plantain-tree, about six feet high, upon the top of which was placed a cocoa-nut shell full of fresh water; against the side of one of the posts hung a small bag,

Otaheitee. containing a few pieces of bread-fruit ready roasted, which had not been put in all at one time, some being fresh, and others stale. This minute examination of the manner of treating their dead, seemed to be very unwelcome to the natives. The food so placed by the corpse is designed as an offering to their gods. They cast in, near the body, small pieces of cloth, on which the tears and blood of the mourners have been shed; for in their paroxysms of grief it is an universal custom to wound themselves with a shark's tooth. The mourner is always a man; and he is dressed in a very singular habit. When the bones are stripped of their flesh, and become dry, they are buried. This regard to their dead is very remarkable: one of the ship's company happening to pull a flower from a tree which grew on one of their sepulchral inclosures, an Indian came suddenly behind him and struck him; and a party of sailors, who were sent to get some stones for ballast for the ship, had like to have been embroiled with the natives, by pulling down some part of an inclosure of this kind. This shade under which their dead are laid is called *tupapow*; the inclosure in which their bones are deposited is called *merai*; these latter as has been already related, are also places of worship. As soon as a native of Otaheite is known to be dead, the house is filled with relations, who deplore their loss; some by loud lamentations, and some by less clamorous, but more genuine expressions of grief. Those who are in the nearest degree of kindred, and are really affected by the event, are silent; the rest are one moment uttering passionate exclamations in a chorus, and the next laughing and talking without the least appearance of concern. In this manner the remainder of the day on which they assemble is spent, and all the succeeding night. On the next morning the body is shrouded in their cloth, and conveyed to the sea-side on a bier, which the bearers support upon their shoulders, attended by the priest, who having prayed over the body repeats his sentences during the procession. When it arrives at the water's edge, it is set down upon the beach; the priest renews his prayers, and taking up some of the water in his hands, sprinkles it towards the body, but not upon it. It is then carried back 40 or 50 yards; and soon after brought again to the beach, where the prayers and sprinkling are repeated. It is thus removed backwards and forwards several times; and while these ceremonies have been performing, a house has been built, and a small space of ground railed in. In the centre of this house, or *tupapow*, as they term it, posts are set up to support the bier, which is at length conveyed thither, and placed upon it; and here the body remains to putrify, till the flesh is wholly wasted from the bones. These houses of corruption are of a size proportioned to the rank of the person whose body they are to contain. Those allotted to the lower class are just sufficient to cover the bier, and have no railing round them. The largest that was seen was 11 yards long; and such are ornamented according to the abilities and inclination of the surviving kindred, who never fail to lay a profusion of good cloth about the body, and sometimes almost cover the outside of the house. Garlands of the fruit of the palm-nut, or pandanus, and cocoa-leaves, twisted by the priests in mysterious knots, with a plant called by them *ethee no marai*; which is parti-

Otaheitee. particularls consecrated to funeral solemnities, are deposited about the place; provision and water are also left at a little distance. As soon as the body is deposited in the tupapow, the mourning is renewed. The women assemble, and are led to the door by the nearest relation, who strikes a shark's tooth several times into the crown of her head; the blood copiously follows, and is carefully received upon pieces of linen, which are thrown under the bier. The rest of the women follow this example; and the ceremony is repeated at the interval of two or three days, as long as the zeal and sorrow of the parties hold out. The tears also which are shed upon these occasions, are received upon pieces of cloth, and offered as oblations to the dead. Some of the younger people cut off their hair, and that is thrown under the bier with the other offerings. This custom is founded on a notion, that the soul of the deceased, which they believe to exist in a separate state, is hovering about the place where the body is deposited; that it observes the actions of the survivors, and is gratified by such testimonies of their affectionate grief. Whilst these ceremonies are carrying on by the women, the men seem to be wholly insensible of their loss; but two or three days after, they also begin to perform a part. The nearest relations take it in turn to assume the dress, and perform the offices.

The chief mourner carries in his hand a long flat stick, the edge of which is set with shark's teeth; and in a frenzy, which his grief is supposed to have inspired, he runs at all he sees, and if any of them happen to be overtaken, he strikes them most unmercifully with his indented cudgel, which cannot fail to wound them in a dangerous manner. The processions continue at certain intervals for five moons; but are less and less frequent, by a gradual diminution, as the end of that time approaches. When it is expired, what remains of the body is taken down from the bier; and the bones, having been scraped and washed very clean, are buried, according to the rank of the person, either within or without a morai. If the deceased was an earee, or chief, his skull is not buried with the rest of his bones, but is wrapped up in fine cloth, and put in a kind of box made for that purpose, which is also placed in the morai. This coffin is called *ewharre no to oremetua*, "the house of a teacher, or master." After this the mourning ceases, except some of the women continue to be really afflicted at the loss, and in that case they will suddenly wound themselves with the shark's tooth wherever they happen to be. The ceremonies, however, do not cease with the mourning; for prayers are still said by the priest, and offerings made at the morai. Some of the things, which from time to time are deposited there, are emblematical: a young plantain is said to represent the deceased, and a bunch of feathers the Deity who is invoked. The priest places himself over-against the symbol of the god, accompanied by some of the relations, who are furnished with a small offering: he repeats his orison in a set form, consisting of separate sentences; at the same time weaving the leaves of the cocoa-nut into different forms, which he afterwards deposits upon the ground where the bones have been interred: the Deity is then addressed by a shrill screech, which is used only upon that occasion. When

the priest retires, the tuft of feathers is removed, and the provisions are left to putrify, or be devoured by the rats.

This ceremony of mourning, as described above, was performed by Tirope, one of the wives of Tubourai Tamaide; who, when the bleeding from the wounds which she had thus given herself ceased, looked up with a smile on the company round her, and who had before inquired of her, very earnestly, the cause of her behaviour, without receiving any answer, or having been at all noticed by her. She then began to pick up some small pieces of cloth which she had spread to catch the blood; and having got them all together, she went to the shore, and threw them into the sea. She then plunged into the river; and having washed her whole body, returned to the company as cheerful as ever. To add to the singularity of this conduct, the Indians who stood round her all the time that this frantic distress was performing, conversed with great indifference and jocularly.

There is not a more ancient custom handed down to us than that of cutting the body to express grief and distress of mind. In the code of laws delivered by Moses to the Israelites, 1400 years before the Christian era, this practice is expressly forbidden to that people: "Ye shall not cut yourselves, or make any baldness between the eyes for the dead," Deut. xiv. 1. Hence it may be supposed that this rite prevailed in Egypt, from whence the Jews derived most of those propensities which were inhibited by their great legislator. We are told likewise in the book of Kings, of the priests of Baal wounding themselves, after they had long waited in vain for the supernatural intervention of their idol. D'Arvieux informs us, that the modern Arabs retain the same custom, and that the part they chiefly wound is their arms. The difference in the practice as now prevailing in O-Taheitee and Arabia seems to be, that in the first none but the women make use of it, and in the latter it is confined to the men, and generally used to express their desperate passion for some favourite mistress.

The mourning which is worn here is an head-dress of feathers, the colour of which is consecrated to death, and a veil over the face. This dress is called *eeva*. The whole nation is said to appear thus on the death of their king. The mourning for fathers is very long. The women mourn for their husbands, but not the husbands for their wives.

We shall conclude this account of Otaheitee with the history of *Omai*, or, as he is improperly called *O-miah*, who was brought over to England. He was a native of Ulietea, or Raietea; and embarked at Huahine with Captain Furneaux, on board the *Adventure*, in September 1773; and the two ships separating in a storm on the coast of New Zealand a few months afterwards, the voyage of the *Adventure* was brought to a much earlier conclusion than that of the *Resolution*, for she arrived at Spithead the 14th of July following. This youth is said to have had some property in his native soil, of which he was dispossessed by the people of Bolabola: but he was not one of the earees, or gentry of that country, but of the middling class of people. He was eminent neither for figure, shape, nor complexion; his colour being of a deep hue, resembling a tow-tow, or one of the common

Otaheites.

people; and both Captain Cook and Mr Forster agree in thinking him no proper sample of the inhabitants of those islands, in respect of personal beauty. However, they are both of opinion, that the qualities of his heart and head resembled those of his countrymen in general, and that no one of the natives would have given more general satisfaction by his behaviour whilst he remained in England. He is described as possessing a good understanding, quick parts, and honest principles: not an extraordinary genius like Tupia; yet not at all deficient in intelligence, which appears from his knowledge of the game of chess, in which he made an amazing proficiency. His principal patrons, whilst in England, were, the Earl of Sandwich, Mr Banks, and Doctor Solander. His noble patron introduced him to his Majesty at Kew; and, during his stay in England, he was caressed by many of the principal nobility. He naturally imitated that easy and elegant politeness which is prevalent among the great, and which is one of the ornaments of civilized society. Indeed he adopted the manners, the occupations, and amusements of his companions in general, and gave many proofs of a quick perception and a lively fancy. He appears, however, to have been treated, whilst he resided here, rather as a fashionable exhibition, than as a rational being. No attention seems to have been paid to the enriching his mind with useful knowledge, such as might have rendered him a valuable acquisition to his country on his return thither; no means were used to instruct him in agriculture, or any mechanical art or useful manufacture; and, above all, to possess him with a moral sense: to teach him the exalted ideas of virtue, and the sublime principles of revealed religion. After a stay of two years in England, and having been inoculated for the small pox, he embarked with Captain Cook on board the *Resolution*, on his return home, loaded with a profusion of presents. At parting with his friends here, his tears flowed plentifully, and his whole behaviour bespoke him to be sincerely affected at the separation: but though he lived in the midst of amusements during his residence in England, his return to his native country was always in his thoughts; and tho' he was not impatient to go, he expressed a satisfaction as the time of his return approached.

Such is the account of this people which our limits permit us to give. In the history of mankind it is not without importance; and in the hands of the philosopher, the moralist, or the divine, it may be useful. The subject, because but new, has been much agitated, and is pretty generally known. Such of our readers as make men and manners their peculiar study, will be anxious for further information; we must refer them, however, to those authors who have written particularly and copiously on the subject. Cook and other voyagers of eminence will at least command attention. We may just remark, that there must surely be something extremely fascinating in the persons, manners, or customs of the inhabitants, or in the soil and appearance of the country, that could tempt the greater part of a ship's crew to resist authority, and forcibly to return to Otaheitee; yet such we know was the case: and the sufferings of the commander, and those who refused to join in this vile conspiracy, and who were

therefore exposed in an open boat, were indeed shocking. An account of it has been lately published.

OTALGIA, the EAR-ACH, in medicine. See there n<sup>o</sup> 80. and 364.

OTELANDS, or OATLANDS, in England, in the county of Surry, near Weybridge, was formerly a royal palace, wherein Henry duke of Gloucester, third son to king Charles I. was born; and had a deer-park, which in the late civil wars was by the parliamentarians laid open, and the house demolished. In 1673 there was a brick-wall remaining, which encompassed ten acres; but there were then small traces of the chief pile, besides the gardener's lodge, wherein was the silk-worm room raised by King James I.'s queen. It is now a most magnificent building, and commands a most extensive prospect, which words cannot describe. In the park there was a paddock, where Queen Elizabeth used to shoot with a cross bow. It is now the property of his royal highness the Duke of York, who purchased it for 43,000 l. of the duke of Newcastle, 1789.

OTFORD, in England, in the county of Kent, by the Darent, at the bottom of a hill. In 793 there was a battle at this place between the two Saxon kings, Offa of Mercia and Alrick of Kent, who was killed by Offa; and another in 1016, wherein the Danish king Canute was routed by King Edmund Ironside. The said Offa, to atone for the blood he had shed in that battle, first gave this place to Christ-church, Canterbury (as the deed says), *in poscua parcorum*, "for the support of the archbishop's hogs;" and so it remained in the archbishop's liberty, till exchanged with King Henry VIII. for other lands. There was a chantry founded at the Rye-house in this parish. The church was once a chapel to Shoreham.

OTHNIEL, in sacred history, the son of Kenaz, of the tribe of Judah. We are told (Josh. xv. 17.), that Othniel was brother to Caleb; and (Judges i. 13.) it is expressly said, that he was Caleb's younger brother. There are, however, some difficulties in this; for if Caleb and Othniel had been brothers, the latter could not have married his niece Achsah the daughter of Caleb. Secondly, the scripture never assigns to Caleb and Othniel the same father: it always names Kenaz as father to Othniel, and Jephunneh as the father of Caleb. Lastly, Caleb must be much older than Othniel, since he gave Othniel his daughter Achsah in marriage. Thus it seems much better to suppose Kenaz and Jephunneh to be two brothers, and that Othniel and Caleb were cousin Germans, and in this sense to be nearly related, or brothers according to the language of scripture. Thus Achsah being but second cousin in respect to Othniel, he might marry her without doing any thing contrary to the letter of the law.

Caleb having received his portion in the mountains of Judah, in the midst of a country that was possessed by giants of the race of Anak, after he had taken the city of Hebron, he advances towards Debir, otherwise called *Kirjath-sepher*, and declares that he would give his daughter Achsah in marriage to him that should take Kirjath-sepher. Othniel took it, and had Achsah to wife.

After the death of Joshua, the Israelites not giving themselves the trouble to exterminate the Canaanites that

Otalgia

Othniel.

Otho. that were then in the land, and not having continued in their fidelity to the Lord, he delivered them over to Chushan-rushathaim king of Mesopotamia (Judges iii. 4, &c.), to whom they contained in subjection for eight years. Then they cried to the Lord, who raised them up a deliverer in the person of Othniel the son of Kenaz, who was filled with the spirit of God, and judged Israel. He came into the field, and gave battle to Chushan-rushathaim, beat him, and delivered Israel in the year of the world 2599; and the country was at rest for 40 years. After this Othniel died; but the precise year of his death is not known.

OTHO (M. Silvius), a Roman emperor, born A. D. 32, of a family descended from the ancient kings of Etruria. He was among the number of Nero's favourites, and accordingly was raised to the highest offices of the state, and made governor of Pannonia by the interest of Seneca, who wished to remove him from Rome, lest Nero's love for Poppæa should prove his ruin. After Nero's death Otho conciliated the favour of Galba the new emperor; but when he did not gain his point, and when Galba refused to adopt him as his successor, he resolved to make himself absolute, without any regard to the age or dignity of his friend. The great debts which he had contracted encouraged his avarice; and he procured the assassination of Galba, and made himself emperor. He was acknowledged by the senate and the Roman people; but the sudden revolt of Vitellius in Germany rendered his situation very precarious, and it was mutually resolved that their respective right to the empire should be decided by arms. Otho obtained three victories, but in a general engagement near Brixellum his forces were defeated, and he stabbed himself when all hopes of success had vanished. This happened about the 37th year of his age, after a reign of about three months. It has been justly observed, that the last moments of Otho's life were those of a philosopher. He comforted his soldiers who lamented his fortune, and he expressed his concern for their safety when they earnestly solicited to pay him the last friendly offices before he stabbed himself; and he observed, that it was better that one man should die than that all should be involved in ruin on account of his obstinacy. His nephew was much affected, and feared exceedingly the anger and haughtiness of the conqueror; but Otho comforted him, and observed, that Vitellius would be kind and affectionate to the friends and relations of Otho, since Otho was not ashamed to say, that in the time of their greatest enmity the mother of Vitellius had received every friendly treatment from his hands. He also burnt the letters which, by falling into the hands of Vitellius, might provoke his resentment against those who had favoured the cause of an unfortunate general. These noble and humane sentiments in a man who was the associate of Nero's shameful pleasures, and who had stained his hand in the blood of his master, have appeared to some wonderful, and have passed for the features of policy, and not of a naturally virtuous and benevolent heart. His father was a favourite of Claudius.

OTHO, a tribune of the people, who, in Cicero's consulship, made a regulation to permit the Roman knights at public spectacles to have the 14 first rows

after the seats of the senators. This was opposed with virulence by some, but Cicero ably defended it, &c.

OTHO (Venus), a very celebrated Dutch painter. He was descended of a considerable family in Leyden, and was born in 1556. He was carefully educated by his parents in the belles lettres, and at the same time learned to design of Isaac Nicholas. He was but 15 when the civil wars obliged him to leave his country. He retired to Liege, finished his studies, and there gave the first proofs of the excellence of his mind. He was well known to Cardinal Groosbeck, who gave him letters of recommendation when he went to Rome, where he was entertained by Cardinal Maduccio. His genius was so active, that he applied himself to philosophy, poetry, mathematics, and painting, all at once. He became a great proficient in designing under Frederico Zuchero. He acquired an excellence in all the parts of painting, especially in the knowledge of the *claro-obscuro*; by which means he came to be accounted one of the most ingenious men of his age. He lived at Rome seven years, during which time he performed several rare pieces; and then passing into Germany, was received into the service of the emperor. After this the duke of Bavaria and the elector of Cologne employed him; but all the advantages he got from the courts of foreign princes could not detain him there. He had a desire to return into the Low Countries, of which Alexander Farnese, prince of Parma, was then governor. He drew the prince's picture, armed *cap-à-pée*, which confirmed his reputation in the Netherlands. After the death of that prince, Venus returned to Antwerp, where he adorned the principal churches with his paintings. The archduke Albert, who succeeded the prince of Parma in the government of the Low Countries, sent for him to Brussels, and made him master of the mint; a place which occupied much of his time, yet he found some time for the exercise of his profession. He drew the archduke and the infanta Isabella's portraits at large, which were sent to James I. of Great Britain; and, to show his knowledge of polite learning likewise, he published several treatises, which he embellished with cuts of his own designing. Louis III. made him very great offers to tempt him into his service; but he would never leave his own country, satisfying himself with the character and employments he held there. He was the first, after Polydore Caravaggio, who reduced the *claro-obscuro* to a principle of the art of painting. Rubens perfected what he began, and the whole Flemish school learned it of him. Venus died at Brussels, 1634, in his 78th year. He had two brothers, Gilbert, who was a graver, and Peter a painter. He had also the honour of breeding up the famous Rubens in his art.

OTHONNA, in botany: A genus of the polygamia necessaria order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked; there is almost no pappus; the calyx is monophyllous, multifid and nearly cylindrical.

OTHRYADES, one of the 300 Spartans who fought against 300 Argives, when those two nations disputed their respective right to Thyreata. Two Argives, Alcino and Cronius, and Othryades, survived

Otis,  
Otley.

the battle. The Argives went home to carry the news of their victory; but Othryades, who had been reckoned among the number of the slain on account of his wounds, recovered himself, and carried some of the spoils of which he had stripped the Argives into the camp of his countrymen; and after he had raised a trophy, and had written with his own blood the word *vini* on his shield, he killed himself, unable or unwilling to survive the death of his countrymen.

OTIS, in ornithology, a genus of birds belonging to the order of *gralæ*. There are four species, principally distinguished by their colour. One of the species, the torda, or bustard, is the largest of the British land-fowl; the male at a medium weighing 25 pounds; there are instances of some very old ones weighing 27: The breadth nine feet; the length near five feet. Besides the size and difference of colour, the male is distinguished from the female by a tuft of feathers about five inches long on each side of the lower mandible. Its head and neck are ash-coloured: the back is barred transversely with black and bright rust colour: the greater quill feathers are black: the belly white; the tail is marked with broad red and black bars, and consists of twenty feathers: the legs dusky.

The female is about half the size of the male: the crown of the head is of a deep orange, traversed with black lines; the rest of the head is brown. The lower part of the fore-side of the neck is ash coloured: in other respects it resembles the male, only the colours of the back and wings are far more dull.

These birds inhabit most of the open countries of the south and east part of this island, from Dorsetshire, as far as the Wolds in Yorkshire. They are exceeding shy, and difficult to be shot; run very fast, and when on the wing can fly, though slowly, many miles without resting. It is said that they take flight with difficulty, and are sometimes run down with greyhounds. They keep near their old haunts, seldom wandering above 20 or 30 miles. Their food is corn and other vegetables, and those large earth-worms that appear in great quantities on the downs before sun-rising in the summer. These are replete with moisture, answer the purpose of liquids, and enable them to live long without drinking on those extensive and dry tracts. Besides this, nature hath given the males an admirable magazine for their security against drought, being a pouch, whose entrance lies immediately under the tongue, and which is capable of holding near seven quarts: and this they probably fill with water, to supply the hen when sitting, or the young before they can fly. Bustards lay only two eggs, of the size of those of a goose, of a pale olive brown, marked with spots of a dark colour; they make no nest, only scrape a hole in the ground. In autumn they are (in Wiltshire) generally found in large turnip-fields near the Downs, and in flocks of 50 or more.

OTLEY, a town of England, in the West Riding of Yorkshire, under a cliff called *Chevin*, on the south side of the river Wharfe. The adjacent parts are reckoned the most delightful in England. Its church has lately been elegantly fitted up, in which are several good old monuments. The adjacent country is much improved, and from the Chevin is a most beautiful view of an extensive scope of undescribed mansions.

This manor was given by Athelstan to the see of York, whose archbishop had a palace here, with several extensive privileges. There is a free grammar-school in this place, founded by Mr Cave, 1611, called *Prince Henry's School*. In 1673, it suffered much by an inundation; which carried away several bridges, mills, &c. as well as much corn, &c.

OTODINI, ancient Britons, seated, as some suppose, to the north east of the Brigantes, in the countries now called Northumberland, Merse, and the Lothians. As the Otodini are not mentioned by any of the Roman historians, but only by Ptolemy, it is uncertain whether they formed a distinct independent state, or were united with the Brigantes. They were, however, a considerable people, and possessed a long tract of the sea-coast, from the river Tyne to the Firth of Forth. Their name is derived by Baxter from the old British words *Ot o dinu*, which signify "a high and rocky shore;" descriptive enough of their country. They were probably reduced by Agricola at the same time with their more powerful neighbours the Brigantes; but as they lived without the wall of Severus, they were, like the rest of the *Mæata*, engaged in frequent revolts. In the most perfect state of the Roman government in this island, the country of the Otodini made a part of the Roman province called *Valestia*; which comprehended all that large tract between the two walls. As this province was never long together in the peaceable possession of the Romans, they had but few stations in the country of the Otodini, except those on the line of the wall of Severus.

Various authors have derived the name of this people in various ways, and it is very differently spelled; and various opinions still seem to be entertained among the learned respecting their real situation: and it is even doubtful whether their country was in England or in Scotland. The celebrated Drummond or Hathernden contends for the latter.

OTRANTO, or TERRA D'OTRANTO, a province of Italy in the kingdom of Naples; bounded on the north by the Terra di Bari and by the gulph of Venice, on the east by the same gulph, and on the south and west by a great bay which is between that and the Basilicata. It is a mountainous country, abounding in figs, olives, and wine. It is often visited by locusts, and by Algerine pirates, who carry off all the people they can catch into slavery. But to keep them off, there are a great many forts on the coasts.

OTRANTO, a city of Italy, in the kingdom of Naples, and capital of the province of the same name, with a commodious harbour, an archbishop's see, and a strong citadel where the archbishop resides. Mr Swinburne\* gives this account of it: "It is (says he) small, stands on a hill, and contains only 3000 inhabitants. Its little harbour is not so bad but it might induce more people to settle here, as no port on the coast lies so convenient for traffic with Greece. The Adriatic gulph is here but 60 miles wide. I climbed to the top of a tower, to get a sight of the Acroceraunian mountains; but a vapour hanging over the sea, along the horizon, hid them from my view: in a clear morning, their snowy tops are said to be very visible. The cathedral of Otranto is Gothic, and, according to the Puglian fashion, has its subterraneous sanctuary. The columns are of beautiful marble and granite; the

the pavement, a rude species of mosaic, commonly called *Saracenic*: As it is to be met with in all churches founded by the Norman kings of Sicily, the artists who laid it were probably Saracens, or at least Greeks, their scholars. These mosaics are composed of pieces of porphyry, serpentine, and cubes of gilt glass,—disposed in stars, circles, or chevrons. The compartments of the stalls are bordered with them; and the small twisted columns, which support the pulpits and canopies, are ornamented with a spiral stripe of the same work. It is a pity so much durability, compactness, and beauty of materials, should have been lavished on such barbarous designs. Otranto was a Roman colony, as is certified by an inscription, almost the only monument of antiquity left there (A). In the 10th century it was made an archbishop's see. In 1480, Laurence de Medici, to deliver himself from the attacks of the king of Naples, persuaded Mahomet II. to invade the realm; and Otranto was the unfortunate place where the Turks landed. It was invested, stormed, and pillaged. Its prelate was slain at the door of his church; 800 principal citizens dragged out of the gates and butchered; their bodies left 12 months unburied, till the duke of Calabria retook the city, and committed them to hallowed earth. About 100 years after a devout person affirmed, that these bones had appeared to him in a dream: and, upon the strength of his vision, they became, for the vulgar, objects of almost equal veneration with the relics of the primitive martyrs."

OTRICOLI, a small town of Italy, in the ecclesiastic state, and in the duchy of Spoleto, in E. Long. 13. 15. N. Lat. 42. 25. situated on a rising ground on the frontiers of the patrimony of St Peter. From this town is seen a fine plain, and some of the windings of the famous river Tiber. The ruins that are scattered here and there at the entrance of the plain, descending from Otricoli, are thought to be the remains of the ancient Otriculum; they consist of some shapeless fragments of columns, cornices, and other pieces of marble. In the middle of the great street of Otricoli, there is a marble pedestal, upon which you see an inscription, showing they had erected a statue to Julia Lucilla, who had built public baths at Otricoli at her own expence.

OTTER, in zoology. See *MUSTELA*.

OTTER of *Roses*. See *ROSES*.

OTTERBURN, in England, in the county of Northumberland, near Elledon. It was the field of battle between the English and Scots in 1388, wherein Henry Percy, called *Hotspur*, was taken prisoner, and Douglas the Scotch general was killed. On this battle was founded the delightful old ballad of Chevy-chase; the village being situated by the river Rhead, on the south side of the Cheviot hills. The entrenchments are still visible; and a number of tumuli scattered over the adjacent ground mark to future ages the slaughter made there.

OTTERY, ST MARY'S, a market town in Devonshire, situated 159 miles west of London, and 10 miles east of Exeter. Its market is on Tuesday, and it has

two fairs. The church is very ancient, and somewhat resembles a cathedral. A very extensive woollen manufactory was lately established here by Sir Geo. Yonge and Sir John Duntze, barts. It has no corporation. It derived its name, as some suppose, from the river Otter, and that from the otters formerly found in it. This town was given by king Edward the Confessor to the church of St Mary at Rouen in Normandy; but was afterwards bought by Grandison bishop of Exeter; who made of it a quarter college in 10 Edward III. and therein placed secular priests, with other ministers to whom he gave the whole manor, parish, tithes, fines, spiritual profits, &c. which amounted to L. 304 : 2 : 10 yearly.

OTWAY (Thomas), an eminent tragic poet, was the son of Mr Humphry Otway, rector of Wolbeding in Suffex; and was born at Trotton in that county on the 3d of March 1651. He was educated at Oxford; when, leaving the university without a degree, he retired to London, where he commenced player, but with indifferent success. However, the prightliness of his conversation gained him the favour of Charles Fitz Charles earl of Plymouth, who procured him a cornet's commission in one of the new-raised regiments sent into Flanders; but he returned from thence in very necessitous circumstances, and applied himself again to writing for the stage. In comedy he has been deemed too licentious; which, however, was no great objection to his pieces in the profligate days of Charles II. But, in tragedy, few English poets have ever equalled him; and perhaps none ever excelled him in touching the passions, particularly the tender passion. There is generally something familiar and domestic in the fable of his tragedies, and there is amazing energy in his expression.—The heart that doth not melt at the distresses of his Orphan must be hard indeed! But though Otway possessed in so eminent a degree the rare talent of writing to the heart, yet he was not very favourably regarded by some of his cotemporary poets, nor was he always successful in his dramatic compositions. After experiencing many varieties of fortune in regard to his circumstances, but generally changing for the worse, he at last died wretchedly in a public house on Tower-hill; whither, it is supposed he had retired, in order to avoid the pressure of his creditors. Some have said, that downright hunger compelling him to fall too eagerly on a piece of bread, of which he had been for some time in want, the first mouthful choked him, and instantly put a period to his days. Dr Johnson gives this account of the matter: "He died in a manner which I am unwilling to mention. Having been compelled by his necessities to contract debts, and hunted as is supposed, by the terriers of the law, he retired to a public house on Tower-hill, where he died of want; or, as it is related by one of his biographers, by swallowing, after a long fast, a piece of bread which charity had supplied. He went out, as is reported, almost naked, in the rage of hunger, and finding a gentleman in a neighbouring coffee-house, asked him for a shilling. The gentleman gave him a guinea; and Ot-

Otway.

way

(A) "Num. Hydr.—ÆR. Caput barb. & laureat. TAPONTINON=Tridens, cum duobus delphinibus."

Oval  
||  
Oudenarde.

way going away bought a roll, and was choaked with the first mouthful. All this I hope, is not true; but that indigence, and its concomitants sorrow and dependency, brought him to the grave, has never been denied."

Johnson speaks of him in nearly these terms: Otway had not much cultivated versification, nor much replenished his mind with general knowledge. His principal power was in moving the passions, to which Dyrden in his latter years left an illustrious testimony. He appears, by some of his verses, to have been a zealous royalist; and had what was in those times the common reward of loyalty; he lived and died neglected.—His dramatic writings are nine in number; the most admired of which are, *The Orphan* and *Venice Preserved*. He had also made some translations, and wrote several miscellaneous poems. His whole works are printed in two pocket volumes. He wrote four acts of a play which are lost.

OVAL, an oblong curvilinear figure, otherwise called *ellipsis*. (See ELLIPSIS). However, the proper oval, or egg-shape differs considerably from that of the ellipsis, being an irregular figure, narrower at one end than at another; whereas the ellipsis, or mathematical oval, is equally broad at each end: though it must be owned, these two are commonly confounded together; even geometers calling the oval a *false ellipsis*.

OVARY, in anatomy, that part of a female animal wherein the ova or eggs are formed or lodged. See ANATOMY, n° 108. p. 740.

OVARIUM, in botany, a name by which botanists who are fond of assimilating the animal and vegetable kingdoms have distinguished the germen or seed-bud, as containing the rudiments of the future seed.

OVATION, in the Roman antiquity, a lesser triumph, allowed to commanders for victories won without the effusion of blood; or for defeating a mean and inconsiderable enemy. The show generally began at the Albanian mountain, whence the general with his retinue made his entry into the city on foot, with many flutes or pipes sounding in concert as he passed along, and wearing a garland of myrtle as a token of peace. The term *ovation*, according to Servius, is derived from *ovis*, a "sheep;" because on this occasion the conqueror sacrificed a sheep, as a triumph he sacrificed a bull. The senate, knights, and principal plebeians, assisted at the procession; which concluded at the Capitol, where rams were sacrificed to Jupiter. The first ovation was granted to Publius Posthumius the consul for his victory over the Sabines in the 253d year of Rome.

OUDENARDE, a rich and strong town of the Austrian Netherlands, in the province of Flanders, in E. Long. 3. 30. N. Lat. 50. 54. fifteen miles south of Ghent, and eighteen from Tournay. It is a large well fortified town, having a very considerable fort in the middle of it, situated on the river Scheldt, which divides it into two parts. It is almost encompassed by meadows, only there is a hill which commands it on the south side. The buildings are pretty good, and the streets wide and handsome. The market-place is adorned with a beautiful town-house, and a fine large fountain. There are several good churches and monasteries well worthy of the notice of travellers. The

town has a very flourishing trade in fine linen and tapestry, and is the capital of a castellany which contains 33 villages. The French laid siege to it in 1708, which brought on an obstinate engagement, wherein they were defeated by the allies under the command of the duke of Marlborough. It was besieged by the French again in 1744, and taken in a few days; but they restored it at the last general peace.

UDRI (Jean Baptiste), a painter, was born at Paris, and died there May 1. 1755, aged about 74. He acquired the principles of his art under the celebrated Largillieres; and from this master he had those sure principles of colouring which he communicated at a meeting of the academy of painting, of which he was a member, and one of the professors. Oudri's superior talent for painting animals is well known: his compositions of this kind are full of truth, and are admirably handled. The Fables of la Fontaine have been engraved in 4 vols. folio from his etchings; but those who finished them possessed not equal abilities. He painted several hunting-pieces for the king, which adorn some of the royal castles, among others that of La Meute. Oudri was so well acquainted with the magic of his art, that he frequently pleased himself with painting white objects on white grounds; and these pictures have a good effect. He would likewise have succeeded in history-painting, as we may easily infer from several pieces which do him honour. He superintended the manufactory of Beauvais, where pieces of tapestry were produced equally brilliant with the pictures which had served for their model. The king gave him a pension, and apartments in the Louvre.

OVERALL (John), a celebrated English bishop, was born in 1559; and, after a proper foundation in grammar learning, was sent to St John's college, Cambridge, and was elected a scholar of that society: but afterwards removing to Trinity, was chosen fellow of that college. In 1596 he was made regius professor of divinity, when he took the degree of D. D. and about the same time was elected master of Catherine-hall. In 1601 he was raised to the deanry of St Paul's London, by the recommendation of his patron Sir Fulk Greville, and Queen Elizabeth; and in the beginning of King James reign, he was chosen prolocutor of the lower house of convocation. In 1612 he was appointed one of the first governors of the Charter-house hospital, then just founded by Thomas Sutton, Esq. In April 1614 he was made bishop of Lichfield and Coventry; and in 1618 he was translated to Norwich, where he died in May 1619, aged, as it is reported, 60 years. He was buried in that cathedral, where he lay unnoticed and forgotten till some time after the restoration of Charles II. when Cosin, bishop of Durham, who had been his secretary, erected a monument in 1669, with a Latin inscription, in which he is said to be, "Vir undequaque doctissimus, et omni encomio major."

Wood observes, that he had the character of being the best scholastic divine in England; and Cosin, who perhaps may be thought to rival him in that sort of learning, calls himself his scholar, and absolutely says that he derived all his knowledge from him. He is also celebrated by Smith for his distinguished wisdom, erudition, and piety. In the controversy which

Oudri,  
Overall.

Overall, Overbury. in his time divided the reformed churches about predestination and grace, he held a middle opinion, inclining perhaps to Armenianism. He seems indeed to have paved the way for the reception of that doctrine in England, where it was generally embraced a few years afterwards, chiefly by the authority and influence of Archbishop Laud. Overall cultivated a particular friendship with Gerard Vossius and Grotius; and was much grieved to see the love of peace, and the projects of this last great man to obtain it, so ill repaid. He laboured heartily himself to settle the differences in Holland, upon what is known by the name of the *Quinquaricular controversy*; as appears in part by his letters to the two learned correspondents just mentioned, some of which are printed in the *Epistolæ præstantium virorum*, &c.

The bishop is known in England chiefly by his *Convocation Book*, of which Bishop Burnet gives the following account: "This book was wrote on the subject of government, the divine institution of which was very positively asserted. It was read in convocation, and passed by that body, in order to the publishing of it; in opposition to the principles laid down in the famous book of Parsons the Jesuit, published under the name of *Doleman*. But King James did not like a convocation entering into such a theory of politics; so he discouraged the printing of it, especially since, in order to justify the owning of the United Provinces, who had lately thrown off the Spanish yoke, to be a lawful government, it was laid down, that when a change of government was brought to a thorough settlement, it was then to be owned and submitted to as a work of the providence of God. Here it slept, till Archbishop Sancroft, who had got the book into his own hands, and not observing the last-mentioned passage in it, resolved to publish it in the beginning of King William's reign, as an authentic declaration the church of England had made in the point of non-resistance. Accordingly it was published in 4to, as well as licensed, by him, a very few days before he was under suspension for not taking the oaths."

**OVERBURY** (Sir Thomas), a learned and worthy English gentleman, was born in 1581; and studied at Queen's college, Oxford, after which he removed to the Middle-temple, London. He afterwards travelled for some time, and returned a most accomplished person; when he contracted an intimate acquaintance with Sir Robert Carr, knight of the bath, who being soon after taken into his majesty's favour, had Mr Overbury knighted at Greenwich. Sir Thomas perceiving the familiarity which subsisted between his patron Carr, now made viscount Rochester, and the lady Frances, the wife of Robert earl of Essex, was so much displeased at it, that he endeavoured to dissuade him from keeping her company, and from proceeding in the base design he had formed of having her first divorced from her husband, and then marrying her. The viscount, resenting this honest advice, told what he had said to the lady, who was as remarkable for her wickedness as for her beauty; on which they immediately resolved on his destruction. About this time, the king wanting to send an ambassador abroad, the viscount recommended Sir Thomas Overbury. His majesty approving the choice, the viscount im-

parted the king's intentions to Sir Thomas; but, under a treacherous show of friendship, dissuaded him from accepting of that employment, as it might hinder him from a better way of advancement; promising that he would prevent his majesty from being displeased at his refusal. The viscount then went to the king, and artfully incensing his majesty against Sir Thomas for refusing to obey his commands, that gentleman was committed to the Tower for his contempt, on the 21st of April 1613, where he continued till he was dispatched by poison on the 15th of September following, and his body was interred in the Tower-chapel the same day. About two years after, the whole contrivance of his death was discovered. On this several persons were condemned and executed; but though Carr, earl of Somerset, and the lady Frances his countess, were condemned to death for contriving the murder, and hiring the persons who were concerned in it, the king only banished them from court, and afterwards pardoned them. Sir Thomas Overbury wrote several poems, &c. and an account of his travels.

His character is represented by an historian of those times; who, after relating the occasion and circumstances of his death, proceeds in the following terms: "In this manner fell Sir Thomas Overbury, worthy of a longer life and a better fate; and, if I may compare private men with princes, like Germanicus Cæsar, both by poison procured by the malice of a woman, both about the 33d year of their age, and both celebrated for their skill and judgment in poetry, their learning, and their wisdom. Overbury was a gentleman of an ancient family, but had some blemishes charged upon his character, either through a too great ambition, or the insolence of a haughty temper.—After the return from his travels, the viscount Rochester embraced him with so entire a friendship, that, exercising by his majesty's special favour the office of secretary provisionally, he not only communicated to Sir Thomas the secrets, but many times gave him the packets and letters unopened, before they had been perused by the king himself; which, as it prevailed too much upon his early years, so as to make him, in the opinion of some, thought high and ambitious; yet he was so far from violating his trust and confidence, that he remains now one example among others who have suffered in their persons or their fortunes for a freedom of advice, which none but sincere friends will give, and which many are such ill friends to themselves as not to receive."

**OVEN**, a kind of domestic furnace, used for baking bread, pies, tarts, &c. of a circular structure, with a very low roof, well lined, both on the top, bottom, and sides, with stone; it has a small entrance in the front, which is exactly fitted by a kind of door, which being clapped to the mouth of the oven confines the heat, while bread, pies, or puddings are baking. Over this, pastry-cooks, &c. have another oven built much in the same manner, which is used for such things as require a less degree of heat. Ovens are heated by burning dry wood, faggots, &c. in them, till all the parts are equally hot.

**OVER-HAULING**, the act of opening and extending the several parts of a tackle, or other assemblage of ropes, communicating with blocks or dead eyes. It is used

Overbury  
||  
Over-haul-  
ing.

Over-haul-  
ing  
Oughtred.

used to remove these blocks to a sufficient distance from each other, that they may be again placed in a state of action, so as to produce the effect required.

*OVER-Hauling*, is also vulgarly expressed of an examination or inspection into the condition of a person or thing.

*OVER-Rake*, among seamen: When a ship riding at anchor so overbeats herself into an high sea, that she is washed by the waves breaking in upon her, they say the waves over-rake her.

*OVER-Reach*, in FARRIERY. See there, § xl. 2.

**OVERSMAN**, in Scots law, a person appointed by arbiters, or by the parties submitters, to determine the matter submitted, in case the parties disagree in their opinion.

**OVERT**, the same with **OPEN**: Thus an overt act signifies an act which, in law, must be clearly proved; and such is to be alleged in every indictment for high treason.

**OVERTURE**, or **Ouverture**, opening or precluding: a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, comedy, concert of music, &c.—The overture of the theatre or scene, is a piece of music usually ending with a fugue: the overture of a jubilee is a general procession, &c.

**OVERYSSEL**, so named from its situation beyond the river Yssel, one of the Seven United Provinces; bounded on the east by the bishopric of Munster, on the north by Friesland and the territory of Groningen, on the west by the river Yssel, and on the south by the county of Zutphen and the bishopric of Munster. It is divided into three distinct parts; which are the territories of Drense, Twente, and Salland. There are many morasses in this province, and but few inhabitants, in comparison of the rest. Its greatest riches consist in turfs; which are dug up here, and sent to the neighbouring provinces, particularly Holland. It extends near 60 miles in length from north to south, and 40 in breadth from east to west. The whole country is low and marshy; but it produces a tolerable quantity of corn. It was formerly a dependence of the bishopric of Utrecht, before Henry of Bavaria, bishop of that see, transferred the sovereignty of it to the emperor Charles V.

**OVIEDA**, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personata*. The calyx is quinquefid: the tube of the corolla almost cylindrical above, and very long; the berry globose and dispermous.

**OVIEDO**, a town of Spain, and capital of Asturias d'Oviedo, with a bishop's see, and an university; seated at the confluence of the rivers Ove and Deva, which form the Asta, 50 miles north-west of Leon, and 208 north-west of Madrid. W. Long. 5. 47. N. Lat. 43. 23.

**OUGHTRED** (William), an eminent mathematician, was born at Eton in 1573, and educated in the school there, whence he was elected to King's-college in Cambridge, of which he afterwards became fellow. Being admitted to holy orders, he left the university about the year 1603, and was presented to the rectory of Aldbury, near Guildford in Surry; and about the year 1628 was appointed by the earl of Arundel to

instruct his son in the mathematics. He kept a correspondence by letters with some of the most eminent scholars of his time, upon mathematical subjects; and the most celebrated mathematicians of that age owed most of their skill to him, whose house was full of young gentlemen that came from all parts to receive his instruction. It is said, that, upon hearing the news of the vote at Westminster for the restoration of King Charles II. he expired in a sudden transport of joy, aged 88. He wrote, 1. *Clavis Mathematica*; which was afterwards published in English. 2. A description of the double horizontal dial. 3. *Opuscula Mathematica*; and several other works. He left also behind him a great number of papers upon mathematical subjects, which are now in the museum of William Jones, Esq; F. R. S.

David Lloyd, in his Memoirs, has given the following short character of him: "That he was as facetious in Greek and Latin, as solid in arithmetic, geometry, and the sphere of all measures, music &c. exact in his style as in his judgment; handling his tube and other instruments at 80 as steadily as others did at 30; owing this, as he said, to temperance and archery; disciplining his people with plain and solid truths, as he did the world with great and useful arts; advancing new inventions in all things but religion, which, in its old order and decency, he maintained secure in his privacy, prudence, meekness, simplicity, resolution, patience, and contentment."—He had one son, whom he put an apprentice to a watchmaker, and wrote a book of instructions in that art for his use.

**OVID**, or *Publius Ovidius Naso*, a celebrated Latin poet of the Augustan age, was a Roman knight born at Sulmo, in the 43d year before the Christian era. He studied rhetoric under Aurelius Fuscus, and for some time frequented the bar. His progress in the study of eloquence was great, but the father's expectations were frustrated; his son was born a poet, and nothing could deter him from pursuing his natural inclination to write poetry, though he was often reminded that Homer lived and died in the greatest poverty. Every thing he wrote was expressed in poetical numbers, as he himself says, *Et quod tentalam scribere versus erat*. A lively genius and a fertile imagination soon gained him admirers: the learned became his friends; Virgil, Propertius, Tibullus, and Horace, honoured him with their correspondence, and Augustus patronized him with the most unbounded liberality. These favours, however, were but momentary; for after having obtained the esteem of Augustus, he incurred his displeasure, and was banished to Tomos, a city on the Pontus Euxinus, near the mouth of the Danube, when he was 50 years of age. The true cause of this sudden exile is unknown. Some attribute it to a shameful amour with Livia the wife of Augustus, while others suppose that it arose from the knowledge which Ovid had of the unpardonable incest of the emperor with his daughter Julia. These reasons are indeed merely conjectural; the cause was of a very private and very secret nature, of which Ovid himself is afraid to speak. It was, however, something improper in the family and court of Augustus, as these lines seem to indicate:

*Cur aliquid vidi? Cur noscia lumina feci?  
Cur imprudenti cognita culpa mihi est?*

*Infelix*

Ovid.

*Inscius Aëdon vidi sine veste Dianam,  
Præda fuit canibus non minus ille suis.*

Again,

*Inscia quod crimen viderunt lumina plebs,  
Peccatumque oculos est habuisse meum.*

And in another place,

*Perdiderunt cum me duo crimina, carmen & error,  
Alterius facti culpa silenda mihi est.*

In his banishment, Ovid betrayed his pusillanimity in a great degree; and however affected and distressed his situation was, yet the flattery and impatience which he showed in his writings are a disgrace to his pen, and lay him more open to ridicule than to pity. Though he prostituted his pen and his time to adulation, yet the emperor proved deaf to all intreaties, and refused to listen to his most ardent friends at Rome who wished for his return. Ovid, who really wished for a Brutus to deliver Rome of her tyrannical Augustus, still continued his flattery even to meanness; and when the emperor died, he was so mercenary as to consecrate a small temple to the departed tyrant on the shore of the Euxine, where he regularly offered frankincense every morning. Tiberius proved as regardless as his predecessor to the intreaties which were made for the poet, and he died in the seventh or eighth year of his banishment, in the 57th year of his age. He was buried at Tomos. In the year 1508 of the Christian era, the following epitaph was discovered at Stain, in the modern kingdom of Austria.

*Hic situs est vates quem Divi Caesaris ira  
Augusti patria cedere jussu humo.*

*Sæpe miser voluit patriis occumbere terris,  
Sed frustra! Hunc illi fata dedere locum.*

This, however, is an imposition to render celebrated an obscure corner of the world, which never contained the bones of Ovid. The greatest part of his poems are remaining. His *Metamorphoses*, in 15 books, are extremely curious, on account of the great variety of mythological facts and traditions which they relate, but they can have no claim to epic honours. In composing this the poet was more indebted to the then existing traditions, and to the theogony of the ancients, than the powers of his own imagination. His *Fasts* were divided into 12 books, like the constellations in the zodiac, but of these six are lost; and the learned world have reason to lament the loss of a poem which must have thrown so much light upon the religious rites and ceremonies, festivals and sacrifices, of the ancient Romans, as we may judge from the six that have survived the ravages of time and barbarity. His *Tristitia*, which are divided into five books, contain much elegance and softness of expression; as also his *Elegies* on different subjects. The *Heroides* are nervous, spirited, and diffuse; the poetry is excellent, the language varied, but the expressions are often too wanton and indelicate, a fault which is very common with him. His three books *Amorum*, and the same number *de Arte Amandi*, with the other *de Remedio Amoris*, are written with peculiar elegance, and contain many flowery descriptions; but the doctrine which they hold forth is dangerous, and they are to be read with caution, as they seem to be calculated to corrupt the heart, and to sap the very foundations of virtue and

VOL. XIII.

morality. His *Ibis*, which is written in imitation of a poem of Callimachus of the same name, is a satirical performance. Besides these, there are extant some fragments of other poems, and among these part of a tragedy called *Medea*. The talents of Ovid as a dramatic writer have been disputed, and some have remarked that he who is so often void of sentiment was not born to shine as a tragedian. He has attempted, perhaps, too many sorts of poetry at once. On whatever he has written, he has totally exhausted the subject. He everywhere paints nature with a masterly hand, and adds strength even to vulgar expressions. It has been judiciously observed, that his poetry after his banishment from Rome was destitute of that spirit and vivacity which we admire in those which were written before. His *Fasts* are perhaps the best written of all his poems; and after them we may fairly rank his love verses, his *Heroides*, and after all his *Metamorphoses*, which were not totally finished when Augustus banished him. His *Epistles from Pontus* are the language of a weak and fordid flatterer. However critics may have cause to censure the indelicacy and the inaccuracies of Ovid, it is to be acknowledged that his poetry contains great sweetness and elegance, and, like that of Tibullus, charms the ear and captivates the mind.—Another person of the name of OVID accompanied his friend Cæsonius, when banished from Rome by Nero.

OVIEDO (John Gonsalvez de), born at Madrid about the year 1478, was educated among the pages of Ferdinand king of Arragon and Isabella queen of Castile; and happened to be at Barcelona in 1493, when Christopher Columbus returned from his first voyage to the island Haiti, which he called Hispaniola, and which now goes by the name of St Domingo. He formed an intimate acquaintance with Columbus and his companions, and was at pains to inform himself of every thing relating to the new discoveries. He rendered such essential service to Spain during the war of Naples, that Ferdinand determined to send him to the island of Haiti, as intendant and inspector general of the trade of the New World. The ravages which the venereal disease had made during that war, induced him to inquire into what were the most efficacious remedies for this malady, which was supposed to have come from the West Indies. His inquiries were extended to every thing which regards the natural history of these regions; and, on his return to Spain, he published *Summario de la Historia general y natural de las Indias Occidentales*, which he dedicated to Charles V. He afterwards made some additions to this work, which he published under the title of *La Historia general y natural de las Indias Occidentales*; Salamanca, 1535, folio. It was translated into Italian, and afterwards into French; Paris, 1556, folio. In this work, Oviedo says that the French pox is endemical in the island of Haiti, and that it has passed from thence into Europe. He greatly extols the use of the wood of guaiacum for the cure of this disease; but whether the disease is now become more obstinate, or the remedy does not possess that efficacy which is ascribed to it, it is at present in little estimation.

OVILIA, or SEPTA, in ancient Rome, a place in the Campus Martius, at first railed in like a sheep-pen, whence its name. Afterwards it was mounted with

4 B

marble,

Ovid

Ovilia.

Oviparous,  
Ovis.

marble, and beautified with walks and galleries, as also with a tribunal, or seat of justice. Within this precinct or inclosure, the people were called to give their suffrages for the election of magistrates. The ascent into the ovilia was not by stairs, but by pontes, or narrow boards, laid there for the occasion; on which account *de ponte dejici*, signified "to be deprived of the privilege of voting;" and persons thus dealt with were called *de pontani*.

OVIPAROUS, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.

OVIS, the SHEEP, in zoology a genus of the mammalia class, and of the order of Pecora; the characters of which are these: The horns are concave, turned backwards, and full of wrinkles; there are eight fore teeth in the under-jaw, and no dog-teeth. The wool of these animals is only a congeries of very long and slender hairs, oddly twisted and contorted, and variously interwoven with one another. This, as far as it is yet known, is a clothing peculiar to the sheep kind, no other animal having been seen to possess it. It is not, however, the clothing of all the species of sheep, some that are found in distant nations having short hair like that of the goat.

Plate  
CCCLXX.

Linnæus enumerates three species, which are perhaps only varieties, viz. 1. The *ovis aries*, or ram sheep, the horns of which are shaped like a half moon, and compressed. 2. The *ovis Guineensis*, or Guinea sheep, which has pendulous ears, lax hairy dewlaps, and a prominence on the hind part of the head. The wool is short like that of the goat. It is, as its name imports, a native of Guinea. And 3. The *ovis strepsiceros*, or Cretan sheep, which has straight cariated horns, twisted in a spiral manner, and is a native of Mount Iola. According to Mr Pennant, the last two are to be reckoned only varieties.

The sheep, unquestionably a mild and gentle creature, is also represented by Buffon, as the most stupid, defenceless, and timid of all quadrupeds; inasmuch that, without the assistance of man, it could never, he thinks, have subsisted or continued its species in a wild state.

Buff. Nat.  
Hist. vol.  
iii. p. 463.

"The female is absolutely devoid of every art and of every mean of defence. The arms of the ram are feeble and awkward. His courage is only a kind of petulance, which is useless to himself, incommensurable to his neighbours, and is totally destroyed by castration. The wedder is still more timid than the ram. It is fear alone that makes sheep so frequently assemble in troops: upon the smallest unusual noise, they run close together; and these alarms are always accompanied with the greatest stupidity. They know not how to fly from danger, and seem not even to be conscious of the hazard and inconvenience of their situation. Wherever they are, there they remain obstinately fixed; and neither rain nor snow can make them quit their station. To force them to move or to change their rout, they must be provided with a chief, who is taught to begin the march: the motions of this chief are followed, step by step, by the rest of the flock. But the chief himself would also continue immovable, if he were not pushed off by the shepherd, or by his dog, an animal which perpetually watches over their safety, which defends, directs, separates, as-

sembles, and in a word, communicates to them every movement necessary to their preservation.

Ovis.

"Of all quadrupeds, therefore, sheep are the most stupid, and derive the smallest resources from instinct. The goat, who so greatly resembles the sheep in other respects, is endowed with much more sagacity. He knows how to conduct himself on every emergency: he avoids danger with dexterity, and is easily reconciled to new objects. But the sheep knows neither how to fly nor to attack: however imminent her danger, she comes not to man for assistance so willingly as the goat; and, to complete the picture of timidity and want of sentiment, she allows her lamb to be carried off, without attempting to defend it, or showing any marks of resentment. Her grief is not even expressed by any cry different from that of ordinary bleating."

The annotator upon this article in the Edinburgh translation of Buffon, denies the above to be the natural character of the animal. "All tame animals (he observes) lose a portion of that sagacity, dexterity, and courage which they are obliged to employ against their enemies in a wild state; because they have been long accustomed to rely upon the protection of man. Sheep, when enslaved by men, tremble at the voice of the shepherd or his dog. But, on those extensive mountains where they are allowed to range without controul, and where they seldom depend on the aid of the shepherd, they assume a very different mode of behaviour. In this situation, a ram or a wedder boldly attacks a single dog, and often comes off victorious. But when the danger is of a more alarming nature, like man, they trust not to the prowess of individuals, but have recourse to the collected strength of the whole flock. On such occasions, they draw up into one compact body; they place the young and the females in the centre; and the strongest males take the foremost ranks, keeping close by each others sides. Thus an armed front is presented on all quarters, which cannot be attacked without the greatest hazard of destruction. In this manner, they wait, with firmness and intrepidity the approach of the enemy. Nor does their courage fail them in the moment of attack. For, if the aggressor advances within a few yards of the line, the ram darts upon him with such impetuosity, as lays him dead at their feet, unless he saves himself by flight. Against the attacks of single dogs, or foxes, they are, when in this situation, perfectly secure. Besides, a ram, regardless of danger, often engages a bull, and never fails to conquer him; for the bull, by lowering his head, without being sensible of his defenceless condition, receives between his horns the stroke of the ram, which usually brings him to the ground."

Ibid. p. 464.  
notes.

"In the selection of food few animals discover greater sagacity than the sheep; nor does any domestic animal show more dexterity and cunning in its attempts to elude the vigilance of the shepherd, and to steal such delicacies as are agreeable to its palate. When perfectly tamed, and rendered domestic, the sportive gambols and troublesome tricks of the animal, are too well known to require any description."

As to the accusations contained in the latter part of the character above quoted, every person, it is observed,

ved,

Ovis. ved who has attended to those animals, at least in this country, must know that they are not altogether just. Ibid. p. 466 "Individuals, in a state of subjection, seem to have no notes. idea of resisting the attacks of an enemy. But they soon learn that their protection lies in the shepherd or his dog: for, when it becomes necessary, in Britain, to watch the folds, in order to prevent assaults from foxes or dogs, upon the first alarm the whole flock run with violence to the place where the watchmen are stationed; so that, when they chance to sleep, they are often hurt by the sheep trampling upon them. On other occasions, they never choose to make a very close approach either to men or dogs; but the sense of immediate danger makes them forget their usual timidity, and their sagacity teaches them where their safety lies. When the female is robbed of her lamb, she bleats in a manner that strongly marks the anguish she feels. In the eagerness of her search, her eye-balls seem to start from their sockets; and her irregular and distracted motions, joined to the violence and contancy of her bleatings, are evident indications of the most pungent grief."

Ibid. p. 467 "These animals (continues the count in the same &c. captious style as before), so simple and dull in their intellect, are likewise very feeble in their constitution. They cannot continue long in motion. Travelling weakens and extenuates them. When they run, they pant, and soon loose their breath. The ardour of the sun is equally incommodious to them as moisture, frost, and snow. They are subject to many diseases, most of which are contagious. A redundancy of fat often kills them, and always renders the ewes barren. They bring forth with difficulty; frequently miscarry, and require more care than any other domestic animal."

Ibid. p. 468 To which the annotator answers, "This is unquestion- notes. ably another exaggeration. The sheep, when nearly in a wild state, is a robust, active animal, and capable of enduring much fatigue without injury. But, when immersed in luxury and pampered in rich pastures, like creatures of a higher nature, the sheep becomes overloaded with fat, and contracts diseases which are not natural to him: besides, no tamed animal requires or receives less assistance in bringing forth its young, for in those parts of Britain where the best sheep are bred, they are never housed, nor, during the lambing season, have any thing administered to them but their ordinary pasture. When in health, sheep have no occasion for water; in our northern climates, it is even injurious to them."

On the whole, many of Buffon's observations and assertions on this article appear to be hasty, and, we presume, very ill founded. Respecting sheep, the learned Count seems to have been strangely misinformed, or grossly prejudiced. We esteem him as a great and an ingenious man, but we do not think that the celebrity of a name can add strength to weakness, or make that be taken for granted on a bare assertion which wants proof, or which is contrary to experience, the boasted guide of modern philosophers. The *objections* and *accusations* of this great naturalist

are well obviated by his learned translator. The great error of Buffon seems to lie in his considering sheep in a domestic state, and as they exist among us, without any reference to them in a state of nature, and without supposing or allowing their existence in such a state (A). That he was wrong in this respect, a very little reflection would convince us; and indeed his translator has shewn it in a very ample manner, by recurring to facts, which is the only legitimate way of reasoning upon this, or any subject of this nature. To set this matter in a still stronger point of view, however, we shall give the following account of the Siberian argali, or wild sheep, as it appeared in the 16th volume of a periodical work entitled *the Bee*; being extracted by a correspondent from the works of the celebrated naturalist Dr. Pallas, who has paid particular attention to this part of his profession.

This accurate observer "found the *ovis fera*, or wild sheep, in all its native vigour, boldness, and activity, inhabiting the vast chain of mountains which run through the centre of Asia to the eastern sea, and the branches which it sends off to great Tartary, China, and the Indies. This wild animal, which our learned naturalist declares to be the *moufflon* of Pliny, and the *ophion* of the Greeks, is called *argali* by the Siberians, which means wild sheep; and by the Russians *kamennoi barann*, or sheep of the rocks, from its ordinary place of abode. It delights in the bare rocks of the Asiatic chain just mentioned, where it is constantly found basking in the sun; but it avoids the woods of the mountains, and every other object that would intercept the direct rays of the glorious luminary. Its food is the Alpine plants and shrubs it finds amongst the rocks. The argali prefers a temperate climate, although he does not disdain that of Asiatic Siberia, as he there finds his favourite bare rocks, sunshine, and Alpine plants; nay, he is even found in the cold eastern extremity of Siberia and Kamtschatka, which plainly proves that nature has given a most extensive range to the sheep in a wild state, equal even to what she has given to man, the lord of the creation; a fact that ought to make us slow in believing the assertions not uncommon, which tend to prove the sheep a local animal; or at least that it must be confined to certain latitudes, to possess it in all its value.

"The argali loves solitude, or possibly perfect liberty, and therefore flees the haunts of all-subduing man; hence it gradually abandons a country in proportion as it becomes peopled, if no unfurmountable obstacle obstructs its flight; inasmuch that Dr Pallas thinks that nothing but the surrounding sea can account for the wild sheep being found in an inhabited island, as is sometimes the case. The ewe of the argali brings forth before the melting of the snow. Her lamb resembles much a young kid; except that it has a large flat protuberance in place of horns, and that it is covered with a woolly hair, frizzled, and of a dark grey. There is no animal so shy as the argali, which it is almost impossible to overtake on such ground."

4 B 2

(A) In his account of sheep this is literally true, though, for the purpose of supporting a favourite hypothesis, he does mention the *argali*, or, as he calls it, *moufflon*; and asserts that it is the parent of all the domestic varieties: but this, in our opinion, only makes his observations in this place more unaccountable at least, if not inconsistent. See below note (c).

Ovis.

ground as it keeps to. When pursued, it does not run straight forward, but doubles and turns like a hare, at the same time that it scrambles up and over the rocks with wonderful agility. In the same proportion that the adult argali is wild and untameable, the lamb is easily tamed when taken young, and fed first on milk, and afterwards on fodder, like the domestic sheep, as has been found on numerous experiments made in the Russian settlements in these parts.

"This animal formerly frequented the regions about the upper Irtysh, and some other parts of Siberia, where it is no longer seen since colonies have been settled in those countries. It is common in the Mongolian, Songarian, and Tartarian mountains, where it enjoys its favourite solitude or liberty. The argali is found likewise on the banks of the Lena, up as high as 60 degrees of north latitude, and it propagates its species even in Kamtschatka, as noticed before. The argali is also found in the mountains of Persia, and is said to obtain in the Kuril islands in great size and beauty. It purges itself in the spring, (like all the domestic varieties of the sheep when left at liberty to follow their instinct) with acrid plants of the anemone kind, till milder plants spring up, and shrubs begin to sprout, which with Alpine plants constitute its usual food. It likewise frequents the salt-marshes which abound every where in Siberia; and even licks the salt efflorescence that rises on the ground, a regimen that fattens them up very quickly, and fully restores the health, vigour, and flesh, they had lost during winter, and during the purging course, which, together with the restorative, is by the Almighty so wonderfully dictated to the sheep species, whether in a wild or tame state, if left to roam at large where the necessary plants are to be found." Here, then, we have a variety of the sheep species, which by some indeed, and by Dr. Pallas among others, is thought to be the parent of all our domestic varieties, and which lives and propagates without any aid from man, and which on all occasions carefully shuns him. That it is the parent sheep we are not convinced; that being an opinion which requires proof, and better proof than we presume the abettors of it are able to produce.

Having given a figure of this animal (see Plate CCCLXXI), we shall add the following description of it, taken likewise from the Bee. The argali is about the height of a small hart, but its make is much more robust and nervous. Its form is less elegant than that of the deer, and its neck and legs shorter. The male is larger than the female, and every way stouter. Its head resembles that of a ram, with long straggling hairs about the mouth; but no beard. Its ears are rather smaller than those of a ram. The horns are exactly represented in the plate: they weigh in an adult sometimes 16 pounds. The tail is very short. The summer coat consists of short hair, sleek, and resembling that of a deer. The winter-coat consists of

wool like down, mixed with hair every where an inch and an half long at least, concealing at its roots a fine woolly down, generally of a white colour. The colour of its coat was in general of a dark greyish brown, with white tips to the longer hairs, and consisted of hair mixed with wool, of a dark iron grey. My accounts lately received from the Tshutski, the argali is found of a white colour on the continent of America, opposite to their country. It is likewise of a whitish colour at Kamtschatka.

But independent of its manners or its mental qualities, this animal is of the most extensive utility to man. We are clothed by its fleece. The flesh is a delicate and wholesome food. The skin, dressed, forms different parts of our apparel: and is used for covers of books. The entrails properly prepared and twined, serve for strings for various musical instruments. The bones calcined (like other bones in general), form materials for tests for the refiner. The milk is thicker than that of cows, and consequently yields a greater quantity of butter and cheese: and in some places is so rich that it will not produce the cheese without a mixture of water to make it part from the whey. The dung is a remarkably rich manure; insomuch that the folding of sheep is become too useful a branch of husbandry for the farmer to neglect. Nature, in short, has given this animal nothing that does not redound to our benefit.

The ram is capable of generation at the age of 18 months; and the ewe can be impregnated when a year old. One ram is sufficient, according to Buffon, for 25 or 30 ewes; they have often been known indeed to beget 100 lambs in a single season. He ought to be large and well proportioned; his head should be thick and strong, his front wide, his eyes black, his nose flat, his neck thick, his body long and tall, his testicles maffy, and his tail long (s). White is the best colour for a ram. The ewes whose wool is most plentiful, bushy, long, soft, and white, are most proper for breeders, especially when at the same time they are of a large size, have a thick neck, and move nimbly.

In this climate ewes fed in good pastures admit the ram in July or August; but September or October are the months when the greatest part of the ewes, if left to nature, take the ram. They go with young about five months, and generally bring forth but one at a time, though frequently two; in warm climates, they may bring forth twice in a year; But in Britain, France, and most parts of Europe only once. They give milk plentifully for seven or eight months. They live from 10 to 12 years: they are capable of bringing forth as long as they live, when properly managed; but are generally old and useless at the age of seven or eight years. The ram, though he lives 12 or 14 years, becomes unfit for propagating when eight years old.

When

(s) Buffon says "he should be garnished with horns; for hornless animals, of which there are some in our climates, are less vigorous and less proper for propagating." On this the annotator observes, that "there are many breeds of sheep in which both males and female want horns; yet they are as vigorous as any of the species. The largest and best sheep in England have no horns. In some counties, the inhabitants are perfectly unacquainted with horned sheep; in other places, a sheep without horns is as great a rarity as one with four or six horns."

Ovis.

When the male lambs are not intended to be kept for propagation, but fattened for food, they ought to be castrated at the age of five or six months. This operation is performed two ways: in the one, an incision is made, and the testicles taken out; in the other, a ligature is tied tight round the scrotum, above the testicles, which soon destroys the vessels which nourish them. After castration they are called *wedders*.

The ram, ewe, and wedder, when one year old, lose the two fore-teeth of the under-jaw; six months afterwards, they lose the two fore-teeth next to these; and at the age of three years, the teeth are all replaced. The age of a ram may likewise be discovered by his horns, which always appear the first year, and frequently as soon as he is brought forth. These horns uniformly acquire an additional ring every year, as long as the creature lives. The ewes commonly have no horns, but a kind of long protuberances in place of them: however, some of them have two and some four horns.

Ibid. p. 481.  
&c.

"It has been remarked by the ancients (says Buffon), that all ruminating animals have suet: But this remark, strictly speaking, holds only with regard to the sheep and goat: The suet of the wedder is more copious, whiter, drier, firmer, and better, than that of any other animal. Fat or grease is very different from suet; the former being always soft, while the latter hardens in cooling. The greatest quantity of suet is found about the kidneys; and the left kidney furnishes more than the right. There are also considerable quantities in the epiploon or web, and about the intestines; but it is not near so firm or good as that of the kidneys, the tail, and other parts of the body. Wedders have no other grease but suet; and this matter is so prevalent in their bodies, that their whole flesh is covered with it. Even the blood contains a considerable quantity of suet; and the semen is so charged with it, as to give that liquor a different appearance from that of other animals. The semen of men, of the dog, horse, ass, and probably of every animal which affords not suet, dissolves with cold; or, when exposed to the air, becomes more and more fluid from the moment it escapes from the body. But the semen of the ram, and perhaps of every animal that has suet, hardens and loses its fluidity with its heat.

Ovis.

"In the sheep, the taste of the flesh, the fineness of the wool, the quantity of suet, and even the size of the body, vary greatly in different countries. In France, the province of Berri abounds most in sheep. Those about Beauvais, and in some other parts of Normandy, are fatter and more charged with suet. They are very good in Burgundy; but the best are fed upon the sandy downs of our maritime provinces. The Italian, Spanish, and even the English wools, are finer than the French wool. In Poitou, Provence, the environs of Bayonne, and several other parts of France, there is a race of sheep which have the appearance of being foreign. They are larger, stronger, and better covered with wool than the common kind. They are likewise more prolific, producing frequently two lambs at a time. The rams of this race engender with the common ewes, and produce an intermediate kind. In Italy and in Spain, there are a great variety of races; but they ought all to be regarded as of the same species with our common sheep, which, though so numerous and diversified, extend not beyond Europe. Those animals with a long broad tail, so common in Asia and Africa, and which are called *Barbary sheep* by travellers, appear to be a species different from the ordinary kind, as well as from the Pacos and Lama of America.

"As white wool is most valued, black or spotted lambs are generally slaughtered. In some places, however, almost all the sheep are black; and black lambs are often produced by the commixture of white rams with white ewes. In France, there are only white, brown, black, and spotted sheep; but in Spain, there is a reddish kind; and in Scotland there are some of a yellowish colour. But all these varieties of colour are more accidental than those produced by different races; which, however, proceed from the influence of climate, and the difference of nourishment."

Respecting the varieties, or, as some will have it, the different species of sheep, there has been a great difference of opinion amongst the learned. Buffon, we find, in the above extract, if we understand him right, regards the variety of races in Italy and in Spain as of the same species with our common sheep: but he considers the Barbary sheep as a distinct species (c). Dr Pallas, the learned naturalist already quoted, in very

(c) How consistent this opinion is with that which makes the *argali* the parent sheep, we shall not pretend to determine. This hypothesis he brings forward in the end of the 7th volume of his natural history\*, \* Edin. and as much of it as concerns the present subject we shall here insert. He concludes from a strain of reasoning, strong and plausible at least, if not absolutely convincing, that "the temperature of the climate, the quality of the food, and the evils produced by slavery, are the three causes of the changes and degeneration of animals. The effects of each merit a separate examination; and their relations, when viewed in detail, will exhibit a picture of Nature in her present condition, and of what she was before her degradation.

"Let us now compare our pitiful sheep with the mouflon, from whom they derived their origin. The mouflon, which is the same with the *argali*, is a large animal. He is fleet as a stag, armed with horns and thick hoofs, covered with coarse hair, and dreads neither the inclemency of the sky nor the voracity of the wolf. He not only escapes from his enemies by the swiftness of his course, but he resists them by the strength of his body, and the solidity of the arms with which his head and feet are fortified. How different from our sheep, who subsist with difficulty in flocks, who are unable to defend themselves by their numbers, who cannot endure the cold of our winters without shelter, and who would all perish, if man withdrew his protection? In the warmest climates of Asia and Africa, the mouflon, who is the common parent of,

all.

Ovis.

very extensive travels in the Russian empire, more particularly in Siberia, and amongst the pastoral nations of great Tartary, found what he regards as only one species of sheep subdivided into four varieties, and

distinguished by their tails, the form of their heads, their ears and fleece. So that he condemns as unfounded and fanciful the erroneous idea of making *specific* differences of the accidental varieties, which, in his opinion, education

Ovis.

all the races of this species, appear to be less degenerated than in any other region. Though reduced to a domestic state, he has preserved his stature and his hair; but the size of his horns are diminished. Of all domestic sheep, those of Senegal and India are the largest, and their nature has suffered least degradation. The sheep of Barbary, Egypt, Arabia, Persia, Culmuck, &c. have undergone greater changes. In relation to man, they are improved in some articles, and vitiated in others: But, with regard to nature, improvement and degeneration are the same thing; for they both imply an alteration of original constitution. Their coarse hair is changed into fine wool. Their tail, loaded with a mass of fat, has acquired a magnitude so inconvenient, that the animals trail it with pain. While swollen with superfluous matter, and adorned with a beautiful fleece, their strength, agility, magnitude, and arms, are diminished: These long-tailed sheep are only half the size of the mouflon. They can neither fly from danger, nor resist the enemy. To preserve and multiply the species, they require the constant care and support of man.

"The degeneration of the original species is still greater in our climates. Of all the qualities of the mouflon, our ewes and rams have retained nothing but a small portion of vivacity, which yields to the crook of the shepherd. Timidity, weakness, resignation, and stupidity, are the only melancholy remains of their degraded nature. To restore their original size and strength, our Flanders sheep should be united with the mouflon, and prevented from propagating with inferior races; and, if we would devote the species to the more useful purposes of affording us good mutton and wool, we should imitate some neighbouring nations in propagating the Barbary race of sheep, which, after being transported into Spain, and even into Britain, have succeeded very well. Strength and magnitude are male attributes; plumpness and beauty of skin are female qualities. To obtain fine wool, therefore, our rams should have Barbary ewes; and to augment the size, our ewes should be served with the male mouflon."

The learned Count seems to speak with more certainty upon this subject than the circumstances of the case, or the nature of the facts (as yet far from being fully ascertained, or completely authenticated), will admit. The editor of the Bee, who is well known to have devoted much time and attention to this subject, thus ably exposes the futility of those arguments which are brought in support of an hypothesis, which he thinks extremely absurd, or at least premature. "Buffon (says he), who is the least scrupulous of all modern naturalists, has been the most forward to decide in this, as in many other cases. He does not so much as condescend to admit that there can be a doubt in this case; but on all occasions assumes it as a certainty, that all the varieties of one species have been derived from one parent; and boldly raises upon that supposition many practical inferences, which, if his theory should prove to be unfounded, might lead to very important errors; so that it is not a matter of idle curiosity to investigate this question." He then goes on to show by some particular instances the gross absurdity of Buffon's opinion. "Were (continues he) these diversities only casual, and apt to vary, it might be more easy for us to give faith to the hypothesis; but this is not the case. Experience hath fully proved, that any one breed may be kept perfectly uncontaminated for any length of time, with all its distinctive peculiarities entire, merely by preventing an intermixture by copulation. Nor is this all; it is also known, that if such an intermixture be permitted, the descendants will undoubtedly be a mixed breed, evidently participating of the qualities and appearances of both their parents. Between a hound and a greyhound, a mongrel breed is obtained which possesses the sense of smelling, though in a less degree than the one, and the faculty of fleetness in a less degree than the other, of its parents; and its whole external appearance evidently indicates at first sight the compound of the stock whence it has descended. But let a small lap dog and a large mastiff by fed with the same food and tended with the same care, the one discovers no symptoms of increasing in size or diminishing it more than the other. Let them be carried from one country to another, they equally preserve their original distinctive qualities, without any farther change than the climate may perhaps produce; which equally seems to affect all the varieties of this animal. Never was there adopted an hypothesis more truly absurd than that of Buffon in this respect. Nor was there ever made such a barefaced attempt to try how far the credulity of mankind could lead them astray in deference to a great name, in direct contradiction to facts which fall immediately under the cognizance of every man who pleases but to open his eyes, and look right before him, as in those bold and unfounded assertions which he has been pleased to make, with regard to the transformation of dogs from one variety into another. Yet these opinions have been inadvertently transcribed many times by learned naturalists, without one symptom of doubt or hesitation. But can any thing be more contrary to reason, experience, and facts than that every man has before his eyes every day in his life, than such opinions? It is indeed humiliating for the pride of man, who plumes himself on the superiority of reason, to remark this. And it is mortifying for modern philosophy, which affects to be founded on experience and accurate observation of facts alone, to point out such things; but truth ought in all cases to be adhered to." Though this note has already extended to an undue length, we cannot omit the following observations by the same patriotic writer: "In regard to sheep, the varieties of this useful class of animals seem to be considerable, and their natural propensities so discriminated as to be admirably calculated for adapting them to different situations on this globe, so as to make them a very universal inhabitant of it: and these are so diversified as to habits and instincts,

as

Ovis.

education or mode of life, climate, food, and crossing the breed, have produced in sheep, as in other animals; and, in conformity to this opinion he considers, not only those varieties found in Europe, but also those of other quarters of the globe, as only accidental varieties of the same species; and his opinion is confirmed, by finding that they produce a prolific race though the breed be ever so much crossed; which he thinks would not be the case were they different species. The varieties which Dr Pallas examined, which, as we have already said, are four, are as follow. The first is named both by the Tartars and Russians *Tscherkeffian* sheep, and by Pallas *dolichura* or long-tailed: it is the *ovis longicauda* of authors.

The second is called the Russian sheep by the natives, and by Pallas *brachiura* or short-tailed: it seems to be the *ovis Islandicus* of authors, with smaller horns.

The third has no fixed trivial name, as its appellations are as various as the provinces where it is reared; Pallas has called it *steatopyga* or fat-tailed: it is the *ovis laticaudata* of authors.

The fourth has likewise no fixed trivial name, but Pallas has called it *bucharian*, from finding it reared by the Bucharian Tartars in immense flocks. The *Tscherkeffian* sheep, or first variety, is a handsome animal, with a noble air, in its native country and the south of Russia, resembling in its habits, horns, fleece, and length of tail, the Spanish, but more particularly the English sheep. Its head is well proportioned, and of an elegant form; ears straight; horns large, even, rounded in the angles, tapering to a point, and bending inwardly towards the back. The rams are seldom without horns, and the ewes have them often bent in a lunar form. The wool, though coarse, is without admixture of hair, which is perhaps but an accidental distinction, and promises to be much meliorated by crossing the breed, and rearing the animal with more care and skill. It is even known to become much finer without the assistance of art, merely from the influence of a temperate climate, as on mount Caucasus. The tail of the ram is covered with fine long wool, like the Indian sheep described by Buffon, which trails on the ground, so as to efface the prints made by the animal's feet on sand, and it contains often 20 joints or vertebrae. In passing from the state of nature to that of servitude, it seems to have lost its native ferocity, together with its coarse fleece. Dr Pallas says it is a mild gentle animal, and is *less degenerated in form* from the argali, which, according to his system, is the parent species, than the *steatopyga*, which on the other hand has preserved much more of its wildness than the *Tscherkeffian*; perhaps because it is allowed to range with little restraint on the wide extended plains of Great Tartary. The *Tscherkeffian* is reared in all the European regions of the Russian Empire, situated on this side the river Occa, in the nearer Poland, and by the pastoral people of

mount Caucasus; and they are commonly of a white colour.

The same variety, we are told by Russel, in his natural history of Aleppo, is reared under the name of *Bedouin sh. ep* by the Arabs, and in the western parts of Mauritania, with a trifling difference in the length and thickness of the tail. There are likewise sheep in Morocco, which belong to this variety, on account of the distinguishing character of it, a long tail, although otherwise different, in having an ugly look, head covered entirely with hair, little hanging ears, and remarkably long wool.

The Indian and Guinea sheep, so well described by Buffon, resemble the *Tscherkeffian* only in the length of their tail, whilst in other respects they come nearer the *steatopyga* or fat-rumped sheep of Pallas in size, form, and fleece mixed with hair. The learned naturalist is of opinion, that the arid burning deserts produce this change on the wool; but his reasoning on this head is to us at least as little satisfactory as that by which he endeavours to prove the argali to be the parent species. The inhabitants of Ukraine and Padoli carry on an extensive and valuable traffic with the skins of *Tscherkeffian* sheep, the beauty of which they heighten in a very curious manner.

The *brachiura*, short-tailed, or second variety which Dr Pallas examined in his travels, is reared throughout all the north of Russia, and resembles that of Iceland in size, tail, and coarseness of fleece; but though this be the case in these few respects, yet it differs from it in a very essential character, that of *horns*, which are much smaller, and have nothing of that exuberance which Buffon and others attribute to the sheep of that island. It resembles the *Tscherkeffian* sheep in the form of its head, straight upright ears, and in thickness of fleece; but the quality of the two fleeces are very different, this variety having wool almost as coarse as dog's hair: but the great distinguishing character between them is the tail, which is almost a quarter of a yard shorter than that of the *Tscherkeffian*. The *brachiura*, or short-tailed sheep, is reared not only by the northern Russians, but likewise by the Fins and other neighbouring nations. Some of this variety have been transported into Siberia, where they have supported themselves on some pastures, though in poor condition; but through all the southern countries they are in less estimation than the long-tailed and fat-tailed varieties, which are much superior to them for size, fat, and good eating. The ewe of this short-tailed variety couples readily with the ram of the *steatopyga* or fat-tailed breed, and produces an animal nobler and larger than its mother, with a tail swelled at the base with fat, but meagre towards the end like that of the mixed breed, which, makes Dr Pallas's fourth and last variety of domestic sheep. The ewe also couples clandestinely with the domestic

Ovis.

as to preserve the principal breeds very distinct, if left to a state of nature. The argali, strong, active, nimble, delights to live among rocks and inaccessible places; while the large sluggish breed of sheep, such as those that have been taken into keeping by our countryman Bakewell, could never ascend these steepes, but are well calculated to consume the produce of the fertile plains; there is therefore no chance that these two breeds would ever intermingle, if left entirely to themselves. The last of these two varieties has indeed been long domesticated by man, as being utterly incapable of withdrawing itself from his sway, though the first has been able to preserve its independence till the present hour in some of the mountainous and least inhabited districts on the globe." He then goes on to mark the lesser distinctions, in which, however, we cannot follow him.

Ovis.

domestic he-goat, and produces an animal much resembling the mother, but with a fleece of wool and hair. The latter is a fact of the truth of which we have some doubt. The Doctor may easily have been misled, and may have adopted his opinion, merely from the shaggy appearance of the fleece of some breeds of sheep, which much resembles the hair of a goat; but these are found as well in countries where no goats exist, as in those where they abound. The fact has not then, we think, been sufficiently ascertained. This variety supports extremely well the severity of a northern climate; and Dr Pallas doubts not but it might pass the winter in the plains of mountainous northern countries where there is not so much snow; nay, he even thinks it might augment their hardiness and strength, if we are to judge from the habits and treatment of the Iceland flocks, so well described by Anderson in his account of that island.

Dr Pallas remarked, that on mountainous pastures exposed to the sun, such as on the activity of the Ouralic chain, the Russian or short-tailed sheep were larger, fatter, and had a finer fleece.

Crossing the breed with the Tscherkessian or long-tailed sheep likewise mends both the stature and fleece of the brachiura; whereas, in its own natural state, without admixture of other varieties of sheep, it is but small, lean, and produces, in the northern parts of Russia, a wool so extremely coarse as only to be fit for the cloth of peasants in a state of vassalage.

Whether coarseness of wool and leanness be indeed characteristic marks of this species, is, we think, extremely doubtful: we are rather inclined to consider them as mere accidental differences.

The Doctor's third variety, or *steatopyga*, which has a different name in almost every country where it is reared, is both the most abundant and largest breed of sheep in the world. It is reared throughout all the temperate regions of Asia, from the frontiers of Europe to those of China, in the vast plains of Tartary. All the Nomade hordes of Asia, the Turcomans, Kirguise, Calmucks, and Mongal Tartars, rear it; and indeed it constitutes their chief riches, the number they possess being enormous. The Persians also rear it in abundance; as likewise the Hottentots, as we are informed by Kolbe in his Travels to the Cape of Good Hope; whilst Osbeck, in his Journey to China, asserts, that the fat-tailed sheep are reared through that whole empire. We are told also by Shaw and the Abbé Demanet, that the same breed obtains in Syria, Mauritania, and the other regions of Africa, under some modifications of form, from different causes; so that Dr Pallas thinks there is sufficient evidence that the *steatopyga*, or fat-rumped sheep, is the most universally reared and multiplied of any breed in the world. The flocks of all the Tartar hordes resemble one another by a large yellowish muzzle, the upper jaw often projecting beyond the lower; by long hanging ears; by the horns of the adult ram being large spiral, wrinkled, angular, and bent in a lunar form. The body of the ram, and sometimes of the ewe, swells gradually with fat towards the posteriors: where a solid mass of fat is formed on the rump, and falls over the anus in place of a tail, divided into two hemispheres, which take the form of the hips, with a little button of a tail in the middle, to be felt with the finger.

Ovis.

See A fig. 16. plate CCCLXXI. The *uropygium* or fat-rump, which is made up of this oily species of fat, is so very large as to incommode the animal in walking; but when the same sheep are carried into the interior parts of Russia, the tail loses half its size and weight, nay sometimes more, from a change in their food and mode of life. This variety, besides the characters mentioned above, have slender legs in proportion to their bodies, a high chest, large hanging testicles, a large prepuce, and tolerably fine wool mixed with hair. Such are the great characteristic marks by which the flocks of all the Tartar hordes resemble one another; but climate, soil, &c. produce some small difference on this variety, whether reared by the Tartars or the Russians, in the western deserts of Great Tartary, from the river Volga to the Irtysh, and the Altaic chain of mountains. In all that tract of country, the pasturage is mostly arid; and it abounds in acrid and liliaceous plants in spring, whilst in summer it produces, at least in the open spots where sheep delight to feed, besides gramin, bitter and aromatic plants, artemisia, camphorosma, and many species of *salsola*, abounding in juices and salts. There is likewise found everywhere an efflorescence of natron, with sea or glaubers salt; nay, even the waters of the desert contain in general the same salts. Now it is almost unnecessary to inform European shepherds, that such pasturage has the effect of augmenting the size of sheep, if it produces no other change upon them; so that we see, in this instance, how some kind of difference may arise amongst sheep of the same breed merely from accidental causes, without the least admixture of heterogeneous blood. This variety changes greatly in size and in other incidental circumstances, according to the method of raising or of treating them in different places and by different people.

The fourth variety, raised by the Boucharian Tartars and Persians in great numbers, Dr Pallas regards as a mixed breed, arising, as he supposes, from the union of the first and third varieties, *i. e.* of the long and fat tailed sheep. The Doctor does not think that they ever attain to the size of either of their parents; though, as he never saw any full grown, he does not speak positively upon the subject. The head of this variety is like that of the Kirguise; but the muzzle is sharper, resembling the Indian of Buffon: the body is rather smaller than that of the Kirguise sheep: the ears are large and pendant: they have a small *uropygium*, like that of the Tartar sheep on the Jenisy, especially when begotten by a Kirguise ram; but in general they have a *tail* fat and broad at the base, with a long narrow appendage, which resembles the tail of the Tscherkessian sheep. The Boucharian Tartars have a very valuable traffic with the furs of the lambs of this variety, which are exquisitely fine and beautiful. This same variety is likewise raised in great numbers by the Persians; and it is more than probable, if we are to give credit to authors ancient and modern, that this very variety obtains in Syria, Palestine, and divers countries of Africa, known to them by the name of *ovis macroceras*. It differs in all those countries from the fat-tailed, or *steatopyga* of Pallas, in having a long tail, fat and broad above, with a long narrow appendage, which is exactly the great

Ovis.

great marked character of the Boucharian breed. Pliny tells us, that the Syrian sheep have long fat tails, and carry wool; and by Russel's account of them, in his Natural history of Aleppo, they resemble the Kirguise sheep in the head, face, and ears hanging on the cheeks; but the tail is that of the Boucharian, fat above, with a long lean appendage. He adds, that they are covered with a soft wool, which is another trait of resemblance with our present variety; and that they weigh sometimes 150 pounds, one third of which is the weight of the tail. Gesner, in his work on quadrupeds, tells us, that the Arab sheep of Kay have nearly the same characteristic marks, especially with regard to the tail.

Shaw relates in his Travels, that sheep with such a compound tail are common in Mauritania, and in all the East; whilst Kolbe assures us, that the sheep which are brought on board the ships at the Cape of Good Hope have tails weighing 25 or 30 pounds, fat above, with a bony appendage hanging from it; and, lastly, the Abbe Demaillet, in his new History of Africa, says, that sheep are found in Africa covered with wool, and with such a tail as we have been describing; whilst at Cape Guardia, in the south of Africa, all the sheep are white, with rather small black heads, otherwise a large handsome breed, with broad fat tails, six or eight inches long.

The Doctor, however, does not entirely close his proofs here; for he quotes several passages from Moses in confirmation of what he has advanced, viz. that the Boucharian sheep obtain in Syria, Palestine, and divers countries of Africa. The passages he quotes are these: Leviticus viii. 25. ix. 19. But whether these verses prove what the Doctor has quoted them as proving, we will not determine.

These are the four varieties which Dr Pallas saw and examined in his extensive travels. The account is, we think, curious; to naturalists interesting; and to farmers it may be useful. If it only excite further research and minuter inquiry, it will answer some purpose. Indeed, the man of science will not rest satisfied with what our prescribed bounds have permitted us to bring forward, but will recur to the original work of the learned author to whom we are primarily indebted for the above account. We refer such readers, then, to his *Spicilegium Zoologicum, fasciculus undecimus*, printed at Berlin in 1776.

It may not be improper to describe the figures of these four varieties. They are all contained in Plate CCCLXXI. fig. 16 of which is the argali. Fig. 17. is a side and back view; letters Aa of the ram of the steatopyga, or fat-rumped variety, in its greatest purity of breed, as obtaining among the Kirguise Tartars in the vast plains of Southern Tartary. The position of the animal marked with a shows the uropygium or fat rump. Letter b is a representation of the head of the same animal, with a couple of noneola hanging from the neck, called by the Russians *ear-rings*. Letter C is a drawing of another Kirguise

VOL. XIII.

ram with five horns, showing at same time the hanging position of the ears of this variety. Fig. 18. is a drawing of a degenerate breed of the steatopyga variety of sheep, reared, on the banks of the Jenisy and Volga, without horns, and with the uropygium or fat rump greatly diminished, and one noneola. Letter b (fig. 19.) is a drawing of a ram of the same variety of sheep, from the flocks of the Jenisy Kirguise, with four horns symmetrically arranged by nature, as is frequently the case with this breed.

In a supplement to his article Sheep, Buffon has these words respecting the strepsiceros: "I here give Buffon, as figures," says the Count (see Plate CCCLXXI. above, fig. 14. and 15.) "of a ram and ewe, of which drawings were sent me by the late Mr Colinson, fellow of the Royal Society of London, under the names of the *Walachian ram* and *ewe*. As this learned naturalist died soon afterwards, I could not discover whether these sheep, whose horns are extremely different from those of the ordinary kind, be common in Walachia, or whether they are only an accidental variety (D).

"In the northern parts of Europe, as Denmark and Norway, the sheep are not good; but, to improve the breed, rams are occasionally imported from England. In the islands adjacent to Norway, the sheep remain in the fields during the whole year; and they become larger and produce finer wool than those which are under the care and direction of men. It is alleged, that those sheep which enjoy perfect liberty always sleep, during the night, on that side of the island from whence the wind is to blow next day. This natural indication of the weather is carefully attended to by the mariners\*.

"The rams, ewes, and wedders of Iceland, differ chiefly from ours by having larger and thicker horns. Some of them have three, four, and even five horns. But this peculiarity of having more horns than two, must not be considered as common to the whole race of Iceland sheep; for in a flock of four or five hundred, hardly three or four wedders can be found with four or five horns, and these are sent to Copenhagen as rarities. As a farther proof of their being scarce, they give a higher price in Iceland than the common kind §."

In Spain and the southern parts of Europe, the flocks of sheep are kept in shades or stables during the night: but in Britain, where there is now no danger from wolves, they are allowed to remain without, both night and day; which makes the animals more healthy, and their flesh a more wholesome food. Dry and mountainous grounds, where thyme and sheep's fescue grass abound, are the best for the pasturing sheep.

The sheep is subject to many diseases: some arising from insects which deposit their eggs in different parts of the animal: others are caused by their being kept in wet pastures; for as the sheep requires but little drink, it is naturally fond of a dry soil. The dropsy, vertigo (the *pendro* of the Welsh), the phthisis, jaundice, and worms in the liver, annually make great ha-

(D) Dr Pallas thinks it very probable that the strepsiceros variety of sheep were produced by propagating a particular configuration of horns. He alludes to the animal which Bellonius first discovered on Mount Ida in Crete, and which he supposes the strepsiceros of the ancients.

tse.

voc among our flocks: for the first disease, the shepherd finds a remedy by turning the infected into fields of broom; which plant has been also found to be very efficacious in the same disorder among the human species — The sheep is also infested by different sorts of insects; like the horse, it has its peculiar œstrus or gad-fly, which deposits its eggs above the nose in the frontal sinuses (see OESTRUS): when those turn into maggots, they become excessively painful, and cause those violent agitations that we so often see the animal in. The French shepherds make a common practice of easing the sheep, by trepanning and taking out the maggot; this practice is sometimes used by the English shepherds, but not always with the same success. Besides these insects, the sheep is troubled with a kind of tick and louse, which magpies and starlings contribute to ease it of, by lighting on its back, and picking the insects off.

We had intended to have introduced into this article some observations from Pennant; but it has already extended beyond its just limits, and we dare not venture to extend it further. Under the article Wool, which is intimately connected with the present, we may perhaps have an opportunity of introducing some additional remarks not without importance. At all events, we trust by that time to be able to give a favourable report of that truly patriotic society which has been lately instituted in the northern part of Great Britain, for meliorating the breed of sheep, and in consequence the nature and quality of the wool. From the active and indefatigable exertions of Sir John Sinclair, baronet, the president of that society, we have every thing to hope from well conducted experiments, and nothing to fear from groundless hypotheses.

OUNCE, a little weight, the 16th part of a pound avoirdupois, and the 12th part of a pound Troy. The word is derived from the Latin, *uncia*, "the twelfth part of any whole," called *as*; particularly in geometrical measures, an inch, or the 12th part of a foot. See INCH and AS.

OUNCE, in zoology. See FELIS.

OVOLO, or OVUM, in architecture, a round moulding, whose profile or sweep, in the Ionic and Composite capitals, is usually a quadrant of a circle: whence it is also commonly called the *quarter-round*. It is usually cut with representations of eggs and arrow-heads or anchors placed alternately.

OU-POEY-TSE, a name given by the Chinese to a kind of nests made by certain insects upon the leaves and branches of the tree called *yen-fou-tse*. These nests are much used in dyeing, and the physicians employ them for curing many distempers. Some of these nests were brought to Europe, and put into the hands of the celebrated Mr Geoffroy. After having examined them with the utmost attention, this learned academician thought he perceived some conformity in them to those excrescences which grow on the leaves of the elm, and which the vulgar call *elm-bladders*: he found these nests so sharp and astringent to the taste, that he considered them as far superior to every other species of galls used by the dyers. According to him, they are the strongest astringents existing in the vegetable kingdom.

It is certain that there is a great affinity between the ou-poey-tse and the elm-bladders. The form of

both is unequal and irregular; they are covered on the outside with a short down, which renders them soft to the touch: within they are full of a whitish-grey dust, in which may be observed the dried remains of small insects, without discovering any aperture through which they might have passed. These nests or bladders harden as they grow old: and their substance, which appears resinous, becomes brittle and transparent; however, the Chinese do not consider the ou-poey-tse, notwithstanding their resemblance to elm-bladders, as excrescences of the tree *yen-fou-tse*, upon which they are found. They are persuaded, that insects produce a kind of wax, and construct for themselves on the branches and leaves of this tree (the sap of which is proper for their nourishment) little retreats, where they may wait for the time of their metamorphosis, or at least deposit in safety their eggs, which compose that fine dust with which the ou-poey-tse are filled. Some of the ou-poey-tse are as large as one's fist; but these are rare, and are generally produced by a worm of extraordinary strength, or which has associated with another, as two silk-worms are sometimes seen shut up in the same ball. The smallest ou-poey-tse are of the size of a chestnut; the greater part of them are round and oblong; but they seldom resemble one another entirely in their exterior configuration. At first, they are of a dark green colour, which afterwards changes to yellow; and the husk, though pretty firm, becomes then very brittle.

The Chinese peasants collect these ou-poey-tse before the first hoar frosts. They take care to kill the worm inclosed in the husks, and to expose them for some time to the steam of boiling water. Without this precaution, the worm might soon break through its weak prison, which would immediately burst and be useless. The ou-poey-tse are used at Peking for giving paper a durable and deep-black colour; in the provinces of Kiang-nan and Tche-kiang, where a great deal of beautiful satin is made, they are employed for dyeing the silk before it is put on the loom. The Chinese literati also blacken their beards with them when they become white.

The medicinal properties of the ou-poey-tse are very numerous. The Chinese physicians introduce them into the composition of many of their remedies. They recommend them for stopping bleedings of every kind; they consider them as an excellent specific for curing inflammations and ulcers, and for counteracting the effects of poison; and they employ them with success in the dropsy, phthisis, epilepsy, catarrhs, sicknesses, fluxions of the eyes and ears, and in many other disorders.

GREATER OUSE, a river which rises near Fitwell in Oxfordshire, and proceeds to Buckingham, Stony-Stratford, and Newport Pagnel, in Buckinghamshire; from thence it proceeds to Bedford, and turning north-east it passes on to Huntingdon and Ely, till at length it arrives at Lynn-Regis in Norfolk, and falls into the sea. It is navigable to some distance above Downham, where there is a good harbour for barges; and a considerable trade is carried on by it to Lynn and other towns.

Smaller Ouse, rises in Suffolk, and, separating that county from Norfolk on the south-west, discharges itself into the Great Ouse near Downham. There is still another of the same name which rises in the west-north

**Ouster** north-west side of Yorkshire, and chiefly running to the south-east, at length falls into the Humber.

**Outlawry.** **OUSTER**, or **DISPOSSESSION**, in law, an injury which carries with it the amotion of possession; for by means of it the wrong doer gets into the actual possession of the land or hereditament, and obliges him that hath a right to seek a legal remedy, in order to gain possession, together with damages. This ouster may either be of the freehold by abatement, intrusion, disseisin, discontinuance, and deforcement; or of chattels real, as an estate by statute-merchant, statute-staple or elegit, or an estate for years.

**OUSTER le main, amovere manum**, in law, denotes a livery of lands out of the king's hands; or a judgment given for him that traversed, or sued, a *montrant le droit*. When it appeared, upon the matter being discussed, that the king had no right or title to the land seized, judgment was given in chancery that the king's hand be removed; and *ouster le main*, or *amoveas manum*, was therefore awarded to the escheator, to restore the land, &c. All wardships, liveries, *ouster le mains*, &c. are now taken away and discharged by statute 12. Car. II.

**OUSTIOUG**, a town of the Russian empire, and capital of a province of the same name, with an archbishop's see and a castle; seated on the river Suchan, over-against the mouth of the Jug, in E. Long. 43. 25. N. Lat. 61. 48.

**OUSTIOUG**, a province of the Russian empire, bounded on the north by Dwina, on the east by the forest of Zirani, on the south by Wologda, and on the west by Cargapol and Waga. It is divided into two parts by the river Suchana; is full of forests; and the rivers yield plenty of fish, which the inhabitants dry in the sun, and which make their principal nourishment.

**OUT-POSTS**, in a military sense, a body of men posted beyond the grand guard; called *out-posts*, as being the rounds or limits of the camp.

**OUTLAW**, signifies one that is deprived of the benefit of the law; and therefore held to be out of the king's protection.

Bracton asserts that an outlaw forfeits all he has; and that, from the time of his outlawry, he wears a wolf's head; and any body may kill him with impunity, especially if he defend himself or fly. But in Edward III's time it was resolved by the judges, that it should not be lawful for any man, but the sheriff alone (having sufficient warrant for it), to put to death a man that was outlawed.

**OUTLAWRY**, the punishment of a person who, being called into law, and lawfully, according to the usual forms, sought, does contemptuously refuse to appear.

The effect of being outlawed at the suit of another, in a civil cause, is the forfeiture of all the person's goods and chattels to the king, and the profits of his land, while the outlawry remains in force. If in treason or felony, all the lands and tenements which he has in fee, or for life, and all his goods and chattels, are also forfeited: and besides, the law interprets his absence as a sufficient evidence of guilt; and without requiring farther proof, account the person guilty of the fact, on which ensues corruption of blood, &c. And then, according to Bracton, he may perish without law, &c. However, to avoid inhumanity, no man is intitled to kill him wantonly or wilfully; but in so

doing he is guilty of murder, unless it happens in endeavouring to apprehend him: for any body may arrest an outlaw, either of his own head, or by writ or warrant of *capias utlagatum*, in order to bring him to execution.

If after outlawry, in civil cases, the defendant publicly appear, he is to be arrested by a writ of *capias utlagatum*, and committed till the outlawry be reversed: which reversal may be had by the defendant's appearing in court (and in the king's-bench, by sending an attorney, according to statute 4 and 5 W. and M. cap. 18.), and any plausible circumstance, however trifling, is in general sufficient to reverse it; it being considered only as a process to force appearance. The defendant must, however, pay full costs, and must put the plaintiff in the same condition as if he had appeared before the writ of *exigi facias* was awarded. It is appointed by magna charta, that no freeman shall be outlawed, but according to the law of the land. A minor or a woman cannot be outlawed.

In Scotland outlawry anciently took place in the case of refusal to fulfil a civil obligation, as well as in criminal cases. At present, however, it only takes place in the two cases of flying from a criminal prosecution, and of appearing in court attended by too great a number of followers. But the defender, upon appearing at any distance of time and offering to stand trial, is intitled *de jure* to have the outlawry reversed, and to be admitted to trial accordingly, and even to bail if the offence be bailable. See **WAIVE**.

**OVUM ANGUINUM**. See **ANGUINUM**.

**OUTWORKS**, in fortification, all those works made without-side the ditch of a fortified place, to cover and defend it. See **FORTIFICATION**.

**OUZEL**, in ornithology; a species of **MOTACILLA**.

**OWEN** (Thomas), a judge of the common-pleas, son of Richard Owen, Esq; of Conover, in Shropshire, was educated at Oxford, and, as is generally supposed, at Christ-church college. Having taken a degree in arts, he left the university, and entered himself of Lincoln's-inn in London, where in process of time he became an eminent counsellor. In 1583 he was elected Lent-reader to that society. In 1590 he was made serjeant at law, and queen's serjeant soon after. He arrived at length at the dignity of judge of the common-pleas; which office he is said to have executed, during five years, with great abilities and integrity. He died in 1598; and was buried on the south side of the choir in Westminster abbey, where a monument was erected to his memory. He had the reputation of a learned man, and a patron of literature. He was the author of "Reports in the common-pleas, wherein are many choice cases, most of them thoroughly argued by the learned serjeants, and after argued and resolved by the grave judges of those times, with many cases wherein the difference of the year-books are reconciled and explained." Lond. 1656, folio.

**OWEN** (Dr John), an eminent and learned dissenting minister, was born in 1616, at Hadham, in Oxfordshire, of which place his father was vicar. He made such surprising proficiency in learning, that at twelve years of age he was admitted into Queen's-college, Oxford, and in 1635 was made master of arts: but soon after, disapproving the new regulations made by Archbishop Laud their chancellor, with which he

Owen  
||  
Owen.

**Owen.** refused to comply, he was obliged, in 1637, to leave the university; when, taking orders, he became chaplain to Sir Robert Dormer of Ascot in Oxfordshire, and was at the same time tutor to his eldest son. He was afterwards chaplain to John Lord Lovelace of Huxley in Berkshire; when the civil war broke out, he openly avowed the cause of the parliament; which was so resented by an uncle, who had intended to leave him his estate, that he discarded him, and left it to another. Yet though Lord Lovelace sided with the king, he treated his chaplain with great civility: but on his going to join the royal army, Mr Owen went to London, and soon after joined the non-conformists. In 1642 he published his book, intitled, *A Display of Arminianism*, which laid the foundation of his future advancement: for the committee for purging the church of scandalous ministers were so pleased with it, that Mr White their chairman sent him a presentation to the living of Fordham in Essex: but when he had been there about a year and a half, the patron hearing that the sequestered incumbent was dead, presented another to the living; upon which the earl of Warwick gave Mr Owen the living of Coggeshal. He had not, however, been long at that town before he left the Presbyterians; and joining the Independents, formed a church there. He was now sent for several times to preach before the parliament; and among the rest on the 21th of February 16489, the day of humiliation for the intended expedition to Ireland. Cromwell who was present at this last discourse, and had never heard him before, was extremely pleased with it, and desired his company into Ireland, and that he would reside in the college of Dublin. This he did; but returned in about half a year. Soon after Cromwell sent him into Scotland; but he also returned from thence after about half a year's stay at Edinburgh. He was then promoted to the deanery of Christ-church, Oxford, whither he went in 1651; and Cromwell, being now chancellor of the university nominated him his vice-chancellor. The next year he was created doctor of divinity by diploma. Dr Owen enjoyed the post of vice-chancellor five years; during which he behaved with the greatest moderation: for, though often solicited, he never molested the meeting of the royalists at the house of Dr Willis the physician, where divine service was performed according to the liturgy of the church of England; and though he was a commissioner for ejecting scandalous ministers, he frequently overruled his brethren in favour of those royalists who were distinguished by their merit. At the death of Cromwell, he was removed from the vice-chancellorship; and at the Restoration was ejected from his deanery of Christ-church. But he had provided himself a comfortable retreat at an estate he had purchased at Hadham. He now employed himself in preaching as often as he had an opportunity, and in writing books; one of which, intitled *Fiat Lux*, falling into the hands of Lord Clarendon, he was so pleased with it, or (as is said) from policy pretended to be so, that he sent for Dr Owen, and acknowledging the service he had done by it to the Protestant religion, offered to prefer him in the church, if he would conform; but he desired to be excused.—His moderation drew him respect from persons of opposite principles; and in the number of his friends were Dr Wilkins bishop of Chester,

and Dr Barlow bishop of London. He died at Ealing in 1683. His works are printed in seven volumes folio. **Owhyhee.**

Wood, after censuring him in many respects, says nevertheless, that, "to speak impartially, he was a person well skilled in the tongues, Rabbinical learning, and Jewish rites and customs; that he had a great command of his English pen, and was one of the gentlest and fairest writers who ever appeared against the church of England."

**OWHYHEE**, the easternmost, and by far the largest, of the Sandwich islands. Its greatest length from north to south is  $28\frac{1}{2}$  leagues, its breadth 24, and its circumference nearly 300 English miles. It is divided into six large districts; two of which on the north-east side are separated by a mountain, that rises in three peaks, which is perpetually covered with snow, and may be seen clearly at 40 leagues distance. To the north of this mountain, the coast consists of high and steep cliffs, down which fall many beautiful cascades of water. The whole country is covered with cocoa nut and bread-fruit trees. The peaks of the mountain on the north-east side appear to be about half a mile in height, and entirely covered with snow. To the south of this mountain, the coast presents a prospect of the most dreary kind, the whole country appearing to have undergone a total change by means of some dreadful convulsion. The ground is every where covered with cinders, and intersected in many places with black breaks, which seem to mark the course of a lava that has flowed not many ages since from the mountain to the shore. The southern promontory looks like the mere dregs of a volcano. The projecting headland is composed of broken and craggy rock, piled irregularly upon one another, and terminating in sharp points; yet amidst these ruins, there are many pieces of rich soil, which are carefully laid out in plantations, and the neighbouring sea affords a vast variety of excellent fish; so that this quarter is much better inhabited than those which are more verdant. The fields are inclosed with stone fences, and are interspersed with groves of cocoa nut trees. We are told indeed by some of Cook's people who walked through a considerable part of it, that they did not observe a spot of ground that was susceptible of improvement left unplanted; and indeed the country, from their account, could scarcely be cultivated to greater advantage for the purposes of the natives. They were surprised at seeing several fields of hay; and upon their inquiry, to what particular use it was applied, they were informed, that it was intended to cover the grounds where the young *taro* grew, in order to preserve them from being scorched by the rays of the sun. They observed among the plantations a few huts scattered about which afforded occasional shelter to the labourers; but they did not see any villages at a greater distance from the sea than four or five miles. Near one of them, which was situated about four miles from the bay, they discovered a cave, forty fathoms in length, three in breadth, and of the same height. It was open at each end; its sides were fluted as if wrought with a chisel; and the surface was glazed over, perhaps by the action of fire. There are supposed to be on this island about 150,000 inhabitants. So long as the name of Captain Cook shall be

Owhyhee be remembered, this island will not be forgotten; for he here fell a victim to a strange concatenation of events. See Cook.

We have the following account of the inhabitants of this island in Ellis's Authentic Narrative, &c. "The men are above the middle size, stout, well made, and fleshy, but not fat. Corpulency is not altogether so great a mark of distinction in these as in the Society Isles; and tallness, for which the Otaheiteans have great partiality, is also overlooked. Their colour is in general brown olive. The women are in general masculine, though there are some delicately made, and the voice of them all is soft and feminine. The hair both of the head and beard is black; that of the head the men wear in the form of a helmet, that is, a long frizzled ridge from the forehead to the neck, the sides being much shorter. This fashion seems to prevail only among the principal people, that of the inferior sort being of an equal length in every part. Most of them were very desirous of parting with their beards, which, they said, were disagreeable and troublesome, and were fond of being shaved by our people. Some of the priests wore their beards long, and would not on any account part with them. The women wear their hair long before, but very short behind, which is not the most becoming mode; and, like those of the Friendly Isles, they have a way of rendering it of different colours, red, yellow, and brown. The features of both sexes are good, and we saw some of the females who might really be called fine women. Their teeth are even and perfectly white. In general, they seem to be very healthy, and we observed several who appeared to be of great age. As to diseases, we saw none who laboured under any during our stay except the venereal complaint; coughs and colds indeed were pretty general, and one man died. From what we could learn of his disorder from the natives, it was a violent griping or colic.

"Both men and women appeared to be of a good disposition, and behaved to each other with the tenderest regard: when they did fall out, which sometimes was the case, occasioned by the upsetting of a canoe, or some such trifling accident, they only scolded a little, and this was soon over and forgotten. We never saw them strike each other upon any occasion. They are all thieves, from the aroe to the towtow, but not quite so expert at it as our Otaheitee friends.

"The custom of tattowing prevails greatly among these people, but the men have a much larger share of it than the women: many (particularly some of the natives of Mow'hee) have one half their body, from head to foot, marked in this manner, which gives them a most striking appearance. It is done with great regularity, and looks remarkably neat: some have only an arm marked in this manner, others a leg; some again have both arm and leg, and others only the hand. The women are the most part marked upon the hand, and some upon the tip of their tongue; but of these we saw but few. Both sexes have a particular mark according to the district in which they live; or it is rather the mark of the aroe, or principal man, under whose jurisdiction they more immediately are. We never saw the operation of tattowing performed, nor could we procure a sight of the instruments used upon

this occasion; but it is likely they are much the same Owhyhee, as those of the Friendly and Society Isles.

"Both men and women are very cleanly in their persons; the latter wash their whole bodies in fresh water twice and sometimes three times a-day; but the women of Otaheitee have the advantage of them in one point of cleanliness, which is eradicating the hairs from under the arm-pits. This is a custom we observed nowhere but at the Society Isles.

"There are no people in the world who indulge themselves more in their sensual appetite than these: in fact, they carry it to a most scandalous and shameful degree, and in a manner not proper to be mentioned. The ladies are very lavish of their favours; but are far from being so mercenary as those of the Friendly or Society Isles, and some of their attachments seemed purely the effect of affection. They are initiated into this way of life at a very early period; we saw some who could not be more than ten years old.

"Their clothing consists of cloth of different kinds: that worn by the men, which is called *marro*, is about half a yard wide, and four yards long; that of the women, three quarters of a yard wide, and of the same length as the mens: this they call *pah-ouwa*; they both wear it round their middle, but the men pass it between their legs. This is the general dress of both sexes; but the better sort sometimes throw a large piece loosely over their shoulders. Besides the *marro*, they have several other kinds of cloth, which derive their names either from the different uses they are applied to, or their different texture and pattern; all, however, as far as we could learn, are made from the Chinese paper mulberry tree. The principal of these is the *cappa*, which is about 10 or 12 feet long, and nearly as many wide, and is thick and warm; they wrap themselves up in this when they retire to sleep. They have another kind, which is white, and much thinner; this, as has been before observed, they throw loosely over their shoulders; it is sometimes 20 or 30 yards long, and wide in proportion. The *marro* and *pah-ouwa* are curiously painted of various patterns, but the others are generally white, or dyed red, black, and yellow.

"The principal ornaments of the men are the feather-caps and cloaks; some of the latter reach down to their heels, and have a most magnificent appearance. They are made for the most part of red and yellow feathers, which are tied upon fine net-work. The caps are composed of the same kind of feathers, which are sometimes intermixed with black; they are secured upon a kind of basket-work, made in the form of a helmet. Both caps and cloaks are made of various patterns and sizes. The cloaks are not all composed of the same kind of feathers, but are sometimes varied with the long tail-feathers of the cock, with a border of yellow or red, and sometimes with those of the tropic bird. Both caps and cloaks, however, are only to be seen in the possession of the principal people. They have also a kind of fly flap, made of a bunch of feathers fixed to the end of a thin piece of smooth and polished wood: they are generally made of the tail-feathers of the cock, but the better sort of people have them of the tropic birds feathers, or those belonging

Owhyhe  
Owling.

ing to a black and yellow bird called *moho'*. The handle is very frequently made of one of the bones of the arm or leg of those whom they have killed in battle, curiously inlaid with tortoise-shell: these they deem very valuable, and will not part with them under a great price. This ornament is common to the superiors of both sexes.

"The women too have their share in the ornamental way: that which they value most is the *orai*. This is a kind of ruff or necklace, made of red, green, black, and yellow feathers, curiously put together, and in most elegant patterns, which really do honour to the fancy of the ladies, whose business it is to make them. They never think themselves dressed without one or two of these round their necks, and those who can afford it wear many. Others again are composed of small variegated shells, disposed in a very neat manner; and some consist of several rows of twisted hair, with a piece of carved wood or bone, highly polished, the bottom part forming a curve. The higher the quality of the wearer, the greater is the size of the wood or bone, and the quantity of the twisted hair. The next thing is the *poo-remah* or bracelet; the most valuable are made of boar's tusks fastened together side by side with a piece of string, by means of a hole drilled through the middle; the larger the tusks, the greater the value. Sometimes two shells tied round the wrists with twisted or braided hair, serve the purpose of bracelets; but even in this case they show great nicety, being particularly careful to match them as near as possible. They were prodigiously fond of those we gave them, which were only a few beads, secured by thread upon a strip of scarlet cloth, and made to button round the wrist. So much did they at first value them, that a small hatchet and one of these would purchase a hog, which without it could not have been bought for three large hatchets. The women were perpetually teasing the men to dispose of their various articles for these bracelets; at least one of them was always to make a part of the price." W. Long. 156. o. S. Lat. 19. 28.

OWL, in ornithology. See STRIX.

OWLING, so called from its being usually carried on in the night, is the offence of transporting wool or sheep out of England, to the detriment of its staple manufacture. This was forbidden at common law, and more particularly by statute 11 Edw. III. c. 1. when the importance of our woollen manufacture was first attended to; and there are now many later statutes relating to this offence, the most useful and principal of which are those enacted in the reign of Queen Elizabeth, and since. The statute 8 Eliz. c. 3. makes the transportation of live sheep, or embarking them on board any ship, for the first offence forfeiture of goods, and imprisonment for a year, and that at the end of the year the left hand shall be cut off in some public market, and shall be there nailed up in the openest place; and the second offence is felony. The statutes 12 Car. II. c. 32. and 7 and 8 Will. III. c. 28. make the exportation of wool, sheep, or fuller's earth, liable to pecuniary penalties, and the forfeiture of the interest of the ship and cargo by the owners, if privy; and confiscation of goods, and three years imprisonment to the master and all the mariners. And the statute 4 Geo. I. c. 11. (amended and farther enforced by 12

Geo. II. c. 21. and 19 Geo. II. c. 34), makes it transportation for seven years, if the penalties be not paid.

OXALIS, WOODSORREL: A genus of the pentagynia order, belonging to the decandria class of plants; and in the natural method ranking under the 14th order, *Gruinales*. The calyx is pentaphyllous; the petals connected at the heels; the capsule pentagonal, and opening at the angles. There are seven species; of which the only remarkable is the acetosella, or common woodsorrel. This grows naturally in moist shady woods, and at the sides of hedges in many parts of Britain, and is but seldom admitted into gardens. The roots are composed of many scaly joints, which propagate in great plenty. The leaves arise immediately from the roots upon single long foot-stalks, and are composed of three heart-shaped lobes. They are gratefully acid, and of use in the scurvy and other putrid disorders.

OXFORD, the capital of a county of the same name in England, celebrated for its university, and pleasantly situated in a plain, with a fine fruitful country all around. The composition of the name is obvious. In the British times it seems to have been a place of study. "The wisdom of our ancestors (says Camden), as appears in our history, consecrated even in the British times this city to the muses, translating them from Greeklade (now a small town in Wilts) hither, as to a more fruitful nursery. For Alexander Necham\*, \* De Na- writes, 'Italy claims superior knowledge of civil law; tura Re. but the study of divinity and the liberal arts prove, rum, lib. 2. that the university of Paris deserves the preference of all others. Agreeable also to Merlin's prophecy, Wisdom has flourished at the Ford of Oxen, and will in its due time pass over also into Ireland.' But in the following Saxon age, when so many critics were destroyed, it underwent the common fate, and for a long while was famous only for the relicks of Frideswide, who was ranked among the saints for her holy life, merely because she had solemnly devoted herself to God; and prince Algar, soliciting her in marriage, was miraculously, as they say, deprived of his eyesight."

Perhaps the following additional extract from Camden will be more to the purpose in developing the ancient state of learning in this city, than any thing which we could bring forward of our own. "When the storm of the Danish war was over, the most religious prince Alfred\* restored their retreats to the long exiled muses, by founding three colleges, one for grammarians, another for philosophy, and a third for divinity. This will be more fully explained by the following passage in the old annals of the New Monastery at Winchester. 'In the year of our Lord 806, the second year of the arrival of St Grymbold in England, the university of Oxford was begun; the first who presided and read divinity lectures in it being St Neoth, an abbot and able divine; and St Grymbold, a most eminent professor of the incomparable sweetness of the sacred pages; After the monk, an excellent scholar, professing grammar and rhetoric; John monk of the church of St David giving lectures in logic, music, and arithmetic; and John the monk, colleague of St Grimbold, a man of great parts, and a universal scholar, teaching geometry and astronomy before the most glo-

Oxford.

glorious and invincible King Alfred, whose memory will dwell like honey in the mouths of all." Soon after, as we find in an excellent MS. of the said *Atter*, who was at that time professor here, 'broke out a sharp and fatal quarrel between Grymbold and those very learned men whom he had brought thither with him, and the old scholars whom he found there; who, on his coming, unanimously refused to receive the rules, methods, and forms of lecturing, that Grymbold introduced. Three years had passed without any great difference between them; but the secret aversion afterwards broke out with the utmost violence. In order to quell it, the invincible King Alfred, as soon as he heard of it by the messages and complaints from Grymbold, went in person to Oxford to put an end to the dispute, and he took the greatest pains to hear the causes and complaints on both sides. The foundation of the difference was this: The old scholars maintained, that before Grymbold came to Oxford learning had flourished there, though the scholars at that time were fewer than in more ancient times, the greater part being driven out by the cruelty and oppression of the Pagans. They also proved and showed, and that by the undoubted testimony of ancient chronicles, that the ordinances and regulations of the place were established by certain religious and learned men, such as Gildas, Melkinus, Ninnius, Kentigern, and others, who had all lived to a good old age in these studies, having settled matters there in peace and harmony; and also that St Germanus came to Oxford, and staid there half a year in his journey over Britain to preach against the Palagian heresies, and wonderfully approved their plan and institution. The king, with unheard-of condescension, gave both parties attentive hearing, and repeated his pious and seasonable advice to maintain mutual union and concord, and left them with the prospect that both parties would follow his advice and embrace his institutions. But Grymbold, offended at this proceeding, immediately retired to the monastery at Winchester lately founded by King Alfred. He also caused his tomb to be removed to Winchester, in which he had intended to lay his bones when his course of life was ended, in the vault under the chancel of St Peter's church at Oxford, which church himself had built from the ground of stone polished in the most costly manner."

"This happy restoration of learning was followed in a few years by various calamities. The Danes in the reign of Edward plundered and burnt the place; and soon after Harold Harefoot practised the most inhuman barbarities here in revenge for some of his men who were killed in an affray; so that the most melancholy remove of the students ensued, and the university remained almost extinct, a lamentable spectacle till the time of William the Norman. Some have falsely supposed this prince took the city, misled by a wrong reading in some copies of *Oxonia* for *Exonia*. At that time, however, it was the seat of an university, as we learn from these words of Ingulphus, who lived at that time. 'I Ingulphus settled first at Westminster, was afterwards sent to study at Oxford, having made greater proficiency than many of my own age in Aristotle, &c.' What we call an *university*, they in that age called a *study*." Many are of opinion that it was deserted till about the year 1129, and that this desertion was in consequence of its having been besieged and

taken by William the Conqueror. About this year, however, Robert Pulen began to read lectures in divinity, or as it is expressed in the Chronicle of Osney abbey) the Holy Scriptures, which had fallen into neglect in England; and such was the resort of students to it, that in the reign of King John there were not fewer than 3000. Robert d'Oily, a Norman, to whom William the Conqueror had given the greatest part of it, built a castle on the west side in 1701; and he is also supposed to have surrounded it with walls. In a palace built by Henry I. was born Richard I. commonly called *cœur de Lion*. About the tenth of King John, there happened a quarrel between the citizens and students; in consequence of which many of the latter quitted it, but returned again a few years afterwards. Here Henry III. held a parliament to settle the differences betwixt him and his barons; when he confirmed the privileges granted to the university by his predecessors, and added others of his own. In this reign the students are said to have been 30,000, who were all excommunicated by the pope for some rudeness to his legate. In the time of Duns Scotus, we are told that 30,000 scholars attended his lectures. Matthew Paris styles the university of Oxford, 'the second school of the church after Paris, and the very foundation of the church.' The popes had before this honoured it with the title of *Univerſity*, which they had conferred by their degrees on no other but that of Paris, this of Oxford, and those of Bologna and Salamanca. It was decreed by the council of Vienne, that 'schools for the study of the Hebrew, Arabic, and Chaldee languages, should be erected in the studies of Paris, Oxford, Bologna, and Salamanca (as the most considerable), that the knowledge of these languages might prevail by their being thus taught; and that Catholic persons be chosen, sufficiently versed therein, two in each language. For those in Oxford, the bishops, monasteries, chapters, convents, colleges, exempt and not exempt; and the rectors of churches thro'out England, Scotland, Ireland, and Wales, were to provide a competent maintenance." In Edw. III.'s time, the scholars were split into two factions, called the *northern* and *southern men*; a division which was attended with many disorders and much violence, but in a short time concord and harmony again prevailed.

As colleges began about this time to be founded and endowed, we shall here present our readers with a list of them, together with the time when, and the persons by whom, they were founded.

Colleges.	Founders.	Kings reigns.
Univ. rity	King Alfred.	Alfred.
Baliol.	Sir John Baliol, father to the king of Scots	Henry III.
Merton.	Walter Merton, lord chancellor and bishop of Rochester.	Edward I.
Oriel.	Edward II.	Edw. II.
Exeter.	Walter Stapleton, bishop.	Edw. II.
Queens	Robert Eglesfield, B. D.	Edw. III.
New College.	William of Wickham, bishop of Winchester, lord chancellor.	Edw. III.
Lincoln.	Richard Fleming, bishop of Lincoln.	Henry VI.
All-Souls.	Hugh Chicheley, archbishop of Canterbury.	Henry VI.
Magdalen.	William Walsley, bishop of Winchester, lord chancellor.	Henry VI.
Craven-Nose	William Smith, bishop of Lincoln, and Richard Sutton, abbot.	Hen VIII.

Oxford.

Colleges.	Founders.	Kings reigns.
Corpus-Christi.	Richard Fox, bishop of Winchester, and lord privy seal.	Hen. VIII.
Christ-Church.	Henry VIII. and Cardinal Wolsey.	Hen. VIII.
Trinity.	Sir Thomas Pope.	Mary.
St John Baptist.	Sir Thomas White, merchant of London.	Mary.
Jesuit.	Queen Elizabeth.	Elizabeth.
Wadham	Nicholas and Dorothy Wadham.	James I.
Pembroke	Thomas Tisdale, Esq; and Dr Richard Whitwick.	James I.

Worcester was called GLOUCESTER-HALL till lately, that it was endowed by Sir Thomas Coke, and made collegiate.  
Hartford was HART-HALL till 1740, that it was erected into a college by Dr Richard Newton.

All these are richly endowed, and have fine gardens, libraries, chapels, &c. The halls in which the students maintain themselves, except a few that have exhibitions, are these: St Edmund's, belonging to Queen's college; Magdalen, to Magdalen college; St Alban's to Merton; St Mary's to Oriel; New-Inn, to New-college. Several persons have been great benefactors to particular colleges, as Dr Ratcliffe to University college; Colonel Codrington and Dr Clarke, to All-souls; Queen Caroline, to Queen's; the before-mentioned Dr Clarke and Mrs Eaton, to Worcester; Dr Wake, archbishop of Canterbury, to Christ-church. The most considerable of these colleges are Magdalen's and Christ-church, which are as noble foundations as any in the world. The church of the latter is the cathedral, and has a dean, eight canons, eight chaplains, eight singing men, eight choristers, a teacher of music, and an organist. Each of the colleges has its visitor appointed by its statutes, except Christ-church, which is subject to the visitation of the Sovereign alone. The other remarkable buildings belonging to the university are, first, the public schools; secondly, the Bodleian or public library; thirdly, Ratcliffe's library, a most elegant structure, for building and furnishing which, Dr Ratcliffe left 40,000l; fourthly, the theatre, built by Sheldon, archbishop of Canterbury; fifthly, the museum, in which is an laboratory and a repository for natural and artificial rarities and antiquities; sixthly, the Clarendon printing house, so called because it was built partly with the money arising to the university by the sale of Lord Clarendon's history. To the south of Magdalen college lies the physic garden, instituted by the Earl of Danby, and much improved by Dr Sherrard. It contains five acres, in which is a complete series of such plants as grow naturally, disposed in their respective classes; together with two neat and convenient green-houses, stocked with a valuable collection of exotics, and a hot-house, where various plants brought from the warmer climates are raised. The whole body of the university, including professors, fellows, and students of all sorts, exceeds 3000. Each college has its particular statutes and rules for government. There are four terms in the year for public exercises, &c. and particular days and hours for public lectures by the several professors. The university is governed by a chancellor, high steward, vice-chancellor, two proctors; a public orator (see *Public Orator*); a keeper of the archives, a register, three esquire-beadles, and three yeoman-beadles. As to the city, it has had the same privileges granted to it as London, particularly an exemption from toll all

over England. It was made an episcopal see in 1541, when Robert King, the last abbot of Oseney, was elected Bishop. It is governed by a mayor, high-steward, recorder, four aldermen, eight assistants, two bailiffs, a town-clerk, two chamberlains, all that have borne the office of bailiff and chamberlain, and twenty-four common-council men: but these are subject to the chancellor or vice-chancellor of the university in all affairs of moment; and not only the mayor, but the principal citizens, and sheriff of the county, take an oath to maintain the privileges of the university. The city, including the colleges, is a place of considerable magnitude, having 13 parish-churches, besides the cathedral, well built, clean, and regular. At the entrance of the town from the Woodstock and Banbury roads, a neat hospital hath been lately erected by the trustees of Dr Ratcliffe's benefaction, out of the surplus money remaining after defraying the expence of his library. The male line of the family of Vere, to whom the city had given the title of earl for 500 years, failing in Aubrey de Vere, who was twentieth earl, Queen Anne conferred the title upon Robert Harley, a descendant of the Veres, in whose family it still continues. The chief trade of the city is in malt, conveyed in barges to London. It is impossible, in the narrow bounds necessarily prescribed to this article, to give so particular an account of this celebrated place as its importance demands: but we shall refer our readers to the article UNIVERSITY, when this feminary, amongst others, shall be more particularly described.

OXFORDSHIRE, which made part of the territory of the ancient *Dobuni*, a county of England, bounded on the west by Gloucestershire; on the south, where it is broadest, the river Isis divides it from Berkshire; on the east, it is bounded by Buckinghamshire, and on the north, where it terminates in a narrow point, it has on the one side Northamptonshire, and on the other Warwickshire. It extends 50 miles from north to south, and 35 from east to west, making about 130 in circumference: within which are contained one city, 15 market-towns, 280 parishes, 14 hundreds, 534,000 acres, and about 120,000 souls. The air is sweet and pleasant, and the soil rich and fertile. The lower parts consist of meadows and corn-fields, and the higher were covered with woods till the civil wars; in which they were so entirely destroyed, that wood is now extremely scarce and dear, except in what is called the chiltern, and so is coal; of consequence fuel bears an exorbitant price. The county is extremely well watered; for besides the Isis, Tame, Cherwell, Evenlode, and Windrush, there is a great number of lesser rivers and brooks. One of the four great Roman ways passes quite thro' this county, entering at the parish of Chinner, and going out at that of Goring. There is another lesser one, that extends between Colnbrook and Wallingford, called *Gremefake*. The county sends nine members to parliament, viz. two for the shire, two for the city, two for the university, two for new Woodstock, and one for Banbury.

OXGANG, or OXGARE, is generally taken, in our old law-books, for 15 acres, or as much ground as a single ox can plough in a year.

OXUCLÆ, in natural history, the name of a genus of fossils of the class of selenites, but of the columnar, not the rhomboidal, kind. Of this genus there are only

Oxford-shire  
|  
Oxucleæ.

**Oxus** only two known species: 1. A fine kind with thin flakes and transverse filaments, found in the clayey banks of the river Nen, near Peterborough in Northamptonshire; and, 2. A dull kind with thick plates and longitudinal filaments. This is not uncommon in Yorkshire, and lies sometimes in a yellow and sometimes in a blue clay.

**Oxyd.**

**OXUS**, or **JIHUN**, a large river of Asia, much taken notice of in Ancient histories, but does not rise in the north of India, as most authors affirm; for, according to the best and latest maps made by those who have been upon the spot, it ran a course of about 260 miles from the Caspian Sea to the lake Aral, whose dimensions have lately been discovered, and is but very lately known to the Europeans; but, as it passes through a desert country abounding with sands, the inhabitants so diverted its course, that the old channel can hardly be discovered.

**OXYCRATE**, in pharmacy, a mixture of vinegar and water, proper to alluage cool and refresh. The usual proportion is one spoonful of vinegar to five or six spoonfuls of water.

**OXYD**, is the term used in the new chemical nomenclature to express a very numerous class of bodies formed by the union of certain bases with a smaller proportion of oxygene than what is necessary for their conversion into acids. (See **OXYGENE**). The most remarkable of these bodies are what were formerly called metallic calces, and have for their base some metallic substance. It is in this state that metals are contained in their ores, from which they are extracted, and converted into the reguline or metallic form, by the process called *reduction*. Metals are converted into oxyds by combustion, and by solution in acids; and many of them assume this form from the action of the atmosphere alone, but more readily when this is assisted by moisture. During their conversion into oxyds, metals lose their splendor, and, acquiring a considerable increase of absolute weight, put on an earthy, pulverulent appearance. It has of late been supposed that all earths are metallic oxyds, and that all of them would be capable of reduction, were we possessed of any body for which oxygene had a stronger elective attraction than that by which it is kept in conjunction with the bases of these supposed oxyds. But this opinion, being perfectly unsupported by experiment, cannot be admitted in a science which, like the chemistry of the present day, aspires to demonstration.

The term oxyd, however, is not confined to the combinations of metals with oxygene, but expresses that first degree of oxygenation in all bodies which, without converting them into acids, causes them to approach to the nature of salts; and of these there is a prodigious variety; as the oxyd of phosphorus, which is the white concrete substance into which that body is converted by combustion; the oxyd of azote, or nitrous air of Dr Priestley; and a great many others. Most of the oxyds from the vegetable and animal kingdoms have bases compounded of different simple combustible bodies. Thus sugar, all the gums, mucus, and starch, are vegetable oxyds; the bases of which are hydrogen and carbone, combined in various proportions. We find accordingly, that all these bodies are, by farther additions of oxygene, convertible into acids; and it is probable that these acids differ from

each other only in the proportion of the hydrogen and carbone in their bases. The bases of the animal oxyds are still more complicated; all, or most of them, consisting of various combinations of azote, phosphorus, hydrogen, carbone, and sulphur. See **CALX**, **CHEMISTRY**, and **TABLE of CHEMICAL NOMENCLATURE**.

**Oxydation,**  
**Oxygene.**

**OXYDATION**, is a term employed by the later chemists to express the process by which bodies are converted into oxyds; and it is allowed on all hands to be exactly similar to combustion. The nature of this process has been much disputed; and the question on this subject involves in itself great part of the controversy between the followers of the immortal Stahl and the justly celebrated Lavoisier, the founders of the phlogistic and antiphlogistic theories, which have for some years divided the chemical world. A view of this question, sufficiently distinct, may be taken from the case of metals and their oxyds. Metallic calces (*oxyds* say the phlogistians) are simple bodies, which, when united with phlogiston, form metals. The process of *reduction* consists in exposing the ores of metals to an intense heat in contact with some inflammable body, most commonly charcoal. During this operation, say they, the charcoal being inflamed, parts with its phlogiston, which is immediately absorbed by the calx and a metal is formed. Lavoisier and his followers, on the contrary, contend that metals are simple bodies; but that in the state of oxyds, that is, as they commonly exist in their ores, they are combined with oxygene. But as oxygene at a high temperature is more strongly attracted by charcoal than by most metals, during the process of reduction the oxyd is decomposed, and the oxygene unites with the charcoal to form carbonic acid, leaving the regulus or metal free. On this point hinges the great question, the decision of which must materially affect almost every part of chemical theory. Without presuming to decide between these two opinions, the former of which is still supported by one or two chemists of the first rank, we agree with Dr Black in thinking that, though there still remain a few facts which have not been thoroughly explained on antiphlogistic principles, this theory is much more simple, and better supported by facts, than any that preceded it. It has this great advantage over the doctrine of Stahl, that it requires not the supposition of an arbitrary body, which does not affect our senses, and of the existence of which we have not even a shadow of proof. Perhaps we may farther venture to assert, that though it may be extremely difficult, or even impossible, to refute the phlogistic theory, influenced as we have all been by a strong prejudice in its favour; yet had it been brought forward for the first time, when our knowledge had arrived at a point which it now holds, it would never have generally been received. See **CALCINATION**, **CHEMISTRY**, **COMBUSTION**, **INFLAMMATION**.

**OXYGENE**, a term adopted in the new chemical nomenclature to express the acidifying principle; from *εξος* "acid," and *γενειναι* "to generate." It is not found naturally in a separate state, but always combined or mixed with some other substance. In its aeriform or elastic state, it is called by the French chemists *oxygeneus gas*, and is the same as the *dephlogisticated air* of

Oxygene  
||  
Oyster.

Priestley and Cavendish, the *empyrean air* of Scheele, the *vital air* and *pure air* of other modern chemists. It was called *déphlogisticated* by the followers of Stahl's doctrine, who imagined it to be air deprived of phlogiston; the epithet of *empyrean* was given to it by Mr Scheele, who first discovered it to be the only constituent part of the atmosphere which contributes to support inflammation or combustion. He made many curious experiments on inflammation, and was the first who completely analysed common air, showing it to consist of 27 parts of empyreal, 72 of soul, and 1 of fixed air. He found, that these 27 parts only were consumed by a burning body; and that these, during the act of combustion, were united and combined with the inflammable body burnt in them, so as to form a compound no longer combustible. Lavoisier extending these experiments, found that the body, thus produced by empyreal air, being combined with the matter of the inflammable body burnt in it, was, in many cases, an acid; in consequence of which property, he gave this air the name of *oxygene*, i. e. "the generator of acidity." He was perhaps too hasty in adopting this name; for the same air is found in combination with inflammable matter, forming compounds that are by no means acid, of which we shall content ourselves with producing only one example, namely *water*, which is the compound resulting from the combination of this air with inflammable air. See WATER.

Common atmospheric air was found by Scheele to promote animal life in a manner somewhat similar to its promoting combustion. He extended his experiments to this subject also; and he concludes, that this empyreal air is the only part of the atmosphere which is capable of supporting animal life, and that no animal can exist a minute without it. In consequence of this property it has been called *vital air*. Since, however, it is absolutely necessary for the support both of combustion and of animal life, and since neither of these can exist without it, both the terms *empyrean* and *vital* are deficient, expressing only certain properties of this elastic fluid (which may be also said of the word *oxygene*); and hence some later chemists have suggested the propriety of designing it by the name of *pure air*. See COMBUSTION, INFLAMMATION, CHEMISTRY, AIR, WATER.

OXYGLYCU, a species of drink prepared of the sweetest honey-combs macerated and boiled. The combs, from which all the honey has been expressed, are put into a pot with pure water, and boiled till they seem to have deposited all their contained honey in the water. This liquor is to be kept; and, when diluted with cold water, is to be drank in the summer-time, in order to remove thirst.

OXYMEL, in pharmacy, a composition of vinegar and honey. See PHARMACY.

OYER, in law-books, seems to have been anciently used for what is now called *giffes*. See ASSISE.

O Yes, a corruption of the French OYEZ, *Hear ye*; a term or formula frequently used by the criers in our courts on making proclamations, or to enjoin silence.

OYSTER, in zoology. See OSTREA.

OYSTER-Catcher. See HÆMATOPUS.

OYSTER-Fishery. See OYSTER-FISHERY and OSTREA.

OYSTERS, *Fossile*. The largest that is known of

*fossile* oysters is that near Reading in Berkshire. They are entirely shaped, and have the same substance with the recent oyster-shells; and yet since the oldest histories that mention the place give an account of them, we must suppose they have lain there for a long time. They extend over no less than six acres of ground; and just above them is a large stratum of a greenish loam, which some writers call a green earth, and others a green sand. It is composed of a crumbly marle, and a large portion of sand. Under them is a thick stratum of chalk. They all lie in a level bed; and the strata above the shells are natural, and appear never to have been dug through till the time of finding the shells.

The oyster-shells and a green earth united make a stratum of about two feet thick; and over this there is a much thicker stratum of a bluish and a very brittle clay; but neither has this ever been dug through, except where the shells are found. This is vulgarly denominated *piercy-clay*, and is esteemed useless. This clay-bed is about a yard deep, and above it is a stratum of fuller's earth, about two feet and a half deep; it is extremely good, and is used by the clothiers. Over this there lies a stratum of a fine white sand, unmixed either with the clay or fuller's earth: this is near seven feet deep, and above it is a stratum of a stiff red clay, of which tiles are made. This is again covered with a little vegetable mould; the depth however of this stratum of tile-clay cannot be ascertained, on account of the unevenness of the hill. These oysters are occasionally found whole, but most frequently in single shells. When they are in pairs, there is generally some of the green sand found within them: they seldom stick very fast together; so that unless very carefully taken up, it is not easy to preserve them in pairs.

OYSTER-Shells, an alkali far more powerful than is generally allowed, and are in all probability much better medicines than many of the more costly and pompous alkalis of the same class. The proof of alkalis is in their solution by acid spirits; and Mr Homberg found, that they dissolved far easier in acids of nitre and sea salt than either pearls or coral, or indeed than any of the rest. This he supposes to be owing to their containing in the body of the shell a large portion of sal-salsus, which is easily perceived upon the tongue, and which keeps the whole substance of the shell in a sort of half dissolved state. These shells are found to produce very sensible effects on the stomach, when it is injured by acid humours; and Mr Homberg thinks, that this easiness of solution is a great argument for their good effects, and that the quantity of sal-salsus which it contains, contributes not a little towards it; for we are not to look upon that as a salt merely, but as a salt of a peculiar nature, formed of sea-salt by the organs of the animal, and the several fermentations it undergoes in the body of it, in the same manner as the nitrous and other salts of the earth cease to be nitrous, &c. whenever they become blended with the juices of plants and form with them a salt peculiar to that plant; which is evidently the case as far as respects this salt, it being plainly of a more penetrating taste, and of a different smell, from the salt left by the sea-water between the several external scales or flakes of the shell.

shell. Oyster-shells being thus found by Mr Homberg to be a very valuable medicine, and as one of the common methods of preparing them is by calcination, which, he observes, considerably impairs their virtues, he gives the following method of preparing them for taking inwardly, which he himself always used. Take the hollow shells of the oysters, throwing away the flat ones, as not sufficiently good: make them perfectly clean, and then dry them in the sun; when they appear dry, beat them to pieces in a marble mortar: they will still be found to contain a large quantity of moisture; lay them therefore again in the sun till perfectly dried, and then finish the powdering them, and sift the powder through a fine sieve. Give 20 or 30 grains of this powder every morning, and continue it three weeks or a month. See CHEMISTRY, n<sup>o</sup> 1087.

OZENA, a foul and malignant ulcer of the nose, distinguished by its fetor, and often accompanied with a caries of the bones of the nose.

OZANAM (James), an eminent French mathematician born at Boligneux in Bresse, in 1640, of a wealthy family. His father gave him a good education, and designed him for the church: but some mathematical books falling into his hands, inspired him with a love for that science; and though he had no master to instruct him, he made such progress in it, that, at 15 years of age, he wrote a piece in mathematics, which he thought proper to insert in the works he afterwards published. He at length taught that science at Lyons; and his mathematical lessons brought him in a considerable revenue, till the year 1701: at which period a war breaking out on the succession to the crown of Spain, he lost almost all his scholars, and was reduced to a very melancholy situation; and his wife dying the same year, he was so afflicted, that he never perfectly recovered it. In 1702 he was admitted into the Royal Academy of Sciences; and died of an apoplexy in 1717.—He was of a mild and serene temper, of singular generosity, and of a cheerful disposition.—He would not allow himself to know more of religion than the common people. He used to say, that “it was the business of the doctors of the Sorbonne to dispute, of the Pope to decide, and of a mathematician to go to heaven in a perpendicular line.” His works are very numerous and have met with the approbation of the learned. The principal are, 1. Practical geometry, 12mo. 2. A mathematical dictionary. 3. A course of mathematics, 5 vols, 8vo. 4. Mathematical and philosophical recreations, the most complete edition of which is that of 1724, in 4 vols, 8vo. 5. An easy method of surveying. 6. New elements of algebra, a work much commended by Monf. Leibnitz. 7. Theoretical and practical perspective, &c.

OZELL (John), a well-known translator, educated in Christ's Hospital, was possessed of a competent fortune, and always enjoyed good places, be-

ing auditor-general of the city and bridge accounts, of St Paul's cathedral, and of St Thomas's hospital. Notwithstanding his attention to business, he still retained a love for polite literature: and though he did not appear as an original author, yet having made himself master of most of the living languages, he favoured the world with many translations from these, as well as from the Latin and Greek; which, if they are not the most elegant, are generally faithful and true to the originals. He died in the year 1743.

OZIAS, in sacred history, the son of Micah, of the tribe of Simeon, one of the governors of Bethulia when it was besieged by Holofernes. He vigorously supported the siege against this general, and received Achior into his house, when he had been driven from the Assyrian camp. Finding however at length that the city was reduced to great necessity for water, and that the people mutinied against him, he promised to surrender the place in five days, if in that time God did not send them relief. Judith (vi. vii. viii. ix. and x.) being informed of this resolution, sent to speak with Ozias and the other leading men of the city; made a prudent remonstrance upon their seeming to prescribe a time to the Lord in which he must succour them; encouraged them to patience; and without discovering her design, told them that she would go out in the night. Ozias being at the gate of the city when Judith departed, opened it to her and waited in the city for the success of her undertaking, praying with her people to god that he would be pleased to deliver them. See the article JUDITH.

OZLEWORTH, in England, in Gloucestershire, about 18 miles from Gloucester. It is remarkable for nothing but that in one year, during the reign of Queen Elizabeth, there were no less than 231 foxes killed at it.

OZOLÆ, or OZOLI, a people who inhabited the eastern parts of Ætolia which were called *Ozolea*. This tract of territory lay at the north of the bay of Corinth, and extended about 12 miles. They received their name from the bad stench (οἶστος) of their bodies and clothes, which were the raw hides of wild beasts. Some derive it from the stench of the stagnated water in the neighbouring lakes and marshes. According to a fabulous tradition, they received their name from a very different circumstance: During the reign of a son of Deucalion, a bitch brought into the world a stick instead of whelps. The stick was planted into the ground by the king, and it grew up to a large vine, and produced grapes, from which the inhabitants of the country were called *Ozoleæ*, not from οἶστος, “to smell bad,” but from οἶστος, “a branch or sprout.” The name *Ozoleæ*, on account of its indelicate signification, was highly disagreeable to the inhabitants; they therefore exchanged it soon for that Ætolians.

Ozias  
||  
Ozolæ.

## P.

## P A C

**P** the 15th letter and 11th consonant of the alphabet; the sound of which is formed by expressing the breath somewhat more suddenly than in forming the sound of *b*; in other respects these two sounds are pretty much alike, and are often confounded one with another. When *p* stands before *t* or *f*, its sound is lost; as in the words *psalms*, *psychology*, *ptolemaic*, *pisian*, &c. When placed before *b*, they both together have the sound *f*; as in *philosophy*, *physic*, &c.

*P* and *B* are so like each other, that Quintilian declares, that in the word *obtinuit*, his reason required him to put a *b*, but that his ears could hear nothing but a *p*, *optinuit*: hence in ancient inscriptions, and old glossaries, it appears that these two letters have often been confounded. Several nations still pronounce one for the other, the Welch and Germans particularly, who say, *ponum vinum*, for *bonum vinum*. Plutarch observes, it was usual for those of Delphi to say *βαρεν* for *παρεν*, *βινρον* for *πινρον*; and among the Latins, as often as an *s* followed, the *b* was changed into a *p*, as *scribo*, *scripsi*.

As an abbreviation, *P* stands for *Publius*, *Pondo*, &c. *P. A. DIG.* for *Patricia Dignitas*; *P. C.* for *Patres Conscripti*; *P. F.* for *Publii Filius*; *P. P.* for *Propositum*, or *Propositum publice*; *P. R.* for *Populus Romanus*; *P. R. S.* for *Prætoris sententia*, *P. R. S. P.* for *Præfes provincie*.

*P. M.* among astronomers, is frequently used for *post meridiem*, or "afternoon;" and sometimes for *post mane*, "after the morning, i. e. after midnight." *P* was also used among the ancients as a numeral letter, signifying the same with the *G*, viz. a hundred; according to the verse of Uguccio,

*P similem cum G numerum monstratur habere.*

Though Baronius thinks it rather stood for seven.

When a dash was added a top of *P*, it stood for four hundred thousand.

St Jerome observes, on Daniel, that the Hebrews had no *P*; but that the *ph* served them instead thereof; adding that there is but one word in the whole Bible read with a *P*, viz. *apadno*. The Greek *π* signified 80. On the French coins, *P* denotes those that were struck at Dijon.

In the Italian music, *F* stands for *piano*, or "softly;" and *P. P. P.* for *pianissimo*, or "very softly."

Among physicians, *P* stands for *puzi*, or the eighth part of an handful; *P. Æ.* *partes æquales*, or equal parts of the ingredients; *P. P.* signifies *pulvis patrum*, or Jesuit's bark in powder; and *ppt.* *preparatus* or prepared.

**PABULUM**, among natural philosophers, the same with **FUEL**.

**PACA**, see **MUS**, p. 465.

**FACE**, a measure taken from the space between

## P A C

the two feet of a man in walking; usually reckoned two feet and a half, and in some men a yard or three feet. The geometrical pace is five feet; and 60,000 such paces make one degree on the equator.

**PACE**, in the manege, is of three kinds, viz. walk, trot, and gallop; to which may be added an amble, because some horses have it naturally.

Horses which go shuffling, or with mixed paces between the walk and amble, are for the most part of no value; which commonly proceeds from their fiery temper, but sometimes from a weakness in their reins or legs.

**PACE** (Richard), a learned Englishman, born about the year 1482. He was educated at the charge of Thomas Langton bishop of Winchester, whom he served as an amanuensis, and afterwards entered into the service of cardinal Bainbridge. His accomplishments rendered him so acceptable to Henry VIII. that he made him secretary of state; and, entering into orders, he was admitted prebendary in the church of York, archdeacon of Dorset, and dean of St Paul's, &c. which preferments were conferred on him during his absence on foreign embassies. In 1524 he was sent to Rome on the death of Pope Leo X. to solicit the papal chair for cardinal Wolsey; but a new pope was elected before his arrival, a circumstance that proved the epocha of his troubles. He fell under the displeasure of the disappointed cardinal; and being soon after employed as ambassador at Venice, he was so neglected and hardly used, that he was seized with a frenzy: upon which the king ordered him home; and being carefully attended by the physicians at the king's command, he was in a short time restored to the use of his reason, and then applied himself to the study of the Hebrew tongue. Being now introduced to his Majesty, he remonstrated against the cardinal's cruelty: who being ordered to clear himself, summoned Pace before him, sitting in judgment with the duke of Norfolk and others; who condemned Pace, and sent him to the Tower; where he remained two years, till he was discharged by the king's command.—When he was enlarged, he resigned his deaneries, and died in retirement at Stepney in 1532; after having wrote several works. There is an elegant and just character of him by Leland, written upon his return from Venice. He was much esteemed by the learned men of his time, especially Sir Thomas More and Erasmus. The latter had a great opinion of Pace on account of his candour and sweetness of temper; so that he was much afflicted at his misfortunes, and could never forgive the man that caused them. Stow gives him the character of a right worthy man, and one that gave in council faithful advice: learned he was also, says that antiquary, and endowed with many excellent parts and gifts of nature; courteous, pleasant, and delighting in music; highly in the king's favour, and

Pachamac  
|  
Pacos.

and well heard in matters of weight. There is extant a remarkable letter of his to the king, written in 1527, wherein he very honestly gives his opinion concerning the divorce; and Fiddes observes, that he always used a faithful liberty to the cardinal, which brought him at last to confinement and distraction.

**PACHAMAC**, a valley of Peru, in South America, ten miles south of Lima; celebrated for its pleasantness and fertility, but more on account of a magnificent temple built by the Incas of Peru, to the honour of their god. When the Spaniards conquered Peru, they found immense riches therein.

**PACHODECARHOMBIS**, in natural history, the name of a genus of fossils, of the class of *selenitæ*. The word is derived from the Greek *παχυς* thick, *δεκα* ten, and *ρhomβος* a rhombus, and expresses a thick rhomboidal body composed of ten planes. The characters of this genus are, that the *selenitæ* of it consist of ten planes; but as the top and bottom in the leptodecarhombes, or most common kind of the *selenitæ*, are broader and larger planes than any of the rest, the great thickness of this genus, on the contrary, makes its four longer planes in all the bodies of it, meeting in an obtuse angle from its sides, its largest planes. There are four species of it.

**PACHSU**, a small island in the Mediterranean sea; near the coast of Epirus, and in European Turkey. It lies south of Corfu, and is subject to Venice.

**PACIFIC OCEAN**, that vast ocean which separates Asia from America. It is called *Pacific*, from the moderate weather the first mariners who sailed in it met with between the tropics: and it was called *South Sea*, because the Spaniards crossed the isthmus of Darien from north to south when they first discovered it; tho' it is properly the Western ocean with regard to America.

Geographers call the South Sea *Mare Pacificum*, "the Pacific Ocean," as being less infested with storms than the Atlantic; but M. Frezier affirms it does not deserve that appellation, and that he has seen as violent storms therein as in any other sea: but Magellan happening to have a very favourable wind, and not meeting with any thing to ruffle him when he first traversed this vast ocean in 1520, gave it the name which it has retained ever since. Maty, however, adds, that the wind is so regular there, that the vessels would frequently go from Acapulco to the Philippine Islands without shifting a sail.

**PACK**, in commerce, denotes a quantity of goods made up in loads or bales for carriage. A pack of wool is 17 stone and 2 pounds, or a horse's load.

**PACKAGE**, is a small duty of one penny in the pound, paid for all goods not particularly rated.

**PACKET**, or *PACKET Boat*, a vessel appointed by the government to carry the mail of letters, packets, and expresses from one kingdom to another by sea in the most expeditious manner. Thus, the packet-boats, under the direction of the post-master-general of Great Britain, carry the mails from Dover to Calais, from Falmouth to Lisbon, from Harwich to Helvoetsluys, and from Parkgate to Dublin. See **POST**.

**PACOS**, in zoology, a name given to a species of

camel, commonly though improperly reckoned a species of sheep; and known among many by the name of the *Indian sheep* or *Peruvian sheep*. See **CAMELUS**, p. 60.

This creature has been accounted a sheep, because its hair is so long as to resemble wool, and it is prodigiously thick, its head and neck alone having more wool on them than the whole body of our largest sheep. Its body is clothed in the same proportion with a woolly hair equally fine.

**PACTOLUS** (anc. geog.), a river of Lydia, called *Chrysoorhoas*, from its rolling down golden sand, according to Herodotus, Plutarch, Pliny, and Strabo; rising in mount Tmolus (Strabo). From this river Cræsus is thought to have had all his riches. In Strabo's time it ceased to roll down any. It ran through Sardes; after which it fell into the Hermus, and both together into the Ægean sea at Phocæa in Ionia. A river celebrated by Virgil, Ovid, Lucon, Lycophron, Horace, Apollonius.

**PACUVIUS** (Marcus), of Brundisium in Calabria, a tragic poet in high reputation about the year of Rome 600. He was nephew of Ennius; published several theatrical pieces, though we have only some fragments of his poetry remaining; and died at Tarentum at above 90 years of age.

**PADAN-ARAM** (Bible), literally the *plains of Aram*, or *Syria*; translated by the Seventy simply *Mesopotamia*, or *Mesopotamia of Syria*; by the vulgate, *Syria*; the Syrians on this and on the other side of the Euphrates, not differing remarkably from each other in language and manners, as Josephus allows.

**PADDOC**, or *Paddock-Course*, a piece of ground encompassed with pales or a wall, and taken out of a park, for exhibiting races with greyhounds, for plates, wagers, or the like.

A paddock is generally a mile long, and a quarter of a mile broad: at the one end is a little house where the dogs are to be entered, and whence they are slipped; near which are pens to inclose two or three deer for the sport. Along the coast are several posts, viz. the low post, which is 160 yards from the dog-house and pens; the quarter of a mile post, half-mile post, and pinching post: besides the ditch, which is a place made to receive the deer, and preserve them from farther pursuit. And near this place are seats for the judges chosen to decide the wager.

The keepers, in order to slip the dogs fairly, put a falling collar upon each, slipped round a ring; and the deer being turned loose, and put forward by a teaser, as soon as he is arrived at the low-post, the dog-house door is thrown open, and the dogs slipped. If now the deer swerve so much, as that his head is judged nearer the dog-house than the ditch before he arrived at the pinching-post, it is no match, and must be run over again three days after: but if the deer runs straight beyond the pinching-post, then that dog which is nearest when he swerves, or is blunched by any accident, wins the match; but if no such swerve happens, then the match is won by the dog who first leaps the ditch.

**PADERBORN**, a duchy of Germany in the circle of Westphalia, has the county of Lippe on the north and west; Hesse Cassel and Waldeck, on the south: and

Pactolus  
|  
Paderborn.

Paderborn

and Munster, with the duchy of Westphalia, on the west. Its greatest length from east to west is about 40 miles, and its breadth where widest 30. Some parts of it yield good pasture and breed abundance of cattle; but it is not very fruitful in corn. There is a heath called the *Senne* or *Sende*, of great extent, but very barren and desolate. There are however, good iron mines in the country, with salt and medicinal springs, plenty of deer and other game; and it is watered with several rivers abounding with fish, as the *Wefer*, the *Dimer*, the *Bever*, the *Nette*, the great *Emmer*, the *Lippe*, the *Alme*, and the *Pader*. It contains 54 parishes, in which are 25 market-towns and 16 monasteries. The Roman Catholic is the predominant religion of the country, yet there are also many Protestants in it. The bishopric was erected by Charlemagne, towards the close of the eighth century; and the cathedral was consecrated by Pope Leo in person, anno 796. The bishop is sovereign of the country, a prince of the empire, and suffragan of the archbishop of Mentz. His revenue is about 30,000 pounds a year, and he is able to raise 3000 men. In the matricula, his assessment is 18 horse and 34 foot, or 352 florins monthly in lieu of them. Towards the charges of the sovereign courts of the empire, he pays for each term 162 rix dollars and 29 kruitzers. The chapter consists of 24 capitular canons, who must prove their noble extraction by four descents. The arms of the bishopric are a cross or, in a field gules. For the government of it, and the administration of justice, there are several councils and colleges under the bishop. Here are also a hereditary marshal, sewer, cup-bearer, chamberlain, steward, and purveyor. It was in this bishopric that Quintilius Varus, with the Roman army under his command, was routed by the Germans under Arminius.

**PADERBORN**, the capital of the above bishopric. It stands 40 miles north-west of Cassel, 50 south-east of Munster, and 60 south-west of Hanover; being a large, populous, well-built, and well-fortified city. Its name is compounded of *pader*, a rivulet, which rises just under the high altar of the cathedral, and *born*, i. e. a spring. It was one of the Hanse-towns; and, till 1604, an imperial city. The cathedral is a grand fabric, inferior to few in the empire. There is a gold crucifix in it of 60 pounds weight, presented by Otho II. The university, of which the Jesuits have the direction, was founded in 1592, and the walls were built in the beginning of the 11th century. In 1530 an attempt was made to introduce Lutheranism; but 16 of the principal citizens who had embraced it were executed, and the rest obliged to abjure it. Duke Christian of Brunswick carried off from hence, in 1692, the silver images of the twelve apostles, and the silver coffin of St Lotharius; and had them coined into money, with this inscription, *God's Friend, the Priests Enemy*. The trade of this town, though formerly great, is now inconsiderable; and the inhabitants subsist mostly by agriculture and breeding of cattle. Though the bishop has a palace in the city, he resides (when he vouchsafes to visit this country, which is seldom, having other and more valuable benefices) at Neuhaus, seven miles off, where he has a magnificent castle. Charlemagne and other em-

perors sometimes resided here, and held diets of the empire.

**PADOGI**, a punishment used in Russia. The body of the criminal is stripped to the waist, and then laid upon the ground; one slave holds the head of the person to be punished between his knees, and another the lower part of the body; then rods are applied to the back till some person gives notice to desist, by crying out, enough. This punishment is considered in Russia merely as a correction of the police, exercised on the soldier by military discipline, by the nobility on their servants, and by persons in authority over all such as are under their command. After the accession of Elizabeth to the throne of Russia, the punishments were reduced to two kinds, viz. the padogi and Knout.

**PADUA**, an ancient, large, and celebrated city of Italy, with an university and a bishop's see. It is also capital of the Paduano; but is much less considerable than it was formerly: for it now contains no more than 30,000 inhabitants, whereas it formerly had 100,000, and many of the houses are gone to ruin: however, the hall where justice is administered is a superb structure. The cathedral church, and the college of the university, are in that part called the *Old Town*; and there are piazzas under all the houses, where persons may walk without being exposed to the weather. The garden of the university is curious, on account of the number of plants. Here a student may take his degrees, let him be of what sect of Christianity he will; nay, though he should be a Jew or a Turk. The patron of this city is St Anthony, who lies in the cathedral; they have such a veneration for him, that the beggars do not ask charity in the name of God, but for the love of St Anthony. The Jews live in a distinct part of the city; and the neighbouring mountains produce excellent wine and oil, with delicious fruit. It was taken by the Venetians in 1706. It is seated on the rivers Brenta and Bachiaglione, in a fine plain; and is about seven miles in circumference. E. Long. 11. 55. N. Lat. 45. 24.

**PADUAN**, among the medalists, a modern medal struck in imitation of the antique, or a new medal struck with all the marks and characters of antiquity. This name is properly applicable to those medals only that were struck in the seventh century by an Italian painter born at Padua; who succeeded so well in the imposture, that the best judges are at a loss to distinguish his medals from the genuine ones. Though it is frequently used in general for all medals of this kind.

**PADUANO**, a small province of Italy, in the territory of Venice, bounded on the east by the Dogado, on the south by the Polesino di Rovigno, on the west by the Veronese, and on the north by the Vicentino. Its soil is well-watered; and is one of the most fertile in Italy. The province is about 40 miles in length, and 35 in breadth. Padua is the capital town.

**PADUS**, anciently called *Eridanus*, especially by the Greeks; a river famous for the fable of Phaeton, (Ovid). It rises in mount Vesulus, in the Alpes Cothiae, from three springs, dividing the Cisalpine Gaul into the Transpadana and Cispadana, (Strabo); and, swelled by other rivers falling into it on each side from the

Padogi  
||  
Padus.

Padus  
|  
Pag an.

the Alps and Apennines, it discharges itself with a course from west to east, at seven mouths, into the Adriatic (Mela). The lake thro' which it discharges itself into the sea, is called by the natives the *Seven Seas*. Now the *Po*.

PADUS, in botany. See PRUNUS.

PÆAN, among the ancient pagans, was a song of rejoicing sung in honour of Apollo, chiefly used on occasions of victory and triumph. See APOLLO.

PÆAN, in ancient poetry, a foot consisting of four syllables; of which there are four kinds, the pæan primus, secundus, &c.

The pæan primus consists of one long syllable and three short ones, or a trochæus and pyrrhichius, as *temporibus*; the pæan secundus consists of a short syllable, a long, and two short, or an iambus and a pyrrhichius, as *potentia*; the pæan tertius consists of two short syllables, a long and a short one, or a pyrrhichius and a trochæus, as *animatus*; the pæan quartus consists of three short syllables and a long one, or a pyrrhichius and iambus, as *celerrimus*.

PÆDEROTA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, *Contortia*. The berry is empty, brittle, and dispersuous; the style bifid.

PÆDO BAPTISM; infant baptism, or that conferred on children; from *παις* *infant*, and *βαπτισμος* *baptism*. This has been the subject of great controversy in the church. See ANABAPTISTS, BAPTISTS, &c.

PÆONIA, PIONY: A genus of the digynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 26th order, *Multiflora*. The calyx is pentaphyllous; the petals five; there are no styles; the capsules are polyspermous. There are two species, both of them very hardy, and will flourish in any common soil. They are large herbaceous flowery perennials, with tuberous roots, sending up strong annual stalks from one to three feet in height; terminated by very large flowers of a beautiful red colour, and much larger than any rose. The common officinal, or male piony, also is remarkable for its capsules turning backward, opening and displaying their red inside, together with the numerous seeds, in a singularly agreeable order, appearing very ornamental after the flower is past. The plants may be propagated either by parting the roots or by seed. This plant was formerly celebrated in nervous distempers, but the present practice pays very little regard to it.

PÆSTUM, called *Posidonia* by the Greeks, a town of Lucania, on the Sinus Pæstinus; an ancient colony prior to the first Punic war, according to Livy; but later, according to Velleius. *Pæstana roses* were in great esteem, and produced twice a-year (Virgil. Ovid).

PAGAN (Blaise Francois Compte de), an eminent French mathematician, was born at Avignon in Provence March 3. 1604; and took to the profession of a soldier at fourteen, having been bred to it with the greatest care. In 1620 he was engaged at the siege of Caen, in the battle of Pont de Ce, and the reduction of the Navareins, and the rest of Bearn; where he signified himself, and acquired a reputation far surpassing his years. He was present, in 1621, at the siege of St John d'Angeli, as also that of Clarac and

Montauban, where he lost his left eye by a musket-shot. At this siege he had another loss, which equally afflicted him, viz. that of the constable of Luynes, who died there of a scarlet fever. The constable was a near relation, and had been his patron at court. He did not, however, sink under the misfortune, but on the contrary took fresh spirits from the necessity he was now in of trusting solely to himself. Accordingly there happened after this time neither siege, battle, nor any other occasion, in which he did not signalize himself by some effort of courage and conduct. At the passage of the Alps, and the barricade of Suza, he put himself at the head of the forlorn hope, consisting of the bravest youths among the guards; and undertook to arrive the first at the attack, by a private way which was extremely dangerous; when, having gained the top of a very steep mountain, he cried out to his followers, "See the way to glory!" He slipped along this mountain; and, his companions following him, they came first to the attack, as they wished to do. They immediately began a furious assault; and, the army coming to assist, they forced the barricades. He had afterwards the pleasure of standing on the left hand of the king, when his majesty related this heroic action to the duke of Savoy with the deserved commendations, in the presence of a very full court. When the king laid siege to Nancy in 1633, our hero had the honour to attend his sovereign, in drawing the lines and forts of circumvallation. In 1642 his majesty sent him to the service in Portugal, in the post of field marshal. In this same year he unfortunately lost his eye sight by a distemper. But though he was thus disabled from serving his country with his conduct and courage, he reassumed, with greater vigour than ever, the study of the mathematics and fortification; and, in 1645, gave the public a treatise on this latter subject. It was allowed by all who understood the science, that nothing had then appeared that was preferable to it; and indeed whatever improvements have been made since, they have perhaps been derived chiefly from this treatise, as conclusions from their principles. In 1651 he published his Geometrical Theorems, which show a perfect knowledge of all the parts of the mathematics. In 1655 he printed A Paraphrase, in French, of the Account, in Spanish, of the River of the Amazons, by Father de Rennes, a Jesuit; and, we are assured, that, though blind, he drew the chart of that river and the parts adjacent, which is seen in this work. In 1657 he published The Theory of the Planets, cleared from that multiplicity of eccentric circles and epicycles, which the astronomers had invented to explain their Motions. This work distinguished him among astronomers as much as that of fortification did among engineers; and he printed, in 1658, his Astronomical Tables, which are very succinct and plain. Few great men are without some foible: Pagan's was that of a prejudice in favour of judicial astrology; and though he is more reserved than most others, yet we cannot put what he did on that subject among those productions which do honour to his understanding. He was beloved and respected by all persons illustrious for rank as well as science; and his house was the rendezvous of all the polite and worthy both in city and court. He died at Paris Nov. 18. 1665; and was never married. The king ordered

Page.

Pagan  
Pagi.

ordered his first physician to attend him in his illness, and gave several marks of the extraordinary esteem which he had for his merit.

He had an universal genius; and, having turned himself entirely to the art of war, and particularly to the branch of fortification he made extraordinary progress in it. He understood mathematics not only better than is usual for a gentleman whose view is to push his fortune in the army, but even to a degree of perfection superior to that of the ordinary masters who teach that science. He had so particular a genius for this kind of learning, that he obtained it more readily by meditation than by reading authors upon it; and accordingly spent less time in such books than he did in those of history and geography. He had also made morality and politics his particular study; so that he may be said to have drawn his own character in his *Homme Heroïque*, and to have been one of the completest gentlemen of his time. Louis XIII. was heard to say several times, that the Count de Pagan was one of the most worthy, best turned, most adroit, and most valiant men in the kingdom.—That branch of his family, which removed from Naples to France in 1552, became extinct in his person.

PAGAN, a heathen, gentile, or idolater; one who adores false gods. See MYTHOLOGY.

PAGANALIA, certain festivals observed by the ancient Romans in the month of January. They were instituted by Servius Tullius, who appointed a certain number of villages (*pagi*), in each of which an altar was to be raised for annual sacrifices to their tutelary gods; at which all the inhabitants were to assist, and give presents in money according to their sex and age, by which means the number of country-people was known. The servants upon this occasion offered cakes to Ceres and Tellus, to obtain plentiful harvests.

PAGANELLUS, in ichthyology. See GobiUS.

PAGANISM, the religious worship and discipline of pagans; or, the adoration of idols and false gods. See IDOLATRY, MYTHOLOGY, and POLYTHEISM.

PAGEANT, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shows, processions, &c.

PAGI (Antony) a very famous Cordelier, and one of the ablest critics of his time, was born at Rogne in Provence in 1624. He took the habit in the convent at Arles in 1641, and was at length four times provincial of his order; but his religious duties did not prevent his vigorous application to the study of chronology and ecclesiastical history, in which he excelled. His most considerable work is, *A Critique upon the Annals of Baronius*; where following the learned cardinal year by year, he has rectified an infinite number of mistakes both in chronology and in the representation of facts. He published the first volume in 1689, dedicated to the clergy of France, who allowed him a pension: the whole was printed after his death, in 4 vols folio, at Geneva, in 1705, by the care of his nephew Francis Pagi, of the same order. He wrote some other things before his death, which happened in 1699, and had the character of an able historian as well as of a learned and candid critic. His nephew Francis, abovementioned, wrote *A Chronological*

*Abridgement of the History of the Popes*, in Latin, 3 vols 4to. Francis had also a nephew Antony Pagi, who added three more volumes to the *History of the Popes*; of which two more were intended, if not executed.

PAGNINUS (Sanctes), an Italian Dominican, eminent for his skill in Oriental languages and biblical learning, was born at Lucca in 1466, and became afterwards an ecclesiastic of the order of St Dominic. He was deeply and accurately skilled in Latin, Greek, Hebrew, Chaldee, and Arabic; but he was particularly excellent in the Hebrew. He applied himself to examine the vulgar translation of the Scriptures; and believing it to be either not of Jerome, or greatly corrupted, he undertook to make a new one from the present Hebrew text; in which he meant to imitate St Jerome, who set about making a new translation at a time when the church would admit no other but the Septuagint. This design of Pagninus so early after the reiteration of letters, seemed a bold one; yet such was the reputation of the man, that it was approved by Pope Leo X. who promised to furnish him with all necessary expences for carrying on the work: and, besides, we find at the beginning of this translation, which was printed at Lyons in 1527, two letters of the succeeding popes, Hadrian VI. and Clement VII. which licensed the printing of it. Pagninus, in his Letters to Pope Clement, for the printing of this translation openly declares, that the Vulgar edition, as it is at present, is not St Jerome's; yet adds, that he has retained in his translation as much of it as he could. It appears by a letter of Picus Mirandula to Pagninus, that he had spent 25 years upon this translation. It is the first modern translation of the Bible from the Hebrew text; and the Jews who read it affirmed, that it agreed exactly with the Hebrew, and was in some respects superior to the ancient translations. The great fault of Pagninus was, that he adhered with too great fervility to the original text; and this scrupulous attachment made his translation, says Father Simon, "obscure, barbarous, and full of solecisms. He imagined, that to make a faithful translation of the Scriptures, it was necessary to follow exactly the letter according to the strictness of grammar. This, however, is quite contrary to his pretended exactness, because two languages seldom agree in their ways of speaking; and therefore, instead of expressing the original in its proper purity, he defaces and robs it of all its ornaments." Father Simon nevertheless allows the great abilities and learning of Pagninus; and all the later commentators and translators of the Scriptures have agreed in giving him his just praise. Huetius, though he thinks Father Simon's criticism of him just and well grounded, yet proposes his manner as a model for all translators of the sacred books: *Scripturæ interpretandæ rationis utilis exemplar proposuit Sanctus Pagninus*. He also translated the New Testament from the Greek, as he had done the Old from the Hebrew, laying the Vulgar all the while before him; and dedicated it to Pope Clement VII. He was author of an Hebrew Lexicon, and an Hebrew Grammar: which Buxtorf, who calls him *vir linguarum Orientalium peritissimus*, made great use of in compiling his. He died in 1536, aged 70. Luther spoke of him and his translations in terms of the highest applause.

PAGO,

Pago.

Pago.

PAGO, an island in the gulph of Venice, separated from the continent of Morlachia by a narrow channel. The ancient geographers have left us no description of it; "though (as Fortis observes) its form (A), extent, and rich produce, unquestionably deserved it." And this is the more unaccountable, as we know the Romans were well acquainted with it; and on the other islands adjoining to it are many vestiges of buildings, inscriptions, tiles, and hewn stones, all sure signs of Roman habitations. Its ancient name was in all probability *Portunata*. "This island (says Mr Fortis\*) is extended from north to south over against maritime Croatia, or the mountain Morlacca. It is about 50 miles long; its breadth is unequal. One particular circumstance distinguishes it from all the other islands of the Adriatic, and is a large internal salt-water lake 15 miles long from south to north, into which the sea enters by a canal not above a quarter of a mile broad in some places. This lake is frequented by the tunny fish, which, when once in, cannot return again to the sea. There are also two smaller lakes on the island; one near Vlassich, abounding in fish, particularly eels; and one near the hamlet of Slabine.

"In this island the winter is dreadfully cold, and the summer scorchingly hot. Those who have been there in the winter time speak of it as a Siberia quite covered with snow and ice, and always exposed to the cold north wind; I, who was there in the hot season, thought it equal to the most scorching parts of the world. The naked rocks, which not only form the organization, but also the superficies of almost all the island; the narrowness of the valleys; the reverberation of the water of the lake, generally quite calm in summer; multiply the heat so prodigiously among those stones, that the vines, which are planted all round the lake, ripen the grapes by the beginning of August: and the few other products that grow there anticipate the usual time of maturity in the same manner. The meteors are exceedingly irregular in the summer time; sudden whirlwinds are frequent, and heavy showers of rain: the last are hurtful to the inhabitants of one part of the island, and favourable to the cultivation of the opposite end.

"They cultivate neither corn nor oil on this island; but it produces plenty of wine, and an immense quantity of salt. The other products are wool, honey, and a little salt fish. The quantity of wine amounts annually, on a medium, to 40,000 Venetian barrels;

Vol. XIII.

and from the husks they distil 2000 barrels of *rakia* or brandy. The salt, in 1663, amounted to 800,000 Venetian *flars*. The salt-works are well contrived and well kept: they extend along a shallow pool, which forms the eastern extremity of the lake within for four miles in length and about half a mile in breadth. On the sides of this fen the best part of the vines lie; but the upper part of the hills on each side is altogether naked and barren; there is not even a sufficiency of fire-wood, and the inhabitants are obliged to provide themselves elsewhere. The soil at the foot of the hills, where the vines are planted, is full of gravel and small stones; and hence the wine is of good quality. The air is not unhealthful, notwithstanding the vicinity of the salt-pits; but the frequent high winds carry off the noxious exhalations. The most considerable product of the island is the salt. The greatest part of the people of Pago live by working in the salt pits, and have a comfortable subsistence regularly paid by the government: it is therefore a very important circumstance for the inhabitants of the city to have a dry summer; and hence the ignorant vulgar look upon rain as a mischief brought upon the country by the force of witchcraft. In consequence of this idea, they elect a friar to exorcise the meteors, and keep the rain off the island. If, notwithstanding the poor friar's endeavours, the summer happens to be rainy, he loses his reputation and his bread; but if two or three dry seasons follow successively, he meets with great reverence and advantage. Part of the salt-works belongs to the government, and the rest to private proprietors; they are meliorated every year; and for that end the public lends money to those proprietors who want it, and who without that assistance could not make the requisite improvements.

"Many vestiges of ancient habitations still remain on the island of Pago, as well as of walled places, which either have been destroyed by the incursions of enemies or by time. Historians say, that the island was often abandoned by its inhabitants; and indeed it is rather to be wondered at how men ever could resolve to settle in so wretched a country. The small number of inhabitants, after so many years of peace and tranquillity under the Venetian government, evidently proves how little the island is really habitable. The town of Pago was built by the Venetians about 300 years ago; and contains upwards of 2000 inhabitants, and all the rest of the island scarcely 900. The difficulty of access to the city of Pago, and the ill accommodation

4 E

commodation

(A) Its figure is indeed remarkably irregular, its breadth being in no proportion to its length; for one of the extremities, called *Punta di Loni*, is above ten miles long, and less than one broad. Almost all the circumference is dismal, without trees or any kind of visible plants or grass, steep, craggy, and uninhabited. On entering the lake through the channel that communicates with the sea, nothing is to be seen either on the right or left but bare hanging rocks, so disfigured on the outside by the violent percussion of the waves, that the stratification is hardly distinguishable. In general, the stone of the island is of the same kind as the Istrian, or *breccia*; and, besides, there are large strata of blue and yellowish sand-stone. The channel, or inward bay of Pago, is not a harbour; on the contrary, it is a very dangerous station, and even inaccessible in winter, when the boreal wind blows with such fury, that the inhabitants of the town dare not stir out of their houses, and much less the few that are scattered over the country. The sky appears always cloudy in that season, by the thick mist that rises from the repercussion of the waves on that long chain of rough and hollow rocks.

Pago,  
Pagod.

commodation as strangers met with, make it very little frequented. Hence the inhabitants are as wild and unpolished as if they lay at the greatest distance from the sea and the commerce of polite people. The gentry, who pretend to show their manners different from those of the vulgar, are truly grotesque figures, both in their dress, behaviour, and insolent pretensions. The ignorance of their clergy is incredible; a priest of the greatest consequence there, and who was thought a man of learning, did not know how Pago was called in Latin. There are two convents of friars in Pago and one of nuns; and several churches, all in very bad order and ill served. At Terra Vecchia also there is a convent of Franciscan monks; a race of men who, under various names and disguises, infest every place where credulous ignorance can be persuaded to maintain the idle and superstitious. One superstitious custom, amongst a variety of others, exists among their women, and particularly among those who have been married but a short time, if their husband happens to die, they tear their hair out in good earnest, and scatter it on the coffin; and this ceremony is so much consecrated by custom, that no woman, even though she had notoriously hated her husband, would fail in performing it."

PAGOD, or PAGODA, a name given by the East Indians to the temples where they worship their gods. We shall not in this place enter into a full detail of the several pagodas of different nations, and their peculiar circumstances. These matters seem to come in more properly under the *religion*, or, as others will call it, the *superstition*, of the people to whom they belong. We shall therefore content ourselves in the present article with an account of a paper in the *Asiatic Researches*, concerning the sculptures, &c. at Mavalipuram, a few miles north of Sadras, and known to seamen by the name of the *seven pagodas*.

The monuments which Mr Chambers (who communicated the paper) describes, appear, he says, to be the ruins of some great city decayed many centuries ago. "They are situated close to the sea, between Covelong and Sadras, somewhat remote from the high road that leads to the different European settlements. And when visited in 1776, there was still a native village adjoining to them which retained the ancient name, and in which a number of *bramins* resided that seemed perfectly well acquainted with the subjects of most of the sculptures to be seen there.—The rock, or rather hill of stone, on which great part of these works are executed, is one of the principal marks for mariners as they approach the coast, and to them the place is known by the name of the *Seven Pagodas*, possibly because the summits of the rock have presented them with that idea as they passed; but it must be confessed, that no aspect which the hill assumes as viewed on the shore, seems at all to authorise this notion; and there are circumstances which will be mentioned in the sequel, that would lead one to suspect, that this name has arisen from some such number of pagodas that formerly stood here, and in time have been buried in the waves." The rock here mentioned, as it rises abrupt-

ly out of a level plain of great extent, naturally engrosses the attention of the eye. It consists chiefly of a single stone; and in its shape (which is singular and romantic), in a distant view, it has the appearance of an antique and lofty edifice. Works of imagery and sculpture crowd thicker upon the eye on a nearer approach, and at first sight at least favours the idea of a petrified town, which, through the credulity of travellers\*, has been believed to exist in various parts of the world. "Proceeding on by the foot of the hill on the side facing the sea, there is a pagoda rising out of the ground of one solid stone, about 16 or 18 feet high, which seems to have been cut upon the spot out of a detached rock that has been found of a proper size for that purpose. The top is arched, and the style of architecture according to which it is formed, different from any now used in those parts." Beyond this a numerous group of human figures in bas-relief, considerably larger than life, attract attention. They represent considerable persons, and their exploits, many of which are now very indistinct thro' the injuries of time, assisted by the corroding nature of the sea air; while others protected from that element, are as fresh as when recently finished.

The hill, which is at first of easy ascent, "is in other parts rendered more so, by very excellent steps cut out in several places, where the communication would be difficult or impracticable without them. A winding stair of this sort leads to a kind of temple cut out of the solid rock, with some figures of idols in high relief upon its walls, very well finished, and perfectly fresh, as it faces the west, and is therefore sheltered from the sea air." This temple our author conjectures to have been a place of worship appertaining to a palace; some remains of which still exist, and to which there is a passage from the temple by another flight of steps. This conjecture (for it is brought forward as merely such) is in some measure favoured by several ruins still remaining, and by the tradition of the bramins who inhabit the place. This finishes the objects "on that part of the upper surface of the hill, the ascent to which is on the north: but on descending from thence, you are led round the hill to the opposite side, in which there are steps cut from the bottom to a place near the summit, where is an excavation that seems to have been intended for a place of worship, and contains various sculptures of Hindoo deities. The most remarkable of these is a gigantic figure of *Vishnou* (A), asleep on a kind of bed, with a huge snake wound about in many coils by way of pillow for his head; and these figures, according to the manner of this place, are all of one piece hewn from the body of the rock." These works, however, although they are unquestionably stupendous, are, in our author's opinion, surpassed by others about a mile and a half to the southward of the hill. "They consist of two pagodas of about 30 feet long by 20 feet wide, and about as many in height, cut out of the solid rock, and each consisting originally of one single stone. Near these also stands an elephant full as big as life, and

Pagod.

(A) See a figure of *Vishnou* in the Plate of Indian gods, with its description, under the article POLYTHEISM.

Pagod.

and a lion much larger than the natural size, but very well executed, each hewn also out of one stone. None of the pieces that have fallen off in cutting these extraordinary sculptures are now to be found near or anywhere in the neighbourhood of them, so that there is no means of ascertaining the degree of labour and time that has been spent upon them, nor the size of the rock or rocks from which they have been hewn; a circumstance which renders their appearance the more striking and singular. And though their situation is very near the sea beach, they have not suffered at all by the corrosive air of that element, which has provided them with a defence against itself, by throwing up before them a high bank that completely shelters them. There is also great symmetry in their form, though that of the pagodas is different from the style of architecture according to which idol temples are now built in that country. The latter resembles the Egyptian; for the towers are always pyramidal, and the gates and roofs flat and without arches; but these sculptures approach nearer to the Gothic taste, being surmounted by arched roofs or domes that are not semicircular, but composed of two segments of circles meeting in a point at top." Our author observes, that the lion in this group, as well as one on a stone couch in what he took to be a royal palace, are perfectly just representations of the true lion, and the natives there give them the name which is always understood to mean a lion in the Hindoo language, to wit, *sing*; but the figure which they have made to represent that animal in their idol temples for centuries past, though it bears the same appellation, is a distorted monster totally unlike the original; inasmuch that it has from hence been supposed, that the lion was not anciently known in this country, and that *sing* was a name given to a monster that existed only in Hindoo romance. But it is plain that that animal was well known to the authors of these works, who in manners as well as arts seem to have differed much from the modern Hindoos.

"There are two circumstances attending these monuments which cannot but excite great curiosity, and on which future inquiries may possibly throw some light. One is, that on one of the pagodas last mentioned, there is an inscription of a single line, in a character at present unknown to the Hindoos. It resembles neither the Deyva-nâgre, nor any of the various characters connected with or derived from it, which have come to the writer's knowledge from any part of Hindostan. Nor did it, at the time he viewed it, appear to correspond with any character, Asiatic or European, that is commonly known. He had not then, however, seen the alphabet of the Balic, the learned language of the Siamese, a sight of which has since raised in his mind a suspicion that there is a near affinity between them, if the character be not identically the same. But as these conjectures, after such a lapse of time, are somewhat vague, and the subject of them is perhaps yet within the reach of our researches, it is to be hoped that some method may be fallen upon of procuring an exact copy of this inscription.

"The other circumstance is, that though the outward form of the pagodas is complete, the ultimate design of them has manifestly not been accomplished, but seems to have been defeated by some extraordi-

nary convulsion of nature. For the western side of the most northerly one is excavated to the depth of four or five feet, and a row of pillars left on the outside to support the roof; but here the work has been stopped, and an uniform rent of about four inches breadth has been made throughout the solid rock, and appears to extend to its foundations, which are probably at a prodigious depth below the surface of the ground. That this rent has happened since the work began, or while it was carrying on, cannot be doubted; for the marks of the mason's tools are perfectly visible in the excavated part on both sides of the rent, in such a manner as to show plainly that they have been divided by it. Nor is it reasonable to suppose, that such a work would ever have been designed or begun upon a rock that had previously been rent in two. Nothing less than an earthquake, and that a violent one, could apparently have produced such a fissure in the solid rock; and that this has been the case in point of fact, may be gathered from other circumstances, which it is necessary to mention in an account of this curious place. The great rock above described is at some small distance from the sea, perhaps 50 or 100 yards, and in that place the Hindoo village before mentioned stood in 1776. But close to the sea are the remains of a pagoda built of brick, and dedicated to Sib, the greatest part of which has evidently been swallowed up by that element; for the door of the innermost apartment, in which the idol is placed, and before which there are always two or three spacious courts surrounded with walls, is now washed by the waves, and the pillar used to discover the meridian at the time of founding the pagoda is seen standing at some distance in the sea. In the neighbourhood of this building there are some detached rocks, washed also by the waves, on which there appear sculptures, though now much worn and defaced. And the natives of the place declared to the writer of this account, that the more aged people among them remembered to have seen the tops of several pagodas far out in the sea, which being covered with copper (probably gilt) were particularly visible at sunrise, as their shining surface used then to reflect the sun's rays, but that now that effect was no longer produced, as the copper had since become incrustated with mould and verdegis."

From these circumstances our author conjectures, and we think reasonably, that the magnificent city of which these appear to be part of the ruins, has been destroyed partly by an earthquake by which the rock was rent, and partly by a sudden inundation of the sea occasioned by this commotion of the earth. The bramins give an account of this matter peculiar to themselves, filled with extravagance, fable, and folly; from which, however, with the assistance of ancient monuments, coins, and inscriptions, some probable conjectures at least, if not important discoveries, may, it is hoped, be made on those subjects, which are far from being uninteresting to us either as men, philosophers, or Christians. Our author thinks, therefore, that the inscription on the pagoda mentioned above is an object which merits considerable attention; and he defends, by very reputable authorities, the conjecture which places it among the languages of *Siam*; but which it is unnecessary for us either to abridge or to transcribe. In the course of this

Pagod.

Pagod.

inquiry, our author remarks a very near resemblance between *Sommonacodon*, the idol of the *Siamese*, and the great idol Buddou, held sacred by the *Chingelays*; and this resemblance extends also to their priests. But from the detail of circumstances which our author brings forward, and to which we refer, he thinks this a system of religion different from that of the *Veds*, and some of them totally inconsistent with the principles and practice of the *Bramins*; none of whom, as far as we can recollect from Mr Knox †, exist among the Chingelays whose religion is totally different from that of the present Hindoos. The only part in which there seems to be any agreement is in the worship of the Debtahs, which has probably crept in among them from their Tamulian neighbours, but that is carried on in a manner very different from the braminical system, and appears to be held by the nation at large in very great contempt, if not abhorrence. Knox's account of it is this: "Their temples (*i. e.* those of the Debtahs) are called *covels*," which is the Tamulic word for pagoda. He then goes on to say, "a man piously disposed builds a small house at his own charge, which is the temple, and himself becomes priest thereof. This house is seldom called *God's House*, but most usually *Jacco the Devils*." But of the prevailing religion he speaks in very different terms, and describes it as carried on with much parade and splendour, and attended with marks of great antiquity. "The pagodas or temples of their gods (says he) are so many, that I cannot number them. Many of them are of rare and exquisite work built of hewn stone, engraven with images and figures, but by whom and when I could not attain to know, the inhabitants themselves being ignorant therein. But sure I am they were built by far more ingenious artificers than the Chingelays that now are on the land. For the Portuguese in their invasions have defaced some of them, which there is none found that hath skill enough to repair to this day." In another place, he says, "here are some ancient writings engraven upon rocks which puzzle all that see them. There are divers great rocks in divers parts in Cande Uda, and in the northern parts. These rocks are cut deep with great letters for the space of some yards, so deep that they may last to the world's end. Nobody can read them, or make any thing of them. I have asked Malabars and Gentoos, as well as Chingelays and Moors, but none of them understood them. There is an ancient temple, Goddiladenni in Yattanour, stands by a place where there are of these letters." From all which the antiquity of the nation and their religion is sufficiently evident, and from other passages it is plain, that the worship of Buddou, in particular, has been from remote times a very eminent part of their religion; for the same author, speaking of the tree at Anurodgburro, in the northern part of the island, which is sacred to Buddou, says, "the due performance of this worship they reckon not a little meritorious; inasmuch that, as they report, 90 kings have reigned there successively, where, by the ruins that still remain, it appears they spared neither pains nor labour, to build temples and high monuments to the honour of this god, as if they had been born to hew rocks and great stones, and lay them up in heaps. These kings are now happy spirits

† Hist. of Ceylon.

having merited it by these labours." And again he says, "For this god, above all others, they seem to have an high respect and devotion," &c.

Such is the nature of Mr Chambers's communication, as far as it respects pagodas; a subject to which the *Asiatic Society* will doubtless again direct their attention; and from the penetration and assiduity of its members we have much to expect. Other parts of this paper shall be brought forward under other articles, to which we refer. Few researches are of more service to true religion, than those which give us a correct view of the false and superstitious modes of worship practised by men who have had no light but reason, or weak and corrupted traditions. They are useful likewise to the philosopher, as they always tend to give us a minuter view of the real nature of man as he is in himself, and show with sufficient strength the imbecillity of the human intellect without some supernatural aid. The external pomp of all Pagan religious seems to have been their essence; a circumstance which alone shows the necessity of that, the intention of which is to reform the heart. See SIAM, SOMMONACODON, TEMPLE, &c.

PAGOD, or *Pagoda*, is also the name of a gold and silver coin, current in several parts of the East Indies.

PAIN, an uneasy sensation, arising from a sudden and violent solution of continuity, or other accident in the nerves, membranes, vessels, muscles, &c. of the body. Pain, according to some, consists in a motion of the organs of sense; and, according to others, it is an emotion of the soul occasioned by those organs.

As the brain is the seat of sensation, so it is of pain. Boerhaave, and most other authors on this subject, assign a stretching of the nerves as the only immediate cause of pain: but as the nerves do not appear to consist of fibres, this cause of pain does not seem to be well founded; nor indeed will it be easy to treat this subject clearly, but in proportion as the means of sensation are understood.

Many kinds of pain are met with in authors: such as, A gravitative pain; in which there is a sense of weight on the part affected, which is always some fleshy one, as the liver, &c. A pulsative pain; which Galen says, always succeeds some remarkable inflammation in the containing parts, and is observed in abscesses while suppurating. A tensive pain, which is also called a *distending* pain; it is excited by the distension of some nervous, muscular, or membranous part, either from some humour, or from flatulence. An acute pain is, when great pain is attended with quick and lively sensations: A dull pain is, when a kind of numbness is as much complained of as the pain is.

The mediate and more remote causes of pain are generally obvious; and when so, the cure will consist for the most part in removing them: for though in many instances the chief complaint is very distant from the seat of these causes, yet their removal is the proper method of relief. See MEDICINE, *passim*.

Perhaps all pains may be included, with irritation, in those that have spasm or inflammation for their source. When pain is owing to inflammation, the pulse is quicker than in a natural state; it is also generally full, hard, and tense; the pain is equal, throbbing, and unremitting. If a spasm is the cause, the pulse is rarely affected; at intervals the pain abates, and then returns with

Pagod. Pain.

Pain.

with some degree of aggravation; gentle motion sometimes abates, or even cures, in some instances: but in inflammatory cases no such effects are ever experienced. See Dr Lobb's *Treatise on Painful Disorders*.

The pain so frequently attendant on women in child-bed, called *after-pains* (from their happening only after being delivered of a child), are often occasioned by scooping to fetch away coagulated blood, which is a needless endeavour. When no improper treatment in delivering the secundines can be suspected, the irritability of the uterus alone is to be considered as the cause. Care should be taken not to confound these after-pains with, or mistake the pains attending puerperal fevers for, the colic. After-pains come by fits, and soon go off; but return at different intervals, which are longer each day, and after two or three days are usually at an end, though sometimes they continue seven or eight: notwithstanding these pains, the lochia flow

properly, and generally more abundantly after the cessation of each fit; this does not happen in colicky complaints, nor is the belly so free from tumefaction when the puerperal fever is attendant.

As these pains are of the spasmodic kind, anodynes and gentle opiates, with frequent draughts of warm caudle, camomile tea, &c. are all that are required in order to their relief.

Among the various causes of pain, a singular one is related in the third vol. of the *Lond. Med. Obs. and Inq.* p. 241, &c. Some persons who had taken cold during their being salivated, were afflicted with pains which resisted all the usual methods of relief. At length the author of the narrative referred to, suggested the cause: and by exciting a fresh salivation the pains abated: the spitting was kept up a little while, and permitted to abate with some caution; and thus the cures were completed.

Pain.

## P A I N T I N G.

**P**AINTING is the art of representing to the eyes, by means of figures and colours, every object in nature that is discernible by the sight; and of sometimes expressing, according to the principles of physiognomy, and by the attitudes of the body, the various emotions of the mind. A smooth surface, by means of lines and colours, represents objects in a state of projection; and may represent them in the most pleasant dress, and in a manner most capable of enchanting the senses. Still farther the objects which delight us by their animation and lively colours, speak to the soul, by giving us the image of what we hold most dear, or by indicating an action which inspires us with a taste for innocent pleasures, with courage, and with elevated sentiments. Such is the definition, and such are the effects of painting.

By an admirable effort of human genius, painting offers to our eyes every thing which is most valuable in the universe. Its empire extends over every age and country. It presents to us the heroic deeds of ancient times as well as the facts in which we are more conversant, and distant objects as well as those which we daily see. In this respect it may be considered as a supplement to nature, which gives us only a view of present objects.

The art of painting is extremely difficult in the execution; and its merit can only be appreciated by those who profess the art.

The painter who invents, composes, and colours conceptions which are only agreeable, and which speak merely to the eye of the spectator, may be reckoned to possess the first merit in the style of embellishment and decoration.

The painter who is distinguished for noble and profound conceptions; who, by means of a perfect delineation, and colours more capable of fixing the attention than dazzling the eye, conveys to the spectators the sentiments with which he himself was inspired: who animates them with his genius, and makes a lasting impression on their minds; this artist is a poet, and worthy to share even in the glories of Homer.

It is in forming this great idea of his art that the painter becomes himself great.

But if he seek only to please or astonish by the illusion of colours, he must rest contented with the secondary merit of flattering the eye with the variety and opposition of tints, or of making an industrious assemblage of a great multiplicity of objects. It is in painting as it is in poetry. The man who clothes trivial or common ideas in verse, exercises the profession of twisting syllables into a certain measure. The poet who clothes in good verse ideas and sentiments, that are merely agreeable, professes an agreeable art. But he who, by the magic of verse, of ideas, of imagery, or of colours, adds sublimity to the sublime objects of nature, is a great poet and a great painter. He deserves the crown which the nations have decreed to Homer, Virgil, Milton, Raphael, and the statuary who modelled the ancient Apollo. It is reasonable to place in the same class those who have expressed the same ideas, whether it be in verse or in colours, on brass or on marble. The painter and statuary, who excel in their professions, deserve all the respect due to genius: they are of the number of those men whom nature, sparing of her best gifts, grants but occasionally to the inhabitants of the earth. If they are sublime, they elevate the human race; if they are agreeable only, they excite those sweet sensations necessary to our happiness.

In laying before our readers a succinct account of this noble art, we shall, first give the history of painting, including its rise, progress, and decline, in ancient and modern times; an account of the schools, and of the different merits of painters; and a comparison between the ancient and modern painting. Secondly, we shall lay down the principles of the art, and the order in which the artist conducts his studies. Thirdly, we shall enumerate the different classes of painting, with observations on each. And, Fourthly, we shall treat of economical or house-painting.

Rise, Pro-  
gress, and  
Decline.

## HISTORY.

SECT. I. *Rise, Progress, and Decline of Painting in Ancient and Modern Times.*

It is to be imagined that men must naturally, and very early, have conceived an idea of the first principles of the art of painting; the shadow of each plant and animal, and of every object in nature, must have afforded them the means of conceiving, and pointed out the possibility of imitating, the figures of all bodies. Thus the savage nations, an emblem of what men were in the infancy of society, possess the first rudiments of this art, even before those which are useful and almost necessary to existence; their naked bodies are covered with punctures of various forms, into which they infuse indelible colours. The next demand for this art, is to preserve the memory of warlike exploits. It is more natural to form some representation of an action, than to give an account of it by means of arbitrary characters. Hence the picture-writing of the Mexicans, and the more artful hieroglyphics of Egypt.

Painting consisted of simple outlines long before the expression of relief or the application of colour. It was simply drawing; and the master-pieces of painting in that rude period were not superior to the sports of children. Although occupied about a single point, it was not brought to perfection; for constant experience instructs us that men never excel in the inferior parts of an art till they are capable of carrying the whole to perfection.

After employing for a long time those simple outlines, the next step in the art of painting was to make the imitation more complete, by applying colours; this was first accomplished by covering the different parts of the figure with different colours in the same way that we colour maps; and several nations, as the Egyptians, the Chinese, and the different nations of India, have never painted in a better manner. Other nations, more ingenious and more attentive to the arts, observing that the objects of nature have relief, have invented what is called *claro-obscuro*. The Greeks, the most ingenious, penetrating, and delicate of all, invented this part antecedent to colours; than which there cannot be a greater proof of their exquisite taste, as the glare of colours without judgment excites more admiration in the minds of the vulgar and ignorant, than the cameo or drawings of one colour executed by the most skilful artist.

These general observations concerning the gradual improvement of this art, will be best illustrated by a more particular attention to the ancient nations in which it flourished.

Plato, who lived 400 years before the Christian era, informs us that painting had been practised in Egypt for ten thousand years; that some of the productions of that high antiquity were in existence; and that they bore an exact resemblance to those which the Egyptians executed in his time. Without regarding the period of ten thousand years mentioned by Plato, it is reasonable to consider it as an indeterminate period, which carries us back to very remote antiquity.

Painting  
among the  
Egyptians.

The figures either in the painting or sculpture of Egypt were extremely stiff; the legs were drawn together, and their arms were pacted to their sides. It appears that their only model was their mummies, and that their skill in anatomy was derived from embalming them. They were extremely incorrect in every part of the head; they placed the ears much higher than the nose. Besides, they gave the face the form of a circle instead of an oval; the chin was short and rounded; the cheeks excessively so; and they turned upwards the corners of the mouth and eyes. Many of these faults may be ascribed to the formation of the human face in Egypt; but the placing of the ears could only be founded in caprice or ignorance.

The exactness of the Egyptian proportion is much celebrated; but although we grant that they observed the proper length of the different parts of the human body, they were still defective artists, since they did not observe the breadth, and were moreover ignorant altogether of the shape and size of the muscles. Works converted to religious purposes chiefly occupied the Egyptian painters. They had figures for imitation from which they would not depart, and those figures were monstrous; the bodies of animals with the heads of men; the bodies of men with the heads of animals: or, if the figure was more agreeable to nature in its parts, yet it was so deformed and imaginary, as to have nothing similar to it as a whole in the creation of God.

The monuments of Egyptian painting with which we are best acquainted (says Winklemann) are the chests of mummies. These works have resisted the injuries of time, and are still submitted to the examination of the curious. The white, made of white lead, is spread over the ground of the piece; the outlines of the figure are traced with black strokes, and the colours are four in number; namely, blue, red, yellow, and green, laid on without any mixture or shading. The red and blue prevail most; and those colours seem to have been prepared in the coarsest manner. The light is formed by leaving those parts of the ground where it is necessary, covered with the white lead, as it is formed by the white paper in some of our drawings. This description is sufficient to convince us that the whole art of painting in Egypt consisted in colouring; but every person knows, that without tints and the mixture of colours painting can never arrive at great perfection.

In Upper Egypt there seems to have existed a kind of colossal painting, which has never been examined except by travellers who were no great critics in the art. Winklemann had some reason to express a desire that those remains of antiquity, with regard to the manner of working, the style, and the character, had been accurately explored. Walls of 24 feet in height, and pillars of 32 feet in circumference, are wholly covered with those colossal figures. According to Norden they are coloured in the same manner with the mummies: the colours are applied to a ground prepared in manner of fresco; and they have retained their freshness for many thousand years. Winklemann adds, that all the efforts of human skill and industry could

make

Rise, Progress, and Decline.

make as little impression on them as the injuries of time. His enthusiasm for antiquity has perhaps led him into this extravagant exaggeration.

It appears that the great employment of the Egyptian painters was on earthen vessels, on drinking-cups, in ornamenting barges, and in covering with figures the chests of mummies. They painted also on cloth; but painting, as an industrious occupation, supposes a workman, not an artist: the decoration of temples, house-painting, and that of the figures relative to religion, are to be considered only in this point of view. The workmen in Russia who paint our Saviour holding the globe in one hand, and blessing the people with the other, are not members of the imperial academy of fine arts.

Pliny informs us that the Egyptian artists painted also the precious metals; that is to say, they varnished or enamelled them. It is doubtful what this art was, but most probably it consisted in covering gold or silver with a single colour.

The Egyptians are supposed to have continued this coarse style till the reign of the Ptolemies

<sup>2</sup>  
In Persia:

The Persians were so far from excelling in the arts, that the paintings of Egypt were highly esteemed among them after they had conquered that country.

The carpets of Persia were of great value in Greece, even in the time of Alexander the Great, and these were adorned with various figures; but this is no proof that they were well executed, any more than a demand for several of the Chinese productions is at present a proof of the taste of that people in the arts. It was the fabrication of the silk, and not the truth of the representation, which made the Greeks admire the carpets of Persia.

The Persians, as well as the Arabians, had some knowledge of Mosaic work. This is only valuable when it copies, in a manner that cannot be destroyed, the works of a great master; but if the Persians had no good pictures to copy into Mosaic, it was of no consequence to be able to arrange, in a solid manner, pieces of flint one beside another.

There is only one Persian painter whose name has descended to posterity; and he is preserved, not because he was a painter, but because he accommodated the ancient doctrine of the two principles to the Christian religion. Besides, it is doubted whether *Manes* was a Persian or a Greek, and it is still less known whether he was a painter. He is praised in Asia for drawing straight lines without a ruler.

The modern Persians have made no kind of progress in the arts. The emperor Schah-abbas, wishing from caprice to be instructed in drawing, was obliged to have recourse to a Dutch painter who happened to be in his dominions.

<sup>3</sup>  
In India and Thibet.

The modern Persians paint on cloth, and the artists in India are their rivals in this branch of industry; but their paintings are purely capricious. They represent plants and flowers which have no existence in nature; and their only merit consists in the brightness and the strength of their colours.

Besides this, the art in India, as it was in the most remote antiquity is confined to monstrous figures connected with their religion, animals not to be found in the world, and idols with a multitude of arms and

heads, which have neither exactness in their forms nor proportions. See POLYTHEISM.

Rise, Progress, and Decline.

The paintings of Thibet discover great patience in the artist, and are remarkable for the fineness of their strokes. Their painters might dispute with Apelles and Protogenes for extreme tenuity of pencil; but it is in this alone, without any regard to the art, in which their merit consists.

Some of the idols in Thibet are executed in a certain style of relieve; but those productions are not only imperfect, they are also so destitute of beauty as to forbid every hope of excellence in the art. The same thing may be observed with regard to many of the eastern nations; they seem to have that want of style which would ever condemn them to mediocrity, even if they should happen to arrive at it.

An obscure Italian painter, named *Giovanni Ghirardin*, who travelled into China, whose judgment is more to be depended on in an art which he practised than that of other travellers, declares that the Chinese have not the least idea of the fine arts; and this opinion is confirmed by every thing which we know of that people.

The Chinese seem not to have the smallest conception of perspective. Their landscapes have no plan, no variety in the appearance of the clouds, and no diminishing of the objects in proportion to their distance.

The great object of their painting seems to consist in making their figures as unlike nature as possible: it is a serious caricature of the human figure.

To make the art flourish, it is necessary that the artist be esteemed and rewarded. In China, there is no artist so poorly paid as the painter.

The ignorant admire the brightness and purity of their colours; but simple colours appear always bright and pure: The difficulty of the art consists in melting them into one another in such a manner that the mixture shall not be perceived. It must at the same time be confessed, that their natural colours are more brilliant than ours; but if there be any merit in this, it is to be ascribed to their climate, not to their ability.

A Jesuit missionary, who in his youth had been a grinder of colours, was raised to the greatest eminence as a painter in the Imperial court of China, and Raphael himself was never so much respected. The Chinese battles sent from that country to Paris, to be engraved, are the works of the Jesuits; and except they were done by the Chinese themselves, it is impossible to conceive that they could be worse executed.

The Chinese, like other eastern nations, have a few simple strokes which they repeat in all their variety of figures. In the figures on the earthen ware, they discover no knowledge of forms, no expression of the most conspicuous muscles, and no idea of proportion. And in all the paintings of China, anatomy seems to bear no relation to the art. Some heads done by a Chinese painter have a sort of resemblance to nature, but they are in a low and vicious taste: The fulness of the drapery conceals the parts in such a manner that they do not seem to exist under it. Sculpture in China is in a state of no great perfection, but at the same time it is better executed than their paintings.

The

Rise, Pro-  
gress, and  
Decline.

5  
In Etruria.

The ancient inhabitants of Etruria, now called *Tuscany*, were the first who connected the arts with the study of nature. In some of their monuments which still remain, there is to be observed a first style, which shows the art in its infancy; and a second, which, like the works of the Florentine artists, shows more of greatness and exaggeration in the character than precision or beauty.

Pliny says that painting was carried to great perfection in Italy before the foundation of Rome; perhaps he means in comparison with the infancy of the art in Greece at that period, but it appears that even in his time the painters of Etruria were held in great reputation.

The only Etrurian paintings which remain, have been found in the tombs of the Tarquins. They consist of long painted frizes, and pilasters adorned with huge figures, which occupied the whole space from the base to the cornice. These paintings are executed on a ground of thick mortar, and many of them are in a state of high preservation.

6  
In Campania.

Winklemann is of opinion that the Greek colonies established at Naples and Nola, had at a very early period cultivated the imitative arts, and taught them to the Campanians, established in the middle of the country. This learned antiquarian considers as works purely Campanian, certain medals of Capua and Teanum, cities of Campania into which the Greek colonies never penetrated. The head of a young Hercules, and the head of a Jupiter, according to Winklemann, are executed in the finest manner. It is still a question, however, in the learned world, whether these medals owe their existence to Carthage or to Campania.

"But there have been discovered (adds Winklemann) a great number of Campanian vases covered with painting. The design of the greatest part of these vases (says he) is such, that the figures might occupy a distinguished place in a work of Raphael. Those vases, when we consider that this kind of work admits of no correction, and that the stroke which forms the outline must remain as it is originally traced, are wonderful proofs of the perfection of the art among the ancients." Winklemann had an opportunity of examining a very fine Campanian vase, on which was painted a burlesque representation of the loves of Jupiter and Alcmena. But as this must have been derived from some fragment of a Grecian comedy, the Count de Caylus is persuaded that the Campanian vases are of Greek origin.

7  
Among the  
Greeks.

Although the history of Greek painting be more fully known than that of the same art among the barbarous nations, it is nevertheless involved in much obscurity. Pliny is almost the only author who has preserved the materials of its history; and he complains, that on this occasion the Greek writers have not discovered their usual exactness. They place, says he, the first painter of whom they speak in the 90th Olympiad, 420 years before the Christian era. It is certain that painting in dry colours existed at the time of the siege of Troy, or at least when Homer wrote the account of it. The buckler of Achilles is a sufficient proof that the Greeks were then acquainted with the basso-relievo, a kind of sculpture which bears a near affinity to painting.

Rise, Pro-  
gress, and  
Decline.

In the *Iliad*, Helen is represented as working at a tapestry, whereon she figured the numerous combats of which she was the cause. When Andromache was informed of her husband's death, she was occupied in representing on tapestry flowers of various colours. From these facts, it is certain that painting was not confined to simple strokes, nor even to the camaieu; and hence it is reasonable to conclude, that what is called *lineary painting* was practised long before the time of Homer. Polygnotus of Thafos, who lived about 420 years before the Christian era, was the first painter of any eminence in Greece. Pliny informs us that he was the first who clothed his female figures, who varied the colours of the different parts of their dress, or who opened their mouths in such a manner as to show their teeth. Aristotle, who flourished in a subsequent period, allows this painter to have excelled in expression. But the art of painting may be still considered in its infancy in Greece, till about 400 years before the Christian era, when Zeuxis and Parrhasius flourished. In the contest between these eminent painters, Zeuxis declared himself to be overcome, because in a cluster of grapes which he painted he had deceived the birds; whereas Parrhasius in a curtain which he executed deceived his rival. The principal works of Zeuxis are his Penelope, in which, according to Pliny, he appears to have expressed the manners of that princess; a Jupiter surrounded by the gods; a Hercules strangling the serpents in the presence of Amphitruon and Alcmena; an Helen and a Mariyas bound. From this enumeration of these works, and from the fame which they have acquired, it is evident that the difficult parts of the art, and those which in the execution render it estimable, were now begun to be studied. By Appelles, Protogenes, and Euphranor, it was carried to the greatest height of perfection. Grace, and symmetry, and proportion, and illusion, were now added by the greatest masters to the noblest objects of nature.

8  
Among the  
Romans.

We have already seen, that before the foundation of Rome the arts were cultivated in Etruria. They were also early introduced in Latium; but whether that country employed its own artists or those of Etruria, remains altogether uncertain. One need not be astonished, that at a period when the arts were in their infancy in Greece, they were raising statues to their kings in Rome: but at that period all their artists were Etrurians or Latins; and when they conquered Italy, they made all the nations of it as barbarous as they were themselves.

In the year 259. from the building of the city of Rome, and 494 years before the Christian era, Appius Claudius consecrated a number of shields in the temple of Bellona, which contained in basso relieve the portraits of his family. This example was followed; and in process of time it was common among the Romans to place those images in private houses. The execution in basso-relievo is a proof that they had an idea of painting, at least with one colour. As long as the Romans employed artists of other nations, they had little desire to cultivate the arts; but towards the year of Rome 450, and 303 years before Christ, one of the Fabii thought it no discredit to a noble family to employ himself in painting. He painted the temple of Safety; and his works remained

Rise, Progress, and Decline.

ed till that temple was destroyed by fire, in the reign of Claudius. It is worthy of remark, that the same man was the first painter and the first historian in his country.

The example of Fabius, surnamed *Pictor* from his profession, did not excite his fellow-citizens to imitation. A century and a half elapsed before the tragic poet Pacuvius, nephew of Ennius, painted the temple of Hercules in the *forum boarium*. The glory which he had acquired by his dramatic works shed some lustre on the art, which he condescended to exercise; but did not confer on it that respect which could recommend it to general practice. The paintings of Fabius were the works or rather the recreations of his youth; those of Pacuvius, the amusements of his old age: but painting is a difficult art, which requires the whole attention, and which can never be prosecuted with success, except those who love it are solely devoted to the performance.

It appears that there were no eminent painters at Rome till the time of the emperors; but as the national spirit was changed, the profession of the fine arts acquired more respectability. The Romans, during the time of the republic, were animated with the spirit of liberty and the desire for conquest. When these two passions were weakened, the love of the arts obtained among them. As a proof of this it is sufficient to say, that Nero himself gloried in being an artist. A Colossian picture of 120 feet was painted at Rome by the command of this emperor, which was afterward destroyed by lightening. The name of the painter is not recorded, and there are various opinions concerning the merit of the performance; but the thing chiefly worthy of observation is, that this is the only painting on cloth mentioned by ancient authors.

The paintings of the ancient artists were either moveable or on the ceilings or compartments of buildings. According to Pliny, the most eminent were those who painted moveable pictures. The latter were either on fir-wood, larch, boxwood, or canvas, as in the colossian picture mentioned above, and sometimes on marble. When they employed wood, they laid on in the first instance a white ground. Among the antiquities of the Herculeum are four paintings on white marble.

Their immovable paintings on walls were either in fresco or on the dry stucco in distemper. Indeed all the ancient paintings may be reduced to, *first*, fresco painting; *secondly*, water-colour or distemper-painting on a dry ground; and, *thirdly*, encaustic painting.

The ancient fresco-paintings appear to have been always on a white stucco-ground, the colours inlaid very deep, and the drawing much more bold and free than any similar performance of modern art. The outlines of the ancient paintings on fresco were probably done at once, as appears from the depth of the incision and the boldness and freedom of the design, equal to the care and spirit of a pencil outline.

In general the ancients painted on a dry ground, even in their buildings, as appears from the Herculean antiquities, most of which are executed in this manner. At Rome and Naples, the first (deepest) coat is of true Pozzolana, of the same nature with the *terras* now used in mortar, required to keep out wet, about one finger thick; the next of ground

marble or alabaster, and sometimes of pure lime or stucco, in thickness about one third of the former. Upon this they appear to have laid a coat of black, and then another of red paint; on which last the subject itself was executed. Such seems to have been their method of painting on wall; but in their moveable pictures, and in the performance of their first artists, and where effect of shade and light were necessary, they double is used white.

The colours employed they seem to have mixed up with size, of which they preferred that made by boiling the ears and genitals of bulls. This appears to have made the colours so durable and adhesive, that the ancient paintings lately found bear washing with a soft cloth and water; and sometimes even diluted aquafortis employed to clean their paintings on fresco. Pliny says that glue dissolved in vinegar and then dried, is not again soluble.

What the encaustic painting of the ancients was, has been much disputed. From the works of Vitruvius and Pliny, it appears evidently that it was of three kinds.

*First*, where a picture painted in the common way, was covered with a varnish of wax melted, diluted with a little oil, and laid on warm with a brush.

*Secondly*, where the colours themselves were mixed up with melted wax, and the mixture used while warm. And,

*Thirdly*, where a painting was executed on ivory by means of the *cestrum* or *variculum*.

Some experiments on this last method by Mr Colebrook may be found in the Phil. Trans. vol. 51. and more particular directions in Muntz's Treatise on Encaustic Painting.

It appears from ancient writings of the best authority, that in the earliest and purest times of this art, the painters used few colours, perhaps not more than four. "The paintings of the ancients (says Dionysius Halicarnassensis) were simple and unvaried in their colouring, but correct in their drawing, and distinguished by their elegance. Those which succeeded, less correct in their drawing, were more finished, more varied in their light and shades, trusting their effect to the multitude of their colours." But no certain conclusion can be drawn, that the more early among the great painters of the ancients, such as Apollodorus, Zeuxis, Timanthes, &c. had no more colours than four to use, merely because they did not use them. On the contrary it may be conjectured with some degree of probability, from their chasteness in design, and from the complaints Pliny makes of the gaudy taste of the Roman painters, that the Greeks in general were *disignedly* chaste in their colouring, and not so merely from necessity, at least about the time of Zeuxis and Apelles; for the former could not have painted grapes so naturally as he is said to have done with four colours only: and the rebuke given by the latter to one of his scholars who had painted an Helen very gaudily, is a confirmation of these observations, "Young man (says Apelles), not being able to make her beautiful, you have made her rich."

Of white colouring substances, the ancients had white lead variously prepared, a white from calcined egg shells, and preparations from cretaceous and argillaceous earths. The moderns in addition have ma-

among the  
ancients.

Rise, Progress, and Decline.

10  
The colours used by the ancients.

Rise, Progress, and Decline.

giftery of bismuth, little used; and *ought* to have the calces of tin and zinc.

Of *blacks*, the ancients had preparations similar to lamp, ivory, blue, and Franckfort black; also to Indian ink and common writing ink; and they used, what we do not, the precipitate of the black dyers vats.

The ancients possessed a species of *vermilion* or fine cinnabar, a coarser cinnabar, red-lead, various earths burnt and unburnt, apparently similar to our red ochre; Venetian red, Indian red, Spanish brown, burnt terra de Sienna, and scarlet ochre; they had also a substance alike in colour and in name to our dragon's blood.

The yellow pigments of the ancients were generically the same with our orpiments, king's-yellow, Naples yellow, &c. They did not possess turbeth-mineral, mineral-yellow, or gamboge; nor do they appear to have known of gall-stone as a pigment.

Of blue paints they had preparations from the lapis syanus and lapis armenus. Indigo they had, and perhaps bice and smelt; for they made blue-glass, but whether from some ore of cobalt or of wolfram must be uncertain: they had not Prussian blue, verditer, nor litmus, which we have. We do not use the blue precipitate of the dyers vats, nor mountain blue, which they certainly employed.

Of green colours, they had verdigrise, terra vert, and malachite or mountain green. The latter is not in use among us. Sap green, green verditer, and Scheele's green, appear to have been unknown to them: like us, they procured as many tints as they pleased from blues and yellow vegetables.

We have no original *purple* in use: that from gold by means of tin, though very good when well prepared, is too dear perhaps, and unnecessary. Their purple was a tinged earth. Their orange or sandarac (red orpiment) we also possess. Hence there does not appear to have been any great want of pigments, or any very material difference between the colours they used and such as we generally employ. Perhaps the full effect of colouring may be obtained without the use of the exceeding brilliant pigments, depending chiefly on the proportion and opposition of tints.

The ancients could not know any thing about the use of varnishes, distillation being a modern invention; but they were undoubtedly acquainted with the use of the better oil varnishes, that is with the use and effect of resinous gums dissolved in boiling inspissated oils.

One of the best preserved mummies in the British museum has an astonishing brightness of colours on the outside of the coffin. Thousands of years have not impaired them; they are as fresh as if they had been laid on yesterday.

The chalk ground, and the excellency of the colours, some of which imply a good deal of chemical and metallurgical knowledge, do not sufficiently account for their splendour and freshness: it must be owing to other circumstances; either to the mixture of shining colours, or to a hard glossy skin which visibly covers them all over.

From an accurate examination of one of those mummies belonging to the university of Cambridge, it appeared, that the varnish which covered the colours

could not be dissolved, or in the least affected by common water; and that it equally resisted the dissolving power of the strongest spirits: hence it is reasonable to conclude, that the coffins of the mummies were not covered with size, whites of eggs, simple gums, or any preparation of wax, but with a fine transparent oil varnish. It was discovered at the same time, that the colours themselves were not prepared or mixed with oil; for where the external glossy skin was damaged, broken or rubbed off, even common water would wash the colours away, and affect the chalk ground under them.

Pliny has described the general and particular effects of the varnish of Apelles, under the name of *at. ar. ent*, so distinctly, that no body can mistake the thing or the mixture he is speaking of. He has mentioned the thing glossy skin of the varnish which excites the brightness of the colours, and preserves them against dust; he observed, that this skin was laid on so thin, that it could not be discerned at any distance: nor was he less accurate in reporting the particular effects of that mixture which Apelles made use of; it harmonized and lowered the tone of the brightest florid colours in an imperceptible manner, and the whole appeared as if it had been seen through isinglass. The chemists and connoisseurs are fully of opinion, that no liquid substance or mixture of any kind is fit to produce these effects besides the oil varnishes; and if there are not, Apelles and the Greeks were certainly acquainted with those varnishes; a fact which might be strongly urged in behalf of their knowledge of oil colours.

The black outlines of the figures on the most ancient Greek paintings yet extant, that is, on Etruscan vases, are so sharp, so thick and drawn in so easy and masterly a manner, that one cannot help looking upon them as having been drawn in oil colours. Had they been in distemper or water colours on the red clay ground on which they are applied, they would have been imbibed and soaked into it. Our china and enamel painters prepare and apply their colours with spike or other liquid oils; and the Greek masters seem to have done the same, unless they should appear to have burnt their vases before they painted them, or to have used a mixture of dissolved wax or gum for giving a body to their colours, which might have answered the same end as oils. And this is the more probable, as there is some reason to believe that these vases went through two different fires, that of baking them, and that of smelting or burning in their colours.

The Greek and Roman paintings that have been preserved or discovered at Rome and Herculaneum do not countenance the supposition of oil colours; at least Turnbull and the academists at Naples, who have described the royal collection at Portici, Couchin, and many other authors who have seen and described them, do not hint any thing of that nature. On the other hand, Vitruvius, who has left us so many valuable notices of the ancient arts, acquaints us, that there was a kind of painting which absolutely required a mixture of oil: And Pliny, to the same purpose, expressly says, "Sun and moon shine are inimical and obnoxious to red lead. The remedy is to apply the red wax when hot and melted *with some oil* on the well-dried walls, which is to be done with brushes."

Rise, Progress, and Decline.

11  
Whether the ancients painted in oil.

From

Rise, Progress, and Decline.

From these observations, the evidence which the ancients have given us in behalf of themselves, and of their knowledge of oil painting, may be summed up in few words.

Their having been acquainted with the white chalk ground, which many modern masters have used for oil painting on boards, proves no more than that the ancients might have done the same.

The oil varnishes used by the Egyptians and by Apelles might have brought them to the discovery of oil painting; but as it appears both from mummies and from the works of Pliny, that their colours were not prepared and mixed with that varnish, and as it is plain rather that this varnish was externally laid over the finished pictures; no other conclusion can be drawn, except that they were within sight of the discovery, and that it is a matter of wonder that they should not have laid hold of it.

The outlines of the old Greek or Etruscan vases are merely fallacious appearances.

The old Greek and Roman paintings on walls and stones are either painted in distemper and fresco, or they have not been sufficiently examined.

The oil used in the coarser wax and wall paintings, proves at most that experiments had been tried with oils; but we have no direct proofs of oil painting having been understood or used by the Egyptians, Greeks, or Romans; and that, however great their skill or ingenuity, they might very well have been within sight and reach of the discovery, and nevertheless have missed it.

12  
Rise, progress, and decline, of modern painting.

The art of painting was revived in Europe about the end of the 13th or beginning of the 14th century. The human mind, however, plunged in profound ignorance, was destitute of every principle of sound philosophy which might enable it to determine on the objects of the arts; and of consequence the painters contented themselves with works adapted to the general taste, without beauty and without proportion. In Italy, where the first attempts were made, they were employed in representing the mysteries of the *passion*, and subjects of a similar nature, on the walls of chapels and churches. Their labours were directed to a vast number of figures, rather than to the beauty and perfection of each; and the art in more modern times has always preserved somewhat of this absurd fault which it contracted at that early period. The artist in our times is not, like those in Greece, at liberty to devote his talents only to men of knowledge and discernment; he is constrained to please those who are rich, and very frequently those who are ignorant. Instead of proposing to himself the perfection of the art as the great object of his pursuit, he must rest his success and character on the facility of his operation and the abundance of his works.

Painting did not long continue in the imperfect condition in which it was left by those who first cultivated it among the moderns. It was natural that their successors should endeavour to surpass them by joining some degree of theory to the barbarous practice they had adopted. The first thing which they discovered, or rather which they revived after the manner of the ancients, was perspective. This made the artists capable of expressing what is called *scenery*, and of giving more effect and more truth to their works.

Dominique Ghirlandaios, a Florentine, was the first who enriched the style of his composition by grouping his figures, and who gave depth to his pictures, by distinguishing, by exact gradations, the spaces which his figures occupied: but his successors have far surpassed him in boldness of composition.

Leonard da Vinci, Michael Angelo, Giorgion, Titian, Bartholomew de St Marc, and Raphael, flourished about the end of the 14th century. Leonard da Vinci was the inventor of a great many details in the art: Michael Angelo, by studying the ancients, and by his knowledge of anatomy, arrived at great elegance in drawing the outlines of his figures: Giorgion enriched the art in general, and gave greater brilliancy to his colours than his predecessors: Titian, by a careful imitation of nature, made great proficiency in the truth and perfection of his tones: Bartholomew de St Marc studied particularly the part of drapery, and discovered the *claro-obscuro*, the best manner of giving drapery to his figures, and of making the naked to be felt even where they were covered: Raphael, endowed with a superior genius, began with studying carefully all his predecessors and all his contemporaries. He united in himself all the excellencies which they possessed; and formed a style more perfect and more universal than any painter who went before or who has succeeded him. But while he excelled in every part of the art, he was chiefly superior in those of invention and of composition. It is probable that the Greeks themselves would have been filled with admiration if they had beheld his chief pieces in the Vatican, where to the greatest abundance of paintings is joined so much perfection, and purity, and ease.

After painting had arrived at the greatest perfection among the Greeks by the exertions of Zeuxis and Parrhasius, Apelles found nothing to add to the art except grace; in the same manner among the moderns, after Raphael had appeared, grace was the only thing wanting to the art, and Correggio became the Apelles of Europe. Painting was by him carried to the highest degree among the moderns; the taste of the best critics and the eye of the vulgar were equally gratified.

After these great masters a considerable interval elapsed till the time of the Carracci. Those artists, born at Bologna, by studying the works of their predecessors with great care, and particularly those of Correggio became the first and the most celebrated of their imitators. Hannibal possessed a very correct design, and united somewhat of the ancient style to that of Lewis his brother; but he neglected to inquire into the intricate principles and philosophy of the art. The pupils of the Carracci formed a school after their manner; but Guido, a painter of an easy and happy talent, formed a style altogether graceful, and rich, and easy. Guershen formed after Carravaggio, or invented himself a particular style of the *claro-obscuro*, composed of strong shades and vivid oppositions.

Peter de Cortone succeeded those great imitators of their predecessors and of nature; who finding it difficult to succeed in that kind of painting, and having besides great natural abilities, applied himself chiefly to composition or arrangement, and to what the artists call taste. He distinguished invention from composition; appeared not to have attended to the former, but

Rise, Pro-  
gress, and  
Decline.

but chiefly to those parts which are most prominent in the picture, and to the contrasting of groups. It was then that the practice was introduced of loading pictures with a great number of figures, without examining whether or not they agreed to the subject of the history. The ancient Greeks employed a very small number of figures in their works, in order to make the perfection of those which they admitted more evident. The disciples or imitators of Cortona, on the other hand, have sought to conceal their imperfections by multiplying their figures. This school of Cortona is divided into many branches, and has changed the character of the art. The multiplication of figures, without a judicious and proper choice, carried back the art of painting to that point where the first restorers of it among the moderns had left it; while at the same time the disciples of Cortona were enabled to give to this first condition of the art a greater degree of perfection than the first artists.

About the middle of the 17th century flourished at Rome Carlo Maratti, who, aiming at the greatest perfection, carefully studied the works of the first painters, and particularly those of the school of the Caracci. Although he had already studied nature, he discovered by the works of these artists that it is not always proper to imitate her with a scrupulous exactness. This principle, which he extended to every part of the art, gave to his school a certain style of carefulness, which however is considerably degenerated.

France has also produced great masters, particularly in the part of composition; in which Poussin, after Raphael, is the best imitator of the style of the ancient Greeks. Charles Le Brun and many others distinguished themselves for great fertility of genius; and as long as the French school departed not from the principles of the Italian school, it produced masters of great merit in the different branches of the art.

Mengs, from whom this account is taken, is not deceived when he declares the art of painting to have degenerated in France after Le Brun; but he seems to be mistaken in giving the imitation of the works of Rubens found at Paris as the cause of this decay. It appears from this opinion, that the recent French school was not well known to him. The French, indeed, if we may believe their own authors, were never much occupied in the imitation of Rubens; and they have for a long time despised him. But the perfection of the dramatic art in France, the dress of their actors, the magnificence and manners of the court, have contributed very much to the decay of painting. Instead of forming their taste on the beautiful simplicity of nature, their painters studied the gestures and the attitudes of comedians, the fopperies of women of fashion, the affected airs of courtiers, the pageantry of Versailles, and the magnificence of the opera. Mengs says, "that the French have formed a national style, of which ingenuity and what they call *esprit* are the discriminating qualities: that they have ceased to introduce Greek, Egyptian, Roman, or barbarian personages into their paintings; and that, after the example of Poussin, they content themselves with figures altogether French, as if it were their intention to hand down to posterity that such a nation once existed."

Since, according to the confession of Mengs, their

Rise, Pro-  
gress, and  
Decline.

figures are altogether French, there is no reason to believe that the French painters have imitated Rubens, whose works are marked much more strongly than those of his master Æneus with his Flemish character. The truth is, that their painters, like Cortona and Maratti, have crowded their pictures with a great number of figures; have grouped them in a manner most calculated to strike the senses; have been more intent on agreeable artifices than expression and beauty; and, finally, that they have borrowed the manners of the court and the theatre.

The first masters of the great schools of painting, with the ancients and nature for their guides, and their genius for their support, carried every part of the art to the greatest height of perfection. Those who followed them, and who had the example of their predecessors in addition to the first sources of truth and beauty, did by no means arrive at the same excellence. The Caraccis in their school, Paul Veronese, and all the painters of his time, Vandyke, and all those who exercised the art in Italy, in Flanders, and in France, supported it with great brilliancy. But soon after the number of artists was multiplied; and slavishly copying men of inferior talents, they produced works of an inferior nature. Some wanting to be colourists, their pieces were exaggerated; others affecting simplicity became cold and insipid. At this period of the art, men of real abilities, and covetous of fame, who wished to rise superior to the mediocrity of the times, seem not to have taken the road of truth and nature. They affected a style of pompous preparation, and annexed a kind of merit to the expert management of the pencil. The affected forms of Cortona and of his pupils, the fantastical attitudes and the poignant effect of Piazzette, and in short the ingenious contrivances of the last masters of the French school, are decided proofs of this increasing bad taste.

It appears, that for some time past greater pains has been taken to form men for the art than to encourage those who possess the talent. In consequence of this ruinous practice, schools for drawing, very different from those formed by able painters, have been exceedingly multiplied; and these give the elements according to an uniform system, by which the mind is laid under a regular restraint at the very threshold of the profession. This evil is productive of two inconveniences; it gives middling painters, and it multiplies them to that degree, as to hasten the downfall and bring into contempt the art itself.

The particular reputation of the Italian painters furnishes another reason for the decline of the art. The first painters of that country were few in number; they were honoured, and they deserved to be honoured. Their distinguished reputation has conferred a value on the general paintings of their countrymen. The desire of possessing taste, or of being thought to possess it, has led the rich and the ignorant of all nations to give a preference to the Italian market. Necessity, in this case, would multiply the painters; and their abilities must bear a pretty exact proportion to the discrimination of those who give the price.

The decline of painting has also arisen from the despotism which for some time reigned in the academic societies. In fact, these have often been ruled by men

Schools.

men who would force every exertion of genius into their peculiar tract of operation. If they required such or such merit of execution, the first principles of the art were neglected for that peculiar excellency. In this manner the schools were absolute in behalf of design as long as statuary was held in chief estimation. The artist, whose abilities and inclination led him to colouring, was obliged to abandon a pursuit which could be of no service to him, and devote himself to that for which he was not qualified by nature. On the other hand, if the instructions of the schools be confined to colouring, a mind disposed to the choice and exactness of forms will find no encouragement, and be for ever lost to the art. In this manner the ignorance of those who wish to be connoisseurs, and the narrow views of those who pretend to direct the general taste, have equally contributed to the decline of the arts.

### SECT. II. *Of the Schools.*

A SCHOOL, in the fine arts, denominates a class of artists who have learned their art from a certain master, either by receiving his instructions, or by studying his works; and who of consequence discover more or less of his manner, from the desire of imitation, or from the habit of adopting his principles.

All the painters which Europe has produced since the renovation of the arts are classed under the following schools: the school of Florence, the school of Rome, the school of Venice, the Lombard school, the French school, the German school, the Flemish school, the Dutch school, and the English school.

13  
School of  
Florence.

This school is remarkable for greatness; for attitudes seemingly in motion; for a certain dark severity; for an expression of strength; by which grace perhaps is excluded; and for a character of design approaching to the gigantic. The productions of this school may be considered as overcharged; but it cannot be denied that they possess an ideal majesty, which elevates human nature above mortality. The Tuscan artists, satisfied with commanding the admiration, seem to have considered the art of pleasing as beneath their notice.

This school has an indisputable title to the veneration of all the lovers of the arts, as the first in Italy which cultivated them.

Painting, which had languished from the destruction of the Roman empire, was revived by Cimabue, born of a noble family in Florence in the year 1240. This painter translated the poor remains of the art from a Greek artist or two into his own country. His works, as may easily be imagined, were in a very ordinary style, but they received the applause and admiration of his fellow-citizens; and if Cimabue had not found admirers, Florence in all probability would not have been honoured with Michael Angelo. The number of painters became soon so considerable in Florence, that in the year 1350 they established a society under the protection of St Luke.

Masaccio, towards the beginning of the 15th century, gave more grandeur to his figures, adjusted their dress better, and shed over them a kind of life and expression. He was surpassed by Masaccio his pupil; who first gave force, animation, and relief to his works.

Andrew Castagna was the first Florentine who painted in oil. But Leonardo da Vinci and Michael Angelo, cotemporary painters, were the glory of the school of Florence. Michael Angelo was superior to Leonardo in grandeur, in boldness of conception, and in knowledge of design; but Leonardo was superior to him in all the amiable parts of the art. Leonardo, possessed of a fine imagination, and full of sensibility, devoted himself in painting to express the affections of the soul; and if in this sublime branch of the art, he was afterwards surpassed by Raphael, he had at least the glory not only of exceeding all the painters who went before him, but of pursuing a path which none of them had attempted. His design was pure and neat, and not wholly destitute of greatness. He never went beyond nature, and he made a good choice of objects for imitation.

Michael Angelo, less formed to experience sweet affections than vehement passions, sought in nature what the strength of man might accomplish, not that which constitutes beauty. He delighted in being great and terrible, more than in graceful and pleasant attitudes. Well acquainted with anatomy, he knew more exactly than any other artist in what manner to express the joining of the bones of the body, and the office and insertion of the muscles; but too eager to display his knowledge of anatomy, he seems to have forgotten that the muscles are softened by the skin which covers them; and that they are less visible in children, in women, and in young men, than in contracted and vigorous manhood. "In his figures (says Mengs) the articulations of the muscles are so easy and free, that they appear to be made for the attitude in which he represents them. The fleshy parts are too much rounded, and the muscles are in general too large and of too equal strength. You never perceive in his figures a muscle at rest; and although he knew admirably well how to place them, their action is very frequently inconsistent with their situation."

"He did not possess (says Sir Joshua Reynolds) so many delightful parts of the art as Raphael; but those which he had acquired were of a more sublime nature. He saw in painting little more than what might be attained in sculpture; and he confined it to exactness of form and the expression of passions."

He informs us, in one of his letters that he modelled in earth or wax all the figures which he intended to paint. This method was familiar to the great painters of his time, and ought never to be abandoned. It appears that in representing them in this manner in relieve, the painter can imitate them much more exactly than when they are drawn with a crayon or pencil on a plane surface.

"Michael Angelo (continues Sir Joshua Reynolds) never attempted the lesser elegancies and graces in the art. Vafari says, he never painted but one picture in oil; and resolved never to paint another, saying it was an employment only fit for women and children."

"If any man had a right to look down upon the lower accomplishments as beneath his attention, it was certainly Michael Angelo; nor can it be thought strange, that such a mind should have slighted, or have been withheld from paying due attention to all those graces and embellishments of art which have diffused such lustre over the works of other painters."

Ancient

Schools.

Schools.

14  
Roman  
school.

Ancient Rome, rich with the works brought from Greece, or finished in its own bosom by Grecian artists, handed down in its ruins the remains of that glory to which it had been elevated. It was by the study of these remains that the modern artists were formed: they derived from them the knowledge of design, the beauty of exquisite forms, greatness of style, and justness of expression, carried to that length only which did not affect the beauty of the figure. From them also they derived the principles of the art of drapery; and they followed these principles even while they made the drapery of modern paintings more large and flowing than what was practised by the ancient sculptors. The Roman school was altogether devoted to the principal parts of the art, to those which require genius and vast conceptions; and was no farther occupied with colours than what was necessary to establish a difference between painting and sculpture, or rather between painting varied with colours and in *claro-obsuro*.

Raphael Sanzio, born at Urbino in 1483, and scholar to Pietro Perugino, was the undoubted founder of this school. His first manner was that of Perugino his master; but he travelled twice to Florence to study the great artists who flourished in that city.

It was fortunate for Raphael, says Mengs, that he was born in what he terms the infancy of the art, and that he formed himself by copying nature before he had access to see the works of any great master. He began by studying, with great exactness, the simple truth in his figures. He was then ignorant that any choice was necessary; but he saw the works of Leonardo da Vinci, of Massacio, and of Michael Angelo, which gave his genius a new direction. After this he perceived that there was something more in the art of painting than a simple imitation of truth. But the works of those masters were not sufficiently perfect to point out the best choice to make; and he continued in uncertainty till he saw at Rome the works of the ancients. Then he perceived that he had found the true models which he wanted; and in imitating them he had only to follow the natural impulse of his genius.

Habituated by his first manner to imitate nature with precision, it was not difficult to carry the same exactness into the imitation of the ancients; and it was a great advantage to him that he flourished in an age wherein the artists were not arrived at facility of execution, at the expence of rigorous exactness. He never lost sight of nature; but he was instructed by the ancients in what manner she should be studied. He perceived, that the Greeks had not entered into minute details, that they had selected what was great or beautiful, and that one of the chief causes of the beauty of their works was the regularity of their proportions: he began, therefore, by carefully studying this part of the art. He saw also that the joinings of the bones, and the free play of their articulations, are the causes of all graceful movement: he therefore, after the example of the ancients, gave the greatest attention to this part, and was led by these observations not to be contented with the simple imitation of nature.

His design is excellent; but neither so perfect nor so finished as that of the Greeks. He excelled in re-

presenting the character of philosophers, apostles, and other figures of that kind; but he did not equal the Greeks in ideal figures, which ought to carry the impression of divinity. His taste for design was more Roman than Greek, because he formed it chiefly on the *basso-relievos* which he found at Rome. On this account he had the habit of marking strongly the bones and the articulations, and labouring the fleshy parts less; but as these *basso-relievos* are very exact with regard to the reciprocal proportions of every member, he excelled in this part, while at the same time he did not give to his figures all the elegance of the Greek artists, nor the flexibility of articulation which is admired in the Laocoon, in the Apollo of Belvidere, and in the Gladiator.

The manners and spirit of his age, and the subjects which he most commonly treated, prevented him from reaching the ideal of the ancients. Having seldom occasion to represent figures altogether ideal, he devoted himself to purity of expression. He knew that the expression of the passions of the soul is absolutely necessary in an art which represents the actions of men, since from those affections the actions may be said truly to originate. To make figures act, and yet neglect the interior springs of action, is nothing more than a representation of automata. The attitudes and action are evident; but they appear not to act of themselves, because they are void of those principles from which alone men are supposed to act. An artist who neglects expression, gives no just representation of character, even though he should take nature for his model.

Raphael's first care, when he wanted to compose a piece, was to weigh the expression; that is to say, to establish, according to the nature of the subject, the passions which were to animate the characters. All the figures, all the accessories, all the parts of the composition, were moulded to the general expression.

As he had not found examples in the ancient statues of *claro-obsuro*, he was comparatively weak in this part; and if there was any thing remarkable in his distribution of light and shade, he owed it to the works of the Florentine painters. It cannot be said, however, even with regard to the *claro-obsuro*, that he imitated nature without taste. He delighted in what are called *masses* of light; and disposed the great lights in the most conspicuous places of his figures, whether naked or in drapery. If this method did not produce effects highly illusive, it gives his works that distinctness which makes his figures conspicuous at a distance; and this must be allowed to be an essential part of the art of painting. He did not proceed beyond this; and content with that kind of *claro-obsuro* which comprehends imitation, he never attempted that which is ideal.

The composition and the *ensemble* of his figures were the chief excellences of Raphael. His philosophical mind could not be affected with objects which had not expression. He had too high an idea of painting to consider it as a mute art; he made it speak to the heart and soul; and he could only do this in subjects which required expression. If Raphael did not reach the Greek excellence, if he did not possess the art of embellishing nature in the same high degree, he saw at least, and imitated her in whatever was expressive and beau-

School's.

Schools.

beautiful. "The Greeks failed with majesty (says Mengs) between earth and heaven: Raphael walked with propriety on the earth."

"Composition is in general (says the same author) of two kinds: Raphael's is the expressive kind; the other is the theatrical or picturesque, which consists of an agreeable disposition of the figures. Lanfranc was the inventor of this last, and after him Pietro de Cortona. I give the preference to Raphael; because reason prevails over all his works, or at least the greatest part of them. He never allowed himself in common ideas, and was never allured to give any thing in his accessory figures which might turn the attention from the principal object of the piece."

A history of the schools is nothing more than a history of the painters who founded them. In those two which we have already given, Michael Angelo and Raphael come readily forward to claim our attention; and therefore we cannot do better than conclude the account by the masterly contrast of these eminent painters given by Sir Joshua Reynolds. "If we put those great artists (says he) in a light of comparison with each other, Raphael had more taste and fancy, Michael Angelo more genius and imagination. The one excelled in beauty, the other in energy. Michael Angelo has more of the poetical in operation; his ideas are vast and sublime; his people are a superior order of beings; there is nothing about them, nothing in the air of their actions, or their attitudes, or the style and cast of their limbs or features, that puts one in mind of their belonging to our species. Raphael's imagination is not so elevated; his figures are not so much disjointed from our own diminutive race of beings, though his ideas are chaste, noble, and of great conformity to their subjects. Michael Angelo's works have a strong, peculiar, and marked character: they seem to proceed from his own mind entirely; and that mind so rich and abundant, that he never needed, or seemed to disdain, to look abroad for foreign help. Raphael's materials, are generally borrowed, though the noble structure is his own. The excellency of this extraordinary man, lay in the propriety, beauty, and majesty of his characters: his judicious contrivance of composition, correctness of drawing, purity of taste, and the skilful accommodation of other mens conceptions to his own purpose."

This school is the child of nature. The Venetian painters, not having under their eyes like the Roman the remains of antiquity, were destitute of the means of forming a just idea of the beauty of forms and of expression. They copied without choice the forms of nature; but they were chiefly delighted with the beauties which presented themselves in the mixture and the variety of natural colours. Their attention not being detached from this part by any thing of greater importance, colouring was their chief object, and they succeeded in it. They did not rest contented with characterizing the objects by comparison, in making the colour proper for one of more value by the colour more proper for another; but they endeavoured still further, by the agreement and opposition of the coloured objects, and by the contrast of light and shade, to produce a vigorous effect, to demand and fix the attention. Dominic, who was said to have perished at Florence by the jealousy of André Castagna,

and who was the second Italian artist who painted in oil, had educated, before he quitted Venice, his native country, Jacques Bellin, who was remarkable for nothing but the picturesque education which he gave to Gentel and John his two sons.

Gentel, who was the eldest, painted chiefly in water colours. John contributed much to the progress of his art in painting constantly in oil, and after nature. Although he always retained great stiffness in his manner, he had less than his father or brother. Great neatness of colouring, and an approach to harmony, are evident in his works. His taste in design is Gothic, the air of his heads is sufficiently noble, his attitudes are without judgment, and his figures without expression. He had for scholars Giorgion and Titian, who deserve to be considered as the founders of the Venetian school.

Giorgion distinguished himself by a design of a better taste than that of his master; but he chiefly surpassed him in colouring. He died in his 32d year: and excited the emulation of Titian, who soon greatly excelled him.

Tiziano Vecelli, known best by the name of *Titian*, was instructed to copy nature in the most servile manner in the school of John Bellin; but when he had seen the works of Giorgion, he began to study the ideal in colouring.

The truth of history is not to be expected in his historical paintings, or in those of the artists of the same school. He seems to have paid little attention to the consistence of scene, to the costume, to expression adapted to the subject, or, finally, to the accommodation of parts which characterise the works of those who have studied the ancients. He was in short a great painter, and nothing more.

But although he deserves not to be placed among the most distinguished artists in point of judgment, yet he is by no means destitute of great and noble conceptions. There is often to be found among his male figures a considerable degree of grandeur: but if he has sometimes, like Michael Angelo, overcharged his design, it was more discovered in the swelling of the soft and fleshy parts, than in vigour and muscular strength.

Almost entirely devoted to simple imitation, he had scarcely greater choice in the *claro-obscuro* than in design. He cannot be justly reproached at the same time for weakness in this particular; because in endeavouring to imitate the colours of nature, he was obliged to observe the degrees of light. And in proportion as he succeeded in the imitation of natural colours, he must be less defective than the *claro-obscuro*; but it is not in the knowledge of this part of the art that we are to seek for the beauties of his works. These are to be found in the happy dispositions of colours both proper and local, and he carries this to the highest point of perfection.
