4th. Though a fraction less than a farthing is of no consequence, and may be rejected, the learner must be careful lest he lose more than a farthing, by rejecting several remainders in the same calculation.

Sect. ii. Deductions *on* Weights, &c.

The full weight of any merchandise, together with that of the cask, box, or other package, in which it is contained, is called the *gross weight*. From this we must make proper deductions, in order to discover the quantity, for which price or duty should be charged, which is called the *nett weight*.

Tare is the allowance for the weight of the package; and this should be ascertained by weighing it before the goods are packed. Sometimes, however, particularly in payment of duty, it is customary to allow so much *per* C. or so much *per* 100 lb. in place of tare.

Tret is an allowance of 4 lb. on 104 granted on currants, and other goods on which their is waste, in order that the weight may answer when the goods are retailed.

Cloff, or Draught, is a further allowance granted on some goods in London, of 2 lb. on every 3 C. to turn the scale in favour of the purchaser. The method of calculating these and the like will appear from the following examples.

Ex. 1st. What is the nett weight of 17 C. 2 q. 14 lb. tare 18 lb. *per* cwt.

	C. q. lb.		C. q. lb.
	17 2 14 gross, or,		17 2 14
			6
16 lb. $=\frac{1}{7}$C.	2 2 2		105 3 —
2lb. $=\frac{1}{8}$ of 16lb	1 7		3
18lb.	2 3 9¼ tare.		317 1
	14 3 4¾ nett.	28)	317¼ lb. C. q. lb.
		4)	11 9¼ (2 3 9¼ t.

In the first method, we add the tare at 16 lb. which is $\frac{1}{7}$ of the gross weight to the tare, at 2lb. which is $\frac{1}{8}$ of the former. In the second, we multiply the gross weight by 18; the tare is 1 lb. for each cwt. of the product, and is reduced by division to higher denominations.

2d.] What is Tret of 158 C. 2 q. 24 lb.?

	C. q. lb.	C. q. lb.
26)	158 2 26.	(6 — 11 Tret.
	156	
	2	
	4	
	10	
	28	
	286	
	280	
	0	

Because tret is always 4 lb. in 104, or 1 lb. in 26, it is obtained by dividing by 26.

3d.]

3d.] What is the closs on 28 C. 2 q.?

```
      C.  q.
      28  2
          2
     ------
   3) 57  (19 lb.
```

This allowance being 2 lb. on every 3 C. might be found by taking ⅓ of the number of C's and multiplying it by 2. It is better to begin with multiplication, for the reason given p. 300. col. 2. par. 1.

19 Sect. iii. Commission, &c.

It is frequently required to calculate allowances on sums of money, at the rate of so many *per* L. 100. Of this kind is Commission, or the allowance due to a factor for buying or selling goods, or transacting any other business; Premium of Insurance, or allowance given for engaging to repay one's losses at sea, or otherwise; Exchange, or the allowance necessary to be added or subtracted for reducing the money of one place to that of another; Premiums on Stocks, or the allowance given for any share of a public stock above the original value. All these and others of a like kind are calculated by the following.

Rule. "Multiply the sum by the rate, and divide the product by 100. If the rate contain a fraction, take proportional parts."

Ex. What is the commission on L. 728, at 2¾ *per cent.*

```
                 728
                   2
                ----
2 per cent.     1456
½                364
¼                182
                ----
       1|00)20|02
              20
             ---
              40
              12
             ---
             4|80
               4 Answ. L. 20——4¾
             ---
             3|20
```

When the rate is given in guineas, which is common in cases of insurance, you may add a twentieth-part to the sum before you calculate. Or you may calculate at an equal number of pounds, and add a twentieth-part to the answer.

When the given sum is an exact number of 10 pounds, the calculation may be done without setting down any figures. Every L. 10, at ½ *per cent.* is a shilling; and at other rates in proportion. Thus, L. 170, at ½ *per cent.* is 17 s.; and, at ¼ *per cent.* 8 s. 6 d.

20 Sect. iv. Interest.

Interest is the allowance given for the use of money by the borrower to the lender. This is computed at so many pounds for each hundred lent for a year, and a like proportion for a greater or a less time. The highest rate is limited by our laws to 5 *per cent.* which is called the *legal interest*; and is due on all debts constituted by bond or bill, which are not paid at the proper term, and is always understood when no other rate is mentioned.

The interest of any sum for a year, at any rate, is found by the method explained in the last section.

The interest of any number of pounds for a year, at 5 *per cent.* is one twentieth-part, or an equal number of shillings. Thus, the interest of L. 34675 for a year is 34675 shillings.

The interest for a day is obtained by dividing the interest for a year, by the number of days in a year. Thus, the interest of L. 34675 for a day is found by dividing 34675 shillings by 365, and comes to 95 shillings.

The interest for any number of days is obtained by multiplying the daily interest by the number of days. Thus, the interest of L. 34675 for 17 days, is 17 times 95 shillings, or 1615 shillings; and this divided by 20, in order to reduce it, comes to L. 80 : 15 s.

It would have served the same purpose, and been easier to multiply at first by 17, the number of days; and, instead of dividing separately by 365, and by 20, to divide at once by 7300, the product of 365 multiplied by 20; and this division may be facilitated by the table inserted p. 298. col. 1.

The following practical rules may be inferred from the foregoing observations.

I. *To calculate interest at 5 per cent.* "Multiply the principal by the number of days, and divide the product by 7300."

II. *To calculate interest at any other rate.* "Find what it comes to at 5 *per cent.* and take a proper proportion of the same for the rate required."

Ex. 1st.] Interest on L. 34675 for 17 days, at 5 *per cent.*

```
           34675
              17
          ------

Practice.

Int. at 5 per cent.	L. —	6	8
Deduce $\frac{1}{5}$	—	1	4
Int. at 4 per cent.	L. —	5	4

When partial payments are made, we proceed in the following manner: Let us suppose a bill of L. 170 was due 12th of August, that L. 54 was paid on the 18th September, L. 56 on the 17th October, and the balance on the 14th November; and let it be required to find how much interest is due.

	L.	Days.		
Aug. 12. L.	170	37	1190	
Sept. 18. pd.	54		510	
				6290
	116	29	1044	
Oct. 17. pd.	56		232	
				3364
	60	28		1680
Nov. 14. pd.	60			
	0		7300)	11334(L. 1 : 11 : $\frac{1}{4}$.

Here we subtract the several payments from the original sum in their order, placing the dates in the margin: and from this it appears that there is interest due on L. 170 from 12th August to 18th September, or L. 110 from 18th September to 17th October, and on L. 60 from 17th October to 14th November. We next compute the number of days in each of these periods, and mark it against the respective sum. Then we multiply each sum by the number of days; reserving a column, when necessary, for the products of the several figures in the multiplier. Lastly, we add these products, and divide their sum by 7300.

Interest on current accounts is calculated nearly in the same manner. For example, let the interest due on the following account be required to 31st July, at 4 per cent?

Dr. Mr A. Baird, his account current with W. Neil, Cr.

1775.					1775.

							1351	
31.		91			12		1092	
					197	7300	25813	(L. 3 10 $8\frac{1}{2}$ at

Deduce $\frac{1}{5}$ part		14	$1\frac{1}{2}$
Interest at 4 per cent.	L. 2	16	7

Here the sums on either side of the account are introduced according to the order of their dates. Those on the Dr. side are added to the former balance, and those on the Cr. side subtracted. Before we calculate the days, we try if the last sum L. 91, be equal to the balance of the account, which proves the additions and subtractions; and, before multiplying, we try if the sum of the column of days be equal to the number of days, from 15th January to 31st of July.

In the 5th and 6th multiplications, we begin at the pence column, and take in the carriage. In the 7th, instead of multiplying the 6s. 8d. by 21, we add the third-part 21 to the product, because 6s. 8d. is the third of a pound. This is done by marking down the second line 1287, instead of 1280. As the computation on the odd shillings and pence is troublesome, and makes a very small increase of the interest, some neglect them altogether; others add one to the pound, when the shillings exceed 10, and neglect them when below it.

2d.] Required interest on the following account to 31st December, allowing 5 per cent, when the balance is due to J. T. and 4 per cent. when due to N. W.

Dr. Mr J. T. his account current with N. W. Cr.

Due to N. W. at 4 per cent.	L. 5	3	4
Due to J. T. at 5 per cent.	3	7	$11\frac{1}{2}$
Balance due to N. W.	L. 1	15	$4\frac{1}{2}$

In

In this account, the balance is sometimes due to the one party, sometimes to the other. At the beginning, there is a balance due to N. W.: and, on the 9th of April, there is L. 200 due him. On the 12th of May, J. T. pays him L. 300, which discharges what he owed, and leaves a balance of L. 100 due him. The balance continues in J. T's favour till the 24th of September, when N. W. pays L. 242. These changes are distinguished by the marks Dr. and Cr. The products are extended in different columns, and divided separately.

When payments are made on constituted debts, at considerable distances of time, it is usual to calculate the interest to the date of each payment, and add it to the principal, and then subtract the payment from the amount.

Ex. A bond for L. 540 was due the 18th Aug. 1772; and there was paid 19th March 1773, L. 50; and 19th December 1773, L. 25; and 23d September 1774 L. 25; and 18th August 1775 L. 110. Required the interest and balance due on the 11th November 1775?

21 ## Chap. VIII. VULGAR FRACTIONS.

In order to understand the nature of vulgar fractions, we must suppose unity (or the number 1) divided into several equal parts. One or more of these parts is called a *fraction*, and is represented by placing one number in a small character above a line, and another under it: For example, two-fifth parts is written thus, $\frac{2}{5}$. The number under the line (5) shows how many parts unity is divided into, and is called the *denominator*. The number above the line (2) shews how many of these parts are represented, and is called the *numerator*.

It follows from the manner of representing fractions, that, when the numerator is increased, the value of the fraction becomes greater; but, when the denominator is increased, the value becomes less. Hence we may infer, that, if the numerator and denominator be both increased, or both diminished, in the same proportion, the value is not altered; and therefore, if we multiply both by any number whatever, or divide them by any number which measures both, we shall obtain other fractions of equal value. Thus, every fraction may be expressed in a variety of forms, which have all the same signification.

A fraction annexed to an integer, or whole number, makes a mixed number. For example, five and two third-parts, or $5\frac{2}{3}$. A fraction whose numerator is greater than its denominator is called an *improper fraction*. For example, seventeen third-parts, or $\frac{17}{3}$. Fractions of this kind are greater than unity. Mixed numbers may be represented in the form of improper fractions, and improper fractions may be reduced to mixed numbers, and sometimes to integers. As fractions whether proper or improper, may be represented in different forms, we must explain the method of reducing them from one form to another, before we consider the other operations.

Problem I. "To reduce mixed numbers to improper fractions; Multiply the integer by the denominator of the fraction, and to the product add the numerator. The sum is the numerator of the improper fraction sought, and is placed above the given denominator." *Ex.* $5\frac{2}{3}=\frac{17}{3}$

5 integer.
3 denominator.
—
15 product
2 numerator given.
—
17 numerator sought.

Because one is equal to two halves, or 3 third parts, or 4 quarters, and every integer is equal to twice as many halves, or four times as many quarters, and so on; therefore, every integer may be expressed in the form of an improper fraction, having any assigned denominator: The numerator is obtained by multiplying the integer into the denominator. Hence the reason of the foregoing rule is evident. 5, reduced to an improper fraction, whose denominator is 3, makes $\frac{15}{3}$, and this added to $\frac{2}{3}$ amounts to $\frac{17}{3}$.

Problem II. "To reduce improper fractions to whole or mixed numbers: Divide the numerator by the denominator."

Ex. $\frac{112}{17}=6\frac{10}{17}$

17)112($6\frac{10}{17}$
102
——
10

1. $\frac{3248}{16}$ 5. $\frac{365}{15}$
2. $\frac{342}{12}$ 6. $\frac{7394}{37}$
3. $\frac{7536}{27}$ 7. $\frac{8642}{93}$
4. $\frac{15764}{378}$ 8. $\frac{4362}{218}$

This problem is the converse of the former, and the reason may be illustrated in the same manner.

Problem III. "To reduce fractions to lower terms. Divide both numerator and denominator by any number which measures both, and place the quotients in the form of a fraction."

Example. $\frac{135}{360} = \frac{27}{72} = \frac{3}{8}$

Here we observe that 135 and 360 are both measured by 5, and the quotients form $\frac{27}{72}$, which is a fraction of the same value as $\frac{135}{360}$ in lower terms. Again, 27 and 72 are both measured by 9, and the quotients form $\frac{3}{8}$, which is still of equal value, and in lower terms.

It is generally sufficient, in practice, to divide by such measures as are found to answer on inspection, or by the rules given p. 396. col 2. But if it be required to reduce a fraction to the lowest possible terms, we must divide

Vulgar Fractions.

vide the numerator and denominator by the greatest number which measures both. What number this is may not be obvious, but will always be found by the following rule.

To find the greatest common measure of two numbers, divide the greater by the lesser, and the divisor by the remainder continually, till nothing remain; the last divisor is the greatest common measure.

Example. Required the greatest number which measures 475 and 589?

```
475)589(1
    475
    ———
    114)475(4
        456
        ———
         19)114(6
            114
            ———
              0
```

Here we divide 589 by 475, and the remainder is 114; then we divide 475 by 114, and the remainder is 19; then we divide 114 by 19, and there is no remainder: from which we infer; that 19 the last divisor, is the greatest common measure.

To explain the reason of this, we must observe, that any number which measures two others, will also measure their sum, and their difference, and will measure any multiple of either. In the foregoing example, any number which measures 589, and 475, will measure their difference 114; and will measure 456, which is a multiple of 114; and any number which measures 475, and 476, will also measure their difference 19. Consequently, no number greater than 19 can measure 589 and 475. Again, 19 will measure them both, for it measures 114, and therefore measures 456, which is a multiple of 114, and 475, which is just 19 more than 456; and, because it measures 475 and 114, it will measure their sum 589. To reduce $\frac{475}{589}$ to the lowest possible terms, we divide both numbers by 19, and it comes to $\frac{25}{31}$.

If there be no common measure greater than 1, the fraction is already in the lowest terms.

If the greatest common measure of 3 numbers be required, we find the greatest measure of the two first, and then the greatest measure of that number, and the third. If there be no numbers, we proceed in the same manner.

Problem IV. "To reduce fractions to others of "equal value that have the same denominator: 1st. "Multiply the numerator of each fraction by all the "denominators except its own. The products are numerators to the respective fractions sought." 2d. "Multiply all the denominators into each other; the "product is the common denominator."

Ex. $\frac{4}{5}$ and $\frac{7}{9}$ and $\frac{3}{8}=\frac{288}{360}$ and $\frac{280}{360}$ and $\frac{135}{360}$.

$4\times9\times8=288$ first numerator.

$7\times5\times8=280$ second numerator.

$3\times5\times9=135$ third numerator.

$5\times9\times8=360$ common denominator.

Here we multiply 4, the numerator of the first fraction, by 9 and 3 the denominators of the two others; and the product 288 is the numerator of the fraction sought, equivalent to the first. The other numerators are found in like manner, and the common denominator 360, is obtained by multiplying the given denominators 5, 9, 8, into each other. In the course of the whole operation, the numerators and denominators of each fraction are multiplied by the same number, and therefore their value is not altered.

The fractions thus obtained may be reduced to lower terms, if the several numerators and denominators have a common measure greater than unity. Or, after arranging the number for multiplication, as is done above, if the same number occur in each rank, we may dash them out and neglect them; and, if numbers which have a common measure occur in each, we may dash them out and use the quotients in their stead; or any number which is a multiple of all the given denominators, may be used as a common denominator. Sometimes a number of this kind will occur on inspection, and the new numerators are found by multiplying the given ones by the common denominator, and dividing the products by the respective given denominators.

If the articles given for any operation be mixed numbers, they are reduced to improper fractions by problem I. If the answer obtained be an improper fraction, it is reduced to a mixed number by problem II. And, it is convenient to reduce fractions to lower terms, when it can be be done, by problem III. which makes their value better apprehended, and facilitates any following operation. The reduction of fractions to the same denominator by problem IV. is necessary to prepare them for addition or subtraction, but not for multiplication or division.

1. Addition *of* Vulgar Fractions. 22

Rule. "Reduce them, if necessary, to a common "denominator; add the numerators, and place the "sum above the denominator."

Ex. 1st.] $\frac{3}{5}+\frac{2}{9}=\frac{27}{45}+\frac{10}{45}$ by problem IV. $=\frac{37}{45}$

2d.] $\frac{5}{7}+\frac{8}{9}+\frac{9}{10}=\frac{450}{630}+\frac{560}{630}+\frac{567}{630}=\frac{1577}{630}$ by problem II. $=3\frac{317}{630}$

The numerators of fractions that have the same denominator signify like parts; and the reason for adding them is equally obvious, as that for adding shillings or any other inferior denomination.

Mixed numbers may be added, by annexing the sum of the fractions to the sum of the integers. If the former be a mixed number, its integer is added to the other integers.

2. Subtraction *of* Vulgar Fractions. 23

Rule. "Reduce the fractions to a common deno"minator; subtract the numerator of the subtrahend "from the numerator of the minuend, and place the "remainder above the denominator."

Ex. Subtract $\frac{2}{7}$ from $\frac{5}{12}$ remainder $\frac{11}{84}$.

$\left.\begin{array}{l}\frac{5}{12}=\frac{35}{84}\\ \frac{2}{7}=\frac{24}{84}\end{array}\right\}$ by Prob. IV.

from 35
take 24
——
rem. 11

To subtract a fraction from an integer: subtract the numerator from the denominator, and place the remainder above the denominator; prefix to this the integer diminished by unity.

Ex. Subtract $\frac{3}{5}$ from 12 remainder $11\frac{2}{5}$

To subtract mixed numbers, proceed with the fractions by the foregoing rule, and with the integers in the common method. If the numerator of the fraction in the subtrahend exceed that in the minuend, borrow the value of the denominator, and repay it by adding 1 to the unit-place of the subtrahend.

Ex.

Ex. Subtract $145\frac{7}{9}$ from $248\frac{3}{5}$

$$\left.\begin{array}{l}\frac{3}{5}=\frac{27}{45}\\ \frac{7}{9}=\frac{35}{45}\end{array}\right\}\text{ by Prob. IV.}\qquad \begin{array}{r}248\frac{27}{45}\\ 145\frac{35}{45}\\ \hline 102\frac{37}{45}\end{array}\qquad \begin{array}{c}27\\45\\72\\35\\37\end{array}$$

Here, because 27 the numerator of the fraction in the minuend is less than 35, the numerator of the subtrahend, we borrow 45 the denominator; 27 and 45 make 72, from which we subtract 35, and obtain 37 for the numerator of the fraction in the remainder, and we repay what was borrowed, by adding 1 to 5 in the unit-place of the subtrahend.

The reason of the operations in adding or subtracting fractions will be fully understood, if we place the numerators of the fractions in a column like a lower denomination, and add or subtract them as integers, carrying or borrowing according to the value of the higher denomination.

24 3. Multiplication *of* Vulgar Fractions.

Rule. "Multiply the numerators of the factors "together for the numerator of the product, and the "denominators together for the denominator of the "product."

Ex. 1st.] $\frac{2}{3}\times\frac{5}{7}=\frac{10}{21}$
$2\times5=10$ num.
$3\times7=21$ den.

2d.] $8\frac{2}{5}\times7\frac{3}{4}=\frac{1302}{20}=65\frac{2}{20}$
$8\frac{2}{5}=\frac{42}{5}$ by prob. I.
$7\frac{3}{4}=\frac{31}{4}$ by ditto.
$42\times31=1302$
$5\times\ 4=\ \ 20$.

To multiply $\frac{5}{7}$ by $\frac{2}{3}$ is the same, as to find what two third-parts of $\frac{5}{7}$ comes to; if one-third part only had been required, it would have been obtained by multiplying the denominator 7 by 3, because the value of fractions is lessened when their denominators are increased; and this comes to $\frac{5}{21}$; and, because two-thirds were required, we must double that fraction, which is done by multiplying the numerator by 2, and comes to $\frac{10}{21}$. Hence we infer, that fractions of fractions, or compound fractions, such as $\frac{2}{7}$ of $\frac{3}{5}$ are reduced to simple ones by multiplication. The same method is followed when the compound fraction is expressed in three parts or more.

If a number be multiplied by any integer, its value is increased: If it be multiplied by 1, or taken one time, it undergoes no alteration. If it be multiplied by a proper fraction, or taken from one-half, two-thirds, or the like, its value is diminished, and the product is less than the number multiplied.

The foregoing rule extends to every case, when there are fractions in either factor. For mixed numbers may be reduced to improper fractions, as is done in Ex. 2d.; and integers may be written, or understood to be written in the form of fractions whose numerator is 1. It will be convenient, however, to give some further directions for proceeding, when one of the factors is an integer, or when one or both are mixed numbers.

1st. To multiply an integer by a fraction, multiply it by the numerator, and divide the product by the denominator. *Ex.* $3756\times\frac{3}{5}=2253\frac{3}{5}$

$$\begin{array}{r}3756\\ 3\\ \hline 5)11268(2253\frac{3}{5}\end{array}$$

2d. To multiply an integer by a mixed number, we multiply it first by the integer, and then by the fraction, and add the products.

Ex. $148\times5\frac{3}{4}=793\frac{1}{2}$

$$\begin{array}{l}138\times5=690\\ 138\times\ \frac{3}{4}\\ \quad\ \ 3\\ \hline 4)414(\quad 103\frac{1}{2}\\ \hline \qquad\qquad 793\frac{1}{2}\end{array}$$

3d. To multiply a mixed number by a fraction, we may multiply the integer by the fraction, and the two fractions together, and add the products.

Ex. $15\frac{3}{8}\times\frac{2}{9}=3\frac{5}{12}$

$$\begin{array}{l}15\times\frac{2}{9}=3\frac{3}{9}=3\frac{4}{12}\\ \frac{3}{8}\times\frac{2}{9}=\frac{6}{72}=\frac{1}{12}\\ \hline \qquad\qquad 3\frac{5}{12}\end{array}$$

4th. When both factors are mixed numbers, we may multiply each part of the multiplicand first by the integers of the multiplier, and then by the fraction, and add the four products.

Ex. $8\frac{2}{5}$ by $7\frac{3}{4}$

$$\begin{array}{lll}8\times7= & 56 & \\ 8\times\frac{3}{4}=\frac{24}{4}= & 6 & \text{by prob. II.}\\ \frac{2}{5}\times7=\frac{14}{5}=2\frac{4}{5}= & 2\frac{16}{20} & \\ \frac{2}{5}\times\frac{3}{4}= & \frac{6}{20} & \\ \hline \end{array}$$

product $65\frac{2}{20}$ as before.

4. Division *of* Vulgar Fractions. 25

Rule I. "Multiply the numerator of the dividend by the denominator of the divisor. The product is the numerator of the quotient."

II. "Multiply the denominator of the dividend by "the numerator of the divisor. The product is the "denominator of the quotient."

Ex. Divide $\frac{2}{5}$ by $\frac{7}{9}$. Quotient $\frac{18}{35}$
$2\times9=18$
$5\times7=35$

To explain the reason of this operation, let us suppose it required to divide $\frac{5}{7}$ by 7, or to take one-seventh part of that fraction. This is obtained by multiplying the denominator by 7; for the value of fractions is diminished by increasing their denominators, and comes to $\frac{2}{35}$. Again, because $\frac{7}{9}$ is nine times less than seven, the quotient of any number divided by $\frac{7}{9}$ will be nine times greater than the quotient of the same number divided by 7. Therefore we multiply $\frac{2}{35}$ by 9, and obtain $\frac{18}{35}$.

If the divisor and dividend have the same denominator, it is sufficient to divide the numerators.

Ex. $\frac{12}{17}$ divided by $\frac{3}{17}$ quotes 4.

The quotient of any number divided by a proper fraction is greater than the dividend. It is obvious, that any integer contains more halves, more third-parts, and the like, than it contains units; and, if an integer and fraction be divided alike, the quotients will have the same proportion to the numbers divided; but the value of an integer is increased when the divisor is a proper fraction; therefore, the value of a fraction in the like case is increased also.

The foregoing rule may be extended to every case, by reducing integers and mixed numbers to the form of improper fractions. We shall add some directions for shortening the operation when integers and mixed numbers are concerned.

1st. When the dividend is an integer, multiply it

Vulgar Fractions.

by the denominator of the divisor, and divide the product by the numerator.

Ex. Divide 368 by $\frac{5}{7}$

$$\begin{array}{l} \quad 7 \\ \hline 5)2576\ (515\tfrac{1}{5} \text{ quotient.} \end{array}$$

2d. When the divisor is an integer, and the dividend a fraction, multiply the denominator by the divisor, and place the product under the numerator.

Ex. Divide $\frac{3}{8}$ by 5 quotient $\frac{3}{40}$

$8 \times 5 = 40$

3d. When the divisor is an integer, and the dividend a mixed number, divide the integer, and annex the fraction to the remainder; then reduce the mixed number thus formed, to an improper fraction, and multiply its denominator by the divisor.

Ex. To divide $576\frac{4}{11}$ by 7 quotient $82\frac{26}{77}$

$$\begin{array}{l} 7)\ 576\ (82 \\ \quad 56 \\ \hline \quad\ 16 \\ \quad\ 14 \\ \hline 2\tfrac{4}{11} = \tfrac{26}{11} \\ 11 \times 7 = 77 \end{array}$$

Here we divide 576 by 7, the quotient is 82, and the remainder 2, to which we annex the fraction $\frac{4}{11}$; and reduce $2\frac{4}{11}$ to an improper fraction $\frac{26}{11}$, and multiply its denominator by 7, which gives $\frac{26}{77}$.

Hitherto we have considered the fractions as abstract numbers, and laid down the necessary rules accordingly. We now proceed to apply these to practice. Shillings and pence may be considered as fractions of pounds, and lower denominations of any kind as fractions of higher; and any operation, where different denominations occur, may be wrought by expressing the lower ones in the form of vulgar fractions, and proceeding by the foregoing rules. For this purpose, the two following problems are necessary.

Problem V. "To reduce lower denominations to "fractions of higher, place the given number for the "numerator, and the value of the higher for the de-"nominator."

Examples.

1. Reduce 7 d. to the fraction of a shilling. Ans. $\frac{7}{12}$
2. Reduce 7 d. to a fraction of a pound. Ans. $\frac{7}{240}$
3. Reduce 15 s. 7 d. to a fraction of a pound. Ans. $\frac{187}{240}$.

Problem VI. "To value fractions of higher deno-"minations, multiply the numerator by the value of "the given denomination, and divide the product by "the denominator; if there be a remainder, multi-"ply it by the value of the next denomination, and "continue the division."

Ex. 1st.] Required the value of $\frac{17}{60}$ of L 1.

$$\begin{array}{lll} \quad 17 & & \\ \quad 20 & & \\ \hline & s. & d. \\ 60)340(& 5 & 8 \\ \quad 300 & & \\ \hline \quad\ 40 & & \\ \quad\ 12 & & \\ \hline 60)480 & & \\ \quad 480 & & \\ \hline \quad\ 0 & & \end{array}$$

2d.] Required the value of $\frac{8}{9}$ of 1 Cwt.

$$\begin{array}{lll} \quad 8 & & \\ \quad 4 & & \\ \hline & qrs. & lb. \\ 9)32(& 3 & 15\tfrac{5}{9} \\ \quad 27 & & \\ \hline \quad\ 5 & & \\ \quad 28 & & \\ \hline 9)140 & & \\ \quad\ 9 & & \\ \hline \quad 50 & & \\ \quad 45 & & \\ \hline \quad\ 5 & & \end{array}$$

In the first example, we multiply the numerator 17 by 20, the number of shillings in a pound, and divide the product 340 by 60, the denominator of the fraction, and obtain a quotient of 5 shillings; then we multiply the remainder 40 by 12, the number of pence in a shilling, which produces 480, which divided by 60 quotes 8 d. without a remainder. In the second example we proceed in the same manner; but as there is a remainder, the quotient is completed by a fraction.

Decimal Fractions.

Sometimes the value of the fraction does not amount to a unit of the lowest denomination; but it may be reduced to a fraction of that or any other denomination, by multiplying the numerator according to the value of the places. Thus $\frac{1}{1289}$ of a pound is equal to $\frac{20}{1289}$ of a shilling, or $\frac{240}{1289}$ of a penny, $\frac{960}{1289}$ of a farthing.

Chap. IX. DECIMAL FRACTIONS.

Sect. i. Notation *and* Reduction. 26

The arithmetic of vulgar fractions is tedious, and even intricate to beginners. The difficulty arises chiefly from the variety of denominators; for when numbers are divided into different kinds of parts, they cannot be easily compared. This consideration gave rise to the invention of decimal fractions, where the units are divided into like parts, and the divisions and subdivisions are regulated by the same scale which is used in the Arithmetic of Integers. The first figure of a decimal fraction signifies tenth parts, the next hundredth parts, the next thousandth parts, and so on: and the columns may be titled accordingly. Decimals are distinguished by a point, which separates them from integers, if any be prefixed.

The use of cyphers in decimals, as well as in integers, is to bring the significant figures to their proper places, on which their value depends. As cyphers, when placed on the left hand of an integer, have no signification, but when placed on the right hand, increase the value ten times each; so cyphers, when placed on the right hand of a decimal, have no signification; but when placed on the left hand diminish the value ten times each.

The notation and numeration of decimals will be obvious from the following examples:

4.7	signifies Four, and seventh tenth-parts.
.47	Four tenth-parts, and seven hundredth-parts, or 47 hundredth-parts.
.047	Four hundredth-parts, and seven thousandth-parts, or 47 thousandth-parts.
.407	Four tenth-parts, and seven thousandth-parts, or 407 thousandth-parts.
4.07	Four, and seven hundredth-parts.
4.007	Four, and seven thousandth-parts.

The column next the decimal point is sometimes called *decimal primes*, the next *decimal seconds*; and so on.

To reduce vulgar fractions to decimal ones: "An-"nex a cypher to the numerator, and divide it by "the denominator, annexing a cypher continually "to the remainder."

Ex.

Decimal Fractions.

Ex. 1st.] $\frac{12}{75}$=.16 2d.] $\frac{5}{64}$=.078125 3d.] $\frac{2}{3}$=.666.

```
75)120(16      64)500(078125     3)20(666.
   75             448              18
   ---            ---              --
   450            520             *20
   450            512              18
   ---            ---              --
    0              80              20
                   64              18
                   --              --
                  160              20
                  128
                  ---
                  320
                  320
                  ---
```

4th.] $\frac{5}{6}$=.833 5th.] $\frac{7}{27}$=.259 6th.] $\frac{7}{22}$=.3, 18, 18,

```
6)50(83      27)70(259      22)70(31818
  48            54             66
  --            --             --
 *20           160            *40
  18           135             22
  --           ---             --
  20           250            180
  18           243            176
  --           ---            ---
  20           *70            *40
                               22
                               --
                              180
```

The reason of this operation will be evident, if we consider that the numerator of a vulgar fraction is understood to be divided by the denominator; and this division is actually performed when it is reduced to a decimal.

In like manner, when there is a remainder left in division, we may extend the quotient to a decimal, instead of completing it by a vulgar fraction, as in the following example.

```
     25)646(25 21/25 or 25.84.
        50
        ---
        126
        125
        ---
Rem.   21.0
       200
       ---
        100
        100
        ---
          0
```

From the foregoing examples, we may distinguish the several kinds of decimals. Some vulgar fractions may be reduced exactly to decimals, as Ex. 1st and 2d, and are called *terminate* or *finite decimals*. Others cannot be exactly reduced, because the division always leaves a remainder; but, by continuing the division, we will perceive how the decimal may be extended to any length whatever. These are called *infinite decimals*. If the same figure continually returns, as in Ex. 3d and 4th, they are called *repeaters*. If two or more figures return in their order, they are called *circulates*. If this regular succession go on from the beginning, they are called *pure repeaters*, or *circulates*, as Ex. 3d and 5th. If otherwise, as Ex. 4 and 6th, they are mixed repeaters or circulates, and the figures prefixed to those in regular succession are called the *finite part*. Repeating figures are generally distinguished by a dot, and cirulates by a comma, or other mark, at the beginning and end of the circle; and the beginning of a repeater or circulate is pointed out in the division by an asterisk.

Decimal Fractions.

Lower denominations may be considered as fractions of higher ones, and reduced to decimals accordingly. We may proceed by the following rule, which is the same, in effect, as the former.

To reduce lower denominations to decimals of higher: "Annex a cypher to the lower denomination, and divide it by the value of the higher. When there are several denominations, begin at the lowest, and reduce them in their order."

Ex. To reduce 5 cwt. 2 qr. 21 lb. to a decimal of a ton?

```
28)210(.75     4)2.75(.6875     20)5.6874(.284375
   196            24                40
   ---            --                --
   140            35               168
   140            32               160
   ---            --               ---
    0             30                87
                  28                80
                  --                --
                  20                75
                  20                60
                  --                --
                   0               150
                                   140
                                   ---
                                   100
                                   100
                                   ---
                                     0
```

Here, in order to reduce 21 lb. to a decimal of 1 qr. we annex a cypher, and divide by 28, the value of 1 qr. This gives .75. Then we reduce 2.75 qrs. to a decimal of 1 cwt. by dividing by 4, the value of 1 cwt. and it comes to .6875. Lastly, 5.6875 cwt. is reduced to a decimal of a ton by dividing by 20, and comes to .284375.

To value a decimal fraction: "Multiply it by the value of the denomination, and cut off as many decimal places from the product as there are in the multiplicand. The rest are integers of the lower denomination.

Example. What is the value of .425 of L. 1?

```
      .425
        20
     -----
sh. 8.500
        6
     -----
 d. 3.000
```

Sect. ii. ARITHMETIC *of* TERMINATE DECIMALS.

THE value of decimal places decrease like that of integers, ten of the lower place in either being equal to one of the next higher; and the same holds in passing from decimals to integers. Therefore, all the operations are performed in the same way with decimals, whether

Decimal Fractions.

whether placed by themselves or annexed to integers, as with pure integers. The only peculiarity lies in the arrangement and pointing of the decimals.

In addition and subtraction, "Arrange units under "units, tenth-parts under tenth-parts, and proceed as "in integers."

```
  32.035      from 13.348     and 12.248
 116.374      take  9.2993        10.6752
 160.63            ------         -------
  12.3645           4.0487         1.5728
 --------
 321.4035
```

In Multiplication, "Allow as many decimal places "in the product as there are in both factors. If the "product has not so many places, supply them by "prefixing cyphers on the left hand."

```
Ex. 1st.) 1.37    2d.] 43.75    3d.] .1572
          1.8            48           .12
          ----        -----        ------
          1096        35000        .01864
          137         17500
          -----       -------
          2.466       21.0000
```

The reason of this rule may be explained, by observing, that the value of the product depends on the value of the factors; and since each decimal place in either factor diminishes its value ten times, it must equally diminish the value of the product.

To multiply decimals by 10, move the decimal point one place to the right; to multiply by 100, 1000, or the like, move it as many places to the right as there are cyphers in the multiplier.

In division, "Point the quotient so that there may "be an equal number of decimal places in the divi-"dend as in the divisor and quotient together."

Therefore, if there be the same decimal places in the divisor and dividend, there will be as many in the quotient.

If there be more in the dividend, the quotient will have as many as the dividend has more than the divisor.

If there be more in the divisor, we must annex (or suppose annexed) as many cyphers to the dividend as may complete the number in the divisor, and all the figures of the quotient are integers.

If the division leave a remainder, the quotient may be extended to more decimal places; but these are not regarded in fixing the decimal point.

The reason for fixing the decimal point, as directed, may be inferred from the rule followed in multiplication. The quotient multiplied by the divisor produces the dividend; and therefore the number of decimal places in the dividend is equal to those in the divisor and quotient together.

The first figure of the quotient is always at the same distance from the decimal point, and on the same side as the figure of the dividend, which stands above the unit place of the first product. This also takes place in integers; and the reason is the same in both.

It was formerly observed, that numbers were diminished when multiplied by proper fractions, and increased when divided by the same. Thus, multiplication by fractions corresponds with division by integers; and division by fractions with multiplication by integers; when we multiply by $\frac{1}{2}$ or .5, we obtain the same answers as when we divide by 2, and every integer has a correspondent decimal, which may be called its *reciprocal*. Multiplication by that decimal supplies the place of division by the integer, and division supplies the place of multiplication.

To find the reciprocal of any number, divide 1 with cyphers annexed by that number.

Ex. Required the reciprocal of 625.

```
625)1.000(.0016
     625
     ----
     3750
     3750
     ----
        0
```

The product of any number multiplied by .0016 is the same as the quotient divided by 625. *Example.*

```
625)9375(15          9375
    625              .0016
    ----             -----
    3125             56250
    3125             9375
    ----             -------
       0             15.0000
```

Because .0016 is $\frac{1}{625}$ of unity, any number multiplied by that fraction will be diminished 625 times. For a like reason, the quotient of any number divided by .0016, will be equal to the product of the same multiplied by 625. *Example.*

```
.0016)516.0000(322500        516
       48 ....               625
       --                    ----
        36                   2580
        32                  1032
        --                 3096
         40                ------
         32                322500
         --
          80

          --
           0
```

Sect. iii. Approximate Decimals. 28

It has been shown that some decimals, though extended to any length, are never complete: and others which terminate at last, sometimes consist of so many places, that it would be difficult in practice to extend them fully. In these cases, we may extend the decimal to three, four, or more places, according to the nature of the articles, and the degree of accuracy required, and reject the rest of it as inconsiderable. In this manner we may perform any operation with ease by the common rules, and the answers we obtain are sufficiently exact for any purpose in business. Decimals thus restricted are called *approximates*.

Shillings, pence, and farthings, may be easily reduced to decimals of three places, by the following rule. Take half the shillings for the first decimal place, and the number of farthings increased by one, if it amount to 24, or upwards; by two, if it amount to 48 or upwards; and by three, if it amounts to 72 or upwards, for the two next places.

The reason of this is, that 20 shillings make a pound, two shillings is the tenth part of a pound; and therefore

fore half the number of shillings makes the first decimal place. If there were 50 farthings in a shilling, or 1000 in a pound, the units of the farthings in the remainder would be thousandth-parts, and the tens would be hundredth-parts, and so would give the two next decimal places; but because there are only 48 farthings in a shilling, or 960 in a pound, every farthing is a little more than the thousandth-part of a pound; and since 24 farthings make 25 thousandth-parts, allowance is made for that excess by adding one for every 24 farthings, as directed.

If the number of farthings be 24, 48, or 72, and consequently the second and third decimal places 25, 50, and 75, they are exactly right; otherwise they are not quite complete, since there should be an allowance of $\frac{1}{24}$ not only for 24, 48, and 72 farthings, but for every other single farthing. They may be completed by the following rule: Multiply the second and third decimal places, or their excess above 25, 50, 75 by 4. If the product amount to 24 or upwards, add 1; if 48, add 2; if 72, add 3. By this operation we obtain two decimal places more; and by continuing the same operation, we may extend the decimal till it terminate in 25, 50, 75, or in a repeater.

Decimals of sterling money of three places may easily be reduced to shillings, pence, and farthings, by the following rule. Double the first decimal place, and if the second be 5 or upwards, add 1 thereto for shillings. Then divide the second and third decimal places, or their excess above 50, by 4, first deducing 1, if it amount to 25, or upwards: the quotient is pence, and the remainder farthings.

As this rule is the converse of the former one, the reason of the one may be inferred from that of the other. The value obtained by it, unless the decimal terminate in 25, 50, or 75, is a little more than the true value; for there should be a deduction not only of 1 for 25, but a like deduction of $\frac{1}{25}$ on the remaining figures of these places.

We proceed to give some examples of the arithmetic of approximates, and subjoin any necessary observations.

Addition.

Cwt.	qrs.	lb.	
3	2	14	= 3.625
2	3	22	= 2.94642
3	3	19	= 3.91964
4	1	25	= 4.47321
14	3	24	14.96427

Subtraction.

Cwt.	qrs.	lb.	
3	2	2	= 3.51785
1	1	19	= 1.41964
2	—	9	2.09821

If we value the sum of the approximates, it will fall a little short of the sum of the articles, because the decimals are not complete.

Some add one to the last decimal place of the approximate, when the following figure would have been 5, or upwards. Thus the full decimal of 3 qrs. 22 lb. is .946,428571, and therefore .94643 is nearer to it than .94642. Approximates, thus regulated, will in general give exacter answers, and sometimes above the true one, sometimes below it.

The mark + signifies that the approximate is less than the exact decimal, or requires something to be added. The mark — signifies that it is greater, or requires something to be subtracted.

Multiplication.

	Meth. 2d.]	Meth. 3d.]
8278 +	8278	8278
2153 +	2153	3512
24834	16556|	16556
41390	827|8	827
8278	413|90	413
16556	24|834	24
1782|2534	1782|2534	1782

Here the four last places are quite uncertain. The right-hand figure of each particular product is obtained by multiplying 8 into the figures of the multiplier; but if the multiplicand had been extended, the carriage from the right-hand place would have been taken in; consequently the right-hand place of each particular product, and the four places of the total product, which depend on these, are quite uncertain. Since part of the operation, therefore, is useless, we may omit it; and, for this purpose, it will be convenient to begin (as in p. 296. col. 1. *fifth* variety) at the highest place of the multiplier. We may perceive that all the figures on the right hand of the line in Method 2. serve no purpose, and may be left out, if we only multiply the figures of the multiplicand, whose products are placed on the right hand of the line. This is readily done by inverting the multiplier in method 3. and beginning each product with the multiplication of that figure which stands above the figure of the multiplier that produces it, and including the carriage from the right-hand place.

If both factors be approximates, there are as many uncertain places, at least in the product, as in the longest factor. If only one be an approximate, there are as many uncertain places as there are figures in that factor, and sometimes a place or two more, which might be affected by the carriage. Hence we may infer, how far it is necessary to extend the approximates, in order to obtain the requisite number of certain places in the product.

Division.

.3724—)798|64327+(2144	or $3\dot{7}\dot{2}\dot{4}$)79864327(2144
744|8	7448
53|84	538
37|24	372
16|602	166
14|896	148
1|7063	18
1|4892	14
2171	4

Here all the figures on the right hand of the line are uncertain; for the right-hand figure of the first product 7448 might be altered by the carriage, if the divisor were extended; and all the remainders and dividuals that follow are thereby rendered uncertain. We may omit these useless figures; for which purpose, we dash a figure on the right hand of the divisor at each step, and neglect it when we multiply by the figure of the quotient next obtained: but we include the carriage. The operation, and the reason of it, will appear clear, by comparing the operation at large, and contracted, in the above example.

Chap. X. INTERMINATE DECIMALS.

29 ### Sect. i. Reduction of Interminate Decimals.

As the arithmetic of interminate decimals, otherwise called the *arithmetic of infinites*, is facilitated by comparing them with vulgar fractions, it will be proper to inquire what vulgar fractions produce the several kinds of decimals, terminate or interminate, repeaters or circulates, pure or mixed. And, first, we may observe, that vulgar fractions, which have the same denominator, produce decimals of the same kind. If the decimals corresponding to the numerator 1 be known, all others are obtained by multiplying these into any given numerator, and always retain the same form, providing the vulgar fraction be in its lowest terms.

Thus, the decimal equal to $\frac{1}{7}$ is .142857,
which multiplied by 3

produces the decimal equal to $\frac{3}{7}$. .428571,

Secondly. If there be cyphers annexed to the significant figures of the denominator, there will be an equal number of additional cyphers prefixed to the decimal. The reason of this will be evident, if we reduce these vulgar fractions to decimals, or if we consider that each cypher annexed to the denominator diminishes the value of the vulgar fraction ten times, and each cypher prefixed has a like effect on the value of the decimal.

Thus, $\frac{1}{7} = .142857$, $\frac{7}{25} = .28$ $\frac{1}{22} = .0,45$,
$\frac{1}{70} = .0,142857$, $\frac{7}{2500} = .0028$ $\frac{1}{2200} = .000,45$,

we may therefore confine our attention to vulgar fractions, whose numerator is 1, and which have no cyphers annexed to the significant figures of the denominator.

Thirdly. Vulgar fractions, whose denominators are 2 or 5, or any of their powers, produce terminate decimals; for, if any power of 2 be multiplied by the same power of 5, the product is an equal power of 10, as appears from the following table:

2	$\times$ 5		=	10
2^2 or	4 $\times$ 5^2	or 25	=	100 or 10^2
2^3 or	8 $\times$ 5^3	or 125	=	1000 or 10^3
2^4 or	16 $\times$ 5^4	or 625	=	10000 or 10^4
2^5 or	32 $\times$ 5^5	or 3125	=	100000 or 10^5

And the reason is easily pointed out; for $2^3 \times 5^3 = 2 \times 2 \times 2 \times 5 \times 5 \times 5$; or, because the factors may be taken in any order, $= 2 \times 5 \times 2 \times 5 \times 2 \times 5$; and this, if we multiply the factors by pairs, becomes $10 \times 10 \times 10$, or 10^3. The like may be shown of any other power. And we may infer, that if any power of 10 be divided by a like power of 2 or 5, the quotient will be an equal power of 5 or 2 respectively, and will come out exact, without a remainder; and, since the vulgar fractions above-mentioned are reduced to decimals by some such division, it follows that the equivalent decimals are terminate.

The number of places in the decimal is pointed out by the exponent of the power; for the dividend must be a like power of 10, or must have an equal number of cyphers annexed to 1, and each cypher of the dividend gives a place of the quotient.

Ex. $\frac{1}{32} = .03125$, a decimal of 5 places, and $32 = 2^5$.

```
32)1.00000(.03125
   96...
   ---
    40
    32
    ---
     80
     64
     ---
     160
     160
```

Again, no denominators except 2, 5, or their powers, produce terminate decimals. It is obvious from p. 298. col. 2. par. 4. that, if any denominator which produces a terminate decimal be multiplied thereby, the product will consist of 1, with cyphers annexed; and consequently the lowest places of the factors, multiplied into each other, must amount to 10, 20, or the like, in order to supply a cypher for the lowest place of the product; but none of the digits give a product of this kind, except 5 multiplied by the even numbers: therefore one of the factors must terminate in 5, and the other in an even number. The former is measured by 5, and the latter by 2, as was observed p. 297. col. 2. par. 7. Let them be divided accordingly, and let the quotients be multiplied. This last product will be exactly one tenth-part of the former; and therefore will consist of 1, with cyphers annexed, and the factors which produce it are measured by 5 and 2, as was shown before. This operation may be repeated; and one of the factors may be divided by 5, and the other by 2, till they be exhausted; consequently they are powers of 5 and 2.

Fourthly. Vulgar fractions, whose denominators are 3 or 9, produce pure repeating decimals.

Thus, $\frac{1}{9} = .11\dot{1}$ $\frac{5}{9} = .55\dot{5}$
$\frac{2}{9} = .22\dot{2}$ $\frac{2}{3}$ or $\frac{6}{9} = .06\dot{6}$
$\frac{1}{3}$ or $\frac{3}{9} = .33\dot{3}$ $\frac{7}{9} = .77\dot{7}$
$\frac{4}{9} = .444$ $\frac{8}{9} = .888$

The repeating figure is always the same as the numerator. Hence we infer, that repeating figures signify ninth-parts; a repeating 3 signifies $\frac{1}{3}$; a repeating 6 signifies $\frac{2}{3}$; and a repeating 9 signifies $\frac{5}{9}$, or 1.

The value of repeating decimals may also be illustrated by collecting the values of the different places: for example, let the value of $11\dot{1}$ be required; the first decimal place signifies $\frac{1}{10}$, the next $\frac{1}{100}$, the next $\frac{1}{1000}$. The sum of the two first places is $\frac{11}{100}$, of the three places $\frac{111}{1000}$; and so on. If we subtract these values successively from $\frac{1}{9}$, the first remainder is $\frac{1}{90}$, the second $\frac{1}{900}$, the third $\frac{1}{9000}$. Thus, when the value of the successive figures is reckoned, the amount of them approaches nearer and nearer to $\frac{1}{9}$, and the difference becomes 10 times less for each figure assumed; and, since the decimal may be extended to any length, the difference will at last become so small, that it need not be regarded. This may give a notion of a decreasing series, whose sum may be exactly ascertained, though the number of terms be unlimited.

Fifthly. Vulgar fractions, whose denominators are a product of 3 or 9 multiplied by 2, 5, or any of their powers, produce mixed repeaters. The reason of this will be evident, if, in forming the decimal, we divide the numerator successively by the component parts of the denominator, as directed p. 297. col 1. par. *ult.*

&c.

Intermi-nate Decimals.

&c. The first divisor is 2, 5, or some of their powers, and consequently gives a finite quotient by p. 316. col. 1. part 3, &c. The second divisor is 3 or 9; and therefore, when the figures of the dividend are exhausted, and figures annexed to the remainder, the quotient will repeat, by p. 316. col. 2. part 2.

Ex. $\frac{1}{144}$ 144=16×9.

```
                                9
144)1.000( 00694̇    or 16)1.00(.0625
    864                  96.00694

  * 640                   80
    576                   80
    ---                   --
    640                   0
```

In order to illustrate this subject further, we shall explain the operation of casting out the threes, which resembles that for casting out the nines, formerly laid down, p. 300. col. 2. par. 4.—p. 301. col. 2 par. 3. and depends on the same principles, being a method of finding the remainder of a number divided by 3. If the same number be divided by 3 and by 9, the remainders will either agree, or the second remainder will exceed the first by 3 or by 6. The reason of this will be obvious, if we suppose a collection of articles assorted into parcels of 3, and afterwards into parcels of 9, by joining three of the former together. If the lesser parcels be all taken up in composing the greater ones, the remainder will be the same at the end of the second assortment as before; but if one of these lesser parcels be left over, the remainder will be more, and if two of them be left over, the remainder will be 6 more. Therefore, when the nines are cast out from any number, and the result divided by 3, the remainder is the same as when the number is divided by 3: Thus, the results on casting out the 3's may be derived from those obtained by casting out the 9's; and the same correspondence which was pointed out with respect to the latter, for proving the operations of arithmetic, applies also to the former.

To cast out the 3's from any number, add the figures, neglecting 3, 6, and 9; and when the sum amounts to 3, 6, or 9, reject them, and carry on the computation with the excess only. For example, take 286754: in casting out the 3's we compute thus, 2 and 8 is 10, which is three times 3, and 1 over; 1 and (passing by 6) 7 is 8, which is twice 3, and 2 over; 2 and 5 is 7, which is twice 3, and 1 over; *lastly*, 1 and 4 is 5, which contains 3 once, and 2 over, so the result is 2.

If the 3's be cast out from 2^2 or 4, the result is 1; from 2^3 or 8, the result is 2; from 2^4 or 16, the result is 1; and universally the odd powers of 2 give a result of 2, and the even powers give a result of 1. As every higher power is produced by multiplying the next lower by 2, the result of the product may be found by multiplying the result of the lower power by 2, and casting out the 3's, if necessary. Therefore, if the result of any power be 1, that of the next higher is 2, and that of the next higher (4 with the 3's cast out or) 1. Thus the results of the powers of 2 are 1 and 2 by turns; also, because the result of 5, when the 3's are cast out, is 2, its powers will have the same results as the corresponding powers of 2.

If the denominator be a product of an even power of 2 or 5, multiplied by 3, the repeating figure of the corresponding decimal is $\dot{3}$; but, if it be the product of an odd power, the repeating figure is 6. For, in forming the decimal, we may divide by the component parts of the denominator, and the first divisor is a power of 2 or 5; therefore the first quotient is a like power of 4 or 2, (p. 316. col. 1. par. 3. &c.) and this power is again divided by 3. If it be an even power, the remainder or result is 1, as was demonstrated above: and if cyphers be annexed to the remainder, and the division continued, it quotes a repeating 3; but if it be an odd power, the remainder is 2, and the quotient continued by annexing cyphers is a repeating 6.

If the denominator be 9, multiplied by 2, or any of its powers, the repeating figure may be found by casting out the 9's from the corresponding power of 5; and if it be multiplied by 5 or any of its powers, by casting out the 9's from the corresponding power of 2. For if the decimal be formed by two divisions, the first quotes the corresponding power; and the second, because the divisor is 9, repeats the resulting figure after the dividend is exhausted.

If any mixed repeater be multiplied by 9, the product is a terminate decimal, and may be reduced (p. 316. col. 1. part 3. &c.) to a vulgar fraction, whose denominator is 2, 5, or some of their powers; therefore all mixed repeaters are derived from vulgar fractions, whose denominators are products of 2, 5, or their powers multiplied by 3 or 9.

Sixthly. All denominators, except 2, 5, 3, 9, the powers of 2 and 5, and the products of these powers, multiplied by 3 or 9, produce circulating decimals. We have already shown, that all terminate decimals are derived from 2, 5, or their powers; all pure repeaters, from 3 or 9; and all mixed repeaters, from the products of the former multiplied by the latter. The number of places in the circle is never greater than the denominator diminished by unity. Thus $\frac{1}{7}$ produces .142857, a decimal of 6 places; and $\frac{1}{17}$ produces .0588235294117647, a decimal of 16 places. The reason of this limit may be inferred from the division; for whenever a remainder which has recurred before returns again, the decimal must circulate, and the greatest number of possible remainder is one less than the divisor: But frequently the circle is much shorter. Thus $\frac{1}{11}$ = .09, a circle of 2 places.

When a vulgar fraction, whose numerator is 1, produces a pure circulate, the product of the circle multiplied by the denominator will consist of as many 9's as there are places in the circle. Thus $\frac{1}{7}$ = .142857, which multiplied by 7 produces 999999. The like holds in every decimal of the same kind; for they are formed by dividing 10, or 100, or 1000, or some like number, by the denominator, and the remainder is 1, when the decimal begins to circulate; for the division must be then exactly in the same state as at the beginning: Therefore if the dividend had been less by 1, or had consisted entirely of 9's, the division would have come out without a remainder; and since the quotient, multiplied by the divisor, produces the dividend, as was shown p. 298. col. 2. part 3. it follows, that the circulating figures, multiplied by the denominator, produce an equal number of 9's.

Every vulgar fraction, which produces a pure circulate

Interminate Decimals.

Interminate Decimals.

late, is equal to one whose numerator is the circulating figures, and its denominator a like number of 9's. If the numerator be one, the vulgar fraction is reduced to that form by multiplying both terms into the circle of the decimal; and if the numerator be more than 1, the equivalent decimal is found by multiplying that which correfponds to the numerator 1 into any other numerator.

Thus $\frac{1}{7}=.142857,=\frac{142857}{999999}$ and $\frac{1}{37}=.027.=\frac{27}{999}$.
$\frac{2}{7}=.285714,=\frac{285714}{999999}$ $\frac{2}{37}=.054.=\frac{54}{999}$
$\frac{3}{7}=.428571,=\frac{428571}{999999}$ $\frac{8}{37}=.216.=\frac{216}{999}$

Hence we may infer, that pure circulates are equal in value to vulgar fractions whose numerators confift of the circulating figures, and denominators of as many 9's as there are places in the circle. To place this in another point of view, we fhall reduce a vulgar fraction, whofe numerator confifts entirely of 9's, to a decimal.

```
375    999)375000(.375,
999        2997..
           ------
            7530
            6993
           ------
             5370
             4995
           ------
           * 375
```

The remainder is now the fame as the dividend, and therefore the quotient muft circulate; and, in general, fince any number with 3 cyphers annexed, may be divided by 1000, without a remainder, and quotes the fignificant figures; therefore, when divided by 999, it muft quote the fame figures, and leave an equal remainder. This alfo applies to every divifor which confifts entirely of 9's. Circles of two places, therefore, fignify ninety-ninth-parts; circles of 3 places fignify nine hundred and ninety-ninth-parts; and fo on.

The value of circulating decimals may alfo be illuftrated by adding the values of the places. Thus, if two figures circulate, the firft circle fignifieth hundredth parts, and every following circle fignifies one hundred-times lefs than the preceding; and their values added, as in p. 316. col. 2. part 3. will approach nearer to ninety-ninth-parts than any affigned difference, but will never exactly complete it.

All denominators which are powers of 3, except 9, produce pure circulates; and the number of places in the circle is equal to the quotient of the denominator divided by 9.

Thus, $\frac{1}{27}=.037$, a circle of 3 places, and 27 divided by 9=3.

$\frac{1}{81}=.012345679$, a circle of 9 places, and 81 divided by 9=9.

Thefe decimals may be formed, by dividing the numerator by the component parts of the denominator. In the firft example, the component parts of the numerator are 9 and 3. The divifion by 9 quotes a pure circulate, and the circulating figure is not 3, 6, or 9, if the vulgar fraction be in its loweft terms. And any other repeating figure divided by 3, quotes a pure circulate of 3 places; for the firft dividual muft leave a remainder of 1 or 2. If the firft remainder be 1, the fecond remainder is 2, (becaufe, if 1 be prefixed to the repeating figure, and the 3's be caft out, the refult is 2); and, for a like reafon, the third dividual clears off without a remainder. If the firft remainder be 2, the fecond is (twice 2 or 4, with the 3's caft out, or) 1, and the third 0; fo the circle is always complete at 3 places, and the divifion begins anew. The fum of fuch a circle cannot be a multiple of 3; for fince the repeating figure is not 3, nor any of its multiples, the fum of three places is not a multiple of 9, and therefore cannot be divided by 9, nor twice by 3, without a remainder.

Again, if the decimal equal to $\frac{1}{27}$ be divided by 3, we fhall obtain the decimal equal to $\frac{1}{81}$. The dividend, as we have fhown already, is a pure circulate of 3 places, whofe fum is not a multple of 3. Therefore, when divided by 3, the firft circle leaves a remainder of 1 or 2, which being prefixed to the fecond, and the divifion continued, the remainder, at the end of the fecond circle, is 2 or 1, and, at the end of the third circle, there is no remainder; all which may be illuftrated by cafting out the 3's. The divifion being completed at 9 places, finifhes the circle; and it may be fhown, as before, that the fum of thefe places is not a multiple of 3. The learner will apprehend all this if he reduce thefe, or the like vulgar fractions, to decimals, by fucceffive divifions.

$27 = 9 \times 3$, and $9)1.0(.111\dot{1}$, and $3).111\dot{1}(.037$,
$81 = 27 \times 3$, and $3)037,037,037(.012345679$.

For the fame reafon, if any circulating decimal, not a multiple of 3, be divided by 3, the quotient will circulate thrice as many places as the dividend; and if any circulate obtained by fuch divifion be multiplied by 3, the circle of the product will be reftricted to one-third of the places in the multiplicand.

All vulgar fractions, whofe denominators are multiples of 2, 5, or their powers, except thofe already confidered, produce mixed circulates; for they may be reduced by dividing by the component parts of the denominator. The firft divifor is 2, 5, or fome of their powers, and therefore gives a finite quotient. The fecond divifor is none of the numbers enumerated p. 317. col. 2. part 2. and therefore gives a circulating quotient when the fignificant figures of the dividend are exhaufted, and cyphers annexed to the remainder.

```
   Ex. 1/216                  216=27×8.
216)1.000(.004,629,        or 8)1.000

All mixed circulates are derived from vulgar fractions

Interminate Decimals.

Interminate Decimals.

tions of this kind, whose denominators are multiples of 2, 5, or their powers; and therefore all other denominators, except 3 and 9, produce pure circulates. The reader will easily perceive, that when a decimal is formed from a vulgar fraction whose numerator is 1, when the remainder 1 occurs in the division, the decimal is a pure circulate; but if any other remainder occurs twice, the decimal is a mixed circulate. We are to show that this last will never happen, unless the divisor be a multiple of 2, 5, or their powers. If two numbers be prime to each other, their product will be prime to both; and if two numbers be proposed, whereof the first does not measure the second, it will not measure any product of the second, if the multiplier be prime to the first. Thus, because 7 does not measure 12, it will not measure any product of 12 by a multiplier prime to 7. For instance, it will not measure 12×3, or 36. Otherwise, the quotient of 12 divided by 7, or $1\frac{5}{7}$ multiplied by 3, would be a whole number, and 5×3 would be measured by 7, which it cannot be, since 5 and 3 are both prime to 7.

Now, if we inspect the foregoing operation, we shall perceive that the product of 136, the remainder, where the decimal begins to circulate, multiplied by 999, is measured by the denominator 216. But 999 is not measured by the denominator, otherwise the decimal would have been a pure circulate; therefore 126 and 136 are not prime to each other, but have a common measure, and that measure must apply to 864, a multiple of 126, and to 1000, the sum of 136 and 864; see p. 309, col. 2. par. *ult.* &c. But it was proven, p. 316. col. 1. par. 1. that no numbers, except the powers of 5 and 2, measure a number consisting of 1 with cyphers annexed; consequently the denominator must be measured by a power of 2 or 5. The reader will perceive, that the exponent of the power must be the same as the number of cyphers annexed to 1, or as the number of figures in the finite part of the decimal.

We shall now recapitulate the substance of what has been said with respect to the formation of decimals. 2, 5, and their powers, produce finite decimals, by p. 316. col. 1 par. 3. &c. and the number of places is measured by the exponent of the power. 3 and 9 produce pure repeaters (p. 316. col. 2. par. 2.) The products of 2, 5, and their powers, by 3, or 9, produce mixed repeaters by p. 316. col. 2. par. *ult.* their products by other multipliers, produce mixed circulates by p. 316. col. 2. par. *ult.* and all numbers of which 2 and 5 are not aliquot parts, except 3 and 9, produce pure circulates. To find the form of a decimal corresponding to any denominator, divide by 2, 5, and 10, as often as can be done without a remainder: the number of divisions shows how many finite places there are in the decimal, by p. 318. col. 2. par. 3. If the dividend be not exhausted by these divisions, divide a competent number of 9's by the last quotient, till the division be completed without a remainder: the number of 9's required show how many places there are in the circle; and the reason may be inferred from p. 317. col. 2. par. 5.

We shall conclude this subject by marking down the decimals produced by vulgar fractions, whose numerator is 1, and denominators 30; and under that the reader may observe their connection with the denominators.

Rules *for reducing interminate decimals to vulgar fractions.*

I. "If the decimal be a pure repeater, place the repeating figure for the numerator, and 9 for the denominator."

II. "If the decimal be a pure circulate, place the circulating figures of the numerator, and as many 9's as there are places in the circle for the denominator."

III. "If there be cyphers prefixed to the repeating or circulating figures, annex a like number to the 9's in the denominator."

IV. "If the decimal be mixed, subtract the finite part from the whole decimal. The remainder is the numerator; and the denominator consists of as many 9's as there are places in the circle, together with as many cyphers as there are finite places before the circle."

Thus, 235,62,=$\frac{23372}{99000}$

From the whole decimal	23562
we subtract the finite part	234
and the remainder	23327 is the numerator.

The reason may be illustrated by dividing the decimal into two parts, whereof one is finite, and the other a pure repeater or circulate, with cyphers prefixed. The sum of the vulgar fractions corresponding to these will be the value of the decimal sought.

.235,62, may be divided into .235 =$\frac{235}{1000}$ by rule I.
and .000,62=$\frac{62}{99000}$ by rules II. III.

In order to add these vulgar fractions, we reduce them to a common denominator; and, for that purpose, we multiply both terms of the former by 99, which gives $\frac{23265}{99000}$; then we add the numerators.

235	or by method explained p. 295. col. 1. par. 3.		
99		Sum of numerators.	
2115	23500	23265	or 23562
2115	235	62	235
23265	23265	23327	23327

The value of circulating decimals is not altered, though one or more places be separated from the circle, and considered as a finite part, providing the circle be completed. For example, .27 may be written .2,72, which is reduced by the last of the foregoing rules to $\frac{270}{990}$, or $\frac{27}{99}$, which is also the value of .27. And if two or more circles be joined, the value of the decimal is still the same. Thus, 2727,=$\frac{2727}{9999}$, which is reduced by dividing the terms 101 to $\frac{27}{99}$.

Interminate Decimals.

All circulating decimals may be reduced to a similar form, having a like number both of finite and circulating places. For this purpose, we extend the finite part of each as far as the longest, and then extend all the circles to so many places as may be a multiple of the number of places in each.

Ex. .34,725, extended .34,725725725725725,
1,4562, 14,562456245624,

Here the finite part of both is extended to two places, and the circle to 12 places, which is the least multiple for circles of 3 and 4 places.

30 Sect. ii. ADDITION *and* SUBTRACTION *of* INTERMINATE DECIMALS.

To add repeating decimals, "Extend the repeating "figures one place beyond the longest finite ones, and "when you add the right-hand column, carry to the "next by 9."

Ex. .37524 or	37524	.25	.296	$\frac{7}{36}$
.8	88888	.328	.42	$\frac{11}{45}$
.643	643	.4697	.7548	$\frac{11}{72}$
.73	73333	.36	.31	$\frac{2}{75}$
	264046			

To subtract repeating decimals, "Extend them as "directed for addition, and borrow at the right-hand "place if necessary, by 9.

.93566	.646	.7358	.7382	.469
.84738	.53427	.62563	.68	.35
.08727	.11172			

The reason of these rules will be obvious, if we recollect that repeating figures signify ninth-parts. If the right-hand figure of the sum or remainder be o, the decimal obtained is finite; otherwise it is a repeater.

To add circulating decimals, "Extend them till they "become similar (p. 319. col. 1. par. ult. &c.); and "when you add the right-hand column, include the figure which would have been carried if the circle had "been extended further.

Ex. 1st.]	*Extended.*	*Ex.* 2d.]	*Extended.*
.574,	.574,574,	.874,	.874,874874,
.2,698,	.266,869,	.1463	.146,333333,
.428	.428	.1,58,	.158,585858,
.37,983,	.379,839,	.32,	.323,232323,
	1.652,284,		1.503,026390,

Note 1. Repeaters mixed with circulates are extended and added as circulates.

Note 2. Sometimes it is necessary to inspect two or more columns for ascertaining the carriage; because the carriage from a lower column will sometimes raise the sum of the higher, so as to alter the carriage from it to a new circle. This occurs in Ex. 2.

Note 3. The sum of the circles must be considered as a similar circle. If it consist entirely of cyphers, the amount is terminate. If all the figures be the same, the amount is a repeater. If they can be divided into parts exactly alike, the amount is a circle of fewer places; but, for the most part, the circle of the sum is similar to the extended circles.

.3,868,	.0842,	$\frac{2}{7}$	.368	.003094,	$\frac{5}{81}$
.4,375,	.08,42	$\frac{3}{5}$	.57,	.765,	$\frac{7}{48}$
.853492,	.0,842	$\frac{8}{11}$	.895	.76,	$\frac{2}{11}$
.62,	.0842	$\frac{16}{17}$	.724	.765,	$\frac{3}{71}$

To subtract circulating decimals, "Extend them till "they become similar; and when you subtract the "right-hand figure, consider whether 8 would have "been borrowed if the circles had been extended fur- "ther, and make allowance accordingly.

.5,72,	.974, or	.974974,	.8,135, or	.8,135135,
.4,86,	.86	.868686,	.452907 or	.4,529074,
.0,85,		.106288,		.3,606060,
			or,	3,60

Sect. iii. MULTIPLICATION *of* INTERMINATE DECIMALS.

CASE I. "When the multiplier is finite, and the "multiplicand repeats, carry by 9 when you multiply "the repeating figure: The right-hand figure of each "line of the product is a repeater; and they must be "extended and added accordingly."

```
Ex. .13494
      .367
    ------
     94461
    809666
   4048333
   -------
 .04952461
```

If the sum of the right-hand column be an even number of 9's, the product is finite; otherwise, it is a repeater.

CASE II. "When the multiplier is finite, and the "multiplicand circulates, add to each product of the "right-hand figure the carriage which would have "been brought to it if the circle had been extended. "Each line of the product is a circle similar to the "multiplicand, and therefore they must be extended "and added accordingly."

The product is commonly a circulate similar to the multiplicand; sometimes it circulates fewer places, repeats, or becomes finite; it never circulates more places.

```
Ex.  .37,46,×.235      1.  .674,  ×.78
        235            2.  .37,   ×.86
     -------           3.  .625,  ×.42
     187,32,           4.  .4793, ×4.8
    1123,93,           5.  .3,75, ×1.24
    7492,92,           6.  .2,963, ×.36
   ---------
  .08804,19,
```

CASE III. "When the multiplier repeats or circulates, find the product as in finite multipliers, and "place under it the products which would have arisen "from the repeating or circulating figures, if extend- "ed."

```
Ex. 1st.]  .958×.8          2d.]  .784×.86,
              8                     36
           -----                  -----
           7664                   4704
            766|4                 2352
             76|64               ------
              7|664              28224|
               |7664               282|24
           ---------                 2|8224
            .8515                ----------
                                  .284,09,
```

           2859142
          35714285
          ------------------------------
          31,571428|571428|571428,
              385714|285714|285714,
                3857|142857|142857,
                    |------|-------
                  38|571428|571428,
                    |385714|285714,
                    |  3857|142875,
                    |      |-------
                    |    38|571428
                    |      |385714
                    |      |  3857
                    |      |    38
          ------------------------------
          38.961038,961038,961038,
```

It is evident, that, if a repeating multiplier be extended to any length, the product arising from each figure will be the same as the first, and each will stand one place to the right hand of the former. In like manner, if a circulating multiplier be extended, the product arising from each circle will be alike, and will stand as many places to the right hand of the former as there are figures in the circle. In the foregoing examples, there are as many of these products repeated as is necessary for finding the total product. If we place down more, or extend them further, it will only give a continuation of the repeaters or circulates.

This is obvious in Ex. 1st and 2d. As the learner may not apprehend it so readily in Ex. 3d, when the multiplicand is a circulate, and consequently each line of the product is also a circulate, we have divided it into columns, whose sums exhibit the successive circles. The sum of the first column is 38,961037, and there is a carriage of 1 from the right-hand column, which completes 38,961038. This one is supplied from the three first lines of the second column, the sum of which is 999999, and being increased by 1, in consequence of the carriage from the third column, amounts to 1,000000, and therefore carries 1 to the first column, and does not affect the sum of the remaining lines, which are the same as those of the first column. The third column contains two sets of these lines, which amount to 999999, besides the line which compose the circle. Each of these sets would be completed into 1,000000 by the carriage from the 4th column, if extended, and each would carry 1 to the second column. One of these would complete the sum of the three first lines, and the other would complete the sum of the circle. In like manner, if the circles be extended ever so far, the increasing carriages will exactly answer for the increasing deficiencies, and the sum will be always a continuation of the circle: but the product could not circulate, unless the sum of the lines marked off in the second column had consisted entirely of 9's; or had been some multiple of a number of 9's; and the circles must be extended till this take place, in order to find the complete product.

The multiplication of intermediate decimals may be often facilitated, by reducing the multiplier to a vulgar fraction, and proceeding as directed p. 311. col. 1. par. 6. Thus,

```
4th.]  .3824×7̇.=7/9          5th.]  .384×.25̇=23/90.
               7                         23      2
        --------                         --     --
       9)2.6768                         1152    23
          .9742̇                          768
                                       -----
                                     90)8.832
                                        .09813̇
```

Therefore, in order to multiply by 3̇, we take one-third part of the multiplier; and, to multiply by 6̇, we take two-thirds of the same. Thus,

```
6th.]  .784=.3̇×1/3.          7th.]  .8761×.6̇=2/3
                                               2
                                         -------
       3).784                           3)1.7522
          .2613̇                            .58406̇
```

As the denominator of the vulgar fractions always consists of 9's, or of 9's with cyphers annexed, we may use the contraction explained p. 298. col. 1. par. *ult.* &c.; and this will lead us exactly to the same operation which was explained p. 320. col. 2. par. *ult.* &c. on the principles of decimal arithmetic.

```
8th.]  .735×.3,26,=323/990    9th.]  .278×365,=365/999
           323      3                     365
        ------   ----                    -----
          2205    323                     1390
         1470                            1668
        2205                             834
        ------                          -------
  99|0)237405                      999)101470,
          2374,05                        101,
            23,74                       ------
              ,23                      .101,571,
      ------------
      .239803,
```

When the multiplier is a mixed repeater or circulate, we may proceed as in Ex. 5th and 8th; or we may divide the multiplier into two parts, of which the first is finite, and the second a pure repeater or circulate, with cyphers prefixed, and multiply separately by these, and add the products.

```
Thus, .384×.25̇  or by .2 =.0768   or thus,   .384
           and by .05 =.02133̇                  .25̇
                      -------                 -----
                       .09813                9)1920
                                              -----

In Ex. 13th, we have omitted the products of the divisor, and only marked down the remainders. These are found, by adding the left-hand figure of the dividual to the remaining figures of the same. Thus 363 is the first dividual, and 3 the left-hand figure, added to 63, the remaining figures, gives 66, for the first remainder; and the second dividual, 666, is completed by annexing the circulating figure 6. The reason of which may be explained as follows. The highest place of each dividual shows, in this example, how many hundreds it contains; and as it must contain an equal number of ninety-nines, and also an equal number of units, it follows, that these units, added to the lower places, must show how far the dividual exceeds that number of ninety-nine. The figure of the quotient is generally the same as the first place of the dividual, sometimes one more. This happens in the last step of the foregoing example, and is discovered when the remainder found, as here directed, would amount to 99, or upwards; and the excess, above 99 only, must in that case be taken to complete the next dividual.

```

The number of places in the circle of the product is sometimes very great, though there be few places in the factors: but it never exceeds the product of the denominator of the multiplier, multiplied by the number of places in the circle of the multiplicand. Therefore, if the multiplier be 3̇ or 6, the product may circulate three times as many places as the multiplicand; if the multiplier be any other repeater, nine times as many; if the multiplier be a circulate of two places, ninety-nine times as many; thus, in the last example, .01, a circulate of two places, multiplied by .01, a circulate of two places, produces a circulate of twice 99, or 198 places. And the reason of this limit may be inferred from the nature of the operation; for the greatest possible number of remainders, including 0, is equal to the divisor 99; and each remainder may afford two dividuals, if both the circulating figures, 3 and 6, occur to be annexed to it. If the multiplier circulate three places, the circle of the product, for a like reason, may extend nine hundred and ninety-nine times as far as that of the multiplicand. But the number of places is often much less.

The multiplication of the interminate decimals may be proven, by altering the order of the factors, (p. 295. col. 2. par. 2.) or by reducing them both to vulgar fractions in their lowest terms, multiplying these as directed p. 310. col. 2. par. 3. and reducing the product to a decimal.

Sect. iv. Division *of* Interminate Decimals. 32

Case I. "When the dividend only is interminate, "proceed as in common arithmetic; but, when the "figures of the dividend are exhausted, annex the re- "peating figure, or the circulating figures in their or- "der, instead of cyphers, to the remainder."

Ex.

3d.] Divide .65328 by [8.

8).65328(.081661.

In theſe accounts the quotient is never finite. It may repeat, if the dividend repeats; or, if the dividend circulate, it may circulate an equal number of places, often more, and never fewer. The greateſt poſſible extent of the circle is found by multiplying the diviſor into the number of places in the circle of the dividend. Thus, a circulate of 3 places, divided by 3, quotes a circulate of 3 times 3, or 9 places.

Case II. "When the diviſor is interminate, the "multiplications and ſubtractions muſt be performed, "according to the directions given for repeating and "circulating decimals."

Ex. 1ſt.] Divide .37845 by 5

```

        0
```

2d.] Divide .245892 by 2,18,

```
.2,18,).245892(1. 127005
        .218181,81,
        -----------
         27710,18,
         21818,18,
         ---------
          5892,00,
          4363,63,
          --------
          1528,36,
          1527,27,
          --------
              1090,90,
             10,90,90,
             ---------
                 0
```

Extraction of Roots.

The foregoing method is the only one which properly depends on the principles of decimal arithmetic; but it is generally ſhorter to proceed by the following rule.

"Reduce the diviſor to a vulgar fraction, multiply "the dividend by the denominator, and divide the product by the numerator."

Ex. 1ſt.] Divide .37845 by 5=5/9

```
       9
    ------
5)3.40605(.68121
```

2d.] Divide .37845 by 6=2/3

```
       3
    ------
2)1.13536(.567683
```

Note 1. Diviſion by 3 triples the dividend, and diviſion by 6 increaſes the dividend one-half.

Note 2. When the diviſor circulates, the denominator of the vulgar fraction conſiſts of 9's, and the multiplication is ſooner performed by the contraction explained p. 295. col. 1. par. 1. It may be wrought in the ſame way, when the diviſor repeats, and the denominator, of conſequence, is 9.

Note 3. If a repeating dividend be divided by a repeating or circulating diviſor; or, if a circulating dividend be divided by a ſimilar circulating dividend; or, if the number of places in the circle of the diviſor be a multiple of the number in the dividend; then the product of the dividend multiplied by the denominator of the diviſor will be terminate, ſince like figures are ſubtracted from like in the contracted multiplication, and conſequently no remainder left. The form of the quotient depends on the diviſor, as explained at large, p. 316. col. 1. par. 1.—p. 318. col. 2. par. 3.

Note 4. In other caſes, the original and multiplied dividend, are ſimilar, and the form of the quotient is the ſame as in the caſe of a finite diviſor. See p. 322. col. 2. par. *ult.* &c.

Note 5. If the terms be ſimilar, or extended till they become ſo, the quotient is the ſame as if they were finite, and the operation may be conducted accordingly; for the quotient of vulgar fractions that have the ſame denominator is equal to the quotient of their numerators.

Chap. XI. Of the EXTRACTION of ROOTS. 33

The origin of powers by involution has already been explained under the article Algebra. There now remains therefore only to give the moſt expeditious methods of exracting the ſquare and cube roots; the reaſons of which will readily appear from what is ſaid under that article. As for all powers above the cube, unleſs ſuch as are multiples of either the ſquare and cube, the extraction of their roots admits of no deviation from the algebraic canon which muſt be always conſtructed on purpoſe for them.

If the root of any power not exceeding the ſeventh power, be a ſingle digit, it may be obtained by inſpection, from the following table of powers.

1st power or root.	2d power or square.	3d power or cube.	4th power or biquadrate.	5th power or surfolid.	6th power or cube squared.	7th power.
1	1	1	1	1	1	1
2	4	8	16	32	64	128

34 Sect. i. EXTRACTION *of the* SQUARE ROOT.

RULE I. "Divide the given number into periods "of two figures, beginning at the right hand in integers, and pointing towards the left. But in decimals begin at the place of hundreds, and point toward the right. Every period will give one figure "in the root."

II. "Find by the table of powers, or by trial, "the nearest lesser root of the left hand period, place "the figure so found in the quot, subtract its square "from the said period, and to the remainder bring "down the next period for a dividual or resolvend."

III. "Double the quot for the first part of the "divisor; inquire how often this first part is contained in the whole resolvend, excluding the unit place; "and place the figure denoting the answer both in the "quot and on the right of the first part; and you have "the divisor complete."

IV. "Multiply the divisor thus completed by the "figure put in the quot, subtract the product from "the resolvend, and to the remainder bring down the "following period for a new resolvend, and then proceed as before."

Note 1. If the first part of the divisor, with unity supposed to be annexed to it, happen to be greater than the resolvend, in this case place 0 in the quot, and also on the right-hand of the partial divisor; to the resolvend bring down another period; and proceed to divide as before.

Note 2. If the product of the quotient-figure into the divisor happen to be greater than the resolvend, you must go back, and give a lesser figure to the quot.

Note 3. If, after every period of the given number is brought down, there happen at last to be a remainder, you may continue the operation, by annexing periods, or pairs of cyphers, till there be no remainder, or till the decimal part of the quot repeat or circulate, or till you think proper to limit it.

Ex. 1st. Required the square root of 133225.

After getting half of the decimal places, work by contracted division for the other half; and obtain them with the same accuracy as if the work had been at large.

3d.]. Required the square root of .2916.

```
.2916(.54 root.
 25
 ---
104)416
    416
```

If the square root of a vulgar fraction be required, find the root of the given numerator for a new numerator, and find the root of the given denominator for a new denominator. Thus, the square root of $\frac{4}{9}$ is $\frac{2}{3}$, and the root of $\frac{16}{25}$ is $\frac{4}{5}$; and thus the root of $\frac{25}{4}$ ($=6\frac{1}{4}$) is $\frac{5}{2}=2\frac{1}{2}$.

But if the root of either the numerator or denominator cannot be extracted without a remainder, reduce the vulgar fraction to a decimal, and then extract the root, as in Ex. 3d. above.

Sect. ii. EXTRACTION *of the* CUBE ROOT. 35

RULE I. "Divide the given number into periods "of three figures, beginning at the right-hand in integers, and pointing towards the left. But in decimals, begin at the place of thousands, and point towards the right. The number of periods shows the "number of figures in the root."

II. "Find by the table of powers, or by trial, the "nearest lesser root of the left-hand period; place the "figure so found in the quot; subtract its cube from "the said period; and to the remainder bring down "the next period for a dividual or resolvend."

The divisor consists of three parts, which may be found as follows.

III.

Extraction of Roots.

III. "The first part of the divisor is found thus: "Multiply the square of the quot by 3, and to the product annex two cyphers; then inquire how often this "first part of the divisor is contained in the resolvend, "and place the figure denoting the answer in the quot."

IV. "Multiply the former quot by 3, and the product by the figure now put in the quot; to this last "product annex a cypher; and you have the second "part of the divisor. Again, square the figure now "put in the quot for the third part of the divisor; "place these three parts under one another, as in addition; and their sum will be the divisor complete."

V. "Multiply the divisor, thus completed, by the "figure last put in the quot, subtract the product from "the resolvend, and to the remainder bring down the "following period for a new resolvend, and then proceed as before."

Note 1. If the first part of the divisor happen to be equal to or greater than the resolvend, in this case, place 0 in the quot, annex two cyphers to the said first part of the divisor, to the resolvend bring down another period, and proceed to divide as before.

Note 2. If the product of the quotient-figure into the divisor happen to be greater than the resolvend, you must go back, and give a lesser figure to the quot.

Note 3. If, after every period of the given number brought down, there happen at last to be a remainder, you may continue the operation by annexing periods of three cyphers till there be no remainder, or till you have as many decimal places in the root as you judge necessary.

Ex. 1st.] Required the cube root of 12812904.

```

                     28.750000 cube.
```

If the cube root of a vulgar fraction be required, find the cube root of the given numerator for a new numerator, and the cube root of the given denominator for a new denominator. Thus, the cube root of $\frac{8}{27}$ is $\frac{2}{3}$, and the cube root of $\frac{27}{64}$ is $\frac{3}{4}$: and thus the cube root of $\frac{125}{8}$ ($=15\frac{5}{8}$) is $\frac{5}{2}=2\frac{1}{2}$.

But if the root of either the numerator or denominator cannot be extracted without a remainder, reduce the vulgar fraction to a decimal, and then extract the root.

ARIUS, a divine of the fourth century, the head and founder of the ARIANS, a sect which denied the eternal divinity and substantiality of the Word. He was born in Libya, near Egypt. Eusebius bishop of Nicomedia, a great favourite of Constantia sister of the emperor Constantine and wife of Licinius, became a zealous promoter of Arianism. He took Arius under his protection, and introduced him to Constantia; so that the sect increased, and several bishops embraced it openly. There arose, however, such disputes in the cities, that the emperor, in order to remedy these disorders, was obliged to assemble the council of Nice, where, in the year 325, the doctrine of Arius was condemned. Arius was banished by the emperor, all his books were ordered to be burnt, and capital punishment was denounced against whoever dared to keep them. After five years banishment, he was recalled to Constantinople, where he presented the emperor with a confession of his faith, drawn up so artfully, that it fully satisfied him. Notwithstanding which, Athanasius, now advanced to the see of Alexandria, refused to admit him and his followers to communion. This so enraged them, that, by their interest at court, they procured that prelate to be deposed and banished. But the church of Alexandria still refusing to admit Arius into their communion, the emperor sent for him to Constantinople; where, upon delivering in a fresh confession of his faith in terms less offensive, the emperor commanded Alexander, the bishop of that church, to receive him the next day into his communion: but that very evening Arius died. The manner of his death was very extraordinary: as his friends were conducting him in triumph to the great church of Constantinople, Arius, pressed by a natural necessity, stepped aside to ease him-

 himſelf; but expired on the ſpot, his bowels guſhing out.

But the hereſy did not die with the hereſiarch; his party continued ſtill in great credit at court. Athanaſius, indeed, was ſoon recalled from baniſhment, and as ſoon removed again; the Arians being countenanced by the government, and making and depoſing biſhops as it beſt ſerved their purpoſes. In ſhort, this ſect continued with great luſtre above 300 years: it was the reigning religion of Spain for above two centuries; it was on the throne both in the eaſt and weſt; it prevailed in Italy, France, Pannonia, and Africa; and was not extirpated till about the end of the 8th century.

This hereſy was again ſet on foot in the weſt by Servetus, who, in 1531, wrote a little treatiſe againſt the myſtery of the Trinity. After his death, Arianiſm got footing in Geneva; from whence it removed into Poland; but at length, degenerated, in a great meaſure, into Socinianiſm. Eraſmus ſeems to have aimed at reviving Arianiſm, in his commentaries on the New Teſtament; and the learned Grotius ſeems to lean a little that way.

With regard to the ſtate of Arianiſm in England, it may be ſufficient to obſerve, that from the numerous publications of that caſt which are daily making their appearance, it ſeems to be rather a growing, than exploded, doctrine there.

Plate LVII. fig. 1 ARK, or *Noah's Ark*, a floating veſſel built by Noah for the preſervation of his family and the ſeveral ſpecies of animals during the deluge.

The ark has afforded ſeveral points of curious inquiry among the critics and naturaliſts, relating to its form, capacity, materials, &c.

The wood whereof the ark was built is called in the Hebrew *Gopher-wood*, and in the ſeptuagint *ſquare timbers*. Some tranſlate the original *cedar*, others *pine*, others *box*, &c. Pelletier prefers cedar on account of its incorruptibility, and the great plenty of it in Aſia: whence Herodotus and Theophaſtrus relate, that the kings of Egypt and Syria built whole fleets thereof, inſtead of deal.

The learned Mr Fuller, in his Miſcellanies, has obſerved, that the wood whereof the ark was built was nothing but that which the Greeks call κυπαρισσος, or or the *cypreſs-tree*; for, taking away the termination, *kypar* and *gopher* differ very little in ſound. This obſervation the great Bochart has confirmed, and ſhown very plainly that no country abounds ſo much with this wood as that part of Aſſyria which lies about Babylon.

In what place Noah built and finiſhed his ark is no leſs made a matter of diſputation. But the moſt probable opinion is, that it was built in Chaldea, in the territories of Babylon, where there was ſo great a quantity of cypreſs in the groves and gardens in Alexander's time, that that prince built a whole fleet out of it for want of timber. And this conjecture is confirmed by the Chaldean tradition, which makes Xithurus (another name for Noah) ſet ſail from that country.

The dimenſions of the ark, as given by Moſes, are 300 cubits in length, 50 in breadth, and 30 in height; which ſome have thought too ſcanty, conſidering the number of things it was to contain; and hence an argument has been drawn againſt the authority of the relation. To ſolve this difficulty many of the ancient fathers, and the modern critics, have been put to very miſerable ſhifts: But Buteo and Kircher have proved geometrically, that, taking the common cubit of a foot and a half, the ark was abundantly ſufficient for all the animals ſuppoſed to be lodged in it. Snellius computes the ark to have been above half an acre in area. Father Lamy ſhows, that it was 110 feet longer than the church of St Mary at Paris, and 64 feet broader: and if ſo, it muſt have been longer than St Paul's church in London, from weſt to eaſt, and broader than that church is high in the inſide, and 54 feet of our meaſure in height; and Dr Arbuthnot computes it to have been 81062 tons.

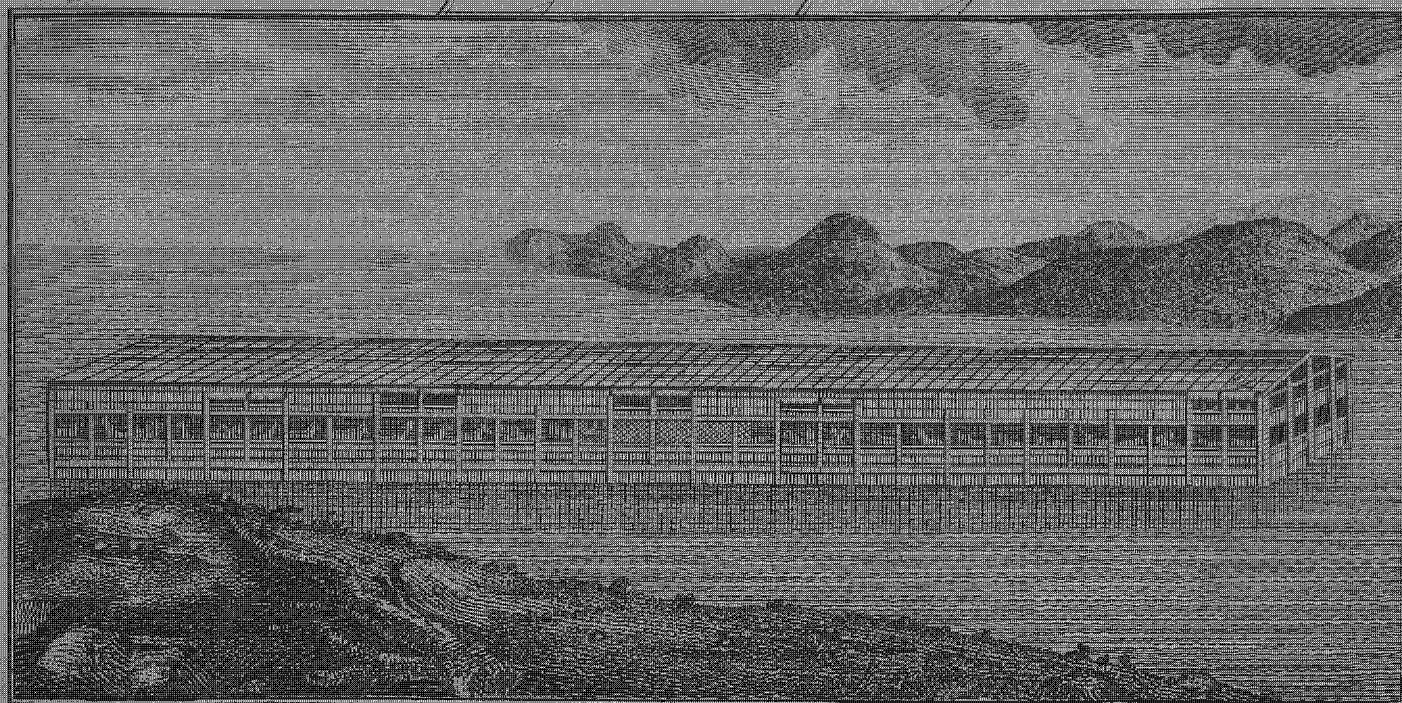
The things contained in it were, beſides eight perſons of Noah's family, one pair of every ſpecies of unclean animals, and ſeven pair of every ſpecies of clean animals, with proviſions for them during the whole year. The former appears, at firſt view, almoſt infinite; but if we come to a calculation, the number of ſpecies of animals will be found much leſs than is generally imagined; out of which, in this caſe, are excepted ſuch animals as can live in the water; and biſhop Wilkins ſhows that only 72 of the quadruped kind needed a place in the ark.

By the deſcription Moſes gives of the ark, it appears to have been divided into three ſtories, each ten cubits or 15 feet high; and it is agreed on, as moſt probable, that the loweſt ſtory was for the beaſts, the middle for the food, and the upper for the birds, with Noah and his family; each ſtory being ſubdivided into different apartments, ſtalls, &c. though Joſephus, Philo, and other commentators, add a kind of fourth ſtory under all the reſt; being, as it were, the hold of the veſſel, to contain the ballaſt and receive the filth and feces of ſo many animals: but F. Calmet thinks, that what is here reckoned a ſtory, was no more than what is called the *keel* of ſhips, and ſerved only for a conſervatory of freſh water. Drexelius makes 300 apartments; F. Fourneir, 333; the anonymous author of the Queſtions on Geneſis, 400; Buteo, Temporarius, Arias Montanus, Hoſtus, Wilkins, Lamy, and others, ſuppoſe as many partitions as there were different ſorts of animals. Pelletier makes only 72, viz. 36 for the birds, and as many for the beaſts. His reaſon is, that if we ſuppoſe a greater number, as 333 or 400, each of the eight perſons in the ark muſt have had 37, 41, or 50 ſtalls to attend and cleanſe daily, which he thinks impoſſible to have been done. But it is obſerved, that there is not much in this: to diminiſh the number of ſtalls without a diminution of animals is vain; it being perhaps more difficult to take care of 300 animals in 72 ſtalls than in 300. As to the number of animals contained in the ark, Buteo computes that it could not be equal to 500 horſes; he even reduces the whole to the dimenſions of 56 pair of oxen. F. Lamy enlarges it to 64 pair of oxen, or 128 oxen; ſo that, ſuppoſing one ox equal to two horſes, if the ark had room for 256 horſes, there muſt have been room for all the animals. But the ſame author demonſtrates, that one floor of it would ſuffice for 500 horſes, allowing nine ſquare feet to a horſe.

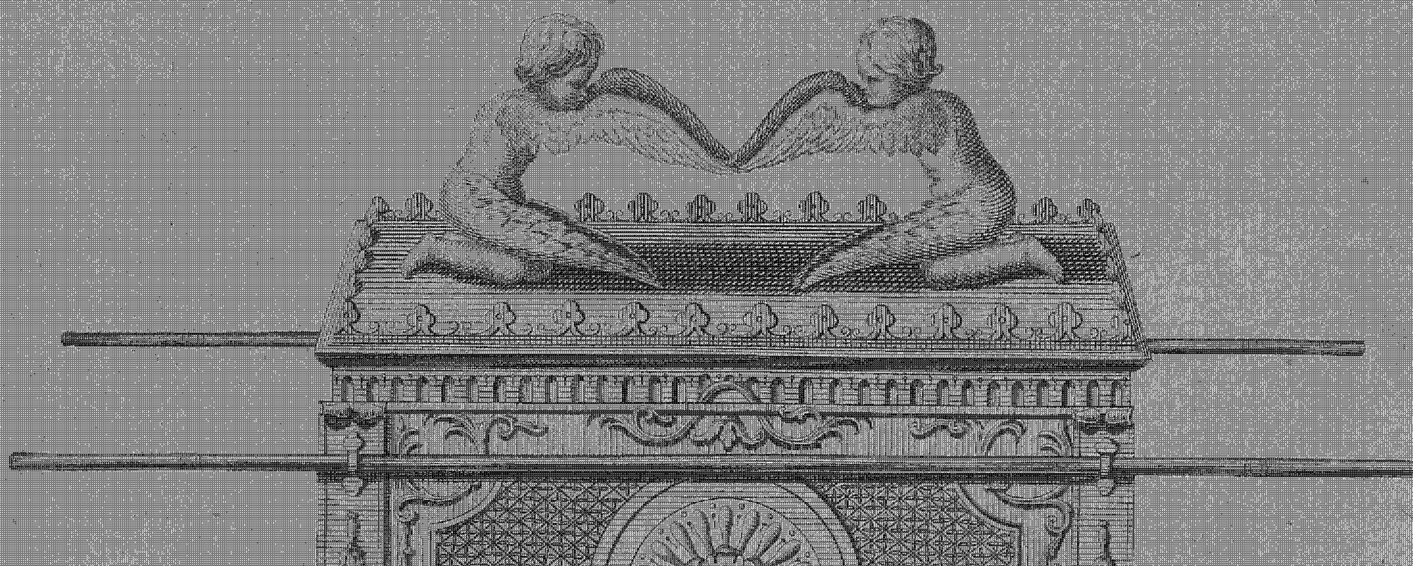
As to the food in the ſecond ſtory, it is obſerved by Buteo from Columella, that 30 or 40 pounds of hay ordinarily ſuffices for an ox a day; and that a ſolid cubit of hay, as uſually preſſed down in our hay ricks, weighs

Noah's Ark. Plate LVII.

floating on the waters of the Deluge.



Ark of the Covenant.



Thackara & Vallance, Sculpt.

weighs about 40 pounds; so that a square cubit of hay is more than enough for one ox in one day. Now, it appears, that the second story contained 150,000 solid cubits; which divided between 206 oxen will afford each more hay, by two-thirds, than he can eat in a year. Bishop Wilkins computes all the carnivorous animals equivalent, as to the bulk of their bodies, and their food, to 27 wolves; and all the rest to 280 beeves. For the former, he allows 1825 sheep; and for the latter, 109,500 cubits of hay: all which will be easily contained in the two first stories, and a deal of room to spare. As to the third story, nobody doubts of its being sufficient for the fowls; with Noah, his sons, and daughters. Upon the whole, the learned bishop remarks, that of the two, it appears much more difficult to assign a number and bulk of necessary things to answer the capacity of the ark, than to find sufficient room for the several species of animals already known to have been there. This he attributes to the imperfection of our list of animals, especially those of the unknown parts of the earth; adding, that the most expert mathematician at this day could not assign the proportion of a vessel better accommodated to the purpose than is here done: and hence he finally concludes, that the capacity of the ark, which had been made an objection against scripture, ought to be esteemed a confirmation of its divine authority; since, in those ruder ages, men, being less versed in arts and philosophy, were more obnoxious to vulgar prejudices than now; so that, had it been an human invention, it would have been contrived according to those wild apprehensions which arise from a confused and general view of things as much too big as it had been represented too little.

But it must be observed, that, besides the places requisite for the beasts and birds, and their provisions, there was room required for Noah to lock up household utensils, the instruments of husbandry, grains and seeds to sow the earth with after the deluge; for which purpose it is thought that he might spare room in the third story for 36 cabbins, besides a kitchen, a hall, four chambers, and a space about 48 cubits in length to walk in.

Plate LVII. fig. 2.

Ark of the Covenant, a small chest or coffer, three feet nine inches in length, two feet three inches in breadth, and two feet three inches in height, in which were contained the golden pot that had manna, and Aaron's rod, and the tables of the covenant. This coffer was made of shittim-wood, and covered with a lid, which was made of solid gold. The ark was reposited in the holiest place of the tabernacle. It was taken by the Philistines, and detained 20, some say 40, years, at Kirjath-jearim; but the people being afflicted with emerods on account of it, returned it with divers presents. It was afterwards placed in the temple.

The lid or covering of the ark was called the *propitiatory* or *mercy-seat*; over which were two figures placed called *Cherubims*, with expanded wings of a peculiar form. Here the Schechinah rested both in the tabernacle and temple in a visible cloud: hence were issued the divine oracles by an audible voice; and the high priest appeared before this mercy-seat once every year on the great day of expiation; and the Jews, wherever they worshipped, turned their faces towards the place where the ark stood.

In the second temple there was also an ark, made of the same shape and dimensions with the first, and put in the same place, but without any of its contents and peculiar honours. It was used as a representative of the former on the day of expiation, and a repository of the original copy of the holy Scriptures, collected by Ezra and the men of the great synagogue, after the captivity. And in imitation of this, the Jews to this day have a kind of ark in their synagogues, wherein their sacred books are reposited. This they call *aron*. Leo of Modena gives a description thereof in his Account of the Customs and Ceremonies of those of his Nation. "The Jews (says he), in the eastern side of their synagogues, have an ark, or armory, called *aron*, in memory of the ark of the covenant. In this are preserved the five books of Moses, written on vellum, with ink made on purpose," &c. Some have supposed that the figure of this ark is still remaining on the triumphal arch of Titus at Rome; though Villalpandus and others, with greater reason, are of opinion, that it is the table of shew-bread. *Prideaux's Con.* Vol. i. p. 209. Tertullian calls this ark *Armarium Judaicum*; whence the phrase, *to be in the armory of the synagogue*, q. d. in the number of canonical writings.

A chest or coffer, very nearly resembling the Jewish ark, and called the *house of the God*, was found in Huaheine, one of the islands in the southern sea. Mr Banks could obtain no other information concerning it than what the name imports. *Hawkesworth's Account*, &c. Vol. ii. p. 252.

ARKLOW, a sea-port town of Ireland, in the county of Wicklow, and province of Leinster. W. Long. 6. 15. N. Lat. 52, 55.

ARLES, a city of Provence in France, seated on the east side of the Rhone, on a hill whose declivity is towards the north. It is an archbishop's see; and is celebrated for its antiquities both within and without the city. Those of which any remains are now to be seen are the amphitheatre, the obelisk, the Elysian Fields, the sepulchres, columns with their capitals, busts, pedestals, aqueducts, with some remains of the capitol, and the temples of their gods. The other ancient monuments are entirely destroyed. Under the amphitheatre. in 1651, they found the statue of venus, which was worshipped by this city; and has been since carried to the castle of Versailles. It is a masterpiece which will always be admired by connoisseurs.

The amphitheatre is one of the most remarkable pieces of antiquity. It was built by the Romans, but the time is unknown though some say by Julius Cæsar. It is of an oval form, and about 400 yards in circumference, and the front is 34 yards in height. The middle, called the *Arena*, is 142 yards wide and 104 broad. The porticos or piazzas are three stories, built with stone of a prodigious size. Each of them consists of 60 arches, which still remain; and the walls are of a surprising thickness, but gone to decay.

The obelisk is the only one of this kind to be seen in France. It seems to be one of the forty brought from Egypt to Rome, because it is of the same oriental granite with them. They are generally full of hieroglyphic characters; but this is quite smooth. In 1675, it was found in a private garden near the walls of the [illegible], not far from the Rhone. It consists of one piece; and is 52 feet high, and 7 in diameter at the base. It is now supported with four lions made of bronze; and on the top a blue ball is placed, with the arms of France, and over that a sun.

The Pagans burying-place, called the *Elysian Fields*, is without the city, upon an agreeable hill, divided into two parts. The first, called *Moulaires*, has very few tombs, they have been broken to build the walls of gardens, which are made in that place. The second, called *Eliscamp*, contains a great number. Those of the Pagans have the letters D. M. which signifies *Diis Manibus*. Those of the Christians have a cross. Pieces of coin of gold, silver, and bronze, are found here; as also urns, lamps, and cups without number.

Here is a royal academy of sciences, consisting of thirty members, who must be natives, gentlemen, and inhabitants of the city. It enjoys the same privileges as that at Paris. Arles is surrounded with marshy land which renders the air full of vapours, and makes it not very wholesome. Long. 4. 48. E. Lat. 43. 40.

ARLEUX, an ancient town of the Netherlands, in Cambresis, with a castle. It was taken by the French in 1645, and retaken by the allies in 1711, but the French got possession again the same month. E. Long. 3. 16. N. Lat. 59. 17.

ARLON, an ancient town of the Netherlands, formerly a strong place, but now dismantled. It belongs to the house of Austria. E. Long. 15. 50. Lat. 49. 4.

ARM, a part of the human body, terminating at one end on the shoulder, and at the other in the hand. See Anatomy, n° 48.

Arm, among sportsmen, is applied to a horse, when, by pressing down his head he endeavours to defend himself against the bit, to prevent his being checked by it. The remedy is, to have a wooden ball covered with velvet, or other matter, put on his chaul, which will so press him between the jaw-bones as to prevent his bringing his head so near his breast.

Arm, in geography, is used for a branch of a sea or river. Italy and Sicily are only parted by an arm of the sea. St George's arm in the Mediterranean is the Thracian Bosphorus.

Arm is also used figuratively for power. The secular arm is the lay or temporal authority of a secular judge; to which recourse is had for the execution of the sentences passed by ecclesiastical judges.

The church sheds no blood: even the judges of inquisition, after they have found the person guilty, surrender him to the secular arm. The council of Antioch, held in 341, decrees, that recourse be had to the secular arm to repress those who refuse obedience to the church: for secular arm, they here use exterior power.

Arm, in respect to the magnet. A loadstone is said to be armed, when it is capped, cased, or set in iron or steel, in order to make it take up the greater weight, and also to distinguish readily its poles. See Magnetism

ARMACALES, a river of Babylon (Abydenus); called *Fossa Regia*, the *Royal Trench* or *Cut* (Polybius); the *Royal River* (Ptolemy); *Almarchur* (Pliny); *Naarmalcha* (Ammian); a factitious channel or cut, made by Nabuchadonosor, and a horn or branch of the Euphrates, (Abydenus). The Euphrates naturally divides into two channels, one passing through Babylon, the other through Seleucia, and then falls into the Tigris: the factitious channel between these two is the Royal River; which mixes with the Tigris, a great deal lower down than Seleucia, at Apamea, (Ptolemy).

ARMADA, a Spanish term, signifying a fleet of men of war. The armada which attempted to invade England in the time of Queen Elizabeth, is famous in history.

This armada, to which the Spaniards in confidence of success, gave the name of *Invincible*, consisted of 150 ships, most of which were greatly superior in strength and size to any that had been seen before. It had on board near 20,000 soldiers and 8000 sailors, besides 2000 volunteers of the most distinguished families in Spain. It carried 2650 great guns, was victualled for half a year, and contained such a quantity of military stores, as only the Spanish monarch, enriched by the treasures of the Indies and America, could supply. The troops on board were to be joined by 34,000 more which the Duke of Parma had assembled in the neighbourhood of Nieuport and Dunkirk. For transporting these, he had, with incredible labour, provided a great number of flatbottomed vessels, and had brought sailors to navigate them from the towns in the Baltic. Most of these vessels had been built at Antwerp; and as he durst not venture to bring them from thence by sea to Nieuport, lest they should have been intercepted by the Dutch, he was obliged to send them along the Scheld to Ghent, from Ghent to Bruges by the canal which joins these towns, and from Bruges to Nieuport by a new canal which he dug on the present occasion. This laborious undertaking, in which several thousand workmen had been employed, was already finished, and the Duke now waited for the arrival of the Spanish fleet; hoping, that as soon as it should approach, the Dutch and English ships which cruised on the coast would retire into their harbours.

When the news reached England that this mighty fleet was preparing to sail, terror and consternation universally seized the inhabitants. A fleet of not above 30 ships of war, and those very small in comparison, was all that was to oppose it by sea. All the commercial towns of England, however, were required to furnish ships for reinforcing this small navy. The citizens of London, instead of fifteen vessels, which they were commanded to equip, voluntarily fitted out double the number; and the gentry and nobility equipped 43 ships at their own charge. Lord Howard of Effingham was admiral; and under him served Drake, Hawkins, and Frobisher, all of them renowned as seamen of courage and capacity. The principal fleet was stationed at Plymouth. A smaller squadron, consisting of 40 vessels, English and Flemish, was commanded by Lord Seymour second son of protector Somerset, and lay off Dunkirk in order to intercept the Duke of Parma.

The land-forces of England were more numerous than those of the enemy, but inferior in discipline and experience. An army of 20,000 men was disposed in different bodies along the south coast, with orders to retire backwards and waste the country, if they could not prevent the Spaniards from landing; 22,000 foot and 1000 horse, under the command of the Earl of Leicester, were stationed at Tilbury, in order to defend the capital; and the principal army, consisting of 34,000 foot and 2000 horse, commanded by Lord Hunsdon

Armada. Hunsdon, was reserved for guarding the Queen's person, and appointed to march whithersoever the enemy should appear. These armies, though all the Spanish forces had been able to land, would possible have been sufficient to protect the liberties of their country. But as the fate of England, in that event, must depend on the issue of a single battle, all men of serious reflection entertained the most awful apprehensions of the shock of at least 50,000 veterans, commanded by experienced officers, under so consumate a general as the Duke of Parma. The Queen alone was undaunted. She issued all her orders with tranquillity, animated her people to a steady resistance, and employed every resource which either her domestic situation or her foreign alliances could afford her. She even appeared on horseback in the camp at Tilbury; and riding through the lines, discovered a cheerful and animated countenance, exhorted the soldiers to remember their duty to their country and their religion, and professed her intention, though a woman, to lead them herself into the field against the enemy, and rather perish in battle than survive the ruin and slavery of her people. "I know (said she, intrepidly) I have but the weak and feeble arm of a woman; but I have the heart of a king, and of a king of England too!" The heroic spirit of Elizabeth communicated itself to the army, and every man resolved to die rather than desert his station.

The Spanish armada was ready in the beginning of May; but its sailing was retarded by the death of the Marquis of Santa Croce the admiral, and that also of the vice-admiral the Duke of Paliano. The command of the expedition was therefore given to the Duke of Medina Sidonia, a man entirely unexperienced in sea affairs. This promotion, in some measure, served to frustrate the design, which was also rendered less successful by some other accidents. Upon leaving the port of Lisbon, the armada next day met with a violent tempest, which sunk some of the smallest of their shipping, and obliged the fleet to put back into the harbour. After some time spent in refitting, they put again to sea. Being descried by Fleming, a Scottish pirate, who was roving in those seas, he immediately sailed towards the English fleet, and informed the admiral of their approach. Effingham had just time to get out of port when he saw the Spanish armada coming full sail towards him, disposed in the form of a crescent, and stretching the distance of seven miles from the extremity of one division to that of the other. The English admiral, considering that the Spaniards would probably be much superior to him in close fight, by reason of the size of their ships and the number of their troops, wisely resolved to content himself with harassing them in their voyage, and with watching attentively all the advantages which might be derived from storms, cross winds, and such like fortuitous accidents. It was not long before he discerned a favourable opportunity of attacking the vice-admiral Recaldo. This he did in person; and on that occasion displayed so much dexterity in working his ship, and in loading and firing his guns, as greatly alarmed the Spaniards for the fate of the vice-admiral. From that time they kept much closer to one another; notwithstanding which, the English on the same day attacked one of the largest galeasses. Other Spanish ships came up in time to her relief; but in their hurry one of the principal galleons, which had a great part of the treasure on board, ran foul of another ship, and had one of her masts broken. In consequence of this misfortune she fell behind, and was taken by Sir Francis Drake; who on the same day took another capital ship, which had been accidentally set on fire.

Several other rencounters happened, and in all of them the English proved victorious, through the great advantage which they derived from the lightness of their ships, and the dexterity of the sailors. The Spaniards in that age did not sufficiently understand nautical mechanics, to be able to avail themselves of the unusual magnitude of their ships. The English sailed round them, approached, or retired, with a velocity that filled them with amazement, and did infinitely greater execution with their cannon: for while every shot of theirs proved effectual, their ships sufferd very little damage from the enemy, whose guns were planted too high, and generally spent their force in air.

The Spaniards, however, still continued to advance till they came opposite to Calais; there the Duke de Medina having ordered them to cast anchor, he sent information to the Duke of Parma of his arrival, and intreated him to hasten the embarkation of his forces. Farnese accordingly began to put his troops on board. But at the same time he informed Medina, that, agreeably to the King's instructions, the vessels which he had prepared were proper only for transporting the troops, but were utterly unfit for fighting; and for this reason, till the armada were brought still nearer, and the coast cleared of the Dutch ships which had blocked up the harbours of Nieuport and Dunkirk, he could not stir from his present station, without exposing his army to certain ruin, the consequence of which would probably be the entire loss of the Netherlands.

In compliance with this request, the armada was ordered to advance; and it had arrived within sight of Dunkirk, between the English fleet on the one hand, and the Dutch on the other, when a sudden calm put a stop to all its motions. In this situation the three fleets remained one whole day. About the middle of the night a breeze sprung up; and Lord Howard had recourse to an expedient which had been happily devised on the day before. Having filled eight ships with pitch, sulphur, and other combustible materials, he set fire to them, and sent them before the wind against the different divisions of the Spanish fleet.

When the Spaniards beheld these ships in flames approaching towards them, it brought to their remembrance the havock which had been made by the fire-ships employed against the Duke of Parma's bridge at the siege of Antwerp. The darkness of the night increased the terror with which their imaginations were overwhelmed, and the panic flew from one end of the fleet to the other. Each crew, anxious only for their own preservation, thought of nothing but how to escape from their present danger. Some of them took time to weigh their anchors, but others cut their cables and suffered their ships to drive with blind precipitation, without considering whether they did not thereby expose themselves to a greater danger than that which they were so solicitous to avoid. In this confusion the ships

ships ran foul of one another: the shock was dreadful, and several of them received so much damage as to be rendered unfit for future use.

When day-light returned, Lord Howard had the satisfaction to perceive that his stratagem had fully produced the desired effect. The enemy were still in extreme disorder, and their ships widely separated and dispersed. His fleet had lately received a great augmentation by the ships fitted out by the nobility and gentry, and by those under Lord Seymour, who had left Justin de Nassau as alone sufficient to guard the coast of Flanders. Being bravely seconded by Sir Francis Drake and all the other officers, he made haste to improve the advantage which was now presented to him, and attacked the enemy in different quarters at the same time with the utmost impetuosity and ardour. The engagement began at four in the morning, and lasted till six at night. The Spaniards displayed in every rencounter the most intrepid bravery; but, from the causes already mentioned, they did very little execution against the English, while many of their own ships were greatly damaged, and twelve of the largest were either run aground, or sunk, or compelled to surrender.

It was now evident that the purpose of the armada was utterly frustrated. The Spanish admiral, after many unsuccessful rencounters, prepared therefore to make his way home; but as the winds were contrary to his return through the channel, he resolved to take the circuit of the island. The English fleet followed him for some time; and had not their ammunition fallen short through the negligence of the public offices in supplying them, they had obliged the armada to surrender at discretion. Such a conclusion of that vain-glorious enterprize would have been truly illustrious to the English, but the event was scarce less fatal to the Spaniards. The armada was attacked by a violent storm in passing the Orkneys; and the ships, having already lost their anchors, were obliged to keep at sea, while the mariners, unaccustomed to hardships, and unable to manage such unwieldly vessels, allowed them to drive on the western isles of Scotland, or on the coast of Ireland, where they were miserably wrecked. Not one half of the fleet returned to Spain, and a still smaller proportion of the soldiers and seamen; yet Philip, whose command of temper was equal to his ambition, received with an air of tranquillity the news of so humbling a disaster. "I sent my fleet (said he) to combat the English, not the elements. God be praised that the calamity is not greater!" This calamity, however, was sensibly felt all over Spain, and there was scarcely a single family of rank in the kingdom that did not go in mourning for the death of some near relation; insomuch that Philip, dreading the effect which this universal face of sorrow might produce upon the minds of the people, imitated the conduct of the Roman senate after the battle of Cannæ, and published an edict to abridge the time of public mourning.

ARMADILLA, in the Spanish America, denotes a squadron of men of war, to the number of six or eight, from twenty-four to fifty pieces of cannon, which the king maintains, to prevent foreigners from trading with the Spaniards and the Indians, both in time of war and peace.

The vessels of this armadilla are those that have been so much talked of under the name of *guarda costas*. They have even power to take all Spanish merchant-ships they meet with on the coasts that have not licences from the king.

The South sea has its armadilla as well as the North sea. The ordinary abode of the former are at Calao, a port of Lima; that of the latter at Carthagena.

ARMADILLO, in zoology, a synonime of the dasypus. See DASYPUS.

ARMAGEDDON, a place spoken of in the Revelations (xvi. 16.), which literally signifies the mountain of Mageddon or Megiddo, a city situated in the great plain at the foot of mount Carmel, where king Josiah received his mortal wound in the battle against Necho king of Egypt. At Armageddon, the three unclean spirits, coming out of the dragon's mouth, shall gather together the kings of the earth to the battle of the great day of God Almighty (Rev. xvi. 13,14). The word Armageddon, according to Mr Pool, does not signify any particular place, but is here an allusion, as some think, to that of Megiddo, mentioned Judges v. 19. where Barak overcame Sisera with his great army, and where Josiah was slain (2 Kings xxiii. 30). Others translate this word, *the mountain of the gospel*, and others *the mountain of apples or fruits*.

ARMAGH, a county of Ireland, bounded by Louth on the south; Lough-neagh, on the north; Tyrone and Monaghan, on the west; and Down, in part, on the east, from which it is separated by the river Newry. It is in length 32 miles, in breadth 17; and is divided into five baronies, containing about 170,620 acres. Both the air and soil are good, especially the latter, which is said to be the richest in Ireland; only there is a certain tract in it called the *Fewes*, that is, *hilly* and *barren*. The members it sends to parliament are six, viz. two for the city of Armagh, two for the county, and two for the borough of Charlemont.

Armagh, standing near the river Kalin, gives name to the country, and is the see of the primate of all Ireland. It is said to have been founded by St Patrick in the fifth century; and in 1142, it was constituted an archbishoprick, together with Dublin, Cashel, and Tuam, by cardinal Papyreo, with the consent of the king, dukes, bishops, abbots, and states of Ireland. This Papyreo was sent into Ireland by Pope Eugenius, to reform the abuses that had crept into the church-discipline of that country. Here was anciently a famous monastery built by St Columbo, or Columbanus, about the year 610. The cathedral was often burnt, but as often rebuilt and enlarged, and particularly by Patrick Scanlain, about 1262. His successor Nicholas, son of Molissa, beside books, rich ecclesiastical vestments, and other things, bestowed on it an annual pension of twenty marks. He appropriated also to his see the manor of Dromyskin. He died the 10th of May, 1303. This town was first subjected to the English by John de Courcy; but afterwards entirely destroyed by Tir Oen, or O'Neal, in Queen Elizabeth's time. However, it was afterwards recovered, rebuilt, and garrisoned by the English.

The see of Armagh is valued in the king's books, by an extent taken *anno* 30th Henry VIII. at L. 183, 17 : 5¼ Irish money *per annum*, which amounts to

L. 137 : 18 : 0¾ (the difference between Irish and Sterling money being at that time one-fourth). But by an extent returned in the 15th of James I. it is valued at L.400 Sterling *per annum*, and pays so much first fruits to this day. It is reputed to be worth annally L.8000. The chapter of Armagh is composed of five dignitaries and four prebendaries, who have voices in every capitular act. The dignitaries are thus ranked, viz. a dean, chapter, chancellor, treasurer, and archdeacon. There are also eight vicars choral, and an organist, attendant on the service of the cathedral. The vicars choral were anciently fewer; and of the number only one priest. Primate Marsh added another priest, but without increasing the number of vicars. In the year 1720, Primate Lindsay obtained a new charter for enlarging the number of the said vicars to eight, and laid out upwards of L.4000 on a purchase, in augmentation of the estate of the choir.

ARMAGNAC, a province of Guienne in France, 55 miles in length, and 40 in breadth; bounded on the east by the river Garonne, on the south by Bigorre and Bearn, and on the west by Gascony, and on the north by Condomois and Agenois: Auch is the capital town. It is fertile in corn and wine, and carries on a considerable trade in brandy, wool, and bonchretien pears, which are excellent.

ARMAMAXI, in antiquity, a kind of Scythian chariots or carriages, composed of two wheels, variously adorned with crowns, shields, breast-plates, and other spoils, carried in procession after the images of the gods and great men.

ARMAMENT, a large body of forces, raised and provided with the furniture of war, either for land or sea service.

ARMATURA, in a general sense, is the same with what we otherwise call armour.

ARMATURA is more particularly used in the ancient military art, for a kind of exercise, performed with missive weapons, as darts, spears, arrows, and the like. In this sense, armatura stands contradistinguished from palaria; the latter being the exercise of the heavy-armed, the former of the light-armed.

The armatura was practised with great diligence among the Romans: they had their *campidoctores*, on purpose to instruct the *tyrones* or young soldiers in it. Under it were included the throwing of the spear or javelin, shooting with bows and arrows, &c.

ARMATURA is also an appellation given to the soldiers who were light-armed.

ARMATURA is also a denomination given to the soldiers in the emperor's retinue. Of these we find two schools, mentioned in the *Notitia imperii*, called the *armaturæ seniores* and *armaturæ juniores*. Their commander was intitled *tribunus armaturarum*.

ARMED, in the sea-language. A cross-bar shot is said to be armed, when some rope-yarn or the like is rolled about the end of the iron-bar, which runs thro' the shot.

ARMED, in heraldry, is used when the horns, feet, beak, or talons, of any beast or bird of prey, are of a different colour from the rest of their body.

Armed-Ship, a vessel occasionally taken into the service of the government in time of war, and employed to guard some particular coast, or attend on a fleet. She is therefore armed and equipped in all respects like a ship of war, and commanded by an officer of the navy, who has the rank of master and commander. All ships of this sort are upon the establishment of the king's sloops, having a lieutenant, master, purser, surgeon, &c.

ARMENE, or ARMINA, anciently a hamlet of Paphlagonia, (Ptolemy). The inhabitants encompassed it with a wall, because of the coldness of the place, imagining by that means to render it warmer. But this proving ineffectual, gave rise to the proverb *Armenen muro cingere*, used to express some egregious folly.

ARMENIA, a country of Asia, anciently divided into Armenia Major and Minor. Armenia Major according to Strabo, was bounded on the south, by mount Taurus, which separated it from Mesopotamia; on the east, by the two Medias; on the north, by Iberia and Albania, or rather that part of mount Caucasus which surrounds them both; and on the west, by Armenia Minor, or the mountains of Paryadres, some Pontic nations, and the Euphrates. The most considerable cities were Artaxata, Tigranocerta, and Thedosiopolis. —Armenia Minor was bounded on the east, by the Euphrates; on the south, by mount Taurus, which separated it from Cilicia; on the west and north, by a long chain of mountains called in different places *Mons Scordiscus*, *Amanus*, and *Antitaurus*, by which it was separated from Cappadocia.

Whence this tract received the name of *Armenia* is not determined. The Greeks suppose it to be so called from one *Armenus*, who attended Jason in the Argonautic expedition, and afterwards settled in this country. Others, transforming Armenia into Aramia, derive its name from Aram the son of Shem, or from one of the kings of Armenia bearing that name. Bochart imagines it to be a contraction or compound of *Aar*, a Hebrew word signifying a "mountain," and *Mini* signifying "metal," and which was the name of a province of Armenia mentioned by the prophet Jeremiah.

Herodotus derives the ancient Armenians from the Phrygians, by reason that several Phrygian words were crept into the ancient Armenian language. But Strabo reckons them to have been originally Syrians, which Bochart looks upon to be the most probable opinion.

Armenia is said to have been very early advanced to the honour of a kingdom. Berosus makes one Sytha the first founder of this monarchy, whose successor Bardanes, he says, was driven out by Ninus king of Assyria. Plutarch mentions one Araxes king of Armenia, who in a war with the Persians, being assured of success by an oracle, provided he sacrificed his two daughters, caused the two daughters of one Miesalcus, a nobleman of his court, to be sacrificed in their stead, flattering himself that he thereby complied with the oracle. But Miesalcus, did not fail to revenge the death of his own daughters by putting the king's two daughters to death, and pursued himself so closely, that he was drowned in attempting to swim across the Araxes, which was then called *Helmus*.

The Armenians were in process of time subdued by the Medes, to whom Astyages made them tributaries, but allowed them to be governed by their own kings; but on the dissolution of the Median empire by Cyrus, the kingdom was reduced to the form of a province, and they were governed by Persian prefects or lieutenants. On the destruction of the Persian empire by

Alexander the Great, Armenia fell into the hands of the Macedonians; to whom it continued subject till the beginning of the reign of Antiochus the Great. This prince having appointed two prefects called *Zadriades* and *Artaxias* to govern Armenia, they excited the people to a revolt, and caused themselves to be proclaimed kings of the provinces over which they presided. Antiochus being then very young, they were attended with success beyond their expectation; which encouraged them to attempt the enlargement of their territories. Accordingly, invading the neighbouring countries, they took from the Medes the provinces of Caspiana, Phaunitis, and Basoropida; from the Iberians, Chorzena and Gogorena on the other side of the Cyrus; from the Chalybes and Mossynæci, the provinces of Pareneta and Herexena, which bordered on Armenia Minor.

On this occasion, the abovementioned division of the kingdom into Armenia Major and Minor first took place. Artaxias became king of Armenia Major, and Zadriades of Armenia Minor; and this distinction subsists even at this day.

By whom Artaxias was succeeded is not known; neither have we any account of the transactions of his reign, farther than that Antiochus led a powerful army against him and Zadriades, but without being able to recover a single province. Upon this he concluded a peace, designing to fall upon them at a proper opportunity; but they having entered into alliance with the Romans, by that means secured themselves in the possession of their kingdom. After this, Artaxias was defeated and taken prisoner by Antiochus Epiphanes; but some how or other, seems to have been restored to his kingdom.

From this time we meet with a chasm in the Armenian history for 70 years; during which all we know is, that Tigranes, the king's son, was delivered up as an hostage to the Parthians; from whence it is plain, that the Armenians had been carrying on an unsuccessful war with that nation. On the news of his father's death, however, the Parthians set the young king at liberty, having first obliged him to give up a considerable part of his kingdom by way of ransom.

Tigranes, being thus restored to his father's kingdom, was prevailed upon in the beginning of his reign to enter into an alliance with Mithridates Eupator against the Romans, whose power began to give jealousy to all the princes of Asia. One of the articles of this treaty was, that Mithridates should have the cities and conquered countries, and Tigranes the captives and plunder. In consequence of this, Tigranes was to invade Cappadocia, which he had lately been obliged, by a decree of the senate of Rome, to give up to Ariobarzanes. But before either of the princes took the field, a marriage was solemnized with all possible magnificence between Tigranes and Cleopatra the daughter of Mithridates.

Immediately after the nuptials, Tigranes set out on his intended expedition; and Ariobarzanes, on the first news of his march, abandoned his kingdom and fled to Rome. Thus Tigranes, without fighting a stroke, enriched himself with the booty, and then proclaimed Ariarathes, Mithridates's son, king of Cappadocia, to the universal satisfaction of the people.

In the mean time the Syrians being harrassed with a long and intestine war of the Seleucidæ, invited Tigranes to come and take possession of their country; which he accordingly did, and kept it for 18 years, till he was driven out by Pompey, and Syria reduced to the form of a Roman province. Encouraged by this success, he next invaded Armenia Minor; defeated and killed king Artanes, who opposed him with a considerable army; and in one campaign made himself master of the whole kingdom. From Armenia Minor he marched against the Asiatic Greeks, the Adiabenians, the Assyrians, and the Gordians, carrying all before him, and obliging the people wherever he came to acknowledge him sovereign. From this second expedition he returned home loaded with booty, which he soon after increased by the spoils of Cappadocia, invading that kingdom a second time at the instance of Mithridates, who had been obliged by the Romans to withdraw his forces from thence. From Cappadocia, Tigranes, besides other booty, brought back into Armenia, no fewer than 300,000 captives, having surrounded the country with his numerous forces in such a manner that none could escape. These, together with the prisoners he had taken in his two first expeditions he employed in building the city of Tigranocerta, which they afterwards peopled.

In the mean time Mithridates, who had concluded a peace with the Romans for no other end than to gain time, sent a solemn embassy to Tigranes, inviting him to enter into a second alliance against the common enemy. This he at first declined, but in the end was prevailed upon by his wife Cleopatra to send him considerable supplies, though he never came heartily into the war, not caring to provoke the Romans, who on their part kept fair with him, taking no notice for the present of the supplies he had sent Mithridates. That unfortunate prince being soon after defeated by Lucullus, was forced to fly for shelter into Armenia, where he met with a very cold reception from his son-in-law, who would neither see him, treat with him, nor own him as his relation: however, he promised to protect his person, and allowed him in one of his castles a princely retinue, and a table suitable to his former condition.

Though this total overthrow of Mithridates might have opened the eyes of Tigranes, and made him oppose with all his might the growing power of the Romans, he foolishly left them to finish their conquest of Pontus, while he marched at the head of a very numerous army against the Parthians, with a design to recover from them the dominions they had formerly extorted from him before they set him at liberty. These he easily retook; and, not satisfied with what formerly belonged to him, he added to them all Mesopotamia, the countries that lay about Ninus and Arbela, and the fruitful province of Migdonia; the Parthians, tho' at that time a mighty people, flying every where before him. From Mesopotamia Tigranes marched into Syria to quell a rebellion which had been raised by Cleopatra surnamed *Selene;* who, after the death of her husband Antiochus Pius, reigned jointly with her sons in that part of Syria which Tigranes had not seized on. The malcontents were quickly reduced; and the queen herself was taken prisoner, and confined to the castle of Seleucia, where she was soon after put to death by the king's orders. From Syria Tigranes passed

Armenia. ed into Phœnice, which he subdued either entirely or in great part, spreading far and wide the terror of his arms, insomuch that all the princes of Asia, except those who were in alliance with the Romans, either in person, or by their deputies, submitted and paid homage to the conqueror.

The king, having now subdued all Syria to the borders of Egypt, and being elated with a long course of victories and prosperous events, began to look upon himself as far above the level of other crowned heads. He assumed the title of *King of kings*, and had many kings waiting upon him as menial servants. He never appeared on horseback without the attendance of four kings dressed in livery, who run by his horse; and when he gave answers to the nations that applied to him, the ambassadors stood on either side the throne with their hands clasped together, that attitude being of all others then accounted among the orientals the greatest acknowledgment of vassalage and servitude. In the midst of all this haughtiness, however, he was unexpectedly visited by an ambassador from Lucullus the Roman general, who without any ceremony told him, that he came to demand Mithridates king of Pontus, who had taken refuge in his dominions, and, in case of his refusal, to declare war against him. Notwithstanding his high opinion of himself, Tigranes returned a mild answer to this message: in which, however, he refused to deliver up his father-in-law; and being highly provoked at Lucullus for not giving him the title of *King of kings* in his letter, he did not so much as bestow upon him the title of *general* in his answer. In the mean time, being informed that Zarbienus king of the Gordians had entered into a private alliance with the Romans, he put him, his wife, and children, to death; and then, returning into Armenia, received with the greatest pomp imaginable his father-in-law Mithridates, whom to that time he had not admitted into his presence, though he had resided a year and eight months in his dominions. They had several private conferences; and at last Mithridates was sent back to Pontus with 10,000 horse, to raise there what disturbances he could.

Lucullus, on the other hand, hearing the king's resolution to protect Mithridates, immediately began his march for Armenia, at the head of only two legions of foot and 3000 horse, having left 6000 men in Pontus to keep that country quiet. Having passed the Euphrates without opposition, he detached two parties; one to besiege a city where he heard that Tigrane's treasure and concubines were kept; and the other under Sextilius, to block up Tigranocerta, in order to draw the king to a battle. But Tigranes, after having put to death the scout that brought him the first intelligence of the approach of the Romans, made towards Mount Taurus, which he had appointed for the place of the general rendezvous. The Roman general then dispatched Muræna in pursuit of the king; who having overtaken him in a narrow pass, defeated him, and, besides all the baggage, carried off a great many prisoners, the king himself having fled in the beginning of the skirmish. After this, he sent out several parties to scour the country, in order to prevent the innumerable forces of Tigranes from joining into one body. This, however, he was not able to effect: Tigranes was joined by such numbers of Gordians, Medes, Adiabenians, Albanians, Iberians, &c. that, before he left Mount Taurus, his army consisted, according to Plutarch, of 150,000 foot armed cap-a-pee, 35,000 pioneers, 20,000 archers and slingers, and 55,000 horse.

Lucullus was so far from being dismayed at this formidable army, that the only fear he had was lest the king should follow the advice of Mithridates, which was not to engage the Romans, but, by ravaging the country, distress them for want of provisions. In order to draw him to a battle, therefore, he formed the siege of Tigranocerta, imagining that Tigranes would never suffer that fine city to be taken without making any attempt to relieve it. The event fully answered his expectations: Tigranes having called a council of war, it was unanimously resolved to attack the Romans; and Taxilis, whom Mithridates sent to dissuade the king from venturing a battle, was in danger of losing his head on account of the advice he gave. The Roman general, finding Tigranes disposed to come to an engagement, left Muræna with 6000 men to carry on the siege, while he himself marched against the king's vast army with only 10,000 men, according to some, and the highest computations make them no more than 18,000. The Romans were at first greatly disheartened; but being encouraged by Lucullus, they immediately broke the Armenian army, who betook themselves to flight almost at the first onset. The Romans pursued them till night, making a most terrible slaughter. Plutarch informs us, that of the Armenians 100,000 foot were killed, and that very few of the cavalry escaped; whereas of the Romans only five men were killed and 100 wounded. Antiochus the philosopher, mentioning this battle, says, that the sun never beheld the like; and Livy, that the Romans never fought at such a disadvantage; the conquerors not amounting to a twentieth-part of the conquered. Tigranes in his flight having met with his son in as forlorn a condition as himself, resigned to him his royal robes and diadem, desiring him to shift for himself and save those royal ensigns. The young prince delivered them to a trusty friend, who, being taken by the Romans, consigned them to Lucullus.

While the king was making his escape after this terrible overthrow, he was met by Mithridates, who was marching to his assistance at the head of a considerable army. The king of Pontus cheered up his son-in-law as well as he could, and encouraged him to continue the war: advising him, instead of fruitlessly bewailing the present disaster, to rally his troops, raise new supplies, and renew the war, not questioning but that in another campaign he might repair all the losses he had sustained: but while the two kings were consulting upon these matters, Lucullus made himself master of Tigranocerta. From this city he marched into the small kingdom of Gordyene, where he celebrated, with the utmost pomp, the obsequies of king Zabienus, whom Tigranes had put to death, lighting the funeral-pile with his own hands. In this kingdom, besides immense sums of gold and silver, he met with such store of provisions as enabled him to carry on the war without putting the republic to any charge.

The two kings, having levied new forces, appointed their troops to rendezvous in the spacious plains on the other side of Mount Taurus; whereupon Lucullus, leaving Gordyene, and passing by Mount Taurus, encamped close by the enemy. Several skirmishes happened for some time between the two armies without any

any considerable advantage; but Lucullus could by no means draw them to a general engagement. Upon this he decamped, as if he designed to march to Artaxata and lay siege to that place, where Tigranes had left his wife and children, with great part of his treasures. He had scarce formed his camp when the enemy appeared, and sat down close by him. Lucullus did not allow them to fortify their camp, but immediately attacked them, and having put them to flight after a faint resistance, pursued them all night with great slaughter, took most of the chief officers prisoners, and returned the next day loaded with booty.

The Roman soldiers now, finding the cold very severe, though it was no later in the year than the autumnal equinox, requested their general to allow them to retire into winter-quarters. This request he rejected with indignation; upon which they mutinied. Lucullus did all he could to persuade them to continue in their duty; and prevailed so far that they consented to lay siege to Nisibis in hopes of booty. This place they took; and Lucullus, to the great satisfaction of his troops, took up his winter-quarters there. The next year, however, his forces again mutinied, accusing him of amassing immense wealth for himself; and throwing their empty purses at his feet, told him, that as he enriched himself alone, he might carry on the war by himself. He endeavoured to appease them as much as possible; but the sedition being fomented by a party who favoured Pompey the great, at that time aspiring to the command of Lucullus's army, the latter found himself obliged to sit still and see Mithridates and Tigranes over-run Cappadocia, and recover all Armenia and great part of Pontus. They would have gained much greater advantages, had not a son of Tigranes taken arms against his father, and obliged him to divide his troops. The father and son coming to a pitched battle, the latter was defeated, and forced to save himself in Parthia, where he persuaded Phrahates, king of that country, to assist him with a numerous army against his father. Phrahates having laid siege to Artaxata, Tigranes the elder was obliged to hide himself in the mountainous parts of his kingdom; upon which the king of Parthia returned home. Of this Tigranes the father being apprised, he immediately abandoned the fastnesses of the mountains; and, falling upon his son at Artaxata, dispersed the rebels with great slaughter; and entered his metropolis in triumph. Tigranes the son first fled to Mithridates; but finding him reduced to great straits, having been overcome a few days before, with the loss of 40,000 men, by Pompey, he went over to the Romans, and led them into Armenia against his father as an ally of Mithridates.

Tigranes, being now quite dispirited, and unable to make head against the Romans, resolved at once to submit. Accordingly he waited on Pompey in his camp, and having delivered his sword to two lictors, prostrated himself before him, and laid his diadem at his feet. Pompey, however, gave him a gracious reception, restored him the kingdom of Armenia, but fined him of 6000 talents for making war on the Roman people without cause. As the king had appealed to the Roman general for justice against his son, Pompey heard both parties the next day, and made the son governor of Gordyene and Sophene; but the treasures that were kept in the latter he adjudged to the father, because without them he could not pay the fine. The son, being thus disappointed, endeavoured first to make his escape, and afterwards, by private messengers, solicited the inhabitants not to deliver up the treasures to his father. This being taken very much amiss by Pompey, he caused him to be kept in irons; and even then he found means to stir up Phrahates king of Parthia, whose daughter he had married, against the Romans, and to form a conspiracy against his father's life, whereupon Pompey sent him in chains to Rome, where he was kept prisoner in the house of L. Flavius a senator, till the tribuneship of P. Clodius, who, being bribed with a large sum of money, set him at liberty in spite of Pompey and the senate.

Tigranes being now thoroughly humbled, willingly yielded to the Romans Cappadocia, Syria Cilicia, and that part of Phœnice which he possessed, contenting himself with his paternal kingdom; and not only paid the fine laid upon him, but made large presents to Pompey, and all the officers of his army, which procured him the title of *the friend and ally of the Roman people*. He afterwards entered into a war with Phrahates king of Parthia, by whom he was overcome, and would have been driven out of his kingdom, had not a peace been brought about by the mediation of Pompey. He ever after cultivated a strict friendship with the Romans; insomuch that he not only refused to receive Mithridates, who fled to him after he had been routed by Pompey near Mount Stella, but even offered a reward of 100 talents to any one that would put him to death. His second son also, by name Sariaster, took up arms against him; but, by the assistance of the Romans, that rebellion was soon quelled. He died in the 85th year of his age; and was succeeded by his son Artuasdes, called by Josephus *Artabazes*, by Orosius *Artabanes*, and by others *Artoadistes*.

From this time to the time of Trajan Armenia was governed by its own kings; but as they were plainly vassals to the Romans, though they did not take that title till the reign of the emperor Nero, their history falls to be considered under that of the Romans.

By Trajan the kingdom of Armenia Major was reduced to the form of a Roman province; but it soon recovered its liberty, and was again governed by its own kings in the reigns of Constantine the Great, and his successor, to whom the kings of Armenia were feudatories. In the reign of Justin II. the Saracens subdued and held till the irruption of the Turks, who possessed themselves of this kingdom, and gave it the name of *Turcomania*. The Turks, after the reduction of Armenia, invaded Persia, and other countries subject to the emperors of the east; which gave the Armenians an opportunity of shaking off the Turkish yoke, and setting up kings of their own, by whom they were governed till the country was again subdued by Occadan, or, as some style him, *Heccata*, the son of Cingis, and first cham of the Tartars. Neither was the conquest of Armenia by the Tartars so absolute as to extirpate the race of their kings; seeing we read of Haithon, surnamed the *Armenian*, reigning some time after, and going in person to treat with Mungo, the great cham of Tartary, of the concerns of his kingdom; and in our chronicles we find mention made of

Armenia. Leo king of Armenia, who, in the reign of Richard II. came into England to sue for aid against the Turks, by whom he had been driven from his kingdom. In the year 1472 of the Christian æra, Uſſan Caſſanes king of Armenia succeeding to the crown of Persia, made Armenia a province of that empire; in which state it continued till the year 1522, when it was subdued by Selim II. and made a province of the Turkish empire. Some say that Selim I. reduced it on his return from Persia, where he had gained a complete victory over the great Sophi Ismael. But Sansovin assures us, that in the reign of Selim I. who died in 1520, both the Lesser and Greater Armenia had their own kings; and adds, that Selim caused the head of the king of the Lesser Armenia to be cut off and sent to Venice as a mark of his victory. We read no where else of any kings of Armenia after it became a province of Persia. Be that as it will, the Turkish annals cited by Calvisius inform us, that Selim II. conquered Armenia in 1522, since which time it has ever continued subject to the Turks, except the eastern part, which the Persians are masters of to this day.

Concerning Armenia Minor we find very little recorded, except what has been already mentioned, and what falls under the Roman history. It was made a Roman province by Vespasian, continued so till the division of the empire, when it was subjected to the emperors of the east; and, on the decline of their power, was subdued first by the Persians, and afterwards by the Turks, who gave it the name of *Genech*, and have kept it ever since.

This country is still divided into the Great and Small. Great Armenia comprehends what is now called *Turcomania*. It has Georgia on the north, from which it is separated by high mountains; the river Euphrates on the west; Diarbeker, Curdistan, and Aderbijan, on the south; and Shirvan on the east. The chief towns in that part of Armenia belonging to Turky are, Arzum the capital, near the springs of the Euphrates, a large city, and a great thoroughfare for the caravans between Turky and Persia; Kara, a strong city, head of the government of the same name; Bayazid, a republic of Hurds, near mount Ararat: Baha, another republic of the same; and Van or Wan, on the lake Van, the head of a government of the same name; with other towns of less note. That part of Armenia subject to Persia is chiefly contained in the province of Aran, in which are several fine towns; as, Erivan or Rivan, the capital of the whole; Ganjals, one of the finest cities in Persia, in the north of the province, near the Kur; Kapan, on the south side, near the Aras; besides Nakchivan, Astabad Sulfa, Ordabad, Baylakan or Pilkan, on the Aras; Berdah and Shilkah on the Kur.

The country in general is full of mountains and valleys, lakes, and rivers; particularly the country about the three churches, near Erivan, is admirably fine, being full of rivulets, which render it extremely fruitful. Besides great quantities of all sorts of grain, here are fields of a prodigious extent covered with tobacco: but it is not a native of the place, though supposed by some to be the terrestrial paradise; for it all came originally from America. The rest of the country produces rice, cotton, flax, melons, and grapes: in short, there is nothing wanting but olives; which is by some thought to prove that the ark could not rest on mount Ararat, because the dove brought an olive branch in her mouth, and this tree never leaves a place where it once grew. It seems, however, to have been otherwise anciently; for Strabo tells us, that the olive grew in Gogarene, a province of Armenia. They got oil to burn from the ricinus, and use linseed oil in the kitchen. The water-melons are as cool as ice in the hottest day, and melt in the mouth: the best are produced in the salt-lands, near the three churches and the river Aras. After rain, the sea-salt lies in crystals upon the fields, and even crackles under the feet. About ten miles from the three churches, in the road to Teflis, there are pits or quarries of fossile salt, which yield enough to supply all Persia, without being exhausted: they cut it into large pieces like stone, and each buffalo carries two of them; the mountain from whence it is dug is nothing but a mass of salt, which appears like a rock of silver, when the sun shines, on the places not covered with earth.

This country has been remarkable for its extreme cold from the remotest antiquity: Sir John Chardin tells us, that he found ice in the rivulets in the mornings even of the month of July. In many places, also, if they had not the convenience of watering their grounds, they would be almost entirely barren.

The Armenians are an honest, civil, polite people, scarce troubling themselves about any thing else but trade, which they carry on in most parts of the world, by which means they have spread themselves over the east, and also great part of Europe; and wherever they come, commerce is carried on with spirit and advantage.

The religion of the Armenians is the Christian, of the Eutychian sect: that is, they own but one nature in Jesus Christ; and when they speak of the hypostatical union, that he is perfect God and perfect man without mixture. They have a high esteem for a book they call the *Little Gospel*, which treats of the Infancy of Jesus, and says that the Virgin Mary being pregnant, her sister Salome accused her of having prostituted herself; to which the Virgin answered, that she needed only to lay her hand on her belly, and she would know how she came to be with child; this Salome accordingly did, and fire came out of her belly, which consumed the half of her arm; upon which she acknowledged her fault, and drew it back: after which it was healed by putting it to the same place.

The Armenian clergy consist of patriarchs, archbishops, doctors, secular priests, and monks. The secular priests are not allowed to marry a second time; and therefore they take care to choose young healthy wives: they maintain themselves and families by following some occupation, insomuch that they have hardly time to perform their ecclesiastical functions: they lie in the churches on the vigils of those days they are obliged to officiate.

The Armenian monks are of the order of St Basil; and every Wednesday and Friday they eat neither fish nor eggs, nor oil, nor any thing made of milk, and during Lent they live upon nothing but roots: they are allowed wine only on the Saturday in the Holy Week, and meat on the Easter Sunday. Besides the great Lent, they have four others of eight days each, which are instituted to prepare for the four great festivals

vals of the Nativity, the Afcenfion, the Annunciation, and of St George; in which times they muft not fo much as fpeak of eggs, fifh, oil, or butter.

The Armenians have feven facraments; baptifm, confirmation, penance, the euchariſt, extreme unction, orders and matrimony. In baptifm, the child is plunged three times into the water, and the fame form of words that is ufed with us is repeated every time; the prieft then puts a fmall cord made with filk and cotton on the neck of the infant, and anoints his forehead, chin, ftomach, arm-pits, hands, and feet, making the fign of the crofs on each part. When the child is baptized, he is carried home by the godfather with the found of drums and trumpets. The women do not go to church till forty days after their delivery; and they obferve many Jewifh cuftoms.

At the communion, to which infants of two or three months old are admitted, the priefts give a piece of the confecrated hoft foaked in the confecrated wine. The elements are covered with a great veil, and placed in a cup-board near the altar, on the fide of the gofpels. When the prieft takes the chalice and pattin, he is followed by his deacons and fubdeacons, with flambeaux and plates of copper furnifhed with bells: in this manner, with a cenfer before him, he goes in proceffion round the fanctuary; he then fets them on the altar, pronounces the words of confecration, and turns himfelf to the people, who fall down, kifs the earth, and beat their breafts: then, after taking it himfelf, he diftributes the hoft foaked in wine to the people.

The Armenians feem to place the chief part of their religion in faftings and abftinences: and among the clergy, the higher the degree the lower they muft live; infomuch that it is faid the archbifhops live on nothing but pulfe. They confecrate holy water but once a-year; at which time every one fills a pot and carries it home, which brings in a confiderable revenue to the church.

ARMENICA. See Prunus.

ARMENIAN, fomething belonging to or produced in Armenia: thus we fay, *Armenian bole*, *Armenian ftone*, &c. See Bole and *Armenus Lapis.*

ARMENTIERS, a fmall handfome town of the Netherlands, in the county of Flanders, and diftrict of Ypres. It was taken by Lewis XIV. in 1667, who difmantled it; and it now belongs to the French. It is feated on the river Lis. E. Long. 3. 3. N. Lat. 50. 40.

ARMENUS lapis, *Armenian ftone*, in natural hiftory, a mineral fubftance, which is but improperly called a *ftone*; being no other than an ocherous earth, and properly called *blue ochre*. It is a very valuable fubftance in painting, being a bright and lively blue. It was in fo high efteem as paint among the ancients, that counterfeits were continually attempted to ferve in its place. Theophraftus has recorded it as a thing judged worthy a place in the Egyptian annals, which of their kings had the honour of inventing the factitious kind; and he tells us the genuine native fubftance was a thing of that value, that prefents were made of it to great perfons, and that the Phœnicians paid their tribute in it.—It is a very beautiful earth, of an even and regular texture; and of a fine blue, fometimes deeper, fometimes paler, and frequently mixed with green. It is foft, tender, and light; of an even, but fomewhat dufty, furface; it adheres firmly to the tongue, and is dry, but not harfh to the touch. It eafily breaks between the fingers, and does not ftain the hands. It is of a brackifh difagreeable tafte, and does not ferment with acids. It is a very fcarce foffil; but is found very pure, though in but fmall quantities, in the mines at Goffelaer in Saxony. It is frequently found fpotted with green, and fometimes with black; and very often is mixed among the green ochre, called *berggruen* by the Germans, which has thence been erroneoufly called by its name. See further the article Bice.

AMIERS, a town of Hainhault, in the French Netherlands, feated on the river Samber. E. Long. 3. 45. N. Lat. 50. 15.

ARMIGER, a title of dignity, belonging to fuch gentlemen as bear arms: and thefe are either by curtefy, as fons of noblemen, eldeft fons of knights, &c.; or by creation, fuch as the king's fervants, &c. See Esquire.

ARMILLARY, in a general fenfe, fomething confifting of rings or circles.

Armillary Sphere, an artificial fphere compofed of a number of circles of the mundane fphere, put together in their natural order, to eafe and affift the imagination in conceiving the conftitution of the heavens, and the motions of the celeftial bodies. The armillary fphere revolves upon its axis within a filvered horizon, which is divided into degrees, and moveable every way upon a brafs fupporter. The other parts are the equinoctial, zodiac, meridian, the two tropics, and the two poplar circles. See Geography.

ARMILUSTRIUM, in Roman antiquity, a feaft held among the Romans, in which they facrificed, armed to the found of trumpets.

ARMINIANS, a religious fect, or party, which arofe in Holland, by a feparation from the Calvinifts. They followed the doctrine of Arminus (fee the next article); who, thinking the doctrine of Calvin, with regard to free-will, predeftination, and grace, too fevere, began to exprefs his doubts concerning them in the year 1591; and upon further inquiry adopted fentiments more nearly refembling thofe of the Lutherans than of the Calvinifts. After his appointment to the theological chair at Leyden, he thought it his duty to avow and vindicate the principles which he had embraced; and the freedom with which he publifhed and defended them expofed him to the refentment of thofe that adhered to the theological fyftem of Geneva, which then prevailed in Holland; but his principal opponent was Gomar, his colleague. The controverfy which was thus begun, became more general after the death of Arminius, in the year 1609, and threatened to involve the United Provinces in civil difcord. The Arminian tenets gained ground under the mild and favourable treatment of the magiftrates of Holland, and were adopted by feveral perfons of merit and diftinction. The Calvinifts, or Gomarifts, as they were now called, appealed to a national fynod: accordingly the fynod of Dort was convened by order of the States General, in 1618, and was compofed of ecclefiaftical deputies from the United Provinces, as well as from the reformed churches of England, Heffia, Bremen, Switzerland, and the Palatinate. The principal advocate in favour of the Arminians was Epifcopius, who at that time was profeffor of divinity at Leyden. It was firft pro-

Arminians posed to discuss the principal subjects in dispute, and that the Arminians should be allowed to state and vindicate the grounds on which their opinions were founded: but some difference arising as to the proper mode of conducting the debate, the Arminians were excluded from the assembly; their case was tried in their absence; and they were pronounced guilty of pestilential errors, and condemned as corrupters of the true religion. In consequence of this decision, they were treated with great severity; they were deprived of all their posts and employments; their ministers were silenced, and their congregations were suppressed. However, after the death of prince Maurice, who had been a violent partizan in favour of the Gomarists, in the year 1625, the Arminian exiles were restored to their former reputation and tranquillity; and under the toleration of the state, they erected churches and founded a college at Amsterdam, appointing Episcopius to be the first theological professor. The Arminian system has very much prevailed in England since the time of archbishop Laud, and its votaries in other countries are very numerous.

The distinguishing tenets of the Arminians may be comprised in the following five articles; relating to predestination, universal redemption, the corruption of man, conversion, and perseverance.

1. With respect to the first, they maintained, "That God, from all eternity, determined to bestow salvation on those who he foresaw would persevere unto the end in their faith in Christ Jesus; and to inflict everlasting punishments on those who should continue in their unbelief; and resist unto the end his divine succours: so that election was conditional, and reprobation in like manner the result of foreseen infidelity and persevering wickedness."

2. On the second point, the Arminians taught, "That Jesus Christ by his sufferings and death, made an atonement for the sins of all mankind in general, and of every individual in particular; that, however, none but those who believe in him can be partakers of their divine benefit."

3. On the third article, they held, "That true faith cannot proceed from the exercise of our natural faculties and powers, nor from the force and operation of free will; since man, in consequence of his natural corruption, is incapable either of thinking or doing any good thing; and that therefore it is necessary, in order to his conversion and salvation, that he be regenerated and renewed by the operation of the Holy Ghost, which is the gift of God through Jesus Christ."

4. "That this divine grace, or energy of the Holy Ghost, begins and perfects every thing that can be called good in man, and consequently all good works are to be attributed to God alone; that, nevertheless, this grace is offered to all, and does not force men to act against their inclination, but may be resisted and rendered ineffectual by the perverse will of the impenitent sinner." Some modern Arminians interpret this and the last article with a greater latitude.

5. "That God gives to the truly faithful, who are regenerated by his grace, the means of preserving themselves in this state;" and though the first Arminians made some doubt with respect to the closing part of this article, their followers uniformly maintain, "that the regenerate may lose true justifying faith, forfeit their state of grace, and die in their sins."

The modern system of Arminianism likewise, founded on a comprehensive plan projected by Arminius himself, as appears from a passage in his last will, extends the limits of the Christian Church, and relaxes the bonds of fraternal communion in such a manner, that Christians of all sects and denominations, whatever their sentiments and opinions may be, papists excepted, may be formed into one religious body, and live together in brotherly love and concord. But, in order to avoid the reproach of being altogether unconnected by any common principles, Episcopius drew up a confession of faith, expressed for the most part in words and phrases of Holy Scripture, which the Arminians have generally adopted, though not enjoined upon them by any authoritative obligation. The Arminians are also called *Remonstrants*, from an humble petition intitled their *Remonstrance*, which, in the year 1610, they addressed to the States of Holland. Their principal writers are, Arminius, Episcopius, Vorstius, Grotius, Curcellæus, Limborch, Le Clerc, and Wetstein, not to mention many others of more modern date.

Arminius. ARMINIUS (James), whose real name in Low Dutch was James Harmanni, a famous protestant divine, from whom the modern sect of Arminians (see the preceding article) take their name, was born at Oude-water, in Holland, in 1560. He was ordained minister at Amsterdam on the 11th of August 1588; when he soon distinguished himself by his sermons, which were remarkable for their solidity and learning, and gained him universal applause: but Martin Lydias, professor of divinity at Franker, judging him a fit person to refute a writing in which Beza's doctrine of predestination had been attacked by some ministers of Delft, Arminius at his intreaties undertook the task; but upon thoroughly examining the reasons on both sides, he came into the opinions he proposed to destroy, and afterwards went still farther than the ministers of Delft had done. In 1600, he opposed those who maintained that ministers should subscribe the confession and catechism every year. In 1602, a pestilential disease raged at Amsterdam, during which he acted with the greatest resolution and courage, in assisting the poor, and comforting the sick; and Lucas Treclatius and Francis Junius dying of that disease at Leyden, the curators of that university chose Arminius professor of divinity there, and he was afterwards made doctor of divinity. Disputes upon grace were soon after kindled in that university; and he was at length engaged in a new contest, occasioned by a disputation of his concerning the divinity of the Son. These contests, his continual labour, and the concern of seeing his reputation blasted by a multitude of slanders in relation to his opinions, impaired his health, and threw him into a fit of sickness, of which he died on the 19th of October 1609. Arminius was esteemed an excellent preacher: his voice was low, but very agreeable; and his pronunciation admirable: he was easy and affable to persons of all ranks, and facetious in his conversation amongst his friends. His great desire was, that Christians would bear with one another in all controversies which did not affect the fundamentals of their religion; and when they persecuted each other for points of indifference, it gave him the utmost diſſatisfaction. The curators of the univerſity of Leyden had ſo great a regard for him, that they ſettled a penſion upon his wife and children. He left ſeveral works, viz. 1. "Diſputationes de diverſis Chriſtianæ religionis capitibus. 2. Orationes itemque tractatus inſigniores aliquot. 3. Examen modeſti libelli Gulielmi Perkinſii de predeſtinationis modo et ordine, itemque de amplitudine gratiæ divinæ. 4. Analyſis capitis noni ad Romanos. 5. Diſſertatio de vero et genuino ſenſu capitis ſeptimi epiſtolæ ad Romanos. 6. Amica collatio cum D. Franciſco Junio de prædeſtinatione per literas habita. 7. Epiſtola ad Hippolytum a collibus."

ARMIRO, a town of Macedonia, in European Turky, ſeated on the Gulph de Velo. E. Long. 23. 40. N. Lat. 38. 34.

ARMISTICE, in military affairs, a temporary truce or ceſſation of arms for a very ſhort ſpace of time. The word is Latin, *armiſtitium;* and compounded of *arma,* "arms," and *ſto*", to ſtand, or ſtop."

ARMOISIN, a ſilk ſtuff, or kind of taffety, manufactured in the Eaſt-Indies, at Lyons in France, and at Lucca in Italy. That of the Indies is ſlighter than thoſe made in Europe.

ARMONIAC. See AMMONIAC.

ARMONICA. See HARMONICA.

ARMORIAL, ſomething relating to arms, or coats of arms. See ARMS and HERALDRY.

ARMORIC, or AREMORIC, ſomething that belongs to the province of Bretagne, or Britanny, in France. The name *Armorica* was antiently given to all the northern and weſtern coaſt of Gaul, from the Pyreneans to the Rhine; under which name it was known even in Cæſar's time. The word is of Bas Breton origin, and denotes as much as *maritime*; compounded, according to M. Menage, of *ar,* "upon," and *more,* "ſea."

ARMORIST, a perſon ſkilled in the knowledge of armory.

ARMORUM CONCUSSIO, the claſhing of armour practiſed by the Roman armies previous to an engagement, and intended to ſtrike a panic into their enemies: It always followed the Claſſicum and the Barritus. See CLASSICUM and BARRITUS.

ARMOUR, a defenſive habit, wherewith to cover and ſecure the body from the attacks of an enemy. In ancient ſtatutes this is frequently called *harneſs*.—Parts of armour are, the buckler, cuiraſs, helmet, coat of mail, gantlet, &c.

A complete armour anciently conſiſted of a caſque or helm, a gorget, cuiraſs, gantlets, taſſes, braſſets, cuiſhes, and covers for the legs, to which the ſpurs were faſtened. This they called *armour cape-a-pie*; and was the wear of the cavaliers and men at arms.—The infantry had only part of it; viz. a pot or head-piece, a cuiraſs, and taſſes; but all light. Laſtly, the horſes themſelves had their armour, wherewith to cover the head and neck.—Of all this furniture of war, ſcarce any thing is now retained except the cuiraſs; the gorget or neck piece, worn by officers, being at preſent only a badge of honour, and of no defence.

The gallantry of going to the battle naked, without any defenſive armour, prevailed ſo far, that the French, during the reign of Lewis XIV. were obliged to be continually iſſuing ordinances to reſtrain it; in conſequence of which the general officers, and thoſe of the cavalry, were obliged to reſume the cuiraſs, which yet has been but ill obſerved.

ARMOUR, Coat, is the eſcutcheon of any perſon, or family, with its ſeveral charges, and other furniture; as mantling, creſt, ſupporters, motto, &c.—Thus we ſay, a gentleman of coat-armour; meaning one who bears arms.

ARMOURER, a maker of arms, or armour.—The Roman armourers were diſpoſed in certain places in the empire, it being forbid either to ſell, or buy, or make arms elſewhere. They were exempt from all offices and taxes, and received a ſalary from the public.

When once they had taken the employment on themſelves, neither they, nor their children, were allowed to quit it. To prevent this, they had a kind of note, or ſtigma, impreſſed on the arm, whereby they might be known. If any of them fled, or ſecreted their ware, the reſt were obliged to anſwer for him; on account of which, the effects of ſuch as died without a legal heir went to the college.—There were 15 armamentaries, or repoſitories of arms, in the Eaſtern empire, placed near the frontiers, and 19 in the Weſtern.

ARMOURER of a ſhip, a perſon whoſe office is to take care that the arms be in a condition fit for ſervice.

ARMOURY, a ſtore-houſe of arms, or a place wherein military habiliments are kept, to be ready for uſe. There are armouries in the Tower of London, and in all arſenals, citadels, caſtles, &c.

ARMOURY is alſo uſed for a branch of heraldry; being the knowledge of coat-armours, as to their blazons, and various intendments.

ARMOZA, or HARMOZIA, a town in Carmania, at the mouth of the Anamis, which falls into the Perſian gulph, (Arrian); *Armuza,* (Ptolemy); and from this the neighbouring iſland, and a ſmall kingdom, take the modern name of *Ormus.* E. Long. 56. 17. N. Lat. 27. 20.

ARMS, ARMA, in a general ſenſe, includes all kinds of weapons, whether for defence or offence. Nicod derives the word from the Latin phraſe *quod operiant armos,* becauſe they cover the ſhoulders or ſides; but Varro derives *arma, ab arcendo, eo quod arceant hoſtes.* It is ſuppoſed that the firſt artificial arms were of wood, and were only employed againſt beaſts; and that Belus, the ſon of Nimrod, was the firſt that waged war: whence, according to ſome came the appellation *bellum.* Diodorus Siculus takes Belus to be the ſame with Mars, who firſt trained ſoldiers up to battle.—Arms of ſtone, and even of braſs, appear to have been uſed before they came to iron and ſteel. Joſephus aſſures us, that the patriarch Joſeph firſt taught the uſe of iron arms in Egypt, arming the troops of Pharoah with a caſque and buckler.

What contributed moſt to render the Romans maſters of the world, was, that having ſucceſſively warred againſt all nations, they conſtantly renounced their own methods, arms, &c. whenever they met with better. Thus Romulus during his war with the Sabins, a bold and warlike nation, adopted their broad buckler in lieu of the ſmall Argian buckler, which he had uſed till that time.

The principal arms of the ancient Britons were hatchets, ſcythes, lances, ſwords, and bucklers: the Saxons, &c. brought in the halbard, bow, arrows, arbalets, &c. By the ancient laws of England, every man was obliged to bear arms, except the judges and clergy. Under Henry VIII. it was expressly enjoined on all persons to be regularly instructed, even from their their tender years, in the exercise of the arms then in use: viz. the long bow and arrows; and to be provided with a certain number of them. 33 H. VIII.

Arms, *Arma*, in law, are extended to any thing which a man takes in his hand in his wrath, to cast at, or strike another

By the common law, it is an offence for persons to go or ride armed with dangerous weapons: but gentlemen may wear common armour, according to their quality, &c. 3d Inst. The king may prohibit force of arms, and punish offenders according to law; and herein every subject is bound to be aiding. Stat. 7. Edw. I. None shall come with force and arms before the king's justices, nor ride armed in affray of the peace, on pain to forfeit their armour, and to suffer imprisonment, &c. 2 Ed. III. c. 3.

The importation of arms and ammunition are prohibited by 1 Jac. II. c. 8. and by 1 W. and M. stat. 2. c. 2. Protestant subjects may have arms for their defence. So likewise arms, &c. shipped after prohibition, are forfeited by 29 Geo. I. c. 16. sec. 2.

Arms of offence in use among us at present are, the sword, pistol, musket, bayonet, pike, &c.

The arms of the Highlanders are, the broad sword, target, poignard, and whinyar or durk, &c. There are several acts of parliament for disarming the Highlanders; see 1 Geo. I. c. 54.; 11 Geo. I. c. 26.; 19 Geo. II. c. 39.; 21 Geo. II. c. 34.; 26 Geo. II. c. 22. and 29.

Fire-Arms are those charged with powder and ball: such are cannon, mortars, and other ordnance; muskets, carabines, pistols, and even bombs, granadoes, carcasses, &c. In the history of the Royal Academy for the year 1707, we have an account of some experiments made with fire-arms differently loaded by M. Cassini. Among other things he observes, that by loading the piece with a ball which is somewhat less than the calibre, and only laying a little gunpowder below the ball and a good deal above it, it will yield a vehement noise, but have no sensible effect or impulse on the ball. This he takes to have been all the secret of those people who pretended to sell the art of rendering one's self invulnerable or shot-proof.

Arms, pass of, was a kind of combat in use among the ancient cavaliers.

Arms, stand of. A stand of arms signifies a musket, a bayonet, a sword, belt, and cartridge-box.

Arms of parade, or *courtesy*, were those used in the ancient justs and tournaments; which were commonly unshod lances, swords without edge or point, wooden swords, and even canes.

Arms denote the natural weapons, or parts of defence, of beasts: as claws, teeth, tusks of elephants, beaks of birds, &c.

Arms are also used figuratively for the profession of a soldier. Thus we say, he was bred to arms.

Arms, or *Armories*, are also used in heraldry for marks of dignity and honour, regularly composed of certain figures and colours, given or authorised by sovereigns, and borne in banners, shields, coats, &c. for the distinction of persons, families, and states; and passing by descent to posterity. They are called *arms*, in regard they are borne principally on the buckler, cuirass, banners, and other apparatus of war. They are also called *coats of arms*, *coat armour*, &c. because anciently embroidered on sur-coats, &c. See Heraldry. Some will have the name to have been first occasioned by the ancient knights, who in their justs and tournaments bore certain marks (which were frequently their mistress's favours) in their armour, i. e. their helms or shield, to distinguish them from each other.

Arms, at present, follow the nature of titles, which being made hereditary, these are also become so, being the several marks for distinguishing of families and kindreds, as names are of persons and individuals.

Arms are variously distinguished by the *Heralds*.

Arms of alliance, are those which families or private persons join to their own, to denote the alliances which they have contracted by marriage.

Arms, assumptive, are such as a man has a right to assume of himself, in virtue of some gallant action.

As, if a man who is no gentleman of blood, nor has coat armour, takes a gentleman, lord, or prince, prisoner, in any lawful war; he becomes intitled to bear the shield of such prisoner, and enjoy it to him and his heirs. The foundation hereof is that principle in military law, that the dominion of things taken in lawful war passes to the conqueror.

Arms, canting, are those wherein the figures bear an allusion to the name of the family. Such are those of the family of La Tour in Auvergne, who bear a tower; that of the family of Prado in Spain, whose field is a meadow. Most authors hold these the most noble and regular, and is shown by an infinity of instances produced by Father Varenne and Menetrier. They are much debased, when they come to partake of the *Rebus*.

Arms, charged, are such as retain their ancient integrity and value, with the addition of some new honourable charge or bearing, in consideration of some noble action.

Arms of community, are those of bishoprics, cities, universities, and other bodies corporate.

Arms of concession, or augmentation of honour, are either entire arms, or else one or more figures given by princes, as a reward for some extraordinary service.

Arms of dominion, are those which emperors, kings, and sovereign states bear; being annexed to the territories which they possess. Thus the three lions are the arms of England; the fleurs de lys those of France, &c.

Arms of family, or *paternal arms*, are such as belong to a particular family, and which no other person has a right to assume.

Arms, full, or *entire*, are such as retain their primitive purity, integrity, or value; without any alterations, diminutions, abatements, or the like. It is a rule, that the simpler and less diversified the arms, the more noble and ancient they are. For this reason Garcias Ximenes, first king of Navarre, and his successors for several ages, bore only gules, without any figure at all.

The arms of princes of the blood, of all younger sons, and junior families, are not pure and full; but distinguished and diminished by proper differences, &c.

Arms of patronage, are those which governors of provinces, lords of manors, &c. add to their family arms, in token of their peculiar superiority and jurisdiction.

Arms of pretension, are those of such kingdoms or territories to which a prince or lord has some claim, and which he adds to his own, though the kingdoms or territories be possessed by a foreign prince or other lord. Thus the kings of England have quartered the arms of France with their own, ever since the claim of Edward III. to that kingdom, in 1330.

Arms of succession, are assumed by those who inherit estates, manors, &c. by will, entail, or donation, and which they either impale or quarter with their own arms.

Arms are also said to be *parted, couped, quartered*, &c.

Arms are said to be *false* and *irregular*, when there is something in them contrary to the established rules of heraldry. As, when metal is put on metal, or colour on colour, &c.

The laws and other affairs of arms, with the cognizance of offences committed therein, belong to the marshals and colleges of arms.

Arms in falconry, denote the legs of an hawk, from the thigh to the foot. See Falconry.

ARMSTRONG (Dr John), an eminent physician, poet, and miscellaneous writer, was born in Castleton parish, Roxburghshire, where his father and brother were ministers; completed his education in the university of Edinburgh, where he took his degree in physic. Feb. 4, 1732, with much reputation; and published his thesis, as the forms of that university require; the subject was, *De tabe purulenta*. In 1735 he published a little humourous fugitive pamphlet in 8vo, entitled, "An Essay for abridging the study of Physic; to which is added a Dialogue betwixt Hygeia, Mercury, and Pluto, relating to the Practice of Physic, as it is managed by a certain illustrious Society. As also an Epistle from Usbek the Persian to Joshua Ward, Esq." This piece contains much fun and drollery: in the dialogue he has caught the very spirit of Lucian. In 1737 he published A Synopsis of the History and Cure of the Venereal Diseases, 8vo. This was soon followed by the *Oeconomy of Love*; a poem which has much merit: but it must be confessed it is too strongly tinctured with the licentiousness of Ovid. It is said, however, that his maturer judgment expunged many of the luxuriances of youthful fancy, in an edition "revised and corrected by the author" in 1768. It appears by one of the cases on literary property, that Mr Millar paid 50 guineas for the copyright of this poem, which was intended as a burlesque on some dictatic writers. It has been observed of Dr Armstrong, that his works have great inequalities, some of them being possessed of every requisite to be sought after in the most perfect composition, while others can hardly be considered as superior to the productions of mediocrity. *The Art of preserving Health*, his best performance, which was published in 1744, will transmit his name to posterity as one of the first English writers, has been honoured with the following testimony of a respectable critic. On this work we shall also transcribe a beautiful elogium from an eminent physician †: "Of all the poetical performances on this subject that have come to my hands. Dr Armstrong's Art of preserving health is by far the best. To quote every charming description and beautiful passage of this poem, one must transcribe the whole. We cannot, however, expect new rules, where the principal design was to raise and warm the heart into a compliance with the solid precepts of the ancients, which he has enforced with great strength and elegance. And upon the whole, he has convinced us by his own example, that we ought not to blame antiquity for acknowledging

One power of physic, melody, and song."

† *Dr Mackenzie's History of Health.*

In 1746 Dr Armstrong was appointed one of the physicians to the hospital for lame and sick soldiers behind Buckingham house. In 1751 he published his poem on Benevolence, in folio; and in 1753, "Taste, an epistle to a young Critic." In 1758 appeared, "Sketches, or Essays on various subjects, by Launcelot Temple, Esq; in two parts." In this production, which possesses much humour and knowledge of the world, and which had a remarkably rapid sale, he is supposed to have been assisted by Mr Wilkes. In 1760 he had the honour of being appointed physician to the army in Germany, where in 1761 he wrote a poem called "Day, an Epistle to John Wilkes of Aylesbury, Esq;" In this poem, which is not collected in his works, he wantonly hazarded a reflection on Churchill, which drew on him the serpent-toothed vengeance of that severest of satirists, whose embalming or corrosive pen could deify or lampoon any man, according as he acquiesced with, or dissented, from his political principles. In 1770 Dr Armstrong published a collection of "Miscellanies in 2 vols.; containing, 1. The Art of preserving Health. 2. Of Benevolence, an Epistle to Eumenes. 3. Taste, an Epistle to a youg critic, 1753. 4. Imitations of Shakespeare and Spencer. 5. The Universal Almanac, by Noureddin Ali. 6. The Forced Marriage, a tragedy. 7. Sketches." In 1771 he published "A short ramble through some parts of France and Italy, by Launcelot Temple: and in 1773, in his own name, a quarto pamphlet, under the title of *Medical Essays*; towards the conclusion of which, he accounts for his not having such extensive practice as some of his brethren, from his not being qualified to employ the usual means, from a ticklish state of spirits, and a distempered excess of sensibility. He complains much of the behaviour of some of his brethren, of the herd of critics, and particularly of the reviewers. He died in Sept. 1779; and to the no small surprise of his friends, left behind him more than L.300 saved out of a very moderate income, arising principally from his half-pay.

ARMUYDEN, a sea-port town of the United provinces, in the island of Walcherin, formerly very flourishing; but now inconsiderable, the sea having stopped up the harbour. The salt-works are its chief resource. E. Long. 3. 40. N. Lat. 51 30.

ARMY, a large number of soldiers, consisting of horse and foot, completely armed, and provided with artillery, ammunition, provisions, &c. under the command of one general, having lieutenant-generals, major-generals, brigadiers, and other officers, under him. An army is composed of squadrons and battalions; and is usually divided into three corps, and formed into three lines: the first line is called the *van-guard*, the second the *main-body*, and the third the *rear-guard* or

body

 body of reserve. The middle of each line is possessed by the foot; the cavalry form the right and left wing of each line; and sometimes they place squadrons of horse in the intervals between the battalions. When the army is drawn up in order of battle, the horse are placed at five feet distance from each other, and the foot at three. In each line the battalions are distant from each other 180 feet, which is nearly equal to the extent of their front; and the same holds of the squadrons, which are about 300 feet distant, the extent of their own front. These intervals are left for the squadrons and battalions of the second line to range themselves against the intervals of the first, that both may more readily march through these spaces to the enemy: the first line is usually 300 feet distant from the second, and the second from the third, that there may be sufficient room to rally when the squadrons and battalions are broken. See the article WAR.

This is to be understood of a land-army only. A naval or sea-army is a number of ships of war, equipped and manned with sailors and mariners, under the command of an admiral, with other inferior officers under him. See *Naval TACTICS*.

It has been observed, that in Europe a prince with a million of subjects cannot keep an army of above 10,000 men, without ruining himself. It was otherwise in the ancient republics: the proportion of soldiers to the rest of the people, which is now as about 1 to 100, might then be as about 1 to 8. The reason seems owing to that equal portion of lands which the ancient founders of commonwealths made among their subjects; so that every man had a considerable property to defend, and means to defend it with: whereas, now, the lands and riches of a nation being shared among a few, the rest have no way of subsisting but by trade, arts, and the like: and have neither any free property to defend, nor means to enable them to go to war in defence of it, without starving their families. A large part of our people are either artisans or servants, and so only minister to the luxury and effeminncy of the great. While the equality of lands subsisted, Rome, though only a little state, being refused the succours which the Latins were obliged to furnish after the taking of the city in the consolate of Camillus, presently raised ten legions within its own walls; which was more, Livy assures us, than they were able to do in his time, tho' masters of the greatest part of the world. A full proof, adds the historian, that we are not grown stronger; and that what swells our city is only luxury, and the means and effects of it.

Armies anciently were a sort of militia, composed chiefly of the vassals and tenants of the lords. When each company had served the number of days or months enjoined by their tenure, or the customs of the fees they held, they returned home. The armies of the empire consisted of divers bodies of troops furnished by the several circles. The gross of the French armies, under the Merovingian race, consisted of infantry. Under Pepin and Charlemagne, the armies consisted almost equally of cavalry and foot: but since the declension of the Carlovingian line, the fees being become hereditary, the national armies, says Le Gendre, are chiefly cavalry.

A well-regulated standing army is greatly superior to a militia; although a militia, it is to be observed, after serving two or three campaigns, may become equal to a standing army, and in every respect a match for veteran troops. See MILITIA.

One of the first standing armies of which we have any distinct account, in any well authenticated history, is that of Philip of Macedon. His frequent wars with the Thracians, Illyrians, Thessalians, and some of the Greek cities in the neighbourhood of Macedon, gradually formed his troops, which in the beginning were probably militia, to the exact discipline of a standing army. When he was at peace, which he was very seldom, and never for any long time together, he was careful not to disband that army. It vanquished and subdued, after a long and violent struggle, indeed, the gallant and well exercised militias of the principal republics of ancient Greece; and afterwards, with very little struggle, the effeminate and ill-exercised militia of the great Persian empire. The fall of the Greek republics and of the Persian empire, was the effect of the irresistible superiority which a standing army has over every sort of militia. It is the first great revolution in the affairs of mankind of which history has preserved any distinct or circumstantial account.

The fall of Carthage, and the consequent elevation of Rome, is the second. All the varieties in the fortune of those two famous republics may very well be accounted for from the same cause.

From the end of the first to the beginning of the second Carthaginian war, the armies of Carthage were continually in the field, and employed under three great generals, who succeeded one another in the command; Amilcar, his son-in-law Asdrubal, and his son Annibal; first in chastising their own rebellious slaves, afterwards in subduing the revolted nations of Africa, and, lastly, in conquering the great kingdom of Spain. The army which Annibal led from Spain into Italy must necessarily, in those different wars, have been gradually formed to the exact discipline of a standing army. The Romans, in the mean time, tho' they had not been altogether at peace, yet they had not, during this period, been engaged in any war of very great consequence; and their military discipline, it is generally said, was a good deal relaxed. The Roman armies which Annibal encountered at Trebia, Thrasymenus, and Cannæ, were militia opposed to a standing army. This circumstance, it is probable, contributed more than any other to determine the fate of those battles.

The standing army which Annibal left behind him in Spain, had the like superiority over the militia which the Romans sent to oppose it, and in a few years under the command of his brother the younger Asdrubal, expelled them almost entirely from that country.

Annibal was ill supplied from home. The Roman militia, being continually in the field, became in the progress of the war a well-disciplined and well-exercised standing army; and the superiority of Annibal grew every day less and less. Asdrubal judged it necessary to lead the whole, or almost the whole, of the standing army which he commanded in Spain, to the assistance of his brother in Italy. In this march he is said to have been misled by his guides; and in a country which

which he did not know, was surprised and attacked by another standing army, in every respect equal or superior to his own, and was entirely defeated.

When Asdrubal had left Spain, the great Scipio found nothing to oppose him but a militia inferior to his own. He conquered and subdued that militia; and in the course of the war, his own militia necessarily became a well-disciplined and well-exercised standing army. That standing army was afterwards carried to Africa, where it found nothing but a militia to oppose it. In order to defend Carthage it became necessary to recall the standing army of Annibal. The disheartened and frequently defeated African militia joined it, and at the battle of Zama composed the greater part of the troops of Annibal. The event of that day determined the fate of the two rival republics.

From the end of the second Carthagenian war till the fall of the Roman republic, the armies of Rome were in every respect standing armies. The standing army of Macedon made some resistance to their arms. In the height of their grandeur, it cost them two great wars, and three great battles, to subdue that little kingdom; of which the conquest would probably have been still more difficult, had it not been for the cowardice of its last king. The militias of all the civilized nations of the ancient world, of Greece, of Syria, and of Egypt, made but a feeble resistence to the standing armies of Rome. The militias of some barbarous nations defended themselves much better. The Scythian or Tartar militia, which Mithridates drew from the countries north of the Euxine and Caspian seas, were the most formidable enemies whom the Romans had to encounter after the second Carthaginian war. The Parthian and German militias too were always respectable, and upon several occasions gained very considerable advantages over the Roman armies. In general, however, and when the Roman armies were well commanded, they appear to have been very much superior.

Many different causes contributed to relax the discipline of the Roman armies. Its extreme severity was, perhaps, one of those causes. In the days of their grandeur, when no enemy appeared capable of opposing them, their heavy armour was laid aside as unnecessarily burthensome, their laborious exercises were neglected as unnecessarily toilsome. Under the Roman emperors besides, the standing armies of Rome, those particularly which guarded the German and Pannonian frontiers, became dangerous to their masters, against whom they used frequently to set up their own generals. In order to render them less formidable, according to some authors, Dioclesian, according to others Constantine, first withdrew them from the frontier, where they had always before been encamped in great bodies, generally of two or three legions each, and dispersed them in small bodies through the different provincial towns, from whence they were scarce ever removed, but when it became necessary to repel an invasion. Small bodies of soldiers quartered in trading and manufacturing towns, and seldom removed from those quarters, became themselves tradesmen, artificers, and manufacturers. The civil came to predominate over the military character; and the standing armies of Rome gradually degenerated into a corrupt, neglected, and undisciplined militia, incapable of resisting the attack of the German and Scythian militias, which soon afterwards invaded the western empire. It was only by hiring the militia of some of those nations to oppose to that of others, that the emperors were for some time able to defend themselves. The fall of the western empire is the third great revolution in the affairs of mankind, of which ancient history has preserved any distinct or circumstantial account. It was brought about by the irresistible superiority which the militia of a barbarous has over that of a civilized nation; which the militia of a nation of shepherds has over that of a nation of husbandmen, artificers, and manufactures. The victories which have been gained by militias have generally been not over standing armies, but over other militias in exercise and discipline inferior to themselves. Such were the victories which the Greek militia gained over that of the Persian empire; and such too were those which in later times the Swiss militia gained over that of the Austrians and Burgundians.

The military force of the German and Scythian nations, who established themselves upon the ruins of the western empire, continued for some time to be of the same kind in their new settlements as it had been in their original country. It was a militia of shepherds and husbandmen, which in time of war took the field under the cammand of the same chieftans whom it was accustomed to obey in peace. It was therefore tolerably well exercised and tolerably well disciplined. As arts and industry advanced, however, the authority of the chieftans gradually decayed, and the great body of the people had less time to spare for military exercises. Both the discipline and the exercise of the feudal militia, therefore, went gradually to ruin, and standing armies were gradually introduced to supply the place of it. When the expedient of a standing army, besides, had once been adopted by one civilized nation, it became necessary that all its neighbours should follow the example. They soon found that their safety depended upon their doing so, and that their own militia was altogether incapable of resisting the attack of such an army.

The soldiers of a standing army, though they may never have seen an enemy, yet have frequently appeared to possess all the courage of veteran troops, and the very moment that they took the field, to have been fit to face the hardiest and most experienced veterans. In a long peace the generals perhaps may sometimes forget their skill; but where a well-regulated standing army has been kept up, the soldiers seem never to forget their valour.

When a civilized nation depends for its defence upon a militia, it is at all times exposed to be conquered by any barbarous nation which happens to be in its neighbourhood. The frequent conquests of all the civilized countries in Asia by the Tartars, sufficiently demonstrates the natural superiority which the militia of a barbarous has over that of a civilized nation. A well-regulated standing army is superior to every militia. Such an army, as it can be best maintained by an opulent and civilized nation, so it can alone defend such a nation against the invasion of a poor and barbarous neighbour. It is only by means of a standing army, therefore, that the civilization of any country can be perpetuated, or even preserved for any considerable time.

As

Army, Arnall.

As it is only by means of a well-regulated standing army that a civilized country can be defended, so it is only by means of it that a barbarous country can be suddenly and tolerably civilized. A standing army establishes, with an irresistible force, the law of the sovereign through the remotest provinces of the empire, and maintains some degree of regular government in countries which could not otherwise admit of any. Whoever examines with attention the improvements which Peter the Great introduced into the Russian empire, will find that they almost all resolve themselves into the establishment of a well-regulated standing army. It is the instrument which executes and maintains all his other regulations. That degree of order and internal peace which that empire has ever since enjoyed, is altogether owing to the influence of that army.

Men of republican principles have been jealous of a standing army as dangerous to liberty. It certainly is so, wherever the interest of the general and that of the principal officers are not necessarily connected with the support of the constitution of the state. The standing army of Cæsar destroyed the Roman republic; the standing army of Cromwell turned the long parliament out of doors. But where the sovereign is himself the general, and the principal nobility and gentry of the country the chief officers of the army; where the military force is placed under the command of those who have the greatest interest in the support of the civil authority, because they have themselves the greatest share of that authority; a standing army can never be dangerous to liberty: on the contrary, it may in some cases be favourable to liberty. The security which it gives to the sovereign renders unnecessary that troublesome jealousy which in some modern republics seems to watch over the minutest actions, and to be at all times ready to disturb the peace of every citizen. Where the security of the magistrate, though supported by the principal people of the country, is endangered by every popular discontent; where a small tumult is capable of bringing about in a few hours a great revolution; the whole authority of government must be employed to suppress and punish every murmur and complaint against it. To a sovereign, on the contrary, who feels himself supported not only by the natural aristocracy of the country, but by a well-regulated standing army, the rudest, the most groundless, and the most licentious remonstrances, can give little disturbance. He can safely pardon or neglect them, and his consciousness of his own superiority naturally disposes him to do so. That degree of liberty which approaches to licentiousness can be tolerated only in countries where the sovereign is secured by a well-regulated standing army. It is in such countries only that the public safety does not require that the sovereign should be trusted with any discretionary power for suppressing even the impertinent wantonness of this licentious liberty.

ARNALL (William), a noted political writer in defence of Sir Robert Walpole, was originally an attorney's clerk; but being recommended to Walpole, he employed him for a course of years in writing the *Free Briton* and other papers in defence of his administration. By the report of the secret committee, he appears to have received, in the space of four years, no less than L. 10,997 : 6 ; 8 out of the treasury for his writings! but spending his money as fast as it came, and his supplies stopping on Sir Robert's resignation, he died broken-hearted and in debt, in the 26th year of his age. His invention was so quick, that his honourable employer used to say, no man in England could write a pamplet in so little time as Arnall.

Arnaud.

ARNAUD DE MEYRVEILH, or MEREUIL, a poet of Provence, who lived at the beginning of the 13th century. He wrote a book intitled *Las recastenas de sa comtesse*, and a collection of poems and sonnets. He died in the year 1220. Petrarch mentions him in his Triumph of Love.

ARNAUD DE VILLA NOVA, a famous physician, who lived about the end of the 13th and beginning of the 14th century. He studied at Paris and Montpelier, and travelled through Italy and Spain. He was well acquainted with languages, and particularly with the Greek, Hebrew, and Arabic. He was at great pains to gratify his ardent desire after knowledge; but this passion carried him rather too far in his researches: he endeavoured to discover future events by astrology, imagining this science to be infallible; and upon this foundation he published a prediction, that the world would come to an end in the middle of the 14th century. He practised physic at Paris for some time: but having advanced some new doctrines, he drew upon himself the resentment of the university; and his friends, fearing he might be arrested, persuaded him to retire from that city. Upon his leaving France, he retired to Sicily, where he was received by king Frederic of Arragon with the greatest marks of kindness and esteem. Some time afterwards, this prince sent him to France, to attend Pope Clement in an illness; and he was shipwrecked on the coast of Genoa, about the year 1313. The works of Arnaud, with his life prefixed, were printed in one volume in folio, at Lyons, in 1520; and at Basil in 1585, with the notes of Nicholas Tolerus.

ARNAUD D'ANDILLY (Robert), the son of a celebrated advocate of the parliament of Paris, was born in 1588; and, being introduced young at court, was employed in many considerable offices, all which he discharged with great integrity and reputation. In 1644 he quitted business, and retired into the convent of Port Royal des Champs, where he passed the remainder of his days in a continued application to works of piety and devotion; and enriched the French language with many excellent translations of different writers, as well as with religious compositions of his own. He died in 1674, and his works are printed in 8 vols folio.

ARNAUD (Anthony), brother of the preceding, and a doctor of the Sorbonne, was born in 1612. He published, in 1643, *A treatise on frequent communion*, which highly displeased the Jesuits; and the disputes upon grace, which broke out about this time in the university of Paris, and in which he took a zealous part with the Jansenists, helped to increase the animosity between him and the Jesuits. But nothing raised so great a clamour against him as the two letters he wrote on *Absolution*; in the second of which the faculty of divinity found two propositions which they condemned, and M. Arnaud was expelled the society. Upon this he retired; and during a retreat which lasted near 25 years, he composed that great variety of works which are extant of his, on grammar, geometry, logic, metaphysics,

taphysics, and theology. In 1679, he withdrew from France, living in obscurity in the Netherlands, and died in 1694. His heart, at his own request, was sent to be deposited in the Port Royal. Arnaud had a remarkable strength of genius, memory, and command of his pen; nor did these decay even to the last year of his life. Mr Bayle says, he had been told by persons who had been admitted into his familiar conversation, that he was a man very simple in his manners; and that unless any one proposed some question to him, or desired some information, he said nothing that was beyond common conversation, or that might make one take him for a man of great abilities; but when he set himself to give an answer to such as proposed a point of learning, he seemed as it were transformed into another man: he would then deliver a multitude of fine things with great perspicuity and learning, and had a particular talent at making himself intelligible to persons of not the greatest penetration.

ARNAY-LE-DUC, a town of France, in the duchy of Burgundy, which carries on a pretty good trade. It is seated on the Auxois, in a valley near the river Aroux. E. Long. 4. 26. N. Lat. 47. 7.

ARNDT (John), a famous Protestant divine of Germany, born at Ballenstad, in the duchy of Anhalt, in the year 1555. At first he applied himself to the study of physic: but falling into a dangerous sickness, he made a vow to change his profession for that of divinity, if he should be restored to health; which he accordingly did upon his recovery. He was minister first at Quedlinburg and then at Brunswick. He met with great opposition in this last city: his success as a preacher raised the enmity of his brethren, who became his bitter enemies. In order to ruin his character, they ascribed a variety of errors to him; and persecuted him to such a degree, that he was obliged to leave Brunswick, and retire to Isleb, where he was minister for three years. In 1611, George Duke of Lunenburg, who had a high opinion of his integrity and sanctity, gave him the church of Zell, and appointed him superintendant of all the churches in the duchy of Lunenburg; which office he discharged for 11 years, and died in 1621. It is reported that he foretold his death, having said to his wife, upon his return home after his last sermon, that now he had preached his funeral sermon. He wrote in High Dutch *A treatise on true Christianity*, which has been translated into several languages.

ARNE (Dr Thomas Augustine), distinguished by his skill in music, was the son of Mr Arne an upholsterer in Covent Garden, whom Addison is supposed to have characterised in N° 155 and N° 160 of The Tatler; and brother of Mrs Cibber the player. He was early devoted to music, and soon became eminent in his profession. July 6. 1759, he had the degree of doctor of music conferred on him at Oxford. His compositions are universally applauded, and he was also particularly skilful in instructing vocal performers. He died March 5. 1778, having written the following pieces: *Artaxerxes*, 1762; *The Guardian outwitted*, 1764; *The Rose*, 1778; all of them operas.

ARNHEIM, a town of the Low Countries, in the province of Guelderland, capital of Veluive. It is adorned with several fine churches, particularly that of St Walburg and of St Eusebius: which last has a very high tower. The town has five gates, and several fine ramparts, part of which are washed by the Rhine, and the other parts have wide and deep ditches before them. There is a canal made between this place and Nimeguen, at the expence of both towns, on which boats pass backwards and forwards to carry on a trade between them. The air is very healthful; on which account it is inhabited by persons of distinction. E. Long. 5. 55. N. Lat. 52. 0.

ARNICA, LEOPARDS BANE, in botany: A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ discoides*. The receptacle is naked; the pappus is simple; and the filaments are five, without antheræ. The

Species are seven, all natives of Ethiopia, except the two following: 1. The montana, with oval leaves, grows naturally on the Alps, and also upon many of the high mountains in Germany, and other cold parts of Europe. The roots of this species, when planted in a proper soil and situation, spread very far under the surface, and put out many entire oval leaves, from between which the flower-stems arise, which grow about a foot and an half high. The top is terminated by a single yellow flower, composed of many florets, like those of the dandelion. These are succeeded by oblong seeds, which are covered with down. 2. The scorpioides, with sawed leaves growing alternately, is a native of Bohemia and Siberia. The roots of this sort are much jointed, and divide into many irregular fleshy off-sets, which are variously contorted; from whence some superstitious persons have imagined that they would expel the poison of scorpions, and cure the wounds made by the sting of that animal.

Culture. The first species delights in a moist shady situation: it may be propagated by parting the roots in autumn when the stalks begin to decay; or by the seeds sown in autumn soon after they are ripe, for those sown in the spring often fail. The second sort is to be propagated in the same manner. Both are very hardy, and require no other care than to be keept free from weeds.

Medicinal Uses. The montana has an acrid bitter taste, and when bruised, emits a pungent odour, which excites sneezing. On this account the country people in some parts of Germany use it in snuff, and smoke it like tobacco. It was formerly represented as a remedy of great efficacy against effusions and suffusions of blood, from falls, bruises, or the like; and it was then also mentioned as a remedy in jaundice, gout, nephritis, &c. but in these affections it is now very little, if at all, employed.

Of late it has been principally recommended in paralytic affections, and in cases where a loss or diminution of sense arises from an affection of the nerves, as in instances of amaurosis. In these it has chiefly been employed under the form of infusion. From a dram to half an ounce of the flowers has been directed to be infused in a pint of boiling water, and taken in different doses in the course of the day: sometimes it produces vomiting, sometimes sweating, sometimes diuresis; but frequently its use is attended with no sensible operation, unless it can be considered as such, that in some cases

Arnisæus Arnobius.

cases of paralysis, the cure is said to be preceded by a peculiar prickling, and by shooting pains in the affected parts.

Besides being employed in paralytic affections, it has also been of late represented as a very powerful antispasmodic; and it is said to have been successfully employed in fevers, particularly those of the intermittent kind, and likewise in cases of gangrene. In those diseases it has been said to prove as efficacious as the Peruvian bark, when employed under the form of a pretty strong decoction taken in small dozes frequently repeated, or under the form of an electuary with honey.

But as these alleged virtues have not been confirmed by any trials made in Britain, its real influence still remains to be determined by future observations. It is, however, one of those active substances from which something may be expected.

ARNISÆUS (Henningus), a philosopher and physician of great reputation, about the beginning of the 17th century. He was born at Halberstad in Germany, and was professor of physic in the university of Helmstad. His political works are much esteemed. The most remarkable of them is his book *De authoritate principum in populum semper inviolabili*, printed at Francfort, in 1612. In this he maintains that the authority of princes ought not to be violated. He wrote also upon the same doctrine his three books *De jure majestatis*, printed at the same place in 1610; and his *Reflectiones politicæ*, printed at Francfort in 1615. Having received an invitation to go to Denmark, he went thither, and was made counsellor and physician to the King. He travelled into France and England, and died in November 1635. Besides the pieces already mentioned, he wrote several philosophical, medicinal and political treatises.

ARNOBIUS, professor of rhetoric at Sicca, in Numidia, towards the end of the third century. It was owing to certain dreams which he had that he became desirous of embracing Christianity. For this purpose he applied to the bishops to be admitted into the church. But they, remembering the violence with which he had always opposed the true faith, had some distrust him; and, before they would admit him, insisted on some proofs of his sincerity. In compliance with this demand, he wrote against the Gentiles; wherein he has refuted the absurdities of their religion, and ridiculed their false gods. In this treatise he has employed all the flowers of rhetoric, and displayed great learning: but from an impatience to be admitted into the body of the faithful, he is thought to have been in too great a hurry in composing his work, and thence it is that there does not appear in this piece such an exact order and disposition as could be wished; and not having a perfect and exact knowledge of the Christian faith, he published some very dangerous errors. Mr Bayle remarks, that his notions about the origin of the soul, and cause of natural evil, and several other important points, are highly pernicious. St Jerom, in his epistle to Paulinus, is of opinion that his style is unequal and too diffuse, and that his book is written without any method; but Dr Cave thinks this judgment too severe, and that Arnobius wants neither elegance nor order in his composition. Vossius styles him *the Varro of the ecclesiastical writers*. Du Pin observes that his work is written in a manner worthy of a professor of rhetoric: the turn of his sentiments is very oratorical; but his style is a little African, his expressions being harsh and inelegant. We have several editions of this work of Arnobius against the Gentiles, one published at Rome in 1542, at Basil in 1546 and 1560, at Paris in 1570, at Antwerp in 1582, and one at Hamburgh in 1610, with notes by Gebhard Elmenhorstius, besides many others. He wrote also a piece intitled *De rhetoricæ institutione*; but this is not extant.

Arnold.

ARNOLD, of Brescia, in Italy, distinguished himself by being the founder of a sect which opposed the wealth and power of the Romish clergy. He went into France, where he studied under the celebrated Peter Abelard. Upon his return to Italy, he put on the habit of a monk, and opened his invectives in the streets of Brescia. The people crowded round him. He told them he was sent to reform abuses, to pull down the proud and to exalt the humble. He then pointed his declamation against the bishops, against the clergy, against the monks, and finally against the Roman pontiff himself: to the laity only he was indulgent. Churchmen, said he, who hold benefices, bishops who have domains, and monks that have possessions, will all be damned. His hearers shouted approbation. These things, continued he, belong to the prince; he may give them to whom he pleases, but he must give them to the laity. It is on their tithes, and the voluntary contributions of the people, that those sons of God must live: they must be frugal, continent, and mortified.

The church of Brescia was soon thrown into the greatest confusion, and the people, already prejudiced against their ministers threatened to overturn their altars. The sacred writings he urged in support of his assertions, and from thenm he denounced the vengeance of Heaven against the violators of the law. Indeed, nothing could be more glaringly offensive than the ostentatious parade of the bishops and great abbots, and the soft and licentious lives of the monks and clergy.

In 1139 was celebrated a grand council at Rome. Arnold was cited to appear before it. His accusers were the bishop of Brescia, and many others, whom he had ridiculed and insulted. Nor from his judges could he look for much indulgence. He was found guilty, and sentenced to perpetual silence. Upon this he left Italy, crossed the Alps, and found a refuge in Zurich.

Though Arnold had quitted Italy, yet had his opinions taken deep root, and Rome itself was infected by them. Irritated by the conduct of their master Innocent II. the Roman people assembled in the Capitol. It was proposed that the power of the pontiff, which they called exorbitant, should be restrained: this was carried: when suddenly, inspired as it were by the genius of the place, they moved that the senate, which for years had been abolished, should be restored. The proposition was received with the loudest acclamations. Innocent in vain opposed the bold design; there was a magic in it which spread irresistibly, and for a moment seemed to rouse the fallen spirit of the nation. The pope viewed with horror the reverse of fortune which threatened the tiara; to be shorn of his

Arnold

his mighty power, and to become the mere ſhepherd of the Chriſtian people, was a thought too afflicting: he fell ſick and died.

Under his two immediate ſucceſſors Celeſtin and Lucius, whoſe reigns were but of a few months, the Romans purſued their darling object. They waited on the latter, and, in an imperious tone, demanded the reſtitution of all the honours and civil rights which had been uſurped from the people. The prince of the ſenate, ſaid they, whom we have choſen, will beſt adminiſter the important truſt: the tithes and offerings of the faithful will ſufficiently anſwer all the exigencies of your holineſs: it was thus that our ancient biſhops lived.—Lucius ſurvived this event but a few days. His ſucceſſor was Eugenius III. the friend and diſciple of the renowned Bernard. The night before his conſecration the ſenators aſſembled, and it was agreed, that either he ſhould ſolemnly confirm all their proceedings, or they would annul his election. This reſolution was notified to him. He called together his friends; and it was their advice, that he ſhould neither accede to the extravagant demand, nor expoſe himſelf, by a refuſal, to the fury of the populace. He therefore ſilently withdrew from Rome, and retired to a neighbouring fortreſs. Here the ceremony of his conſecration was performed.

Arnold, who in baniſhment had contemplated the effect of his admonitions on the minds of the Romans, and the ſucceſs which ſeemed to follow their exertions, was now informed that the pope had retired, and that the gates of the capital were open to receive him: it was likewiſe ſuggeſted to him, that his preſence was more than ever neceſſary, to give energy to their reſolves, form to their plans, and ſtability to their undertakings. Arnold took fire at the news; an unuſual ſwell of enthuſiaſm filled his breaſt; and he fancied that, like Junius Brutus, he was called at once to give liberty to Rome. At his appearance a new ſtream of vigour animated the citizens; they called him their friend and deliverer. The Breſcian walked amongſt them; his deportment was humble, his countenance emaciated, his addreſs affable, and he ſpoke to them of moderation, of ſubmiſſion, of obedience. With the the nobles and new ſenators he held another language; though to them alſo he was mild and diffident, ſpeaking much of virtue and of reſpect for religion and the laws. But no ſooner was he ſenſible of his own real influence, and ſaw the lengths to which the revolters had already carried their deſigns, than he threw aſide the maſk, and appeared in his own character, daring, impetuous, ſelf-ſufficient, vain. He harangued the people; he talked of their forefathers the ancient Romans, who, by the wiſdom of their ſenate and the valour of their armies, had conquered nations and ſubdued the earth. He dwelt on the names and the atchievements of the Bruti, the Gracchi, and the Scipios; and of theſe men, ſaid he, are you not the children? He adviſed, that the capital be inſtantly repaired; that the equeſtrian order be reſtored; that the people have their tribunes; that dignity attend the ſenate; and that the laws, which had been ſilent and neglected, be revived in all their vigour. He ſpoke of the pope as of a depoſed and baniſhed tyrant: "But ſhould you again be diſpoſed (continued he) to admit him within theſe walls; firſt fix your own rights and determine his. He is but your biſhop: let him therefore have his ſpiritual juriſdiction. The government of Rome, its civil eſtabliſhments, and its territories, belong to you. Theſe you will keep if you have the ſpirit of men and the hearts of Romans." Fired by this harangue, the people, headed by the moſt diſaffected of the nobles, publicly attacked the few cardinals and churchmen who remained in the city; they ſet fire to the palaces; and they compelled the citizens to ſwear obedience to the new government. Moderate men, who ſaw the folly of the attempt, were ſhocked at theſe exceſſes of popular phrenzy; but it was in vain to oppoſe the torrent: they ſubmitted, looking forward, with ſome curioſity, to the termination of an event which had begun in extravagance, and muſt end in diſappointment.

Arnold.

Eugenius till now had viewed with ſome concern, the wild derangement of his people: but when it ſeemed that their eyes opened to their own exceſſes, he could be inactive no longer. He excommunicated the ringleaders of the faction; and at the head of his troops, who were chiefly compoſed of Tiburtini, a people always hoſtile to the Romans, he marched againſt the enemy. His friends within the walls, who were numerous, co-operated with his deſigns, and in a few days overtures for peace were made to the pontiff. He acceded to them, but on condition that they ſhould annul the arrangements they had made, and if they would have ſenators, that they ſhould acknowledge all their power was from him. The people were ſatisfied, and they threw open the gates, through which Eugenius entered, among the acclamations of a fawning and inconſtant multitude.—Before this event, Arnold had retired; but he left behind him many friends ſtrongly attached to his perſon and principles. Of himſelf we hear little more till the reign of Adrian; when, on account of freſh tumults, he and his adherents were excommunicated, and Rome was threatened with an interdict unleſs they expelled the whole party from their walls. This they did. The Arnoldiſts retired with their champion into Tuſcany, where he was received as a prophet and honoured as a ſaint. His enemies, however, prevailed: he was made priſoner, and conducted under a ſtrong eſcort to Rome. In vain was great intereſt made to ſave his life; he was condemned and executed, and his aſhes thrown into the Tiber, leſt the people ſhould collect his remains and venerate them as the relics of a ſainted martyr.

"Such was Arnold of Breſcia; a man (ſays Mr Berington*), whoſe character, whoſe principles, and whoſe views, we perhaps ſhould be diſpoſed to admire, had his life been recorded by unprejudiced hiſtorians, and not brought down to us drawn in the blackeſt colours which party, bigotted zeal, and enthuſiaſm, could lay on. He was raſh, miſjuding, and intemperate, or never would he have engaged in ſo unequal a conteſt.—The view of ſuch a phenomenon in the 12th century excites a pleaſing admiration. To attack the Roman pontiff and his clergy in the very centre of their power, required a more than common ſhare of fortitude; to adopt a ſettled ſcheme of reſtoring to its priſtine glory the republic of Rome, demanded a ſtretch of thought comprehenſive and enterpriſing; and to forego the eaſe and indulgence of a diſſipated age, for the reformation of manners and the ſuppreſ-

* *Hiſt. of the Lives of Abelard and Heloiſa.*

ſion

sion of what he thought usurped dominion, argued a character of mind disinterested, generous, and benevolent. But Arnold, like other reformers, went too far; and passion soon vitiated undertakings which were begun perhaps with motives the most laudable.—The readiness with which the Roman people embraced this plan of lowering the jurisdiction of the pontiff, and restraining it within those bounds which the true spirit of Christianity had fixed, at once shows that they could reason justly, and that they considered the unbounded sway of the triple crown, to which reluctantly they submitted, as an assumed prerogative, to which violence or misconstruction, and not Christian right, had given efficacy."

ARNOLDISTS, in church-history, a sect so called from their leader Arnold of Brescia. See the preceding article.

ARNOLDUS (Gothofredus), pastor and inspector of the churches of Perleberg, and historiographer to the king of Prussia, was born at Annaburg in the mountains of Misnia in 1666. He was a zealous defender of Pietists, a sect among the German Protestants, and composed a great number of religious works; particularly an *Ecclesiastical History*, which exposed him to the resentment of the divines; and another giving an account of the doctrines and manners from the first ages, in which he frequently animadverts upon Cave's primitive Christianity. He died in 1714. Various are the opinions concerning Arnoldus in Germany; some of his own countrymen and profession extolling him to the skies as a saint of the last century, and setting an inestimable value upon his works; while others pronounce damnation upon him as an arch-heretic, and condemn his writings as heterodox.

ARNON (anc. geog.), a brook running between the borders of the Moabites and Ammonites on the other side Jordan (Moses, Joshua): Josephus calls it a river, rising on the borders of Arabia, and at length falling into the Dead Sea. It is also called the river of Gad, as appears 2 Sam. xxv. 5. compared with 2 Kings x. 33.

ARNOT, in botany, the English name of the bunium. See BUNIUM.

ARNOTTO. The same with Anotta. See ANOTTA and BIXA.

ARNSTADE, a town of Germany, in Thuringia, on the river Gera. E. Long. 11. 3. N. Lat. 50. 54.

ARNULPH, or ERNULPH, bishop of Rochester in the reign of Henry I. He was born in France, where he was sometime a monk of St Lucian de Beauvais. The monks led most irregular lives in this monastery; for which reason he resolved to quit it, but first took the advice of Lanfranc archbishop of Canterbury, under whom he had studied in the abbey of Becc, when Lanfranc was prior of that monastery. This prelate invited him over to England, and placed him in the monastery of Canterbury, where he lived a private monk till Lanfranc's death. When Anselm came to the archiepiscopal see, Arnulph was made prior of the monastery of Canterbury, and afterwards abbot of Peterborough. In 1115, he was consecrated bishop of Rochester, which see he held nine years, and died in March 1124, aged 84.

Arnulph wrote, 1. A piece in Latin concerning the foundation, endowment, charters, laws, and other things relating to the church of Rochester: it is generally known by the title of *Textus Roffensis*, and is preserved in the archives of the cathedral church of Rochester. 2. An Epistle in Answer to some Questions of Lambert abbot of Munster; and, 3. An Epistle on incestuous Marriage.

ARNUS, now *Arno*, a very rapid river of Tuscany, which it divides, and in its course washes Florence and Pisa; rising in the Apennine, to the east of Florence, near a village called *S. Maria della Gratie*, on the borders of Romagna, 15 miles to the west of the sources of the Tiber; and then turning southward towards Arretium, it is there increased by the lakes of the Clanis; after which it runs westward, dividing Florence into two parts, and at length washing Pisa, falls eight miles below it into the Tuscan Sea.

ARNWAY (John), a clergyman distinguished by his benevolence and loyalty to King Charles I. was descended from a very good family in the county of Salop, from which he inherited a considerable estate. He was educated at Oxford; and, having received holy orders, obtained the rectories of Hodnet and Ightfield, where he distinguished himself by his piety and exemplary charity: for it was his custom to clothe annually 12 poor people, and every Sunday to entertain as many at his table, not only plentifully, but with intimacy and respect. The civil war breaking out, he preached against rebellion, and raised and clothed eight troopers for the service of King Charles I. upon which his house was plundered by the parliament's army. He then went to Oxford to serve the king in person, which subjected him to a new train of misfortunes: for his estate was soon after sequestered, and himself imprisoned till the king's death; after which, he went to the Hague, where he published, 1. The Tablet, or the Moderation of Charles I. the Martyr; and, 2. An Alarm to the Subjects of England. He at last went to Virginia, where he died in 1653.

AROBE. See ARROBAS.

AROLEO, an American weight, equal to 25 of our pounds.

AROMA PHILOSOPHORUM, denotes either saffron, or the aroph of Paracelsus; as *aroma germanicum* denotes elecampane. See AROPH.

AROMATA (anc. geog.), a town of Lydia, famous for its generous wines; and hence the appellation (Strabo). Also the name of a trading town, and promontory of Ethiopia, at the termination of the Sinus Avalites of the red Sea (Arrian).

AROMATIC, an appellation given to such plants as yield a brisk fragrant smell, and a warm taste; as all kinds of spices, &c. See MATERIA MEDICA.

ARONA, a town of Italy, in the duchy of Milan, with a strong castle. It stands on the lake Maggiore. E. Long. 8. 25. N. Lat. 45. 41.

ARONCHES, a town of Portugal in Alantejo, on the confines of Spain, seated on the river Caro. It is well fortified, and has about 500 inhabitants. W. Long. 5. 16. N. Lat. 14. 39.

AROOL, a town of the empire of Russia, in the Ukrain, seated on the river Occa. E. Long. 38. 15. N. Lat. 51. 48.

AROPH, a contraction of *aroma philosophorum*; a name given to saffron.

AROPH Paracelsi, a name given to a kind of chemi-

cal

cal flowers, probably of the same nature with the Ens Veneris, elegantly prepared by sublimation from equal quantities of lapis hæmatitis and sal ammoniac.

AROPH is also a term used frequently by Paracelsus in a sense synonimous with *lithontriptic*.

AROSBAY, a town of the East Indies, on the coast of the island of Madura, near Java. E. Long. 14. 30. N. Lat. 9. 30.

AROURA, a Grecian measure of 50 feet. It was more frequently used for a square-measure of half the plethron. The Egyptian aroura was the square of 100 feet.

ARPAD (anc. geog.), is thought to have been a city of Syria. It was always placed with Hamath (2 Kings xviii. 34. xix. 13. Isai. x. 9. xxxvi. 19. xxxvii. 13. Jerem. xlix. 23.) Sennacherib boasts of having reduced Arpad and Hamath, or of having destroyed the gods of these two places. Hamath is known to be the same with Emesa; and it is thought that Arpad is the same with Arad or Arvad, as it is sometimes called in Hebrew. See ARAD.

ARPAGIUS, or HARPAGIUS, among the ancients, a person who died in the cradle, at least in early youth. The word is formed from the Greek αρπαζω, *I snatch*. The Romans made no funerals for their *arpagii*. They neither burnt their bodies, nor made tombs, monuments, or epitaphs for them; which occasioned Juvenal to say,

> ——*Terra clauditur infans*
> *Et minor igne rogi.*

In after times it became the custom to burn such as had lived to the age of 40 days, and had cut any teeth; and these they called Αρπακτοι, or Αρπαγμενοι, q. d. *rapti, ravished*. The usage seems to have been borrowed from the Greeks; among whom, Eustathius assures us, it was the custom never to bury their children either by night or full day, but at the first appearance of the morning; and that they did not call their departure by the name of *death*, but by a softer appellation, Ημερας αρπαγη, importing that they were ravished by Aurora, or taken away to her embraces.

ARPENT, signifies an acre or furlong of ground; and, according to the old French account in domesday-book, 100 perches make an arpent. The most ordinary acre, called *l'arpent de France*, is 100 perches square: but some account it but half an acre.

ARPHAXAD, the son of Shem and father of Salah. Arphaxad was born in the year of the world 1658, a year after the deluge, and died in the year of the world 2096, at the age of 438 years, (Genes. xi. 12, &c.)

ARPI. See *ARGOS Hippium*.

ARPINAS, or ARPINO, (Joseph Cæsar), a famous painter, born in the year 1560, at the castle of Arpinas, in the kingdom of Naples. He lived in great intimacy with Pope Clement VIII. who conferred upon him the honour of knighthood, and bestowed on him many other marks of his friendship. In the year 1600, he went to Paris with cardinal Aldobrandin, who was sent legate to the French court on the marriage of Henry IV. with Mary of Medicis. His Christian majesty gave Arpinas many considerable presents, and created him a knight of St. Michael. The colouring of this painter is thought to be cold and inanimate; yet there is spirit in his designs, and his compositions have somewhat of fire and elevation. The touches of his pencil being free and bold, give therefore pleasure to connoisseurs in painting; but they are generally incorrect. What he painted of the Roman history is the most esteemed of all his works. The French king has in his collection the following pieces of this master, viz. the nativity of our Saviour, Diana and Acteon, the rape of Europa, and a Susanna. He died at Rome in 1640.

ARPINUM, a town of the Volsci, a little to the east of the confluence of the rivers Liris and Fibrenus, in the Terra di Lavora; now decayed, and called *Arpino*. It was the native place of Cicero, and of C. Marius, (Sallust).

ARQUA, a town of Italy, in the Paduan, and territory of Venice, remarkable for the tomb of Petrarch. E. Long. 11. 43. N. Lat. 45. 43.

ARQUEBUS. See HARQUEBUS.

ARQUES, a town of Normandy, in France, seated on a small river of the same name. E. Long. 1. 30. N. Lat. 49. 54.

ARRACHEE, in heraldry, a term applied to the representations of plants torn up by the roots.

ARRACHIS, in botany. See ARACHIS.

ARRACK. See ARACK.

ARRAGON, a province of Spain, bounded on the north by the Pyrenæan mountains, which separate it from France; on the west, by Navarre and the two Castiles; on the south, by Valencia; and on the east, by Catalonia. It is in length about 180 miles, and in breadth 149; but the land is mountainous, dry, sandy or stony, badly cultivated, and worse peopled. However it does not want rivers: for besides the Ebro, which crosses it in the middle, there are the Xalo, the Cinea, the Galego, and the Arragon. The air is pure and wholesome; and there are mines of iron, and some say of gold. The most fertile parts are about the rivers: for there the land produces corn, wine, oil, flax, hemp, various fruits, and a small quantity of saffron, besides large flocks of sheep, and plenty of game in the woods.

The Arragonese have the character of being bold, courageous, and well-bred; but positive in their opinions, and bigotted in their religion. These were the first of the Spaniards that threw off the Moorish yoke. Saragossa is the capital of this province; and the other chief towns are Balbastro, Jaca, Sarazona, Haesca, Calatajud, Albarrazin, Trevel, Daroca, and Boria.

ARRAIGNMENT, in law, the arraigning or setting a thing in order, as a person is said to arraign a writ of novel disseisin, who prepares and fits it for trial.

ARRAIGNMENT is most properly used to call a person to answer in form of law upon an indictment, &c.

When brought to the bar, the criminal is called upon by name to hold up his hand; which, though it may seem a trifling circumstance, yet is of this importance, that by the holding up of his hand *constat de persona*, and he owns himself to be of that name by which he is called. However it is not an indispensable ceremony; for, being calculated merely for the purpose of identifying the person, any other acknowledgement will answer the purpose as well: therefore, if the prisoner obstinately and contemptuously refuses to hold

Arraignment. up in his hand, but confesses he is the person named, it is fully sufficient.

Then the indictment is to be read to him distinctly in the English tongue (which was law, even while all other proceedings were in Latin), that he may fully understand his charge. After which it is to be demanded of him, whether he be guilty of the crime whereof he stands indicted, or not guilty?

When a criminal is arraigned, he either stands mute, or confesses the fact, or else he pleads to the indictment.

1. If he says nothing, the court ought *ex officio* to impanel a jury to enquire whether he stands obstinately mute, or whether he be dumb *ex visitatione Dei*. If the latter appears to be the case, the judges of the court (who are to be of counsel for the prisoner, and to see that he hath law and justice) shall proceed to the trial, and examine all points as if he had pleaded not guilty. But whether judgment of death can be given against such a prisoner, who hath never pleaded, and can say nothing in arrest of judgment, is a point yet undetermined.

If he be found to be obstinately mute (which a prisoner hath been held to be that hath cut his own tongue), then, if it be on an indictment of high treason, it hath long been clearly settled, that standing mute is equivalent to conviction, and he shall receive the same judgment and execution.

The English judgment of penance for standing mute was as follows: That the prisoner be remanded to the prison from whence he came, and put into a low, dark chamber; and there be laid on his back, on the bare floor, naked, unless where decency forbids; that there be placed upon his body as great a weight of iron as he could bear, and more; that he have no sustenance, save only, on the first day, three morsels of the worst bread; and, on the second day, three draughts of standing water that should be nearest to the prison door; and in this situation this should be alternately his daily diet, *till he died*, or, as anciently the judgment ran, *till he answered*.

It hath been doubted whether this punishment subsisted at the common law, or was introduced in consequence of the statute Westm. 1. 3 Edw. I. c. 12. which seems to be the better opinion. For not a word of it is mentioned in Glanvil or Bracton, or in any ancient author, case, or record (that hath yet been produced), previous to the reign of Edward I.: but there are instances on record in the reign of Henry III. where persons accused of felony, and standing mute, were tried in a particular manner, by two successive juries, and convicted,; and it is asserted by the judges in 8 Henry IV. that, by the common law before the statute, standing mute on an appeal amounted to a conviction of the felony. This statute of Edward I. directs such persons, "as will not put themselves upon inquests of felonies before the judges at the suit of the king, to be put into hard and strong prison (*soient mys en la prisone fort et dure*), as those which refuse to be at the common law of the land." And, immediately after this statute, the form of the judgment appears in Fleta and Britton to have been only a very strait confinement in prison, with hardly any degree of sustenance; but no weight is directed to be laid upon the body, so as to hasten the death of the miserable sufferer: and indeed any surcharge of punishment on persons adjudged to penance, so as to shorten their lives, is reckoned by Horne in the Mirror as a species of criminal homicide. It also clearly appears, by a record of 31st Edw. III. that the prisoner might then possibly subsist for forty days under this lingering punishment. It is therefore imagined that the practice of loading him with weights, or, as it is usually called, *pressing him to death*, was gradually introduced between 31 Edward III. and 8 Henry IV. at which last period it first appears upon the books; being intended as a species of mercy to the delinquent, by delivering him the sooner from his torment: and hence it is also probable, that the duration of the penance was then first altered; and instead of continuing *till he answered*, it was to continue *till he died*, which must very soon happen under an enormous pressure.

The uncertainty of its original, the doubts that were conceived of its legality, and the repugnance of its theory (for it rarely was carried into practice) to the humanity of the laws of England, all concurred to require a legislative abolition of this cruel process, and a restitution of the ancient common law; whereby the standing mute in felony, as well as in treason—as in trespass, amounted to a confession of the charge.

2. If the prisoner made a simple and plain confession, the court hath nothing to do but to award judgment: but it is usually very backward in receiving and recording such confession, out of tenderness to the life of the subject; and will generally advise the prisoner to retract it, and,

3. Plead to the indictment; as to which, see the article *PLEA of Indictment*.

ARRAN, an island of Scotland, in the Frith of Clyde, between Kintyre and Cunningham. Of this island the best description we have is that given by Mr Pennant, in his Tour through Scotland, Vol. II. 172.—184.

"Arran, or properly *Arr-inn*, or 'the island of mountains,' seems not to have been noticed by the ancients, notwithstanding it must have been known to the Romans, whose navy, from the time of Agricola, had its station in the *Glota Æstuarium*, or the Frith of Clyde. Camden indeed makes this island the Glota of Antonine, but no such name occurs in his itinerary: it therefore was bestowed on Arran by some of his commentators. By the immense cairns, the vast monumental stones, and many relics of Druidism, this island must have been considerable in very ancient times. Here are still traditions of the hero Fingal, or Fin-mac-coul, who is supposed here to have enjoyed the pleasures of the chace; and many places retain his name: but I can discover nothing but oral history that relates to the island till the time of Magnus the Barefooted, the Norwegian victor, who probably included Arran in his conquests of Kintyre, if he did not conquer that island, it was certainly included among those that Donald-bane was to cede; for it appears that Acho, one of the successors of Magnus, in 1263 laid claim to Arran, Bute and the Cumrays, in consequence of that promise: the two first he subdued, but the defeat he met with at Largs soon obliged him to give up his conquests. Arran was the property of the crown. Robert Bruce retired thither during his distresses, and met with protection from his faithful vassals. Numbers of them followed his fortunes, Arran.

fortunes; and after the battle of Bannock-burn he rewarded several, such as the Mac-cooks, Mackinnons, Mac-brides, and Mac-louis, or Fullerton's, with different charters of lands in their native country. All these are now absorbed by this great family, except the Fullerton's, and a Stewart, descended from a son of Robert III. who gave him a settlement here. In the time of the Dean of the Isles, his descendant possessed Castle Douan; and *he and his bluid*, says the Dean, *are the best men in that countrey*. About the year 1334, this island appears to have formed part of the estate of Robert Stewart, great steward of Scotland, afterwards Robert II. At that time they took arms to support the cause of their master; who afterwards, in reward, not only granted at their request an immunity from their annual tribute of corn, but added several new privileges, and a donative to all the inhabitants that were present. In 1456, the whole island was ravaged by Donald Earl of Ross and Lord of the Isles. At that period, it was still the property of James II.; but in the reign of his successor James III. when that monarch matched his sister to Thomas Lord Boyd, he created him Earl of Arran, and gave him the island as a portion. Soon after, on the disgrace of that family, he caused the countess to be divorced from her unfortunate husband; and bestowed both the lady and island on Sir James Hamilton, in whose family it continues to this time, a very few farms excepted.

"Arran is of great extent, being 23 miles from Sgreadan point north to Beinnean south; and the number of inhabitants are about 7000, who chiefly inhabit the coasts; the far greater part of the country being uninhabited by reason of the vast and barren mountains. Here are only two parishes, Kilbride and Kilmore; with a sort of chapel of ease to each, founded in the last century, in the golden age of this island, when it was blessed with Anne Duchess of Hamilton, whose amiable disposition and humane attention to the welfare of Arran render at this distant time her memory dear to every inhabitant. The principal mountains of Arran are, Goatfield, or Gaoilbheinn, or "the mountain of the winds, of a height equal to most of the Scottish Alps, composed of immense piles of moorstone, in form of wool-packs, clothed only with lichens and mosses, inhabited by eagles and ptarmigans; Beinbharrain, or, "the sharp-pointed;" Ceum-na-caillich, "the step of the carline or old hag; and Grianan-Athol, that yields to none in ruggedness. The lakes are, Loch-jorsa, where salmon come to spawn; Loch-tana; Loch-nah-jura, on the the top of a high hill; Loch-mhachrai; and Loch-knoc-a-charbeil, full of large eels. The chief rivers are, Abhan-mhor, Moina-mhor, Slondrai-machrei, and Jorsa; the two last remarkable for the abundance of salmon.

"The quadrupeds are very few; only otters, wild-cats, shrew-mice, rabbits and bats: the stags which used to abound, are reduced to about a dozen. The birds are, eagles, hooded-crows, wild-pigeons, stares, black game, grous, ptarmigans, daws, green plovers, and curlews. It may be remarked, that the partridge at present inhabits this island, a proof of the advancement of agriculture.

"The climate is very severe: for besides the violence of wind, the cold is very rigorous; and snow lay here in the valley for 13 weeks of the last winter. In summer, the air is remarkably salubrious; and many invalids resort here on that account, and to drink the whey of goats milk.

"The principal disease here is the pleurisy: small-pox, measles, and chincough, visit the island once in seven or eight years. The practice of bleeding twice every year seems to have been intended as a preventative against the pleurisy: but it is now performed with the utmost regularity at spring and fall. The duke of Hamilton keeps a surgeon in pay; who at those seasons makes a tour of the island. On notice of his approach, the inhabitants of each farm assemble in the open air; extend their arms and are bled into a hole made in the ground, the common receptacle of the vital fluid. In burning fevers, a tea of *wood sorrel* is used with success, to allay the heat. An infusion of *ramsons*, or *allium ursinum*, in brandy, is esteemed here a good remedy for the gravel.

"The men are strong, tall, and well made; all speak the Erse language, but the ancient habit is entirely laid aside. Their diet is chiefly potatoes and meal; and during winter some dried mutton or goat is added to their hard fare. A deep dejection appears in general through the countenances of all: no time can be spared for amusement of any kind; the whole being given for procuring the means of paying their rent, or laying in their fuel, or getting a scanty pittance of meat and clothing.

"The leases of farms are 19 years, the succeeding tenants generally find the ground little better than a *caput mortuum:* and for this reason; Should they at the expiration of the lease leave the lands in a good state, some avaricious neighbours would have the preference in the next setting, by offering a price more than the person who had expended part of his substance in enriching the farm could possibly do. This induces them to leave it in the original state. The method of setting a farm is very singular; each is commonly possessed by a number of small tenants; thus a farm of 40*l.* a year is occupied by 18 different people, who by their leases are bound, conjunctly and severally, for the payment of the rent to the proprietor. These live in the farm in houses clustered together, so that each farm appears like a little village. The tenants annually divide the arable land by lot; each has his ridge of land to which he puts his mark, such as he would do to any writing: and this species of farm is called *run-rig*, i. e. ridge. They join in ploughing; every one keeps a horse or more; and the number of those animals consume so much corn as often to occasion a scarcity; the corn and peas raised being (much of it) designed for their subsistence, and that of the cattle during the long winter. The pasture and moor-land annexed to the farm is common to all the possessors. All the farms are open. Inclosures of any form, except in two or three places, are quite unknown: so that there must be a great loss of time in preserving their corn, &c. from trespass. The usual manure is sea-plants, coral, and shells. The run-rig farms are now discouraged: but since the tenements are set by roup or auction, and advanced by an unnatural force to above double the old rent, without any allowance for inclosing, any example set in agriculture, any security of tenure by lengthening the leases, affairs will turn retrograde, and the farms relapse into their old state of rudeness;

migration

migration will increase (for it has begun), and the rents be reduced even below their former value: the late rents were scarce 1200l. a-year; the expected rents 3000l.

"The produce of the island is oats; of which about 5000 bolls, each equal to nine Winchester bushels, are sown; 500 of beans, a few peas, and above 1000 bolls of potatoes, are annually set: notwithstanding this, 500 bolls of oat-meal are annually imported, to subsist the natives.

"The live stock of the island is 3183 milch-cows; 2000 cattle, from one to three years old; 1058 horses; 1500 sheep; and 500 goats: many of the two last are killed at Michaelmas, and dried for winter-provision, or sold at Greenock. The cattle are sold from 40 to 50s. per head, which brings into the island about 1200l. per annum: I think that the sale of horses also brings in about 300l. Hogs were introduced here only two years ago. The herring-fishery round the island brings in 300l. the sale of herring-nets 100l. and that of thread about 300l. for a good deal of flax is sown here. These are the exports of the island; but the money that goes out for mere necessaries is a melancholy drawback.

"The women manufacture the wool for the cloathing of their families; they set the potatoes, and dress and spin the flax. They make butter for exportation, and cheese for their own use.

"The inhabitants in general are sober, religious, and industrious; great part of the summer is employed in building or repairing their houses, for the badness of the materials requires annual repairs: before and after harvest; they are busied in the herring-fishery; and during winter the men make their herring-nets; while the women are employed in spinning their linen and woollen yarn. The light they often use is that of lamps. From the beginning of February to the end of May, if the weather permits, they are engaged in labouring their ground: in autumn they burn a great quantity of fern, to make kelp. So that, excepting at new year's day, at marriages, or at the two or three fairs in that island, they have no leisure for any amusements: no wonder then at their depression of spirits.

"Arran forms part of the county of Bute, and is subject to the same sort of government: but, besides, justice is administered at the baron's baily-court, who has power to fine as high as 20s.; can decide in matters of property not exceeding 40s.; can imprison for a month; and put delinquents into the stocks for three hours, but that only during day-time."

In this island there are many of those rude antiquities or monuments called *cairns*, *druidical circles*, &c. See CAIRNS.

ARRANGEMENT, or RANGEMENT, the disposition of the parts of a whole, in a certain order.

The modern philosophy shows us, that the diversity of the colours of bodies depends entirely on the situation and arrangement of the parts, which reflect the light differently; the diversity of tastes and smells on the different arrangements of the pores, which render them differently sensible; and the general diversity of bodies on the different arrangement of their parts. The happy arrangement of words makes one of the greatest beauties of discourse.

ARRAS, the capital city of Artois, a province in the French Netherlands. It is seated on a mountain; and the parts about it are full of quarries, where they get stone for building. It is divided into two parts, the town and the city. The abbe of St Vaast is lord of the town, and the bishop of Arras of the city, which is the least part. They are divided by a strong wall, a large fosse, and the little river Chrinchron, which 100 paces below falls into the Scarp. They are both well fortified, inclosed by high ramparts, and by double deep fosses, which in several places are cut out of the rock. It has four gates; and since the French are become masters of it, has a strong citadel with five bastions. The most remarkable places are, the great square where the principal market is kept; this is full of fine buildings, with piazzas all round it like those of Covent-garden. Not far from this is the lesser market, which contains the town-house, a very noble structure, with a high tower covered with a crown, on the top of which is a brazen lion which serves for a vane. In the midst of this market is the chapel of the Holy Candle, which the papists pretend was brought by the Virgin Mary herself above 600 years ago, when the city was afflicted with divers diseases, and every one that touched the candle was cured; it is kept in a silver shrine. This chapel has a spire-steeple, adorned with several statues. The cathedral church of Notre-Dame stands in the city: it is a very large Gothic building, extremely well adorned; the tower is very high, and has a fine clock embellished with little figures in bronze, which represent the passion of Jesus Christ; they pass before the bell to strike the hours and half hours. In this church there is a silver shrine, enriched with pearls and diamonds, which contains a sort of wool, which they call *manna*; that they say fell from heaven in the time of a great drought, almost 1400 years ago: they carry it very solemnly in procession when they want rain. The abbey-church of St Vedast is the greatest ornament of Arras, it being adorned with a fine steeple, and seats for the monks of admirable workmanship; the pulpit is of brass, fashioned like a tree, supported by two bears of the same metal, sitting on their hind legs; there are little bears in different postures coming to climb up the tree. The chimes are remarkable for the different tunes which they play. There are 11 parish churches, and a great many convents of men and women. It is from this city that the tapestry called *arras hangings* takes its denomination. E. Long. 2. 56. N. Lat. 50. 17.

ARRAS, or *Araxes*, is also the name of a river of Georgia, which discharges itself into the Caspian sea.

ARRAY, in law, the ranking or setting forth of a jury, or inquest of men impanelled on a cause.

Battle-ARRAY, the order or disposition of an army, drawn up with a view to engage the enemy. See ARMY.

ARRAYERS, or ARRACERS, ARRAITORES, is used, in some ancient statutes, for such officers as had care of the soldiers armour, and saw them duly accoutred in their kinds. In some reigns, commissioners have been appointed for this purpose. Such were the commissioners of array appointed by king Charles I. in the year 1642.

ARREARS, the remainder of a sum due, or money remaining in the hands of an accountant. It likewise signifies

signifies the money due for rent, wages, &c. or what remains unpaid of pensions, taxes, &c.

ARRENTATION, in the forest laws, implies the licensing the owner of lands in a forest to inclose them with a low hedge and a small ditch, in consideration of a yearly rent.

ARREST, in English law (from the French word *arrester*, to *stop* or *stay*), is the restraint of a man's person, obliging him to be obedient to the law; and is defined to be the execution of the command of some court of record or office of justice. An arrest is the beginning of imprisonment; where a man is first taken, and restrained of his liberty, by power or colour of lawful warrant.

Arrests are either in *civil* or *criminal* cases.

1. An arrest in a *civil cause* is defined to be the apprehending or restraining one's person by process in execution of the command of some court.

An arrest must be by corporal seising or touching the defender's body; after which the bailiff may justify breaking open the house in which he is, to take him: otherwise he has no such power; but must watch his opportunity to arrest him. For every man's house is looked upon by the law to be his castle of defence and asylum, wherein he should suffer no violence. Which principle is carried so far in the civil law, that, for the most part, not so much as a common citation or summons, much less an arrest, can be executed upon a man within his own walls. Peers of the realm, members of parliament, and corporations, are privileged from arrests; and of course from outlawries. And against them the process to inforce an appearance must be by summons and distress *infinite*, instead of a *capias*. Also clerks, attorneys, and all other persons attending the courts of justice (for attorneys, being officers of the court, are always supposed to be there attending), are not liable to be arrested by the ordinary process of the court, but must be sued by bill (called usually a *bill of privilege*) as being personally present in court. Clergymen performing divine service, and not merely staying in the church with a fraudulent design, are for the time privileged from arrests, by statute 50 Edw. III. c. 5. and 1 Rich. II. c. 86.; as likewise members of convocation actually attending thereon, by statute 1 Hen. VI. c. 1. Suitors, witnesses, and other persons, necessarily attending any courts of record upon business, are not to be arrested during their actual attendance, which includes the necessary coming and returning. Seamen in the king's service are privileged from arrests for debts under L.20. (1 Geog. II. c. 14. and 14 Geo. II. c. 38.); and soldiers or marines are not liable to arrests for a debt of less than L.10. (30 Geo. II. c. 6, 11.) And no arrest can be made in the king's presence, nor within the verge of his royal palace, nor in any place where the king's justices are actually sitting. The king hath moreover a special prerogative (which indeed is very seldom exerted), that he may by his *writ of protection* privilege a defendant from all personal, and many real, suits, for one year at a time, and no longer, in respect of his being engaged in his service out of the realm. And the king also by the common law might take his creditor into his protection, so that no one might sue or arrest him till the king's debt was paid: but by the statute 25 Edw. III. c. 19. notwithstanding such protection, another creditor may proceed to judgment against him, with a stay of execution, till the king's debt be paid; unless such creditor will undertake for the king's debt, and then he shall have execution for both. And, lastly, by statute 29 Car. II. c. 7. no arrest can be made, nor process served, upon a Sunday, except for treason, felony, or breach of the peace.

2. An arrest in *criminal cause* is the apprehending or restraining one's person, in order to be forthcoming to answer an alleged crime. To this arrest all persons whatsoever are, without distinction, equally liable; and doors may be broken open to arrest the offender: but no man is to be arrested, unless charged with such a crime as will at least justify holding him to bail when taken. There is this difference also between arrests in civil and criminal cases, that none shall be arrested for debt, trespass, or other cause of action, but by virtue of a precept or commandment out of some court; but for treason, felony, or breach of the peace, any man may arrest with or without warrant or precept. But the king cannot command any one by word of mouth to be arrested; for he must do it by writ, or order of his courts, according to law: nor may the king arrest any man for suspicion of treason, or felony, as his subjects may; because, if he doth wrong, the party cannot have an action against him.

Arrests by private persons are in some cases commanded. Persons present at the committing of a felony must use their endeavours to apprehend the offender, under penalty of fine and imprisonment; and they are also, with the utmost diligence, to pursue and endeavour to take all those who shall be guilty thereof out of their view, upon a hue and cry levied against them. By the vagrant act 17 Geo. II. c. 5. every person may apprehend beggars and vagrants; and every private person is bound to assist an officer requiring him to apprehend a felon.

In some cases likewise arrests by private persons are rewarded by law. By the 4 and 5 William and Mary, c. 8. persons apprehending highwaymen, and prosecuting them to a conviction, are intitled to a reward of L.40, and if they are killed in the attempt, their executors, &c. are intitled to the like reward. By the 6 and 7 William III. c. 17. persons apprehending counterfeiters and clippers of the coin, and prosecuting them to conviction, are intitled to L.40.

By 5 Ann, c. 31. persons who shall take any one guilty of burglary, or the felonious breaking and entering any house in the day-time, and prosecute them to conviction, shall receive the sum of L.40 within one month after such conviction.

With regard to arrests by public officers, as watchmen, constables, &c. they are either made by their own authority, which differs but very little from the power of a private person; or they are made by a warrant from a justice of peace. See WARRANT.

ARREST of Judgment, in law, the assigning just reason why judgment should not pass: as, Want of notice of the trial; a material defect in the pleading; when the record differs from the deed impleaded; when persons are misnamed; where more is given by the verdict than is laid in the declaration, &c. This may be done either in criminal or civil cases.

ARRESTMENT, in Scots law, signifies the securing of a criminal till trial, or till he find caution to stand trial, in what are called *bailable crimes*. In civil cases, it signifies either the detaining of strangers or natives *in meditatione fugæ*, till they find caution *judicio sisti*, or the attaching the effects of a stranger in order to found jurisdiction. But, in the most general acceptation of the word, it denotes that diligence by which a creditor detains the goods or effects of his debtor in the hands of third parties till the debt due to him be either paid or secured. See LAW, Part III. Nº clxxviii.

ARRESTO FACTO SUPER BONIS, &c. a writ brought by a denizen against the goods of aliens found within the kingdom, as a recompence for goods taken from him in a foreign country.

ARRESTS, in farriery, mangy tumors upon a horse's hinder-legs, between the ham and the pastern.

ARRETIUM, (Cicero, Cæsar); *Arrhetium*, (Ptolemy); *Urbs Arrhetinorum*, (Polybius); one of the twelve ancient towns of Tuscany, near the Arnis and Clanis, situated in a pleasant valley. Now *Arezzo*, 42 miles east of Florence. E. Long. 13. 18. Lat. 43. 15.

ARRHABONARII, a sect of Christians, who held that the Eucharist is neither the real flesh or blood of Christ, nor yet the sign of them; but only the pledge or earnest thereof.

ARRHEPHORIA, a feast among the Athenians, instituted in honour of Minerva, and Herse, daughter of Cecrops. The word is composed of αρρητον, *mystery*, and φερω, *I carry*; on account of certain mysterious things which were carried in procession at this solemnity.—Boys, or, as some say, girls, between seven and twelve years of age, were the ministers that assisted at this feast, and were denominated αρρηφοροι. This feast was also called *Hersiphoria*, from the daughter of Cecrops, already mentioned.

ARRIAN, a famous philosopher and historian under the emperor Hadrian and the two Antonines, was born at Nicomedia in Bithynia. His great learning and eloquence procured him the title of *The second Xenophon;* and raised him to the most considerable dignities at Rome, even the consulship itself. We have four books of his *Dissertations upon Epictetus*, whose scholar he had been; and his *History of Alexander the Great*, in seven books, is greatly admired by the best judges.

ARRIERE, the hinder or posterior part of any thing.

ARRIERE Ban, in the French customs is a general proclamation, whereby the king summons to the war all that hold of him, both his vassals, i. e. the noblesse, and the vassals of his vassals.

ARRIERE Fee, or *Fief*, is a fee dependent on a superior one. These fees commenced, when the dukes and counts, rendering their governments hereditary in their families, distributed to their officers parts of the royal domains which they found in their respective provinces, and even permitted those officers to gratify the soldiers under them in the same manner.

ARROBAS, or AROBAS, a weight used in Spain, Portugal, and the foreign dominions of both. The Arrobas of Portugal is also called *Arata*, and contains thirty-two Lisbon pounds; that of Spain contains twenty-five Spanish pounds. In Peru it is called *Arrove*.

ARROE, a small island of Denmark, in the Baltic Sea, a little south of the island of Funen. It is eight miles in length, and about two in breadth; and produces corn, anniseed, black cattle, and horses. It has three parishes, the most considerable of which is Koping. It stands at the south-side of the island, in the bottom of a bay, and has a port with some trade. E. Long. 9. 40. N. Lat. 55. 20.

ARROJO, DE ST SERVAN, a town in Spain, in Estramadura. W. Long. 5. 20. N. Lat. 38. 40.

ARRONDEE, in heraldry, a cross, the arms of which are composed of sections of a circle, not opposite to each other, so as to make the arms bulge out thicker in one part than another; but the sections of each arm lying the same way, so that the arm is every where of an equal thickness, and all of them terminating at the edge of the escutcheon like the plain cross.

ARROW, a missive weapon of offence, slender, pointed and barbed, to be cast or shot with a bow. See ARCHERY.

ARROW-Makers are called *fletchers;* and were formerly, as well as bowyers, persons of great consequence in the commonwealth.

Arrow-heads and quarrels were to be well boched or brased, and hardened at the points with steel: the doing of which seems to have been the business of the arrow-smith.

ARROW-Head, in botany. See SAGITTARIA.

ARROW-Root. See MARANTA.

ARSACES, otherwise MITHRIDATES, a king of the Parthians, spoken of in the first book of Maccabees, xiv. 2. He considerably enlarged the kingdom of Parthia by his good conduct and valour. See PARTHIA.

ARSCHIN, in commerce, a long measure used in China to measure stuffs. Four arschins made three yards of London.

ARSENAL, a royal or public magazine, or place appointed for the making or keeping of arms, necessary either for defence or assault. Some derive this word from *arx*, a *fortress*; others from *ars*, denoting a *machine;* others again from *arx* and *senatus*, because this was the defence of the senate: but the more probable opinion derives it from the Arabic *darsenaa*, which signifies *arsenal*.

The arsenal of Venice is the place where the galleys are built and laid up. The arsenal of Paris is that where the cannon or great guns are cast. It has this inscription over the gate:

Ætna hæc Henrico vulcania tela ministrat,
Tela Gigantæos debellatura furores.

There are arsenals, or store-houses, appropriated to naval furniture and equipments. At Marseilles is the arsenal for the galleys; and at Toulon, Rochefort, and Brest, are those for the men of war.

ARSENIC, in mineralogy and chemistry, an heavy opake substance, usually sold in white masses, which, when broken, discover a semi-transparency somewhat resembling that of sal ammoniac, but by exposure to the air become white and opake like the outside of the original mass. By various chemical processes it may be

Arsenic.

be made to assume the appearance either of an acid salt or metal, at the pleasure of the operator; and therefore has been considered both as a saline substance and as a semi-metal. It is not known at what time this mineral was discovered; though as it abounds in many different kinds of ores, it is probable that the pernicious properties it manifests would very soon make it be taken notice of by metallurgists. Aristotle makes mention of a substance called Σανδαρακη; and his disciple Theophrastus makes mention of one named Αρρενικον, which by Dioscorides and others was called Αρσενικον, about the beginning of the Christian æra. By this, however, it appears, that they only meant the substances now called *Sandarach* and *orpiment*; and Avicenna, who lived in the 11th century, is the first who expressly mentions white arsenic, as well as its sublimate. It is not known by whom arsenic was first reduced to a metallic form. Paracelsus asserts that arsenic, sublimed with egg-shell lime becomes like silver; and, in 1675, M. Lemeri makes mention of a method of subliming arsenic with fixed alkali and soap.

1 Is not mentioned till the time of Avicenna.

The true nature of arsenic being thus so little known, it is no wonder to find chemists differing very much as to the class of natural bodies in which it ought to be placed. Avicenna and a great number of others class it with the sulphurs; Albertus Magnus and his followers, among the salts. Becher considers it as a kind of soap, or saline suphureous body. Later experiments, however, have made it evident, that white arsenic consists of an acid united to phlogiston; and that by diminishing the latter, the acid becomes more and more apparent; while, on the contrary, by augmenting the quantity of phlogistic matter, the arsenic assumes the metallic form. With respect to the sulphureous nature of arsenic, it appears indeed that the regulus itself, as well as orpiment and realgar, are inflammable substances; but it is not so with white arsenic. This inflammability, therefore, which arsenic in a certain state has in common with zinc and several other substances, will not denominate it sulphureous, any more than those of other bodies which possess the common property of inflammability can be denominated *sulphurs*.

2 Composed of an acid and phlogiston.

It is commonly said that arsenic mineralizes metals; and therefore, says Mr Bergman, it is considered as a sulphur by some, who yet extend the idea of mineralization so far, as under it to comprehend all mixtures of which metals make a part. But if we examine this signification a little more accurately, we shall see that it is extended too far; for if this be admitted, we must at the same time allow, that no native metal is to be found. Thus the gold called *native*, is seldom if ever found pure, but more or less mixed with copper or silver; and so with other metals. If, therefore, arsenic, which, unless in its reguline state, never dissolves other metals, be considered as a mineralizing substance, what hinders us from saying that gold is mineralized by silver or copper, and in general every metal mineralized by some other? It is much more natural to suppose that those metals are mineralized which are actually dissolved and concealed by a menstruum. Sulphur is the chief agent employed by nature for this purpose; and though the acids of vitriol, phosphorus, nitre, and sometimes even the aërial acid, occasion the metals to put on an appearance foreign to their nature, yet the number of these is so small, that, compared with the sulphurated minerals, they almost vanish.

3 Is not to be considered as a substance by which other metals are mineralized.

4 Sulphur the chief mineralizer of metals.

This mineral, so troublesome to the mineralogist, occasioned the alchemists to suspect the existence of a certain arsenical principle indispensibly necessary to the perfection of every metal. Even as late as 1773 a question to this purpose was proposed by the Royal Academy of Sciences at Berlin: the prize was adjudged to M. Monnet, who, in his answer considered arsenic as a semi-metal of a peculiar kind, which is so far from constituting any essential part of metals, that its presence is always attended with inconveniences, either by carrying off the metal as it flies away, or spoiling the mass in which it remains. These considerations, however, do not hinder us from asserting that the acid of arsenic, like others, is a mineralizing substance, if at any time it happens to meet with metals in the bowels of the earth, and to unite with it in that form.

5 An arsenical principle erroneously supposed necessary for the perfection of metals.

6 Acid of arsenic a mineralizing substance.

Arsenic in its pure state is well known to be a most destructive and deadly poison, for which the art of medicine has scarcely as yet afforded a cure. Mr Bergman is of opinion that it acts as an highly corrosive acid, even when applied externally. He also tells us, that the dry acid is more destructive than white arsenic; the regulus and realgar less so. From an experiment of Mr. Scheele, however, in which eight grains of arsenic were given to a cat, it does not appear that it acts more violently than white arsenic. The extreme danger attending this substance when taken into the human body, arises from its insolubility, and the difficulty of decompounding it; for there can but little danger arise from a liquid, unless, like corrosive acids, it should at once burn the substance of the stomach like fire: or, like laurel-water suspend the action of the nervous system. Corrosive sublimate, solutions of mercury in aquafortis, &c. will as certainly poison as arsenic; but they are much less difficult to cure, because any alkaline substance will certainly decompound them and destroy their deleterious efficacy. Arsenic, on the contrary, cannot be decompounded, nor united with any known substance, at least in such a short time as the exigence of the case we speak of would require, without a considerable degree of heat. It therefore remains in the stomach, continually exerting its mischievous qualities, unless it can be discharged by vomiting.

7 Poisonous qualities of arsenic and its acid.

8 Why it is more dangerous than other.

The symptoms attending arsenic when swallowed are, nausea, sickness, and retching to vomit, about half an hour after it is taken. These are followed by violent vomitings, hiccups, and pains in the stomach and bowels. Convulsions and palsies of the limbs presently succeed, with intense heats, cold sweats, palpitation of the heart, extreme anxiety, prostration of strength, thirst and dryness of the mouth and throat, loss of reason, and at last death. If the quantity taken was considerable, the patient dies in seven or eight hours after taking it; and the stomach and intestines are found, upon dissection, to be corroded and perforated. When this is not the case, violent putrefactive symptoms soon ensue after arsenic is swallowed; for the bodies of those who are poisoned by it generally have abundance of red or purple spots even before death. It remarkably inflames the coats of the stomach, and the putrefaction

9 Symptoms attending the swallowing of arsenic.

 faction is ſaid particularly to take place in the genitals of men. Mr Bergman relates, that in the body of a man who was poiſoned with arſenic and diſſected in the anatomical theatre at Upſal, the putrefaction had been ſo ſtrong that the mineral was deprived of part of its phlogiſton, and emitted the garlic ſmell, that peculiar characteriſtic of arſenic when in this ſituation.

10 Antidotes ineffectually propoſed.

Many antidotes have been propoſed againſt this dreadful poiſon by authors of the higheſt reputation; but it is to be feared without that ſucceſs which the confidence of thoſe who propoſed them ſeemed to enſure. Indeed, previous to any great hope of ſucceſs in this reſpect, it ought to be ſhown that theſe antidotes are able to effect ſome conſiderable change on arſenic when out of the body; and that not in ſolution, but when in a powder not very fine, as is the caſe with arſenic when it is uſually taken. Mr Bergman, recommends alkalies in diſeaſes occaſioned by arſenic: Nay he tells us, that "ſince phlogiſton and alkalies are the moſt powerful correctors of acid acrimony, it will *readily occur*, how it may be mitigated, and its deleterious effects obviated." But the many fatal accidents conſequent on taking this mineral, ſhow that none of thoſe are to be depended upon. Bergman himſelf indeed cautions us againſt truſting to phlogiſton correctors alone; and perhaps the ſolution of hepar ſulphuris, which contains the united powers of both the alkaline and phlogiſtic antidotes united, might prove more efficacious than either of them ſingly. Oils, fats, milk, warm fat broths, freſh butter, &c. have all been recommended; and, no doubt, in ſuch deplorable caſes, are thoſe remedies to which we can moſt readily have recourſe: but even here it is evident that their efficacy muſt be exceedingly dubious, whatever their intrinſic virtues may be; and for this plain reaſon, that the arſenic is already in contact with the ſtomach, and tho' the remedies might have prevented its action had they been *firſt* ſwallowed, their operation muſt be much leſs powerful after the poiſon has had acceſs to the ſtomach and begun to exert its pernicious effects.

11 Arſenic recommended as a medicine both internally and externally.

Notwithſtanding theſe dreadful effects of arſenic when taken in large quantity, attempts have not been wanting to introduce it into the materia medica. The diſeaſe indeed in which they have been recommended (the cancer) is of a very incurable nature, at leaſt by ordinary medicines. M. le Febure, a French phyſician, ſome time ago publiſhed a treatiſe, in which he recommended pure white arſenic as a ſpecific in that diſtemper. The doſe was four French grains, equal to 3¼ Engliſh, diſſolved in a French pint (32 troy ounces) of diſtilled water. A table-ſpoonful of this ſolution is to be taken with an equal quantity of milk, and half an ounce of ſyrup of poppies, every morning faſting, and taking care to taſte nothing for an hour after. This courſe muſt be continued eight days; after which a doſe is to be taken twice every day in the ſame manner, one in the morning and another about eight at night. At the end of a fortnight three doſes may be exhibited daily, the third being taken at mid-day. Thus people of a weakly conſtitution may continue till the cure is completed; but ſuch as are more robuſt may gradually augment the doſe till two table-ſpoonfuls are taken at each time with as much milk, and half an ounce of ſyrup of poppies. Children muſt on no account take more than three tea-ſpoonfuls a day, with a proportional quantity of ſyrup of poppies. For adults, the ſtrength of the ſolution, as well as the quantity, is to be augmented; ſix grains being put into the ſecond bottle and eight into the third; and a purgative, compoſed of manna, rhubarb, and ſal ſeignette, is to be given every eight or twelve days. An iſſue he conſiders as uſeful in every caſe. The tumor, if not ulcerated, ought to be waſhed with a ſolution of arſenic in the proportion of eight grains to a pint; and he adviſes the following cataplaſm. "Take of carrot juice one pound, of ſugar of lead half an ounce, of arſenic, diſſolved in diſtilled vinegar, half an ounce, of liquid laudanum a dram and an half; form the whole into a maſs with as much powder of hemlock as is ſufficient for the purpoſe. The tumor is to be covered to a moderate thickneſs with this cataplaſm, which is to be kept on by a diachylon plaſter." When the cancer is of the ulcerated kind, he directs the ichorous ſeroſity to be taken away by means of dry *charpee* at each dreſſing, and the ſore to be fomented with the arſenical ſolution with the chill taken off it, and having about a third-part of red wine added to it. When the ſore is of a very bad kind, he propoſes the arſenic to be diſſolved in decoction of bark for the purpoſe of fomentation; after which the cataplaſm and plaſter are to be applied, and this is to be renewed every twelve hours.

Mr Le Febure aſſerts, that the arſenic, when taken with the precautions juſt mentioned, is not attended with any bad conſequences, nor has it a diſagreeable taſte. Its action is ſcarcely perceived on any of the ſecretions or excretions; though ſome diſcharge their urine more freely than uſual, and with ſome the belly is more looſe. In ſome the perſpiration is more copious; but theſe effects are neither regular nor conſtant. He does not conſider it as an infallible cure for the diſtemper in every poſſible ſtage; but thinks that the diſeaſe is incurable, when, in its progreſs, it has eroded a blood-veſſel, and occaſioned a conſiderable hemorrhagy; alſo when the patient is of a hectic or phthiſical habit of body. With reſpect to regimen, he directs whey, with twelve grains of nitre to the bottle, or a weak decoction of althea with an equal quantity of nitre; and to abſtain from wine and fermented liquors. Broth made with beef, veal, or chicken, is alſo proper.

12 Mr Bergman's opinion.

Mr Bergman informs us, that "it can hardly be doubted but arſenic may be applied to valuable purpoſes in medicine, and experiments have long ago put that out of doubt; but with reſpect both to its doſe and preparation, the utmoſt caution is neceſſary."

13 The internal exhibition of arſenic diſapproved by Dr Black.

Dr Black, however, has ſeen the internal exhibition of arſenic, in thoſe caſes where it is recommended by foreign phyſicians, attended with very dangerous conſequences, ſuch as hectics, &c. He has likewiſe known obſtinate ulcers healed by it. Yet though the external uſe of arſenic has proved ſucceſsful in ſome caſes, it has often, even in this way, produced very terrible conſequences: ſo that the Doctor, far from recommending the internal uſe of it, reprobates it even in external applications.

As phyſicians are often called in caſes where it is ſuſpected that people have died from the effects of arſenic

Arsenic.

Lectures on Chemistry.

14
Directions to a physician how to act when called in cases of arsenic being swallowed.

senic taken internally, Doctor Black gives the following directions to the physician who happens to be thus employed.

"He should answer every question put to him with caution, as the lives and reputations of many often depend on his opinions.

"The first question usually put is, Whether, from the symptoms of the patient, or the appearance of the body after death, he imagines the deceased died by being poisoned with arsenic? The symptoms attending the taking of arsenic are, in about a quarter of an hour, sickness at stomach, succeeded by vomiting, purging, burning pain in the bowels, heat and thirst, pains and cramps in the legs and thighs, syncope, and death. When the body is examined, the intestines appear inflamed and corroded; nay, some ulcerations appear about the anus even before death. But we must take care not to be deceived by erosions of the stomach occasioned by the gastric juice, which has a power of dissolving the stomach after death. The difference is, that the arsenic occasions inflammation and blackness, whereas none appears in the other case. If the person escapes, he is in danger of being afflicted by marasmus, paralytic affections of the limbs, great debility, &c.

"The second question generally asked is, Whether any arsenic has been found in the intestines? The method of discovering this is as follows. The contents of the stomach and intestines should be taken out and washed in water; and any powder it contains suffered to separate. If any arsenic be mixed with it, it will fall to the bottom, and must then be examined by the following methods.

"1. By laying it on a red hot iron. If it be arsenic, it will evaporate, without melting, in a thick white vapour; and this may be shown by the 40th part of a grain.

"2. We may mix some of it with charcoal; in which state, if it be arsenic, it will emit an odour very like garlic; but this will not be perceived unless it be mixed with charcoal or some inflammable matter.

"3. We may inclose the powder with some charcoal, between two polished bits of copper, the edges of which are moistened with a lute made of two parts of fine sand and one of pipe-clay. The plates being then bound together with a wire, and the whole made red hot, the arsenical powder will thus be metallized, and, penetrating the copper, a blackish skin will first appear upon it; which being rubbed off, the parts which the arsenical vapour has touched will appear of a whitish or lead colour.

"4. We may metallize or reduce the arsenic in a glass tube by means of the black flux. This is easily done by mixing two or three parts of the flux with one of the powder. This mixture being put into a small glass tube, and a heat applied sufficient for volatalizing the arsenic, the greatest part of it will be metallized. One end of the tube is to be left open at first, and then stopped with lint or wool; the other made red hot; and if the tube be then broken, the arsenic is found metallized. One grain of arsenic will be sufficient for all those experiments."

The first symptoms which ensue on the taking of arsenic show that it is of a highly inflammatory, caustic, and corrosive nature with regard to the system in general, and the intestines in particular: the pulse becomes extremely weak and irritable, and this is attended with a kind of paralytic affection of the limbs, marasmus, &c. Milk and oil have been recommended as antidotes; but the milk may curdle, and the oil will not mix with the fluids in the intestines. It is therefore advisable, when the physician is called to a patient who has swallowed arsenic, to make use of mucilages. A friend of Dr Black's, who had no mucilage at hand, thought of the whites of eggs, and succeeded. After the violence of the first attack is over, a milk diet, opiates, &c. are proper; and some time after, electricity has been found of great service. Some have advised to exhibit hepar sulphuris, as already noticed: but this is founded, not on experience, but theory; and it cannot be supposed that such a quantity can enter the system as will be sufficient for neutralizing the arsenic, and converting it into orpiment, which is the design of exhibiting it.

Edinburgh New Dispensatory.

The following account of the use of arsenic in medicine is given by Dr Duncan. "Notwithstanding, however, the very violent effects of arsenic, it has been employed in the cure of diseases, both as applied externally and as taken internally. Externally, white arsenic has been chiefly employed in cases of cancer; and as used in this way, it is supposed that its good effects depend on its acting as a peculiar corrosive: and it is imagined, that arsenic is the basis of a remedy long celebrated in cancer, which, however, is still kept a secret by a family of the name of *Plunket* in Ireland. According to the best conjectures, their application consists of the powder of some vegetables, particularly the ranunculus flammeus and cotula fœtida, with a considerable proportion of arsenic and flower of sulphur intimately mixed together. This powder, made into a paste with the white of an egg, is applied to the cancerous part which it is intended to corrode; and being covered with a piece of thin bladder, smeared also with the white of an egg, it is suffered to lie on from 24 to 48 hours; and afterwards the eschar is to be treated with softening digestive, as in other cases.

"Arsenic, in substance, to the extent of an eight of a grain for a dose, combined with a little of the flowers of sulphur, has been said to be employed internally in some very obstinate cases of cutaneous diseases, and with the best effect. But of this we have no experience.

"Of all the diseases in which white arsenic has been used internally, there is no one in which it has been so frequently and so successfully employed as in the cure of intermittent fevers. It has long been used in Lincolnshire, and some other of the fenny countries, under the name of the *arsenic drop*, prepared in different ways: And it is conjectured, that an article, which has had a very extensive sale, under the title of the *tasteless ague-drop*, the form of preparing which, however, is still kept a secret, is nothing else but a solution of arsenic. But whether this be the case or not, we have now the most satisfactory information concerning this article in the "Medical Reports, of the effects of Arsenic in the cure of agues, remitting fevers, and periodic headachs," by Dr Fowler of Stafford. He directs, that 64 grains of arsenic, reduced to a very fine powder, and mixed with as much fixed vegetable alkaline salt, should be added to half a pound of distilled water in a florence flask; that it should be then placed in a sand-heat,

heat, and gently boiled till the arsenic be completely dissolved; that after the solution is cold, half an ounce of compound spirit of lavender be added to it, and as much distilled water as to make the whole solution amount to a pound. This solution is taken in doses, regulated according to the age, strength, and other circumstances of the patient, from two to twelve drops, once, twice, or oftener in the course of the day. And in the diseases mentioned above, particularly in intermittents, it has been found to be a safe and very efficacious remedy, both by Dr Fowler and by other practitioners: but in some instances, even when given in very small doses, we have found it excite violent vomiting. But besides this, it has also been alleged by some, that those cured of intermittents by arsenic are very liable to become phthisical. If arsenic shall ever be extensively employed internally, it will probably be most certain and most safe in its operation when brought to the state of a salt readily soluble in water."

15 Other uses of arsenic.

With regard to its other uses he expresses himself thus: "Philosophers are wont to evince the extraordinary porosity of bodies, and the wonderful subtilty of vapours, by a sympathetic ink made with orpiment and lime*; for writing made with vinegar of litharge, by itself invisible, exposed to the vapour of this liquor becomes in a few minutes brown, even though a great many folds of paper be interposed.

* See *Sympathetic* INK.

16 Of the adulteration of wines.

"Wines naturally acid, or grown so by age, still continue to be edulcorated by lead, notwithstanding the punishments attending the detection of this fraud: it is therefore of great consequence to be in possession of an easy method of discovering such a sophistication. For this purpose a probatory liquor has been recommended, composed of caustic fixed alkali and orpiment; which instantly throws down a black or dark brown precipitate in consequence of the union of the sulphur of the orpiment with the metal. The same effect will take place on the addition of common hepar sulphuris: but methods have been contrived of eluding this proof. If a small quantity of chalk be contained in the wine, the saline hepar does not produce the intended effect; for the falling of the white calcareous earth diminishes the blackness. The other probatory liquor is also rendered ineffectual by a large quantity of tartar; because the tartareous acid, uniting with the lime, forms a kind of selenite, which in like manner diminishes the blackness.

17 Arsenic in composition with metals, &c.

"Arsenic sometimes enters metallic compositions, especially copper and tin; but it were much to be wished that such compositions were banished, at least from the kitchen. Shot made of lead is sometimes hardened by orpiment.

"Regulus of arsenic enters into the composition of Meuder's phosphorus. The power of the calx in vitrification was long ago known to Geber; and it is frequently employed in glass-houses, either for facilitating fusion, for acquiring a certain degree of opacity, or finally for carrying off phlogiston. The method in which mountain-crystals, placed over orpiment, white arsenic, crude antimony, and sal ammoniac, mixed in a crucible, are tinged by means of heat, is described by Neri, and upon trial is found to be true. I have thus obtained these crystals beautifully marked with red, yellow, and opal spots; but at the same time cracked, which could scarcely be avoided.

18 In painting

"In painting, too, the artists sometimes employ arsenic. Painters in oil frequently use both orpiment and realgar; and it is probable that wood covered with a pigment mixed with white arsenic would not be spoiled by worms. A most beautiful green pigment may be precipitated from blue vitriol by means of white arsenic dissolved in water, together with vegetable alkali. This prepared either with water or oil, affords a colour which suffers no change in many years. The playthings of children however, should not be painted with this or any other preparation of arsenic, on account of their custom of putting every thing into their mouths."

Arsenic is also used in dying, and the yellow combination of it with sulphur has the property of readily dissolving indigo; for which purpose it is used in cloth-printing. It lets it fall again, however, on exposure to the air; and therefore can be employed only in pencil-colours, where a large quantity is laid on at once. The neutral arsenical salt is used in some manufactures in France; but for what purposes is not known.

ARSENIUS, a deacon of the Roman church, of great learning and piety. He was pitched upon by the pope to go to the emperor Theodosius, as tutor to his son Arcadius. Arsenius arrived at Constantinople in the year 383. The emperor happening one day to go into the room where Arsenius was instructing Arcadius, his son was seated and the preceptor standing; at this he was exceedingly displeased, took from his son the imperial ornaments, made Arsenius sit in his place, and ordered Arcadius for the future to receive his lessons standing uncovered. Arcadius, however, profited but little by his tutor's instructions, for some time after he formed a design of dispatching him. The officer to whom Arcadius had applied for this purpose, divulged the affair to Arsenius, who retired to the desarts of Scete, where he passed many years in the exercises of the most strict and fervent devotion. He died there, at 95 years of age.

ARSHOT, a town of the Austrian Netherlands, situated about 14 miles east of the city of Mechlin, in E. Long. 4. 45. N. Lat. 51. 5.

ARSINOE (anc. geog.), a town of Egypt, on the west side of the Arabian gulf, near its extremity, to the south of Heroopolis, (Strabo, Ptolemy); called *Cleopatris* by some. Another Arsinoe, a town of Cilicia, (Ptolemy); and the fifth of that name in Cilicia, (Stephanus); with a road or station for ships, (Strabo). A third Arsinoe, in the south of Cyprus, with a port between Citium and Salamis, (Strabo). A fourth, an inland town of Cyprus, called *Marium* formerly, (Stephanus). A fifth in the north of Cyprus, between Acamas and Soli, (Strabo); so called from Arsinoe, a queen of Egypt, Cyprus being in the hands of the Ptolemies. A sixth Arsinoe, a maritime town of Cyrene, formerly called *Teuchira*. A seventh Arsinoe, in the Nomos Arsinoites, to the west of the Heracleotes, on the western bank of the Nile, formerly called *Crocodilorum Urbs*, (Strabo); the name *Arsinoe* continued under Adrian, (Coin). Ptolemy calls this Arsinoe an inland metropolis, and therefore at some distance from the Nile, with a port called *Ptolemais*. An eighth Arsinoe, a maritime town of Lycia; so called by Ptolemy Philadelphus, after the name of his consort, which did not hold long, it afterwards recovering its ancient name

Patara,

Patara, (Strabo). A ninth, a town of the Troglodytæ, near the mouth of the Arabian Gulf, which towards Ethiopia is terminated by a promontory called *Dire*, (Ptolemy). This Arsinoe is called *Berenice*, and the third of that name in this quarter, with the distinction *Epidires*; because situate on a neck of land running a great way out into the sea.

ARSIS *and* THESIS, in music, is a term applied to compositions in which one part rises and the other falls.

ARSMART, in botany. See PERSICARIA.

ARSON, in English law, is the malicious and wilful burning of the house or out-house of another man; which is felony at common law.

This is an offence of very great malignity, and much more pernicious to the public than simple theft: because, first, it is an offence against that right of habitation, which is acquired by the law of nature as well as by the laws of society; next, because of the terror and confusion that necessarily attend it; and, lastly, because in simple theft the thing stolen only changes its master, but still remains *in esse* for the benefit of the public; whereas by burning the very substance is absolutely destroyed. It is also frequently more destructive than murder itself, of which too it is often the cause: since murder, atrocious as it is, seldom extends beyond the felonious act designed; whereas fire too frequently involves in the common calamity persons unknown to the incendiary, and not intended to be hurt by him, and friends as well as enemies.

ARSURA, in ancient customs, a term used for the melting of gold or silver, either to refine them, or to examine their value.—The method of doing this is explained at large in the Black Book of the Exchequer, ascribed to Gervaise, in the chapter *De Officio Militis Argentarii*, being in those days of great use, on account of the various places and different manners in which the king's money was paid.

ARSURA is also used for the loss or diminution of the metal in the trial. In this sense, a pound was said *tot ardere denarios*, to lose so many penny-weights.

ARSURA is also used for the dust and sweepings of silver-smiths, and others, who work in silver, melted down.

ART is defined by Lord Bacon, a proper disposal of the things of nature by human thought and experience, so as to answer the several purposes of mankind; in which sense *art* stands opposed to *nature*.

Art is principally used for a system of rules serving to facilitate the performance of certain actions; in which sense it stands opposed to *science*, or a system of speculative principles.

Arts are commonly divided into *useful* or *mechanic*, *liberal* or *polite*. The former are those wherein the *hand* and *body* are more concerned than the mind: of which kind are most of those which furnish us with the *necessaries* of life, and are popularly known by the name of *trades*; as baking, brewing, carpentry, smithery, weaving, &c.—The latter are such as depend more on the labour of the mind than that of the hand; they are the produce of the *imagination*, their essence consists in *expression*, and their end is *pleasure*. Of this kind are poetry, painting, music, &c.

1 Origin

Progress of the Arts. Some useful arts must be nearly coeval with the human race; for food, cloathing, and habitation, even in their original simplicity, require some art. Many other arts are of such antiquity as to place the inventors beyond the reach of tradition. Several have gradually crept into existence without an inventor. The busy mind, however, accustomed to a beginning in things, cannot rest till it finds or imagines a beginning to every art. The most probable conjectures of this nature the reader may see in the historical introduction to the different articles.

and progress of useful arts. [Kames's Sketches, Sk. V.]

In all countries where the people are barbarous and illiterate, the progress of arts is extremely slow. It is vouched by an old French poem, that the virtues of the loadstone were known in France before anno 1180. The mariner's compass was exhibited at Venice anno 1260, by Paulus Venetus, as his own invention. John Goya of Amalphi was the first who, many years afterward, used it in navigation; and also passed for being the inventor. Though it was used in China for navigation long before it was known in Europe, yet to this day it is not so perfect as in Europe. Instead of suspending it in order to make it act freely, it is placed upon a bed of sand, by which every motion of the ship disturbs its operation. Hand-mills, termed *querns*, were early used for grinding corn; and when corn came to be raised in greater quantity, horse-mills succeeded. Water-mills for grinding corn are described by Vitruvius. Wind-mills were known in Greece and in Arabia as early as the seventh century; and yet no mention is made of them in Italy till the fourteenth. That they were not known in England in the reign of Henry VIII. appears from a houshold book of an Earl of Northumberland, cotemporary with that king, stating an allowance for three mill-horses, "two to draw in the mill, and one to carry stuff to the mill and fro." Water-mills for corn must in England have been of a later date. The ancients had mirror-glasses, and employed glass to imitate crystal vases and goblets; yet they never thought of using it in windows. In the 13th century, the Venetians were the only people who had the art of making crystal-glass for mirrors. A clock that strikes the hours was unknown in Europe till the end of the 12th century. And hence the custom of employing men to proclaim the hours during night; which to this day continues in Germany, Flanders and England. Galileo was the first who conceived an idea that a pendulum might be useful for measuring time; and Huygens was the first who put the idea in execution, by making a pendulum clock. Hook, in the year 1660, invented a spiral spring for a watch, though a watch was far from being a new invention. Paper was made no earlier than the 14th century; and the invention of printing was a century later. Silk manufactures were long established in Greece before silkworms were introduced there. The manufacturers were provided with raw silk from Persia: but that commerce being frequently interrupted by war, two monks in the reign of Justinian, brought eggs of the silkworm from Hindostan, and taught their countrymen the method of managing them.—The art of reading made a very slow progress. To encourage that art in England, the capital punishment for murder was remitted if the criminal could but read, which in law-language is termed *benefit of clergy*. One would imagine that the art must have made a very rapid progress when so greatly favoured: but there is a signal proof of of the contrary; for so small an edition of the Bible as 600 copies, translated into English in the reign of Henry VIII. was not wholly sold off in three years. The people of England must have been profoundly ignorant in Queen Elizabeth's time, when a forged clause added to the 20th article of the English creed passed unnoticed till about 50 years ago.

The discoveries of the Portuguese in the west coast of Africa is a remarkable instance of the slow progress of arts. In the beginning of the 15th century, they were totally ignorant of that coast beyond Cape Non, 28 deg. north latitude. In 1410, the celebrated Prince Henry of Portugal fitted out a fleet for discoveries, which proceeded along the coast to Cape Bojadore in 26 deg. but had not courage to double it. In 1418, Tristan Vaz discovered the island Porto Santo; and the year after, the island Maderia was discovered. In 1439, a Portuguese captain doubled Cape Bojadore; and the next year the Portuguese reached Cape Blanco, lat. 20 deg. In 1446, Nuna Tristan doubled Cape Verd, lat. 14. 40. In 1448, Don Gonzallo Vallo took possession of the Azores. In 1449, the islands of Cape Verd were discovered for Don Henry. In 1471, Pedro d'Escovar discovered the island St Thomas and Prince's Island. In 1484, Diego Cam discovered the kingdom of Congo. In 1486, Bartholomew Diaz, employed by John II. of Portugal, doubled the Cape of Good Hope, which he called *Cabo Tormentoso*, from the tempestuous weather he found in the passage.

2 Causes which advance the progress of art.

The exertion of national spirit upon any particular art, promotes activity to prosecute other arts. The Romans, by constant study, came to excel in the art of war, which led them naturally to improve upon other arts. Having, in the progress of society, acquired some degree of taste and polish, a talent for writing broke forth. Nevius composed in verse seven books of the Punic war; besides comedies, replete with bitter raillery against the nobility. Ennius wrote annals, and an epic poem. Lucius Andronicus was the father of dramatic poetry in Rome. Pacuvius wrote tragedies. Plautus and Terence wrote comedies. Lucilius composed satires, which Cicero esteems to be slight and void of erudition. Fabius Pictor, Cincius Alimentus, Piso Frugi, Valerius Antias, and Cato, were rather annalists than historians, confining themselves to naked facts, ranged in order of time. The genius of the Romans for the fine arts was much inflamed by Greek learning, when free intercourse between the two nations was opened. Many of those who made the greatest figure in the Roman state commenced authors; Cæsar, Cicero, &c. Sylla composed memoirs of his own transactions, a work much esteemed even in the days of Plutarch.

The progress of art seldom fails to be rapid, when a people happen to be roused out of a torpid state by some fortunate change of circumstances. Prosperity, contrasted with former abasement, gives to the mind a spring, which is vigorously exerted in every new pursuit. The Athenians made but a mean figure under the tyranny of Pisistratus; but upon regaining freedom and independence, they were converted into heroes. Miletus, a Greek city of Ionia, being destroyed by the king of Persia, and the inhabitants made slaves, the Athenians, deeply affected with the misery of their brethren, boldly attacked the king in his own dominions, and burnt the city of Sardis. In less than 10 years after, they gained a signal victory at Marathon; and, under Themistocles, made head against that prodigious army with which Xerxes threatened utter ruin to Greece. Such prosperity produced its usual effect: arts flourished with arms, and Athens became the chief theatre for sciences as well as for fine arts. The reign of Augustus Cæsar, which put an end to the rancour of civil war, and restored peace to Rome with the comforts of society, proved an auspicious æra for literature; and produced a cloud of Latin historians, poets, and philosophers, to whom the moderns are indebted for their taste and talents. One who makes a figure rouses emulation in all: one catches fire from another, and the national spirit is every where triumphant: classical works are composed, and useful discoveries made in every art and science. With regard to Rome, it is true, that the Roman government under Augustus was in effect despotic: but despotism, in that single instance, made no obstruction to literature, it having been the politic of that reign to hide power as much as possible. A similar revolution happened in Tuscany about three centuries ago. That country having been divided into a number of small republics, the people, excited by mutual hatred between small nations in close neighbourhood, became ferocious and bloody, flaming with revenge for the slightest offence. These republics being united under the Great Duke of Tuscany, enjoyed the sweets of peace in a mild government. That comfortable revolution, which made the deeper impression by a retrospect to recent calamities, roused the national spirit, and produced ardent application to arts and literature. The restoration of the royal family in Englannd, which put an end to a cruel and envenomed civil war, promoted improvements of every kind: arts and industry made a rapid progress among the people, though left to themselves by a weak and fluctuating administration. Had the nation, upon that favourable turn of fortune, been blessed with a succession of able and virtuous princes, to what a height might not arts and sciences have been carried! In Scotland, a favourable period for improvement was the reign of the first Robert, after shaking off the English yoke; but the domineering spirit of the feudal system rendered abortive every-attempt. The restoration of the royal family mentioned above, animated the legislature of Scotland to promote manufactures of various kinds: but in vain; for the union of the two crowns had introduced despotism into Scotland, which sunk the genius of the people, and rendered them heartless and indolent. Liberty, indeed, and many other advantages, were procured to them by the union of the two kingdoms; but the salutary effects were long suspended by mutual enmity, such as commonly subsists between neighbouring nations. Enmity wore out gradually, and the eyes of the Scots were opened to the advantages of their present condition; the national spirit was roused to emulate and to excel; talents were exerted, hitherto latent; and Scotland at present makes a figure in arts and sciences above what it ever made while an independent kingdom.

Another cause of activity and animation, is the being engaged in some important action of doubtful event; a struggle for liberty, the resisting a potent invader, or the like. Greece, divided into small states frequently at war with each other, advanced literature and

Arts.

and the fine arts to unrivalled perfection. The Corsicans, while engaged in a perilours war for defence of their liberties exerted a vigorous national spirit; they founded a university for arts and sciences, a public library and a public bank. After a long stupor during the dark ages of Christianity, arts and literature revived among the turbulent states of Italy. The royal society in London, and the academy of sciences in Paris, were both of them instituted after civil wars that had animated the people and roused their activity.

As the progress of arts and sciences toward perfection is greatly promoted by emulation, nothing is more fatal to an art or science than to remove that spur, as where some extraordinary genius appears who soars above rivalship. Mathematics seem to be declining in Britain: the great Newton having surpassed all the ancients, has not left to the moderns even the faintest hope of equalling him; and what man will enter the lists who despairs of victory?

In a country thinly peopled, where even necessary arts want hands, it is common to see one person exercising more arts than one: in several parts of Scotland, one man serves as physician, surgeon, and apothecary. In every populous country, even simple arts are split into parts, and each part has an artist appropropriated to it. In the large towns of ancient Egypt, a physician was confined to a single disease. In mechanic arts that method is excellent. As a hand confined to a single operation becomes both expert and expeditious, a mechanic art is perfected by having its different operations distributed among the greatest number of hands; many hands are employed in making a watch, and a still greater number in manufacturing a web of woollen cloth. Various arts or operations carried on by the same man, envigorate his mind, because they exercise different faculties; and as he cannot be equally expert in every art or operation, he is frequently reduced to supply want of skill by thought and invention. Constant application, on the contrary, to a single operation, confines the mind to a single object, and excludes all thought and invention: in such a train of life, the operator becomes dull and stupid, like a beast of burden. The difference is visible in the manners of the people: in a country where, from want of hands, several occupations must be carried on by the same person, the people are knowing and conversable: in a populous country, were manufactures flourish, they are ignorant and unsociable. The same effect is equally visible in countries where an art or manufacture is confined to a certain class of men. It is visible in Indostan, where the people are divided into casts, which never mix even by marriage, and where every man follows his father's trade. The Dutch lint-boors are a similar instance; the same families carry on the trade from generation to generation; and are accordingly ignorant and brutish even beyond other Dutch peasants. The inhabitants of Buckhaven, a sea-port in the county of Fife, in Scotland, were originally a colony of foreigners, invited to teach the people the art of fishing. They continue fishers to this day, marry among themselves, have little intercourse with their neighbours, and are dull and stupid to a proverb.

3
Progress of the *fine arts.*

Useful arts paved the way to fine arts. Men upon whom the former had bestowed every convenience, turned their thoughts to the latter. Beauty was studied in objects of sight; and men of taste attached themselves to the fine arts, which multiplied their enjoyments and improved their benevolence. Sculpture and painting made an early figure in Greece; which afforded plenty of beautiful originals to be copied in these imitative arts. Statuary, a more simple imitation than painting, was sooner brought to perfection: the statue of Jupiter by Phidias, and of Juno by Polycletes, though the admiration of all the world, were executed long before the art of light and shade was known. Apollodorus, and Zeuxis his disciple, who flourished in the 15th Olympiad, were the first who figured in that art. Another cause concurred to advance statuary before painting in Greece, viz. a great demand for statues of the gods. Architecture, as a fine art, made a slower progress. Proportions, upon which its elegance chiefly depends, cannot be accurately ascertained, but by an infinity of trials in great buildings: a model cannot be relied on; for a large and a small building, even of the same form, require different proportions.

4
Literary composition.

From the fine arts mentioned, we proceed to literature. It is agreed, among all antiquaries, that the first writings were in verse, and that writing in prose was of a much latter date. The first Greek who wrote in prose was Pherecides Syrus: the first Roman was Appius Cæcus, who composed a declamation against Pyrrhus. The four books of the Chatah Bhade, which is the sacred book of Hindostan, are composed in verse stanzas; and the Arabian compositions in prose followed long after those in verse. To account for that singular fact, many learned pens have been employed; but without success. By some it has been urged, that as memory is the only record of events where writing is unknown, history originally was composed in verse for the sake of memory. This is not satisfactory. To undertake the painful task of composing in verse, merely for the sake of memory, would require more foresight than ever was exerted by a barbarian: not to mention that other means were used for preserving the memory of remarkable events; a heap of stones, a pillar, or other object that catches the eye. The account given by Longinus is more ingenious. In a fragment of his treatise on verse, the only part that remains, he observes, "that measure or verse belongs to poetry, because poetry represents the various passions with their language; for which reason the ancients, in their ordinary discourse, delivered their thoughts in verse rather than in prose." Longinus thought, that anciently men were more exposed to accidents and dangers, than when they were protected by good government and by fortified cities. But he seems not to have adverted, that fear and grief, inspired by dangers and misfortunes, are better suited to humble prose than to elevated verse. It may be added, that however natural poetical diction may be when one is animated with any vivid passion, it is not supposable that the ancients never wrote nor spoke but when excited by passion. Their history, their laws, their covenants, were certainly not composed in that tone of mind.

An important article in the progress of the fine arts, which writers have not sufficiently attended to, will perhaps explain this mystery. The article is the profession

Art. fession of a bard, which sprung up in early times, before writing was known †, and died away gradually as writing turned more and more common ‡.

† See the article *Writing*.
‡ See *Bard*.

The songs of the bards, being universal favourites, were certainly the first compositions that writing was employed upon: they would be carefully collected by the most skilful writers, in order to preserve them in perpetual remembrance. The following part of the progress is obvious. People acquainted with no written compositions, but what were in verse, composed in verse their laws, their religious ceremonies, and every memorable transaction that was intended to be preserved in memory by writing. But when subjects of writing multiplied, and became more and more involved; when people began to reason, to teach, and to harangue; they were obliged to descend to humble prose: for to confine a writer or speaker to verse in handling subjects of that nature, would be a burden unsupportable.

5 History.

The prose compositions of early historians are all of them dramatic. A writer destitute of art is naturally prompted to relate facts as he saw them performed: he introduces his personages as speaking and conferring; and he himself relates what was acted, and not spoke. The historical books of the Old Testament are composed in that mode; and so addicted to the dramatic are the authors of those books, that they frequently introduce God himself into the dialogue. At the same time, the simplicity of that mode is happily suited to the poverty of every language in its early periods. The dramatic mode has a delicious effect in expressing sentiment, and every thing that is simple and tender. Read, as an instance of a low incident becoming, by that means, not a little interesting, Ruth i. 8. to iv. 16.

The dramatic mode is far from pleasing so much in relating bare historical facts. Read, as an example, the story of Adonijah in 1. Kings i. 11.—49.

In that passage there are frequent repetitions; not however by the same person, but by different persons who have occasion in the course of the story to say the same things; which is natural in the dramatic mode, where things are represented precisely as they were transacted. In that view, Homer's repetitions are a beauty, not a blemish; for they are confined to the dramatic part, and never occur in the narrative.

But the dramatic mode of composition, however pleasing, is tedious and intolerable in a long history. In the progress of society new appetites and new passions arise; men come to be involved with each other in various connections; incidents and events multiply, and history becomes intricate by an endless variety of circumstances. Dialogue accordingly is more sparingly used, and in history plain narration is mixed with it. Narration is as it were the ground-work; and dialogue is raised upon it, like flowers in embroidery. Homer is admitted by all to be the great master in that mode of composition.

The narrative mode came in time so to prevail, that in a long chain of history, the writer commonly leaves off dialogue altogether. Early writers of that kind appear to have very little judgment in distinguishing capital facts from minute circumstances, such as can be supplied by the reader without being mentioned. The history of the Trojan war by Dares Phrygius is a curious instance of that cold and creeping manner of composition. The Roman histories before the time of Cicero are chronicles merely. Cato, Fabius Pictor, and Piso, confined themselves to naked facts. In the Augustæ Historiæ Scriptores we find nothing but a jejune narrative of facts, commonly of very little moment, concerning a degenerate people, without a single incident that can rouse the imagination or exercise the judgment. The monkish histories are all of them composed in the same manner.

The dry narrative manner being very little interesting or agreeable, a taste for embellishment prompted some writers to be copious and verbose. Saxo-Grammaticus, who in the 12th century composed in Latin a history of Denmark, surprisingly pure at that early period, is extremely verbose and full of tautologies. Such a style, at any rate unpleasant, is intolerable in a modern tongue, before it is enriched with a stock of phrases for expressing aptly the great variety of incidents that enter into history.

The perfection of historical composition, which writers at last attain to after wandering through various imperfect modes, is a relation of interesting facts, connected with their motives and consequences. An history of that kind is truly a chain of causes and effects.

The history of Thucydides, and still more that of Tacitus, are shining instances of that mode.

6 Eloquence.

Eloquence was of a later date than the art of literary composition: for till the latter was improved, there were no models for studying the former. Cicero's oration for Roscius is composed in a style diffuse and highly ornamented; which, says Plutarch, was universally approved, because at that time the style in Asia, introduced into Rome with its luxury, was in high vogue. But Cicero, in a journey to Greece, where he leisurely studied Greek authors, was taught to prune off superfluities, and to purify his style, which he did to a high degree of refinement. He introduced into his native tongue a sweetness, a grace, a majesty, that surprised the world, and even the Romans themselves. Cicero observes with great regret, that if ambition for power had not drawn Julius Cæsar from the bar to command legions, he would have become the most complete orator in the world. So partial are men to the profession in which they excel. Eloquence triumphs in a popular assembly, makes some figure in a court of law composed of many judges, very little where there is but a single judge, and none at all in a despotic government. Eloquence flourished in the republics of Athens and of Rome; and makes some figure at present in a British house of Commons.

7 Tragedy.

The Greek stage has been justly admired among all polite nations. The tragedies of Sophocles and Euripides in particular are by all critics held to be perfect in their kind, excellent models for imitation, but far above rivalship. If the Greek stage was so early brought to maturity, it is a phenomenon not a little singular in the progress of arts. The Greek tragedy made a rapid progress from Thespis to Sophocles and Euripides, whose compositions are wonderful productions of genius, considering that the Greeks at that period were but beginning to emerge from roughness and barbarity into a taste for literature. The compositions of Eschylus, Sophocles, and Euripides, must

Art. have been highly relished among people who had no idea of any thing more perfect. We judge by comparison, and every work is held to be perfect that has no rival. It ought at the same time to be kept in view, that it was not the dialogue which chiefly enchanted the Athenians, nor variety in the passions represented, nor perfection in the actors; but machinery and pompous decoration, joined with exquisite music. That these particulars were carried to the greatest height, we may with certainty conclude from the extravagant sums bestowed on them: the exhibiting a single tragedy was more expensive to the Athenians than their fleet or their army in any single campaign.

One would imagine, however, that these compositions were too simple to enchant for ever; as variety in action, sentiment, and passion is requisite, without which the stage will not continue long a favourite entertainment: and yet we find not a single improvement attempted after the days of Sophocles and Euripides. The manner of performance, indeed, prevented absolutely any improvement. A fluctuation of passion and refined sentiments would have made no figure on the Grecian stage. Imagine the discording scene between Brutus and Cassius in Julius Cæsar to be there exhibited, or the handkerchief in the Moor of Venice: how slight would be their effect, when pronounced in a mask, and through a pipe? The workings of nature upon the countenance, and the flections of voice expressive of various feelings, so deeply affecting in modern representation, would have been entirely lost. If a great genius had arisen with talents for composing a pathetic tragedy in perfection, he would have made no figure in Greece. An edifice must have been erected of a moderate size: new actors must have been trained to act with a bare face, and to pronounce in their own voice. And after all, their remained a greater miracle still to be performed, viz. a total reformation of taste in the people of Athens. In one word, the simplicity of the Greek tragedy was suited to the manner of acting; and that manner excluded all improvements.

8 Comedy.

With respect to comedy, it does not appear that the Greek comedy surpassed the tragedy in its progress toward perfection. Horace mentions three stages of Greek comedy. The first well suited to the rough and course manners of the Greeks, when Eupolis, Cratinus, and Aristophanes, wrote. These authors were not ashamed to represent on the stage real persons, not even disguising their names: of which we have a striking instance in a comedy of Aristophanes, called *the Clouds*, where Socrates is introduced, and most contemptuously treated. This sort of comedy, sparing neither gods nor men, was restrained by the magistrates of Athens, so far as to prohibit persons to be named on the stage. This led writers to do what is done at present: the characters and manners of known persons were painted so much to the life, that there could be no mistake: and the satire was indeed heightened by this regulation, as it was an additional pleasure to find out the names that were meant in the representation. This was termed the *middle comedy*. But as there still remained too great scope for obloquy and licentiousness, a law was made prohibiting real events or incidents to be introduced upon the stage. This law happily banished satire against individuals, and confined it to manners and customs in general. Obedient to this law are the comedies of Menander, Philemon, and Diphilus, who flourished about 300 years before the Christian æra. And this is termed the *third stage* of Greek comedy. The comedies of Aristophanes which still remain, err not less against taste than against decency. But the Greek comedy is supposed to have been considerably refined by Menander and his cotemporaries. Their works, however, were far from perfection, if we can draw any conjecture from their imitator Plautus, who wrote about a century later. Plautus was a writer of genius; and it may be reasonably supposed that his copies did not fall much short of the originals, at least in matters that can be faithfully copied: and he shows very little art, either in his compositions or in the conduct of his pieces. With respect to the former, his plots are wondrous simple, very little varied, and very little interesting. The subject of almost every piece is a young man in love with a music-girl, desiring to purchase her from the procurer, and employing a favourite slave to cheat his father out of the price; and the different ways of accomplishing the cheat is all the variety we find. In some few of his comedies the story rises to a higher tone, the music-girl being discovered to be the daughter of a freeman, which removes every obstruction to a marriage between her and her lover. In the conduct of his pieces there is a miserable defect of art. Instead of unfolding the subject in the progress of the action, as is done by Terence, and by every modern writer, Plautus introduces a person for no other end but to explain the story to the audience. In one of his comedies, a household-god is so obliging as not only to unfold the subject, but to relate before-hand every particular that is to be represented, not excepting the catastrophe.

The Roman theatre, from the time of Plautus to that of Terence, made a rapid progress. Aristotle defines comedy to be "an imitation of light and trivial subjects, provoking laughter." The comedies of Plautus correspond accurately to that definition: those of Terence rise to a higher tone.

Nothing is more evident than the superiority of Terence above Plautus in the art of writing; and, considering that Terence is a later writer, nothing would appear more natural, if they did not copy the same originals. It may be owing to genius that Terence excelled in purity of language and propriety of dialogue; but how account for his superiority over Plautus in the construction and conduct of a play? It will not certainly be thought, that Plautus would imitate the worst constructed plays, leaving the best to those who should come after him. This difficulty does not seem to have occurred to any of the commentators. Had the works of Menander and of his cotemporaries been preserved, they probably would have explained the mystery; which for want of that light will probably remain a mystery for ever.

Homer has for more than 2000 years been held the prince of poets. Such perfection in an author who flourished when arts were far short of maturity, is truly wonderful. The nations engaged in the Trojan war are described by him as in a progress from the shepherd-state to that of agriculture. Frequent mention is made in the Iliad of the most eminent men being shepherds. Andromache, in particular, mentions seven of her brethren who were slain by Achilles as they tended their father's 9 Epopee.

father's flocks and herds. In that state, garments of woollen cloth were used; but the skins of beasts, the original clothing, were still worn as an upper garment: every chief in the Iliad appears in that dress. Such indeed was the simplicity of this early period, that a black ewe was promised by each chief to the man who would undertake to be a spy. In times of such simplicity, literature could not be far advanced; and it is a great doubt, whether there was at that time a single poem of the epic kind for Homer to imitate or improve upon. Homer is undoubtedly a wonderful genius, perhaps the greatest that ever existed; his fire, and the boldness of his conceptions, are inimitable. But in that early age, it would fall little short of a real miracle, to find such ripeness of judgment, and correctness of execution, as in modern writers are the fruits of long experience and progressive improvements during the course of many centuries. Accordingly, that Homer is far from being so ripe, or so correct, cannot escape the observation of any reader of taste and discernment. One striking particular is, his digressions without end, which draw our attention from the principal subject. Diomedes, for instance, meeting with Glaucus in the field of battle, and doubting, from his majestic air, whether he might not be an immortal, inquires who he was, declaring that he would not fight with a god. Glaucus lays hold of this very slight opportunity, in the very heat of action, to give a long history of his family. In the mean time, the reader's patience is put to a trial, and his ardour cools. Again, Agamemnon desiring advice how to resist the Trojans, Diomedes springs forward; but, before he offers advice, gives the history of all his progenitors, and of their characters, in a long train. And, after all, what was the sage advice that required such a preface? It was, that Agamemnon should exhort the Greeks to fight bravely. At any rate, was Diomedes so little known, as to make it proper to suspend the action at so critical a juncture, for a genealogical history? There is a third particular which justly merits censure; and that is, an endless number of minute circumstances, especially in the description of battles, where they are most improper. The capital beauty of an epic poem is, the selection of such incidents and circumstances as make a deep impression, keeping out of view every thing low or familiar. An account of a single battle employs the whole fifth book of the Iliad and a great part of the sixth: yet in the whole there is no general action; but unknown warriors whom we never heard of before, killed at a distance with an arrow or a javelin; and every wound described with anatomical accuracy. The whole seventeenth book is employed in the contest about the dead body of Patroclus, stuffed with minute circumstances, below the dignity of an epic poem. In such scenes the reader is fatigued with endless particulars; and has nothing to support him but the melody of Homer's versification.

10
Causes of the decline of the fine arts.

Having traced the progress of the fine arts toward maturity, in a summary way, the decline of these arts comes next in order. An art, in its progress toward maturity, is greatly promoted by emulation; and, after arriving at maturity, its downfal is not less promoted by it. It is difficult to judge of perfection but by comparison; and an artist, ambitious to outstrip his predecessors, cannot submit to be an imitator, but must strike out something new, which, in an art advanced to ripeness, seldom fails to be a degeneracy. This cause of the decline of the fine arts may be illustrated by various instances. The perfection of vocal music is to accompany passion, and to enforce sentiment. In ancient Greece, the province of music was well understood; which, being confined within its proper sphere, had an enchanting influence. Harmony at that time was very little cultivated, because it was of very little use; melody reaches the heart, and it is by it chiefly that a sentiment is enforced, or a passion soothed: harmony, on the contrary, reaches the ear only; and it is a matter of undoubted experience, that the most melodious airs admit but of very simple harmony. Artists, in later times, ignorant why harmony was so little regarded by the ancients, applied themselves seriously to its cultivation; and they have been wonderfully successful. But they have been successful at the expence of melody; which, in modern compositions, generally speaking, is lost amid the blaze of harmony. These compositions tickle the ear by the luxury of complicated sounds, but seldom make any impression on the heart. The Italian opera, in its form, resembles the Greek tragedy, from which it is evidently copied; but very little in substance. In the latter, music being made subservient to sentiment, the dialogue is nervous and sublime: in the former, the whole weight is laid on music; and the dialogue, devoid of sentiment, is weak and spiritless. Restless man knows no golden mean, but will be attempting innovations without end.—By the same ambition, architecture has visibly declined from its perfection. The Ionic was the favourite order when architecture was in its height of glory. The Corinthian order came next; which, in attempting greater perfection, has deviated from the true simplicity of nature: and the deviation is still greater in the Composite order. With respect to literary productions, the first essays of the Romans were very imperfect. We may judge of this from Plautus, whose compositions are abundantly rude, though much admired by his cotemporaries, being the best that existed at that time. The exalted spirit of the Romans hurried them on to the grand and beautiful; and literary productions of all kinds were in perfection when Augustus reigned. In attempting still greater perfection, the Roman compositions became a strange jumble of inconsistent parts: they were tumid and pompous; and, at the same time, full of antitheses, conceit, and tinsel wit. Every thing new in the fine arts pleases, though less perfect than what we are accustomed to; and, for that reason, such compositions were generally relished. We see not by what gradual steps writers, after the time of Augustus, deviated from the patterns that were before them; for no book of any moment after that time is preserved till we come down to Seneca, in whose works nature and simplicity give place to artificial thought and bastard wit. He was a great corrupter of the Roman taste; and after him nothing was relished but brilliant strokes of fancy, with very little regard to sentiment: even Virgil and Cicero made no figure in comparison. Lucan has a forced elevation of thought and style very difficult to be supported; and, accordingly, he sinks ofen into puerile reflections; witness his encomium on the river Po; which, says he, would equal the Danube, had it the

Art. ſame number of tributary ſtreams. Quintilian, a writer of true and claſſical taſte, who was protected and encouraged by Veſpaſian, attempted to ſtem the tide of falſe writing. His rhetoric is compoſed in an elegant ſtyle; and his obſervations contain every delicacy of the critical art. At the ſame time flouriſhed Tacitus, poſſeſſing a more extenſive knowledge of the nature of man than any other author, ancient or modern, if Shakeſpeare be not excepted. His ſtyle is original, conciſe, compact, and comprehenſive; and, in what is properly called his *hiſtory*, perfectly correct and beautiful. He has been imitated by ſeveral, but never equalled by any. Brutus is ſaid to be the laſt of the Romans for love of liberty: Quintilian and Tacitus may be ſaid to be the laſt of the Romans for literary genius. Pliny the Younger is no exception: his ſtyle is affected, turgid, and full of childiſh brilliancy. Seneca and Pliny are proper examples of writers who ſtudy ſhow more than ſubſtance, and who make ſenſe yield to ſound. The difference between theſe authors and thoſe of the Auguſtan age, reſembles the difference between Greek and Italian muſic. Muſic, among the Greeks, limited itſelf to the employment to which it is deſtined by nature, viz. to be the handmaid of ſenſe, to enforce, enliven, or ſweeten a ſentiment. In the Italian opera, the miſtreſs is degraded to be handmaid; and harmony triumphs, with very little regard to ſentiment.

Another great cauſe that precipitates the downfal of every fine art is deſpotiſm. The reaſon is obvious; and there is a diſmal example of it in Rome, particularly with regard to eloquence. We learn from a dialogue accounting for the corruption of the Roman eloquence, that in the decline of the art it became faſhionable to ſtuff harangues with impertinent poetical quotations, without any view but ornament merely; and this alſo was long faſhionable in France. It happened unluckily for the Romans, and for the world, that the fine arts were at their height in Rome, and not much upon the decline in Greece, when deſpotiſm put an end to the republic. Auguſtus, it is true, retarded their fall, particularly that of literature; it being the politic of his reign to hide deſpotiſm, and to give his government an air of freedom. His court was a ſchool of urbanity, where people of genius acquired that delicacy of taſte, that elevation of ſentiment, and that purity of expreſſion, which characteriſe the writers of his time. He honoured men of learning, admitted them to his table, and was bountiful to them. It would be painful to follow the decline of the fine arts in Rome to their total extirpation. The tyranny of Tiberius, and of ſubſequent emperors, broke at laſt the elevated and independent ſpirit of the brave Romans, reduced them to abject ſlavery, and left not a ſpark of genius. The ſcience of law is the only exception, as it flouriſhed even in the worſt of times: the Roman lawyers were a reſpectable body, and leſs the object of jealouſy than men of power and extenſive landed property. Among the Greeks alſo, a conquered people, the fine arts decayed; but not ſo rapidly as at Rome; the Greeks, farther removed from the ſeat of government, being leſs within the reach of a Roman tyrant. During their depreſſion, they were guilty of the moſt puerile conceits: witneſs verſes compoſed in the form of an ax, an egg, wings, and ſuch like. The ſtyle of Greek authors, in the reign of the emperor Adrian, is unequal, obſcure, ſtiff, and affected. Lucian is the only exception that may be made. Art.

We need ſcarce any other cauſe but deſpotiſm, to account for the decline of ſtatuary and painting in Greece. Theſe arts had arrived at their utmoſt perfection about the time of Alexander the Great; and from that time they declined gradually with the vigour of a free people; for Greece was now enſlaved by the Macedonian power. It may in general be obſerved, that when a nation becomes ſtationary in that degree of power which it acquires from its conſtitution and ſituation, the national ſpirit ſubſides, and men of talents become rare. It is ſtill worſe with a nation that is ſunk below its former power and pre-eminence; and worſt of all when it is reduced to ſlavery. Other cauſes concurred to accelerate the downfal of the arts mentioned. Greece, in the days of Alexander, was filled with ſtatues of excellent workmanſhip, and there being little demand for more, the later ſtatuaries were reduced to heads and buſts. At laſt the Romans put a total end both to ſtatuary and painting in Greece, by plundering it of its fineſt pieces; and the Greeks, expoſed to the avarice of the conquerors, beſtowed no longer any money on the fine arts.

The decline of the fine arts in Rome is by a *writer of taſte and elegance aſcribed to a cauſe different from any above-mentioned, a cauſe that overwhelms manhood as well as the fine arts wherever it prevails; and that is opulence, joined with its faithful attendants avarice and luxury. "In ancient times, (ſays he), when naked virtue had her admirers, the liberal arts were in their higheſt vigour; and there was a generous conteſt among men, that nothing of real and permanent advantage ſhould long remain undiſcovered. Democritus extracted the juice of every herb and plant; and, leſt the virtue of a ſingle ſtone or twig ſhould eſcape him, he conſumed a lifetime in experiments. Eudoxus, immerſed in the ſtudy of aſtronomy, ſpent his age upon the top of a mountain. Chryſippus, to ſtimulate his inventive faculty, thrice purified his genius with hellebore. To turn to the imitative arts: Lyſippus, while labouring on the forms of a ſingle ſtatue, periſhed from want. Myron, whoſe powerful hand gave to the braſs almoſt the ſoul of man and animals,—at his death found not an heir! Of us of modern times what ſhall we ſay? Immerſed in drunkenneſs and debauchery, we want the ſpirit to cultivate thoſe arts which we poſſeſs. We inveigh againſt the manners of antiquity; we ſtudy vice alone; and vice is all we teach. Where now is the art of reaſoning? Where aſtronomy? Where is the right path of wiſdom? What man now a-days is heard in our temples to make a vow for the attainment of eloquence, or for the diſcovery of the fountain of true philoſophy? Nor do we even pray for health of body, or a ſound underſtanding. One, while he has ſcarce entered the porch of the temple, devotes a gift in the event of the death of a rich relation; another prays for the diſcovery of a treaſure; a third for a miniſteral fortune. The ſenate itſelf, the exemplary preceptor of what is good and laudable, has promiſed a thouſand pounds of gold to the capitol; and, to remove all reproach from the crime of avarice, has offered a bribe to Jupiter himſelf. How ſhould we wonder that the art of painting has declined, when,

* Petronius Arbiter.

when, in the eyes both of the gods and men, there is more beauty in a mass of gold than in all the works of Phidias and Apelles."—In England, the fine arts are far from such perfection as to suffer by opulence. They are in a progress, it is true, toward maturity; but they proceed in a very slow pace.

There is still another cause that never fails to undermine a fine art in a country where it is brought to perfection, abstracting from every one of the causes above-mentioned. It is remarked a little above, that nothing is more fatal to an art or to a science than a performance so much superior to all of the kind as to extinguish emulation. This remark is exemplified in the great Newton, who, having surpassed all the ancients, has not left to his countrymen even the faintest hope of rivalling him; and to that cause is attributed the visible decline of mathematics in Great-Britain. The same cause would have been fatal to the arts of statuary and painting among the Greeks, even though they had continued a free people. The decay of painting in modern Italy is, probably, owing to the same cause: Michael Angelo, Raphael, Titian, &c. are lofty oaks that bear down young plants in their neighbourhood, and intercept from them the sunshine of emulation. Had the art of painting made a slower progress in Italy, it might have there continued in vigour to this day. Velleius Paterculus says judiciously, "Ut primo ad consequendos quos priores ducimus accendimur; ita, ubi aut præteriri aut æquari eos posse desperavimus, studium cum spe senescit; et quod adsequi non potest, sequi desinit: præteritoque eo in quo eminere non possimus, aliquid in quo nitamur conquirimus."

The decline of an art or science proceeding from the foregoing cause, is the most rapid where a strict comparison can be instituted between the works of different masters. The superiority of Newton above every other mathematician can be ascertained with precision: and hence the sudden decline of that science in Great Britain. In Italy a talent for painting continued many years in vigour, because no painter appeared with such superiority of genius as to carry perfection in every branch of the art. As one surpassed in designing, one in colouring, one in graceful attitudes, there was still scope for emulation. But when at last there was not a single perfection but what one or other master had excelled in, from that period the art began to languish. Architecture continued longer in vigour than painting, because the principles of comparison in the former are less precise than in the latter. The artist who could not rival his predecessors in an established mode, sought out a new mode for himself, which, though perhaps less elegant or perfect, was for a time supported by novelty.

11 Useful arts less subject to decline.

Useful arts will never be neglected in a country where there is any police; for every man finds his account in them. Fine arts are more precarious. They are not relished but by persons of taste, who are rare; and such as can spare great sums for supporting them are still more rare. For that reason, they will never flourish in any country, unless patronized by the sovereign, or by men of power and opulence. They merit such patronage, as one of the springs of government: and a capital spring they make, by multiplying amusements, and humanizing manners; upon which account they have always been encouraged by good princes.

12 Theory of the polite arts.

General Theory of the Polite Arts. The essence of the polite arts, as before observed, consists in *expression*. The end of all these arts is *pleasure*; whereas the end of the sciences is *instruction* and *utility*. Some of the polite arts indeed, as eloquence, poetry, and architecture, are frequently applied to objects that are useful, or exercised in matters that are instructive, as we shall show more particularly in their proper place; but in these cases, though the ground-work belongs to those sciences which employ the understanding, yet the expression arises from the inventive faculty. It is a picture that is designed by Minerva, to which the muses add the colouring, and the graces the frame. This union forms therefore the perfection of the art, according to that sententious and well known precept of Horace: *Omne tulit punctum, qui miscuit utile dulci.*

13 What arts so denominated.

Under the denomination, therefore, of Polite Arts, we comprehend, 1. Eloquence; 2. Poetry; 3. Music; 4. Painting; 5. Sculpture; 6. Graving; 7. Architecture; 8. Declamation; 9. Dancing. Particular descriptions of these arts are given under their respective names. This branch of the present article is intended as a general introduction to them; and, as such, will be occasionally referred to.

There is one very essential reflection, which it appears to us proper to make in the first place, on the polite arts in general. All the rules of the world are not sufficient to make a great poet, an able orator, or an excellent artist; because, the quality, necessary to form these, depends on the natural disposition, the fire of genius, which no human art can confer, but which is the pure gift of heaven. The rules, however, will prevent a man from being a bad artist, a dull orator, or a wretched poet; seeing they are the reflections of the greatest masters in those arts, and they point out the rocks which the artist should shun in the exercise of his talents. They are of use moreover, in facilitating his labours, and in directing him to arrive by the shortest and surest road to perfection. They refine, strengthen, and confirm, his taste. Nature abandoned to herself, has constantly something wild and savage. Art, founded on just and sagacious rules, gives her elegance, dignity, and politeness; and it is impossible to sacrifice properly to the graces, without knowing the incense that is pleasing to them.

14 Use of precepts.

15 *Beauty, genius, taste,* what.

Beauty is the object of all the polite arts. It is not, however, so easy, as it may seem, to give a clear and determinate idea of what we precisely mean by that term*. Many able writers, who have treated expressly on the subject, have shown that they were totally ignorant of what it was. It is one of those expressions that we comprehend immediately, that present us with a clear and precise idea, that leave a distinct impression on our minds, when it is simply written or pronounced; but which philosophers envelope in darkness, when they attempt to elucidate it by definitions and descriptions, and the more, as mankind have different ideas of beauty, their opinions and tastes being as various as their understandings and physiognomies. We may say, however, in general, that beauty results from the various perfections of which any object is susceptible, and which it actually possesses; and that the perfections which produce beauty consist principally in the

* See the article *Beauty*.

the agreeable and delightful proportions which are found, 1. Between the ſeveral parts of the ſame object; 2. Between each part and the whole together; 3. Between the parts and the end or deſign of the object to which they belong. *Genius*, or invention, is that faculty of the mind by which *beauty* is produced. † See *Taſte*. *Taſte* †, diſpoſition, or rather the natural ſenſation of the mind refined by art, ſerves to guide the genius in diſcerning, embracing, and producing, that which is beautiful of every kind. From whence it follows, that the general theory of the polite arts is nothing more than the knowledge of what they contain that is truly beautiful and agreeable; and it is this knowledge, this theory, which modern philoſophers call by the Latin name of *æſthetica*.

It ſhould be conſtantly remembered, that the eſſence of the polite arts conſiſts in expreſſion. This expreſſion lies ſometimes in the words, and ſometimes in the pen; ſometimes in ſounds and their harmony, and at others in corporeal attitudes; ſometimes in the pencil, or in the chiſel, and at others in the graver; ſometimes in a proper diſpoſition or judicious employment of the mechanic arts, and at others merely in their manner of acting. From whence ariſe thoſe arts that we have mentioned, and which are deſcribed in their order.

16 First general rule.

The general theory of the polite arts, or *eſthetics*, neceſſarily ſuppoſes, therefore, certain rules; but theſe general rules are of no great number. The firſt is, That whoever would devote himſelf the polite arts, ſhould above all things *conſult his genius*; diveſt himſelf of all ſelf-love; and examine if he be a true ſon of Apollo, and cheriſhed by the muſes: for

In vain, raſh author, doſt thou ſtrive to climb,
By lofty verſe, Parnaſſus' height ſublime,
If heaven does not by ſecret powers inſpire,
Or if thy natal ſtar darts not poetic fire.

17 Imagination, what.

This precept with regard to poetry in particular, is applicable to all the polite arts in general; for their moſt happy ſucceſs is founded on *imagination*. By this term we underſtand, in general, a faculty of the mind, a particular genius, a lively invention, a certain ſubtile ſpirit, which gives a facility in diſcovering ſomething new. But it is neceſſary alſo to preſcribe

18 Novelty and Invention.

juſt bounds to this term *new*, which muſt not be here taken in an abſolute ſenſe. Solomon wiſely remarks, that, even in his time, *there was nothing new under the ſun*. In fact, all that exiſts, and all that is capable of being diſcovered in the known world, has already been diſcovered. The fine arts in their imitations of nature, in their expreſſions, can borrow images, figures, compariſons, from thoſe things only that exiſt and are known. As there have been from the beginning of the world to our days, millions of authors in each of the polite arts, almoſt all the poſſible combinations of the various ſubjects have been produced by their lively imaginations; and when we hear the ignorant part of mankind talk of a work of wit or of art *that is entirely new*, that offers ideas which were before utterly unknown, that had never entered into the brain of any other man, we ſhould refer ſuch aſſertions to the claſs of popular errors; and reflect on thoſe ſtories we every day hear of certain empirics, who pretend to be alone poſſeſſed of marvellous methods of cure by means of ſimples; as if there were any plant, any ſtalk of graſs that grows in our world, that can have eſcaped the reſearches of botaniſts. But the novelty, of which we here ſpeak, conſiſts in the ingenious uſe of combinations of all the various objects of nature, that are new, happy, and agreeable, that have not yet been exhauſted, and which appear even to be inexhauſtible, and of the uſe which the artiſt makes of all new diſcoveries, which he turns to his advantage, by a judicious application. Invention therefore ſuppoſes a conſiderable fund of preliminary knowledge, ſuch as is capable of furniſhing ideas and images, to form new combinations. But there is no art by which invention itſelf can be produced; for that, as we have already ſaid, is the gift of heaven; and it is an endowment which we cannot even make uſe of whenever we pleaſe. We would rather ſay, therefore, that invention conſiſts in producing, in works of genius, *that which is unexpected;* an object, a harmony, a perfection, a thought, an expreſſion, of which we had no idea, that we could not foreſee, nor hope to find, where the artiſt has ſo happily placed it, and where we perceive it with delight. This idea appears applicable to ſuch of the polite arts as affect the mind by the hearing as well as by the ſight; and it is a matter that is highly eſſential. 19

The ſecond rule is, That every artiſt ought inceſſantly to labour in the improvement of his *taſte;* in acquiring that ſenſible, refined, and clear diſcernment, by which he will be enabled to diſtinguiſh the real beauties in each object, the ornaments that are agreeable to it, and the proportions and relations that ſubſiſt among the ſeveral parts: and by this faculty, he will be regulated in the employment of his natural talents. This labour conſiſts not only in the profound reflections he will make on the properties of objects as they relate to the fine arts, but alſo in a conſtant, aſſiduous ſtudy of the grand models of beauty. 20

2d Rule, Improvement of taſte.

The third rule to be obſerved in the practice of the polite arts, is *the imitation of nature*. Every object in the univerſe has its peculiar nature, of which the artiſt ſhould never loſe ſight in his manner of treating it. In vain will he otherwiſe ornament his work with the moſt refined and moſt brilliant ſtrokes; for, if nature be not juſtly imitated, it will for ever remain imperfect. The ſublime Homer has ſometimes ſinned againſt this rule: for, as the gods have a nature peculiar to themſelves, it cannot be a juſt imitation when we attribute to them paſſions that are ſcarce pardonable in mortals, and make them frequently converſe in a language that is at once vulgar and ridiculous. It was not to imitate nature, to put into the mouth of a hero, at the moment of a deciſive battle, an harangue that muſt become tedious by its exceſſive length, and which certainly could not have been heard by the thouſandth-part of a numerous army: but we have already touched upon ſome of the faults that are ſtrewed over the poems of that great man; to multiply or dwell upon them would be ungrateful. We muſt, however, obſerve that this imitation of nature, which appears at firſt view ſo ſimple and ſo eaſy, is of all things the moſt difficult in practice; and that it requires a diſcernment ſo ſagacious, and an expreſſion ſo happy, as is rarely beſtowed by heaven on mortal man. 21

3d, Imitation of nature.

Perſpicuity forms the fourth rule of expreſſion. In all the fine arts, in general, an obſcure, perplexed, ambiguous, and elaborate expreſſion, is always bad. The

4th, Perſpicuity.

true ſtriking beauty muſt be manifeſt and perceptible to the moſt ignorant of mankind as well as the moſt learned. Thoſe are ever falſe or inferior beauties that have occaſion for a covering, a kind of veil that may make them appear greater than they really are: true beauty wants no veil, but ſhines by its native luſtre. From the union of the true imitation of nature with perſpicuity of expreſſion, ariſes that *truth* which is ſo eſſential in the productions of the fine arts.

22
5th, Elevation of ſentiment.

In all the polite arts, and in all the ſubjects they embrace, there muſt neceſſarily reign an elevation of ſentiment, that expreſſes each object in the greateſt perfection of which it is ſuſceptible; that imitates nature in her moſt exalted beauty. This makes the fifth general rule. The deſign of the fine arts being to excite pleaſure by the expreſſion of that which is beautiful, every artiſt ſhould raiſe himſelf above the ſubject; and, chooſing the moſt favourable light wherein to place it, ſhould there embelliſh it with the greateſt, moſt noble, and beautiful ornaments, that his own genius can ſuggeſt; ſtill, however, obſerving a ſtrict imitation of nature.

23
6th, The ſublime to be endeavoured after.

From the obſervation of theſe two laſt rules reſults the *ſublime*, which is the union of the greateſt perſpicuity with the ſtricteſt truth and moſt exalted elevation poſſible. It is neceſſary to remark here, that the moſt ſimple and common ſubjects are ſuſceptible of a ſublime that is agreeable to their nature. An idyl or landſcape may be as ſublime in their kinds as an epic poem or a hiſtory-piece. When Moſes begins the book of Geneſis with theſe words, *In the beginning God created the heaven and the earth;* or when he tells us, that God ſaid, *Let there be light, and there was light;* theſe expreſſions are ſublime in the higheſt degree, becauſe they are perfectly clear, true, and elevated. Every author ſhould therefore endeavour after the ſublime* in every ſubject that he undertakes; and this makes the ſixth and laſt general rule in the practice of the polite arts. But if he cannot attain to this, it is, however, indiſpenſably neceſſary that he conſtantly make uſe of expreſſions that are *noble and refined*. Every thing that is *low*, *indecent*, or *diſagreeable*, is naturally repugnant to the ſublime, and ought to be for ever baniſhed from all works that proceed from the noble and liberal arts.

* See the article Grandeur *and Sublimity*.

Art is alſo an appellation given to ſeveral ſuperſtitious practices, as, *St Anſelhm's art*, *St Paul's art*, &c.

Art and Part, in Scots law. See Accessory.

ARTA, by ſome called *Larta*, a town of Lower Albania, in Turkey in Europe, with a Greek archbiſhop's ſee. It is a pretty large town, and contains about 7 or 8000 inhabitants, Greeks and Turks, but the former are the moſt numerous. The cathedral has as many windows and doors as there are days in the year. It is ſupported by above 2000 marble pillars; and was built by Michael Ducas Commeno emperor of Conſtantinople, as appears by an inſcription over the great door. It carries on a conſiderable trade, particularly in tobacco and furs. E Long. 31. 30. N. Lat. 39. 28.

ARTABA, an ancient meaſure of capacity uſed by the Perſians, Medes, and Egyptians.

The Perſian artaba is repreſented by Herodotus as bigger than the Attic medimnus by three Attic choenixes: from which it appears that it was equal to $6\frac{3}{4}$ Roman modii, conſequently that it contained $166\frac{2}{3}$ pounds of wine or water, or $126\frac{2}{3}$ pounds of wheat. The Egyptian artaba contained five Roman modii, and fell ſhort of the Attic medimnus by one modius; conſequently held $133\frac{1}{3}$ pounds of water or wine, 100 pounds of wheat, or 60 of flour.

ARTABANUS, the name of ſeveral kings of Parthia. See Parthia.

ARTABAZUS, the ſon of Pharnaces, commanded the Parthians and Choraſmians in the famous expedition of Xerxes. After the battle of Salamis, he eſcorted the king his maſter to the Helleſpont with 60,000 choſen men; and after the battle of Platæa, in which Mardonius engaged contrary to his advice, he made a noble retreat, and returned to Aſia with 40,000 men under his command.

ARTAXATA, *orum*, the royal reſidence and metropolis of Armenia Major (Strabo, Pliny, Juvenal); and built according to a plan of Hannibal, for king Artaxias, after whom it was called. It was ſituated on an elbow of the river Araxes, which formed a kind of peninſula, and ſurrounded the town like a wall, except on the ſide of the Iſthmus, but this ſide was ſecured by a rampart and ditch. This town was deemed ſo ſtrong, that Lucullus, after having defeated Tigranes, durſt not lay ſiege to it; but Pompey compelled him to deliver it up without ſtriking a blow. It was then levelled with the ground; but the Armenians have a tradition, that the ruins of it are ſtill to be ſeen at a place called *Ardachat*. Sir John Chardin ſays, that it has the name of *Ardachat* from Artaxias, whom in the Eaſt they call *Ardechier*. Here are the remains of a ſtately palace which the Armenians take to be that of Tiridates who reigned in the time of Conſtantine the Great. One front of this building is but half ruined, and there are many other fine antiquities which the inhabitants call *Tact. Tradat*, that is, the throne of Tiridates. Tavernier alſo mentions the ruins of Artaxata between Erivan and mount Ararat, but does not ſpecify them. The ancient geographers mention another city of the ſame name, likewiſe ſituated on the Araxes, but in the northern part of Media, known among the ancients by the name of *Atropatia*.

ARTAXERXES, the name of ſeveral kings of Perſia. See Persia.

ARTEDIA: A genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The involucra are pinnatifid; the floſcules of the diſc are maſculine; and the fruit is hiſpid with ſcales.—There is but one ſpecies, the ſquamata with ſquamoſe ſeeds, a native of the Eaſt: Rewvolf found it growing on mount Libanus. It is an annual plant, whoſe ſtalks riſe about two feet high, ſending out a few ſide branches, which are garniſhed with narrow compound leaves reſembling thoſe of dill; the extremity of the ſtalk is terminated by a large umbel of white flowers, compoſed of five unequal petals. Theſe are ſucceeded by roundiſh compreſſed fruit, each having two ſeeds, whoſe borders are ſcaly.

ARTEMIDORUS, famous for his Treatiſe on Dreams. He was born at Epheſus, but took upon him the ſurname of *Daldianus* in this book, by way of reſpect to his mother's country, Daltis. He ſtyled himſelf

Artemisia. ſelf *the Epheſian* in his own performances. He not only bought up all that had been written concerning the explication of dreams which amounted to many volumes: but he likewiſe ſpent many years in travelling, in order to contract an acquaintance with fortune-tellers: he alſo carried on an extenſive correſpondence with all the people of this ſort in the cities and aſſemblies of Greece, Italy, and the moſt populous iſlands; collecting at the ſame time all the old dreams, and the events which are ſaid to have followed them. The work which he wrote on dreams conſiſted of five books: the firſt three were dedicated to one Caſſius Maximus; and the laſt two to his ſon, whom he took a good deal of pains to inſtruct in the nature and interpretation of dreams. This work, though filled with frivolous obſervations, contains ſome things that are intereſting. It was firſt printed in Greek at Venice in 1518; and Rigaltius publiſhed an edition at Paris, in Greek and Latin, in 1603, and added ſome notes. Artemidorus wrote alſo a treatiſe upon Auguries, and another upon Chiromancy; but they are not exſtant. He lived under the emperor Antoninus Pius.

ARTEMISIA, wife of Mauſolus king of Caria, has immortalized herſelf by the honours which ſhe paid to the memory of her huſband. She built for him in Halicarnaſſus a very magnificent tomb, called the *Mauſoleum*, which was one of the ſeven wonders of the world, and from which the title of *Mauſoleum* was afterwards given to all tombs remarkable for their grandeur; but ſhe died of regret and ſorrow before the Mauſoleum was finiſhed. She appointed panegyrics to be made in honour of him, and propoſed a prize of great value for the perſon who ſhould compoſe the beſt. He died about the end of the 106th Olympiad, 351 years before the Chriſtian æra.

ARTEMISIA, queen of Caria, and the daughter of Ligdamis, marched in perſon in the expedition of Xerxes againſt the Greeks, and performed wonders in the ſea-fight near Salamis, 480 years before the Chriſtian æra. Being purſued by an Athenian veſſel, ſhe attacked one of the Perſian ſhips, commanded by Demaſithymus, king of Calyndus, her enemy, and ſunk it; on which the Athenians, thinking that her ſhip was on the ſide of the Greeks, ceaſed their purſuit: but Xerxes was the principal perſon impoſed upon in this affair; for believing ſhe had ſunk an Athenian veſſel, he declared, that "the men had behaved like women, and the women like men." Xerxes intruſted her with the care of the young princes of Perſia, his ſons, when, agreeably to her advice, he abandoned Greece, in order to return to Aſia. Theſe great qualities did not ſecure her from the weakneſs of love: ſhe was paſſionately fond of a man of Abydos, whoſe name was Dardanus, and was ſo enraged at his neglect of her, that ſhe put out his eyes while he was aſleep. The gods, in order to puniſh her for this, inſpired her with a ſtill ſtronger paſſion for him; ſo that the oracle having adviſed her to go to Leucas, which was the uſage of deſperate lovers, ſhe took the leap from thence, and was interred in that place.—Many writers confound this Artemiſia with the former, the wife of Mauſolus.

ARTEMISIA, *Mugwort, Southernwood,* and *Wormwood:* A genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method rank under the 49th order, *Compoſitæ-nucamentaceæ*. The receptacle is either naked, or a little downy; it has no pappus; the calyx is imbricated with roundiſh ſcales; and the corolla has no radii.—The

Species are 23; of which the moſt noted are the following. 1. The vulgaris, or common mugwort, grows naturally on banks and by the ſides of foot-paths in many parts of Britain; ſo is ſeldom admitted into gardens, where it would prove a troubleſome weed, as it ſpreads very faſt by its creeping roots. It flowers in June, at which time the plant is ready for uſe. 2. The dracunculus, or tarragon, which is frequently uſed in ſallads, eſpecially by the French, is a very hardy plant, and ſpreads greatly by its creeping roots. 3. The abrotanum, or ſouthernwood, which is kept in gardens for the ſake of its agreeable ſcent, is a low ſhrub, ſeldom riſing more than three or four feet high, ſending out lateral ſhruby branches, growing erect, garniſhed with five briſtly leaves, having an agreeable ſcent when bruiſed: the flowers are produced in ſpikes from the extremity of the branches; but unleſs the autumn proves warm, they ſeldom open in England. 4. The ſantonicum produces the ſemen ſantonicum, which is much uſed for worms in children. It grows naturally in Perſia, from whence the ſeeds are brought to Europe. It hath the appearance of wild mugwort; the branches are ſlender, erect, and garniſhed with linear winged leaves, and terminate by recurved ſlender ſpikes of flowers which have naked receptacles. 5. The artemiſia maritima, or ſea-wormwood, grows naturally on the ſea-coaſts in moſt parts of Britain, where there are ſeveral varieties, if not diſtinct ſpecies, to be found. Theſe are low under ſhrubs, moſt of which creep at the root, by which they multiply greatly in their natural ſituation, but when tranſplanted into gardens ſeldom thrive ſo well. 6. The pontica, or pontic wormwood, commonly called *Roman wormwood*, is a low herbaceous plant, whoſe ſtalks die in autumn, and new ones appear in the ſpring. Theſe are garniſhed with finely-divided leaves, whoſe under-ſides are woolly: and the upper part of the ſtalks are furniſhed with globular flowers which nod on one ſide, having naked receptacles. Theſe appear in Auguſt, but are rarely ſucceeded by ſeeds in Britain. 7. The abſinthium, or common worm-wood, grows naturally in lanes and uncultivated places, and is too well known to require any particular deſcription. 8. The arboreſcens, or tree-wormwood, grows naturally in Italy and the Levant near the ſea. It riſes, with a woody ſtalk, ſix or ſeven feet high, ſending out many ligneous branches, garniſhed with leaves ſomewhat like thoſe of the common wormwood, but more finely divided, and much whiter. The branches are terminated by ſpikes of globular flowers in the autumn, which are ſeldom ſucceeded by ſeeds in Britain.

Culture. The ſouthernwood is propagated by ſlips or cuttings planted in a ſhady border about the beginning of April, obſerving to water them duly in dry weather. In this border they may remain till the following autumn, when they ſhould be tranſplanted, either into pots or thoſe parts of the garden where they are to remain. The ſantonicum is likewiſe propagated by ſlips: but the plants ſhould be placed in a dry ſoil and ſheltered ſituation, where they will endure the cold of

Artemisia. of our ordinary winters pretty well; though it will be proper to have a plant or two in pots, which may be ſheltered under a common hot-bed frame in winter, to preserve the ſpecies. The true wormwood is eaſily propagated in the ſame manner. The cuttings muſt be planted in a ſhady border, and duly watered during the ſummer ſeaſon, in which caſe they will take root freely. In autumn, ſome of the young plants ſhould be potted, that they may be ſheltered in winter; the others may be planted in a warm border, where they will live, provided the winter proves favourable. The other ſorts ſpread by their creeping roots; and require no culture, as they are very hardy, and will thrive any where.

Medicinal Uſes. The ſeeds of the ſantonicum are ſmall, light, chaffy, compoſed as it were of a number of thin membranous coats, of a yellowiſh colour, an unpleaſant ſmell, and a very bitter taſte. They are celebrated for anthelmintic virtues (which they have in common with other bitters), and are ſometimes taken in this intention, either along with molaſſes or candied with ſugar. They are not very often met with genuine in the ſhops. The leaves of the ſea, common, and Roman wormwoods, are uſed as ſtomachics, but are all very diſagreeable: the Roman is the leaſt ſo, and therefore is to be preferred; but the other two kinds are generally ſubſtituted in its place. The diſtilled oil of wormwood is ſometimes made uſe of to rub on the belly as a cure for worms.

The leaves of the vulgaris, or common mugwort, have a light aromatic ſmell, and an herbaceous bitteriſh taſte. They were formerly celebrated as uterine and antihyſteric: an infuſion of them is ſometimes drank, either alone or in conjunction with other ſubſtances, in ſuppreſſion of the menſtrual evacuations. This medicine is certainly a very mild one, and conſiderably leſs hot than moſt others to which theſe virtues are attributed. In ſome parts of Britain, mugwort is of common uſe as a pot-herb. It is now, however, very little employed in medicine; and it is probably with propriety that the London College have rejected it from their pharmacopœia.

The moxa, ſo famous in the eaſtern countries for curing the gout by burning it on the part affected, is the lanugo or down growing on the under ſide of the leaves of a ſpecies of mugwort, ſuppoſed to be the ſame with the common ſort. From ſome dried ſamples of this plant which were brought into England Mr Miller reckons them to be the ſame, differing only in ſize; in which the Eaſt Indian kind is inferior to it. He ſuppoſes that the lanugo of our mugwort would be equally efficacious. But according to Abbé Groſier, "the leaves are more deeply indented than thoſe of the common kind; it is alſo ſofter, and of a more ſilky texture. The ancient Chineſe made great uſe of it in medicine. In all the northern provinces, the principal remedy for moſt diſeaſes conſiſted in making deep punctures in the body, upon which ſmall balls of the down of this plant were burnt. Theſe punctures were made with needles of gold or ſteel, without drawing blood; and all the ſkill required in the phyſician, was to determine their number and depth, and where it was neceſſary to make them. It was neceſſary that the down of the mugwort ſhould be very old; and, as every kind of fire was not proper for lighting theſe ſalutary balls, they employed mirrors made of ice or metal. "They cauſed the water to freeze (ſays the ancient text) in a round convex veſſel; and the ice being preſented to the ſun, collected its rays, and ſet fire to the down of the plant." The literati are not at preſent agreed whether the ſecret of curing diſeaſes by punctures be preſerved; but theſe downy balls are ſtill uſed inſtead of cupping-glaſſes in apoplectic and lethargic caſes. Girdles made of this down are alſo recommended for the ſciatica, and thoſe afflicted with the rheumatiſm in their legs are adviſed to quilt their ſtockings with it. The mugwort deſtined for this purpoſe is gathered only in autumn; and care muſt be taken to pick that which has the ſhorteſt and ſofteſt down.

Hiſt. of China.

"In China, the juice of the common mugwort, when green, is uſed to ſtop ſpitting of blood: and the ſeeds are employed for the ſame purpoſe. The doſe of the latter is divided into two parts; one of which is reduced to aſhes, and put into water in which the other has been boiled. Theſe aſhes, it is ſaid, when taken as ſnuff, immediately ſtop bleedings of the noſe. The Chineſe preſcribe this plant alſo with ſucceſs for dyſenteries which proceed from weakneſs, and for pleuriſies, and diſorders of the ſtomach. An infuſion of the ſtalks and buttons of mugwort is recommended to old people inſtead of tea.—Mugwort was formerly conſidered there as a powerful preſervative againſt witchcraft. The ancient books relate, that, in the third century of the Chriſtian æra, it was cuſtomary for people to gather this plant before ſun-riſe, and to ſuſpend it afterwards over their doors. The poets of the ſeventh century mention this cuſtom, and deſcribe the manner in which the ſtreets of the capital were ornamented with it on the fifth day of the fifth moon; that is to ſay, about midſummer.

"Of a ſpecies which bears prickles on the edges of its leaves, the leaves, when dried, are beaten with a wooden bat until the ſoft part is entirely ſeparated from the fibres; and, after they have been dipped in water mixed with ſaltpetre, they are uſed for tinder; no other kind is known at Pe-king; and it is equal to that of Europe. It appears that the ancient Chineſe made uſe of the ſoft part of this plant for quilting, for making mattreſſes, and even for cloth. They alſo employed it for manufacturing a kind of paper."

Artemiſia, Artemiſium.

ARTEMISIUM (anc. geog.), a promontory on the north-eaſt of Eubœa (called *Leon* and *Cale Acte* by Ptolemy), memorable for the firſt ſea-engagements between the Greeks and Xerxes.

The Grecian fleet was ſtationed in the harbour; while that of the Perſians, too numerous for any harbour to contain, had anchored in the road that extends between the city of Caſtanæa and the promontory of Sepias, on the coaſt of Theſſaly.

The firſt line of their fleet was ſheltered by the coaſt of Theſſaly; but the other lines, to the number of ſeven, rode at anchor, at ſmall intervals, with the prows of the veſſels turned to the ſea. When they adopted this arrangement, the waters were ſmooth, the ſky clear, the weather calm and ſerene: but on the morning of the ſecond day after their arrival on the coaſt, the ſky began to lour; the appearance of the heavens grew threatening and terrible; a dreadful ſtorm ſucceeded; and for three days raged with unabating fury. Four hundred

hundred galleys were destroyed by its violence, besides a vast number of storeships and transports. Eight hundred ships of war, however, besides innumerable vessels of burthen, sailed into the Pegasean bay, and anchored in the road of Apheté, which, at the distance of a few miles, lies directly opposite to the harbour of Artemisium.

From *Gillies's History of Greece.*

The Grecians had posted centinels on the heights of Euboea to observe the consequences of the storm, and to watch the motion of the enemy. When informed of the disaster which had befallen them, they poured out a joyous libation, and sacrificed, with pious gratitude, to "Neptune the Deliverer."

The Persians, however, having recovered from the terrors of the storm, prepared for battle; and as they entertained not the smallest doubt of conquering, they detached 200 of their best sailing vessels round the isle of Euboea, to intercept the expected flight of the enemy through the narrow Euripus.

About sun-set the Grecian fleet approached in a line; and the Persians met them with the confidence of victory, as their ships were still sufficiently numerous to surround those of their opponents. At the first signal the Greeks formed into a circle, at the second they began the fight. Though crowded into a narrow compass, and having the enemy on every side, they soon took 30 of their ships, and sunk many more. Night came on, accompanied with an impetuous storm of rain and thunder; the Greeks retired into the harbour of Artemisium; the enemy were driven to the coast of Thessaly.

By good fortune, however, rather than by design, the greatest part of the Persian fleet escaped immediate destruction, and gained the Pegasean bay; but the ships ordered to sail round Euboea met with a more dreadful disaster. They were overtaken by the storm, after they had adventured further from the shore than was usual with the wary mariners of antiquity. Clouds soon intercepted the stars, by which alone they directed their course; and after continuing during the greatest part of the night the sport of the elements, they all perished miserably amidst the shoals and rocks of an unknown coast.

The morning arose with different prospects and hopes to the Persians and the Greeks. To the former it discovered the extent of their misfortunes; to the latter it brought a reinforcement of 53 Athenian ships. Encouraged by this favourable circumstance, they determined again to attack the enemy, at the same hour as on the preceding day, because their knowledge of the coast and their skill in fighting their ships rendered the dusk peculiarly propitious to their designs. At the appointed time, they sailed towards the road of Apheté; and having cut off the Cilician squadron from the rest, totally destroyed it, and returned at night to Artemisium.—The Persian commanders being deeply affected with their repeated disasters, but still more alarmed at the much dreaded resentment of their king, they determined to make one vigorous effort for restoring the glory of their arms. By art and stratagem, and under favour of the night, the Greeks had hitherto gained many important advantages. It now belonged to the Persians to choose the time for action. On the third day at noon, they sailed forth in the form of a crescent, which was still sufficiently extensive to infold the Grecian line. The Greeks, animated by former success, were averse to decline any offer of battle; yet it is probable that their admirals, and particularly Themistocles, would much rather have delayed it to a more favourable opportunity. Rage, resentment, and indignation, supplied the defect of the Barbarians in skill and courage. The battle was longer, and more doubtful, than on any former occasion; many Grecian vessels were destroyed, five were taken by the Egyptians, who particularly signalized themselves on the side of the Barbarians, as the Athenians did on that of the Greeks. The persevering valour of the latter at length prevailed, the enemy retiring, and acknowledging their superiority, by leaving them in possession of the dead and the wreck. But the victory cost them dear; since their vessels, particularly those of the Athenians, were reduced to a very shattered condition; and their great inferiority in the number and size of their ships, made them feel more sensibly every diminution of strength.

Artemisium, a town of Oenotria, (Stephanus): now *S. Agatha*, in the Hither Calabria, on the river Pisaurus, or la Foglia, distant eight miles from the Tuscan sea.—Another of the Contestani, in Spain, (Strabo); otherwise called *Dianium:* now *Denia*, on the sea-coast of Valencia.

ARTERIOTOMY, the opening an artery, with design to procure an evacuation of blood. See Surgery.

ARTERY, in anatomy, a conical tube or canal which conveys the blood from the heart to all parts of the body. See Anatomy, n° 117,—125.

ARTHRITIS, in medicine, the gout. See the *Index* subjoined to Medicine.

ARTHRODIA, in natural history, a genus of imperfect crystals, found always in complex masses, and forming long single pyramids, with very short and slender columns.

Arthrodia, in anatomy, a species of articulation, wherein the flat head of one bone is received into a shallow socket in the other. The humerus and scapula are joined by this species of articulation.

ARTHUR, the celebrated hero of the Britons, is said to have been the son of Uther Pendragon king of Britain, and to have been born in 501. His life is a continued scene of wonders. It is said that he killed four hundred and seventy Saxons with his own hand in one day; and after having subdued many mighty nations, and instituted the order of the Knights of the Round Table, died A. D. 542, of wounds which he received in battle. The most particular detail of his story and his exploits is that given by Geffroy of Monmouth: but the probable is there so blended with the mavellous and the extravagant, that not only the truth of the whole, but even the reality of Arthur's existence has been called in question.

In this controversy, Mr Whittaker has taken much pains to vindicate the existence, and discriminate between the real and the fabulous transactions, of the British worthy. "Many of the actions (he observes) attributed to Arthur by the Welch chronicles of Britain, are as absurd in themselves as they are spurious in their authority. Written, as those narratives were many centuries after the facts, and being merely the authentic accounts of Arthur, embellished with the fictions and distorted by the perversions of folly; they are inconsistent equally with the state of the times, and the

Arthur. the history of the continent and the island. And the ignorance of the forgers, and the credulity of their abettors, can be equalled only by the injudiciousness and incredulity of the opponents to both. If some accounts of Arthur and Cunobeline in these histories be certainly spurious, others are as certainly genuine. And the relations of Suetonius, Dio, and Nennius, are not to be rejected, because of the falsehoods which imposture has engrafted upon them, and absurdity admitted with them.

History of Manchester, vol. ii. 4to. edit. p. 31. *et seq.*

"The existence of Arthur is evinced by that of the fables, which have at once annihilated his actions and his name with the misjudging critic. And the reasoners own arguments really turn against himself, and demonstrate the point which they were intended to disprove. The annals of Wales have long laboured in Arthur's commendation. The highlanders have long had a poetical history of his exploits in their own language. The whole island is in traditionary possession of his character, and 600 or 700 places within it are still distinguished by his name.

"The genuine actions of the chief are mentioned by his own historians, with a modesty and conciseness that is no bad argument of the truth, and with a particularity of time and place that is a good evidence of the facts. They are noticed by men whom the death of the hero had exempted from all temptation to flattery: they are recited by persons, whom a proximity to the times had precluded from all possibility of mistake: and they are attested by the best historical authority, writers who lived cotemporary with him, authors who conversed with his warriors, and historians that wrote within a few years after him. He is spoken of as the honourable father of the British heroes by the aged Llomarch, a writer actually cotemporary with him, and some time resident at his court. One of his greater actions is incidentally recorded by Taliesin, an historical bard living under Maelgwn Gwined, who was a sovereign among the Britons in the days of Arthur, Gildas, and Llomarch. Another of his considerable exploits is casually intimated by Myrdhin Wyhlt or Merlinus Caledonius, who complains of the severe treatment which he himself received from Rydderch Hael, a king cotemporary with Urien Reged, and engaged with him in a war against the Saxons on the death of Ida in 560. And all his actions are particularly recited by Nennius.

"In the *Historia Britonum* of this last author, Arthur's victories over the Saxons are thus recorded. The first battle was fought at the mouth of the river, which is denominated *Glem*. The second, third, fourth, and fifth, were upon another river, that is called *Duglas*, and lies in the region Linuis. The sixth was on a stream, which bears the appellation of *Bassas*. The seventh was in the wood of Celidon, that is, in Cat Coit Celidon. The eighth was at Castle Gunnion. And the ninth was at the city of the Legion. The tenth was on the bank of the river Ribroit; the eleventh at the hill AgnedCathregonion; and the twelfth at Mount Badon. These twelve battles of Arthur are described to us in the same manner as Vortimer's three. Only the general facts are mentioned, and only the common names of places are recited, in both. And from the whole air and aspect of the history, the remarkable conciseness with which the notices are given, and the great ease with which the places are pointed out, the detail appears to have been drawn up at the distance only of a few years from the transactions, and when these little references were sufficiently understood."

Mr. Whittaker proceeds to ascertain the scenes of Arthur's battles; after which he gives a relation of them with a surprising particularity. A severe critic might be apt to say, as Dr. Kippis observes, that it requires all our faith in the author's judgment, as well as in his ingenuity and learning, not to suspect that he sometimes allows too much scope to fancy and conjecture. However, the whole of what he hath advanced is singularly curious, and deserves peculiar attention and consideration. And no one can help admiring the penetration with which he hath formed such a regular detail of facts, from the combined aid of history, romance, and tradition. According to Mr Whittaker, Arthur's principal exploits were against the northern Saxons, whilst he was only prince of the Silures, and Ambrosius was the dictator or pendragon of the Britons. "In a series probably of five campaigns, and in a succession certainly of eleven victories, this great commander had repelled the Saxons from the north of Flavia, dislodged them from all Maxima, and dispossessed them of all Valentia. And these were successes so unchequered with misfortunes, so great in themselves, and so beneficial to the public, that the name of Arthur claims the first rank in the list of military, and the better one of patriot, heroes." The twelfth battle of Arthur was fought in the south of England, after he was elected to the pendragonship, against Cerdic the Saxon. "This (says Mr Whittaker) was a most extraordinary victory, and completes the circle of Arthur's military glories." In the author's account of this prince's conduct in peace, he asserts, that "Arthur saw that an appointment was wanted, which should at once be a more regular and more honourable signature of merit; by the certainty of the honour and the greatness of the dignity, call out all the worth of all the worthy in the nation; and collect it round the throne of the pendragon. Accordingly he established a military order. It was the first that had ever been instituted in the island; and it has since been imitated by all the nations on the continent. By means of this association, Arthur raised among the provincials a general glow of ingenuous heroism, the first spirit of chivalry that ever appeared in Europe; that manly and honourable gallantry of soul, which has made him and his worthies the subject of romantic histories over all the west of it. By this, and this alone, could he have been what history represents him, the Reverend Father of the British Heroes in general, even to the conclusion of the sixth century, and nearly the middle of the seventh. The order naturally survived its founder. And the members of it were denominated the Warriors of Arthur, though the persons were born half a century after his death." Mr Whittaker goes on to inform us, that, under the prudent management of Arthur for 20 years together, a fair prospect dawned upon the Britons, and long scenes of future glories opened to their imaginations. "But the gay vision was destroyed at once by the commencement of a civil war. Many towns still remained in ruins, the memorial of the former wars, and the disgrace of the present. The diffused spirit of chivalry was turned up-

Ibid. p. 43—64.

on the nation, and heroiſm became the tool of diſſenſion. And the dreadful combination of civil evils was begun and conſummated, at once, by the death of the renowned Arthur in battle. Thus died the incomparable hero in 542."

To theſe obſervations it may not be improper to add the following account of the diſcovery of Arthur's tomb, which appears to be tolerably well authenticated. Henry II. who was the firſt of the Plantagenet line, being, in the laſt year of his reign, at Pembroke, and hearing there a Welſh bard ſinging to his harp the ſtory of Arthur, concluding with an account of his death and burial in the church-yard of Glaſtenbury between two pyramids; the king inſtantly gave orders that the matter ſhould be enquired into, and the body dug up. This was done as the king directed; and at the depth of ſeven feet was found a vaſt ſtone, whereon was faſtened a leaden croſs, with this inſcription on the inſide: *Hic Jacet Sepultus Inclytus Rex Arturius in Inſula Avalonia*; i. e. "Here lies the famous King Arthur, buried in the iſle of Avalon." Digging ſtill lower, they found the king's body in the trunk of a tree, his beautiful queen lying by him, with long flowing hair, in colour bright as gold, which however ſunk into duſt when touched. The king's bones were very large ſized; and in his ſkull there were ten wounds or more, all cicatrized, except that of which he died. This diſcovery was made in the year 1189, as Giraldus Cambrenſis tells us, who ſaw theſe bones, and examined the whole matter carefully. There was alſo a table containing this ſtory, ſet up in the monaſtery of Glaſtenbury, and the leaden croſs with the inſcription remained there till the diſſolution of the monaſtery, where it was ſeen by the great antiquary Leland, but what is become of it ſince does not appear.

On the different places above alluded to as being diſtinguiſhed by our hero's name, and ſerving to evince his exiſtence, the following may be mentioned as one of the principal.

Arthur's Seat, a high hill in the neighbourhood of Edinburgh, ſaid to have been ſo denominated from a tradition that king Arthur ſurveyed the country from its ſummit, and had alſo defeated the Saxons in its neighbourhood. This hill riſes by a ſteep and rugged aſcent, till it terminates in a rocky point near 700 feet high from the baſe, being more than double the height of the croſs on the top of St. Paul's, London, which is 340 feet. On the ſouth it is in many parts a perpendicular rock, compoſed of baſaltic pillars, regularly pentagonal or hexagonal, about three feet in diameter, and from 40 to 50 feet in height. Contiguous, upon the weſt, and partly connected with it at the baſe, are Saliſbury craggs, of inferior height, but exhibiting an appearance equally ſingular and grand. They preſent to the city an awful front of broken rocks and precipices, forming a ſort of natural amphitheatre of ſolid rock; and backward from the craggy verge above, the hill forms an extenſive irregular ſlope, the ſurface affording paſture to numerous flocks of ſheep. The craggs, beſides ores, ſpars, rock-plants, and here and there it is ſaid ſome precious ſtones, afford an inexhauſtible ſupply of granite for paving the ſtreets and other purpoſes. In quarrying, a part of the craggs has been worn down into a ſpacious ſhelf, having the appearance of a lofty terrace, and ſtretching a conſiderable length. From hence is a near and diſtinct proſpect of the city with its environs and the adjacent country. But from the pinnacle called Arthur's Seat the view is more noble and extenſive. The traveller may here ſit and ſurvey at his eaſe the centre of the kingdom, beſides having a complete view of Edinburgh and its caſtle, on which he looks down as if ſeated among the clouds. In a word, the German ocean, the whole courſe of the Forth, the diſtant Grampians, and a large portion of the moſt populous and beſt cultivated part of Scotland, form a landſcape ſublime, various, and beautiful.

The denomination of this hill, derived as above, has been adduced as an argument againſt thoſe who diſpute the exiſtence of the Britiſh Arthur. That derivation, however, though probable, is not without uncertainty. For *Arthur's Seat* is ſaid to be derived, or rather corrupted, from *Ard Seir*, a "place or field of arrows," where people ſhoot at a mark: And this not improperly; for among theſe cliffs is a dell or recluſe valley, where the wind can ſcarcely reach, now called the *Hunter's bog*, the bottom of it being a moraſs. The adjacent craggs are ſuppoſed to have taken their name from the Earl of *Saliſbury*, who in the reign of Edward III. accompanied that prince in an expedition againſt the Scots.

ARTICHOAK, in botany. See Cinara.

ARTICLE, a clauſe or condition of a contract, treaty, &c. It is alſo a ſmall part or diviſion of a diſcourſe, book, or writing, &c.

Article of Death, the laſt pangs or agony of one juſt expiring.

Article of Faith, is by ſome defined a point of Chriſtian doctrine, which we are obliged to believe, as having been revealed by God himſelf, and allowed and eſtabliſhed as ſuch by the church.

The thirty-nine articles were founded, for the moſt part, upon a body of articles compiled and publiſhed in the reign of Edward VI. They were firſt paſſed in the convocation, and confirmed by royal authority in the year 1562. They were afterwards ratified anew in the year 1571, and again by Charles I. The law requires a ſubſcription to theſe articles of all perſons ordained to be deacons or prieſts, 13 El. cap. 12. of all clergymen inducted to any eccleſiaſtical living, by the ſame ſtatute, and of licenſed lecturers and curates, 13 El. cap. 12. and 13. and 14. Ch. 2. cap. 4. of the heads of colleges, of chancellors, officials and commiſſaries, and of ſchool-maſters. By 1 Will. 3. cap. 18. diſſenting teachers are to ſubſcribe all, except the 34th, 35th, and 36th, and part of the 20th (and in the caſe of Anabaptiſts, except alſo part of the 27th); otherwiſe they are exempted from the benefits of the act of toleration.

Article, in grammar, denotes a particle uſed in moſt languages for the declining of nouns, and denoting the ſeveral caſes and genders thereof.

The uſe of articles ariſes chiefly hence, that in languages which have no different terminations, to expreſs the different ſtates and circumſtances of nouns, there is ſomething required to ſupply that office.

The Latins have no articles; but the Greeks, and moſt of the modern languages, have had recourſe to them for fixing and aſcertaining the vague ſignification of common and appellative names.

The

The Greeks have their ο, the eastern tongues their *he emphaticum*; the Italians their *il*, *lo*, and *la*. The French their *le*, *la*, and *les*. The Germans their *der*, *das*, *dat*.

The English also have two articles *a* and *the*; which being prefixed to substantives, apply their general signification to some particular things.

Some grammarians make the article a distinct part of speech; others will have it a pronoun, and others a noun adjective. See GRAMMAR.

Articles are of great service in a language, as they contribute to the more neat and precise expressing of several properties and relations, which must otherwise be lost. And hence one great advantage of such languages over the Latin, in that the article being either expressed or left out, makes an alteration in the sense, which the Latins cannot distinguish. Thus when the devil said to our Saviour, *Se tu es Filius Dei*, it may be either understood, "if thou art *a* son of God," or, "if thou art *the* son of God." The Italians even prefix articles to proper names, which do not naturally need any, because they themselves signify things individually. Thus they say, *il Ariosto, il Tasso, il Petrarcha*. Even the French join the article to the proper names of kingdoms, provinces, &c. as *la Suede*, *la Normandie*. And we likewise annex it to the names of certain mountains and rivers; as The *Rhine*, The *Danube*, The *Alps*, &c.

ARTICULATE SOUNDS are such sounds as express the letters, syllables, or words, of any alphabet or language; such are formed by the human voice, and by some few birds, as parrots, &c.

ARTICULATION, or JOINTING, is the joining of bones together. See ANATOMY, nº 46.

ARTICULATION, in botany, is the connection of parts that consist of joints or knees, such as the pods of French honey-suckles, which when ripe divide into so many parts as there are knees or joints; also those parts of plants which swell into nodes or joints; and which usually send forth branches.

ARTIFICER, a person whose employment it is to manufacture any kind of commodity, as in iron, brass, wool, &c. such are smiths, braziers, carpenters, &c. The Roman artificers had their peculiar temples, where they assembled and chose their own patron, to defend their causes: they were exempted from all personal services. Taruntenus Paternus reckons 32 species of artificers, and Constantine 35, who enjoyed this privilege. The artificers were incorporated into divers colleges or companies, each of which had their tutelar gods, to whom they offered their worship. Several of these, when they quitted their profession, hung up their tools, a votive offering to their gods. Artificers were held a degree below merchants, and *argentarii* or money-changers, and their employment more sordid. Some deny, that in the earliest ages of the Roman state artificers were ranked in the number of citizens: others, who assert their citizenship, allow that they were held in contempt, as being unfit for war, and so poor that they could scarce pay any taxes. For which reason they were not entered among the citizens in the censor's books; the design of the census being only to see what number of persons were yearly fit to bear arms, and to pay taxes towards the support of the state. It may be added, that much of the artificers business was done by slaves and foreigners, who left little for the Romans to mind but their husbandry and war. By means of the arts, the minds of men are engaged in inventions beneficial to the whole community; and thus prove the grand preservative against the barbarism and brutality, which ever attend on an indolent and inactive stupidity.

By the English laws, artificers in wool, iron, steel, brass, or other metal, going out of the kingdom into any foreign country without licence, are to be imprisoned three months, and fined in a sum not exceeding one hundred pounds. And such as going abroad, and not returning on warning given by ambassadors, &c. shall be disabled from holding lands by descent or devise, from receiving any legacy, &c. and be deemed aliens. Stat. 5. Geo. I. cap. 27. By 23 Geo. II. cap. 13. § 1. penalty is also inflicted on seducing artificers to go abroad. Ramazini has a treatise on the diseases of artificers.

ARTIFICIAL, in a general sense, denotes something made, fashioned, or produced by art, in contradistinction from the productions of nature.

ARTIFICIAL is also frequently used for factitious. Thus we have artificial sal ammoniac, artificial borax, &c.

ARTIFICIAL Fire-works are compositions of inflammable materials, chiefly used on solemn occasions, by way of rejoicing. See PYROTECHNY.

ARTIFICIAL Lightening. See ELECTRICITY and LIGHTNING.

ARTIFICIAL Lines, on a sector or scale are certain lines so contrived, as to represent the logarithmic sines and tangents; which, by the help of the line of numbers, will solve all questions in trigonometry, navigation, &c. pretty exactly.

ARTIFICIAL Magnets. See MAGNETS.

ARTIGI, indeclinable, (Pliny); *Artigis*, (Ptolemy); a town of the Turduli, in Bætica. Now *Alhama*.

ARTILLERY, in its general sense, denotes the offensive apparatus of war, particularly of the missile kind. Among the French the term was anciently appropriated to ARCHERY. In its modern acceptation it signifies fire-arms, mounted on their carriages and ready for action, with their balls, their bombs, their grenades, &c.

If we take the term in a more extensive meaning, it includes the powder, the matches, instruments for fireworks, the utensils of ordnance, the machines which facilitate their motion and transport them, the vehicles over which they traverse rivers, every thing necessary to them, and all that enters into the form of a train of artillery.

The same word, still farther extended in its meaning, likewise comprehends the men destined for the service of the *artillery*; the people who provide the artillery with materials and implements when engaged, the cannoniers, the bombardiers, the officers of every rank, and engineers of every kind.

By *artillery* is likewise understood the science which the officers of artillery ought to possess. This science teaches to know the nature of all the materials and ingredients which enter into the composition and the structure of every thing relative to the artillery, such as nitre, sulphur, charcoal: the properties of air and fire;

Artillery. fire; the compoſition and preparation of gun-powder; the materials for fire-works; the conſtruction, proportions, &c. of the different warlike machines; the arrangement, movement, and whole management, of cannon, &c. in the field or in ſieges, in ſuch a manner, that each of them, according to the length of its tube, and the diameter of its bore, may be ſituated in the beſt place and at the propereſt diſtance for execution, and that the whole train taken together may reciprocally aſſiſt and ſupport each other with the greateſt advantage.

Artillery has undergone many changes from its origin to the preſent time. The artillery of the ancients were the catapulta, the baliſtæ, the different kinds of ſlings, &c. In latter ages, the Franks uſed the hatchet as a miſſile weapon, throwing it in the ſame manner as the Americans do theirs, called the *tomahawk*. The Gaſcons and Genoeſe were excellent croſs-bow-men. The Swiſs owed their victories to their ſtrength and ſkill in the uſe of the pike, halberd, and eſpadon or two-handed ſword; and the victories of Creſſy, Poictiers, and Agincourt, will occaſion the valour and ſkill of the Engliſh archers to be tranſmitted down to lateſt poſterity. See ARCHERY.

The chevalier Folard was extremely attached to the ancient machines firſt mentioned, and ſeemed even to prefer them to our fire-arms: an opinion which muſt appear not a little extraordinary from ſuch a perſon. Father Daniel might well be miſtaken in the compariſon which he made between the effects of ancient and modern artillery, and in his concluſion that the latter was of little uſe: the ſituation of this good father removed him from the ſcenes of war and the opportunities of military experience. But it is aſtoniſhing, that one ſo learned in the military art as the commentator of Polybius, who had ocular demonſtration of the ſucceſs of modern artillery, ſhould have declared ſo violently againſt it. Whatever be the caſe with theſe authors and their maxims, it may be aſſerted, that cannon is one of the moſt ſingular diſcoveries which have been made amongſt men; and by little and little it has changed the whole art of war, and of conſequence influenced the whole ſyſtem of policy, in Europe. The æra of artillery is dated from the battle of Creſſy in 1346, becauſe it is only from that day that cannons were mentioned in battle. Edward III. of England ſucceſsfully employed ſome pieces of artillery placed in the front of his army. The invention of artillery was then known in France as well as in England; but probably Philip VI. marched with ſo much hurry and precipitation to attack his enemy, that he left his cannon as uſeleſs incumbrances behind him. The ignorance of that age in mechanical arts conſiderably retarded the progreſs of artillery; and that of which they were then poſſeſſed was ſo unwieldy and imperfect, that they could not poſſibly diſcern its importance and efficacy in practice.

After the invention of gun-powder, the Spaniards were the firſt who armed part of their foot with muſkets and harquebuſſes, and mixed them with the pikes. In this they were ſoon imitated by moſt other nations; though the Engliſh had not entirely laid aſide their favourite weapon the long-bow, and generally taken to the uſe of fire arms, during the reign of queen Elizabeth.

The firſt muſkets were very heavy, and could not be fired without a reſt: they had matchlocks, and barrels of a wide bore, that carried a large ball and charge of powder, and did execution at a great diſtance. The muſketeers on a march carried only their reſts and ammunition, and had boys to bear their muſkets after them, for which they were allowed great additional pay. They were very ſlow in loading, not only by reaſon of the unwieldineſs of the pieces, and becauſe they carried the powder and balls ſeparate, but from the time it took to prepare and adjuſt the match; ſo that their fire was not near ſo briſk as ours is now. Afterwards a lighter kind of matchlock-muſket came into uſe; and they carried their ammunition in bandeliers, which were broad belts that came over the ſhoulder, to which were hung ſeveral little caſes of wood covered with leather, each containing a charge of powder; the balls they carried looſe in a pouch, and they had alſo a priming-horn hanging by their ſide. Matchlocks were, about the beginning of this century, univerſally diſuſed in Europe, and the troops were armed with firelocks; to which, much about the ſame time, the bayonet being added, pikes alſo were laid aſide; which latter change, whether it was for the better or not, is a point that ſtill admits of diſpute among the beſt military writers, who are divided in their opinions about it, though moſt of them diſapprove of it.

The old Engliſh writers call thoſe large muſkets *calivers;* the harquebuſs was a lighter piece, that could be fired without a reſt. The matchlock was fired by a match, fixed by a kind of tongs in the ſerpentine or cock, which by pulling the trigger was brought down with great quickneſs upon the priming in the pan, over which there was a ſliding cover, which was drawn back by hand, juſt at the time of firing. There was a great deal of nicety and care required to fit the match properly to the cock, ſo as to come down exactly true on the priming, to blow the aſhes from the coal, and to guard the pan from the ſparks that fell from it: a great deal of time was alſo loſt in taking it out of the cock, and returning it between the fingers of the left-hand, every time that the piece was fired; and wet weather often rendered the matches uſeleſs. However, moſt writers allow that they were very ſure, and leſs apt to miſs fire than the firelock.

The firelock is ſo called, from producing fire of itſelf, by the action of the flint and ſteel. The moſt ancient invention of this ſort is the wheel-lock, which we find mentioned in Luigi Collado's Treatiſe of Artillery, printed at Venice, 1586, as then lately invented in Germany. This ſort of lock was uſed till within theſe hundred years, eſpecially for piſtols and carbines. It was compoſed of a ſolid ſteel wheel, with an axis, to which was faſtened a chain, which, by being round it, drew up a very ſtrong ſpring; on pulling the trigger, the ſpring acting, whirled about the wheel with great velocity, and the friction of the edge of it (which was a little notched) againſt the ſtone produced the fire: the cock was made ſo as to bring the ſtone upon the edge of the wheel, part of which was in the pan, and touched the priming; they uſed any common hard pebble for that purpoſe, which ſerved as well as flint.

Theſe locks were inconvenient, took time to wind up (or ſpan, as they termed it), and ſometimes would not go off; an inſtance of which may be ſeen in Ludlow's Memoirs.

When

When the firelock, such as we now use, was invented, we cannot ascertain: it is called, by writers of about the middle of the last century, a *snaphane* or *snaphance*; which being the Dutch word for a *firelock*, seems to indicate that it is a Dutch invention, and that we took it from them. But Ward, in his Animadversions of War, printed in 1639, p. 502, after describing the exercise of the firelock, pistol, and carbine (by which he means the wheel-lock), says, that as most of our pieces go with English locks, which differ from firelocks, he shall add the method of handling them; and then gives the exercise of the snaphine carbine; by which it appears, that there was little or no difference between that and the pieces now in use. The more modern writers call it a *fusee*, from the French word *fusil*; whence the name of fusileers is still continued to several regiments, which were the first that were armed with them on the disuse of matchlocks.

They used the musket and rest in England so late as the beginning of the civil wars, as may be seen in Col. Bariffe's Young Artillery Man, printed at London, 1643.

Figuerra, in his embassy in 1518, relates, that the Persians would neither make use of infantry nor of artillery, because by them the impetuosity of attack, and the facility of retreat were equally incumbered and retarded: in these expedients alone their address and their glory consisted. This method of advancing and recalling is widely different from the present conduct of war, as the artillery in armies is now prodigiously multiplied, and must be transported to every place where any body of troops whatever is destined to operate.

The length and diameter of cannon has been much diminished, which must likewise proportionably diminish their weight. It is by long practice and experience that they have discovered how much might be deduced from their magnitude in both these respects with propriety, without hurting the grand effects which, on some occasions, it is necessary they should produce, by rendering them more easy to be wielded, which was the advantage pursued by lessening their size. See further the articles CANNON, GUNNERY, and PROJECTILES.

Improvements, however, are still making, and will probably long continue to be made, in these ignivomous machines that mock the thunder, which, though they seem to be invented for the destruction of the human race, and the subversion of empires, have yet by their effects rendered war less savage and less sanguine; political alliances have been more successfully conciliated among all nations, conquests are become less frequent and less rapid, and successes in war have been more easily reduced to calculation.

Wealth of Nations, Philad. edit vol. iii. 65.

The change introduced into the military art by the modern artillery, Dr Smith observes, has enhanced greatly both the expence of exercising and disciplining any particular number of soldiers in time of peace, and that of employing them in time of war. Both their arms and their ammunition are become more expensive. A musket is a more expensive machine than a javelin or a bow and arrows; a cannon or a mortar, than a balista or a catapulta. The powder which is spent in a modern review is lost irrecoverably and occasions a very considerable expence. The javelins and arrows which were thrown or shot in an ancient one, could easily be picked up again, and were besides of very little value. The cannon and the mortar are not only much dearer, but much heavier machines than the balista or catapulta, and require a greater expence, not only to prepare them for the field, but to carry them to it. As the superiority of the modern artillery too over that of the ancients is very great, it has become much more difficult, and consequently much more expensive, to fortify a town so as to resist even for a few weeks the attack of that superior artillery.

In modern war the great expence of fire-arms gives an evident advantage to the nation which can best afford that expence; and consequently, to an opulent and civilized, over a poor and barbarous nation. In ancient times, the opulent and civilized found it difficult to defend themselves against the poor and barbarous nations. In modern times the poor and barbarous find it difficult to defend themselves against the opulent and civilized. The invention of fire-arms, an invention which at first sight appears to be so pernicious, is certainly favourable both to the permanency and to the extension of civilization.

It has to many appeared matter of surprise, that the battles of the ancients should be described with an order, perspicuity, and circumstantial minuteness, which are not to be found in the military writers of modern times. Scholars have endeavoured to explain this difference, by observing the immense disproportion, in point of dignity and abilities, between the military historians of modern Europe and those of Greece and Rome. But the difficulty will be better solved, Dr Gillies thinks, by reflecting on the changes introduced into the art of war by the change of artillery; which, in military operations, form the pivot on which the whole turns. 1. From the nature of fire-arms, modern battles are involved in smoke and confusion. 2. From the same cause, modern armies occupy a much greater extent of ground, and begin to act at much greater distances; which renders it more difficult to observe and ascertain their manœuvres. 3. The immense train of artillery, ammunition, &c. required in the practice of modern war, gives a certain immobility to our armies which renders it impossible to perform, without great danger, those rapid evolutious in sight of an enemy, which so often decided the battles of the ancients. With us almost every thing depends on the judicious choice of ground, a matter requiring greater military genius, but not admitting the embellishments of historical description.

In the battles of the Greeks and Romans, the extraordinary disproportion between the numbers slain on the side of the victors and the vanquished, has been observed as another remarkable circumstance. But this necessarily resulted from the nature of their arms. Their principal weapons being not missile, but manual, armies could not begin to act till they had approached so nearly to each other, that the conquered found themselves cut off from all possibility of retreat. In modern times, such consequences seldom take place. The use of fire-arms (which often renders the action itself more bloody) furnishes the defeated party with various means of retreating with considerable safety. The sphere of military action is so widely extended in modern times, that before the victors can run over the space which separates

Artillery, Artobriga.

parates them from the vanquished, the latter may fall back, and proceed with little loss beyond their reach; and should any village, hedge, ravine, &c. be found in their way may often check the ardour of the pursuers. Upon these considerations, the invention of gun-powder and modern artillery may be said to have saved the effusion of human blood. Equestrian engagements (since the principles on which cavalry act remain nearly the same in every age) are still distinguished by similar circumstances to those which appear so extraordinary in the battles of antiquity.

Artillery-Park, the place in the rear of both lines in the army; for encamping the artillery, which is drawn up in lines, of which one is formed by the guns; the ammunition waggons make two or three lines, 60 paces behind the guns, and 30 distant from one another; the pontoons and tumbrils make the last line. The whole is surrounded with a rope which forms the park: the gunners and matrosses encamp on the flanks; and the bombardiers, pontoonmen, and artificers, in the rear.

Artillery-Train, a certain number of pieces of ordnance, mounted on carriages, with all their furniture fit for marching.

ARTIST, in a general sense, a person skilled in some art. Mr Harris defines an artist to be, "A person possessing an habitual power of becoming the cause of some effect, according to a system of various and well-approved precepts." See Art.

*Evel, Discourse of Medals, p. 237, &c.

We are told* of a privilege granted at Vicenza to artists, like that of *clergy* in England: in virtue thereof, criminals adjudged to death save their lives if they can prove themselves the most excellent and consummate workmen in any useful art. This benefit is allowed them *in favorem artis*, for the first offence, except in some particular crimes, of which coining is one; for here the greater the artist, the more dangerous the person.

Artist *(Artista)*, in an academical sense, denotes a philosopher or proficient in the faculty of arts.

In the early ages of universities, the seven liberal arts completed the whole course of study, or philosophy, as it was called; whence the masters of this faculty were denominated *Artists*. What they understood by the liberal arts used to be summed up in the following Latin verse:

Lingua, Tropus, Ratio, Numerus, Tonus, Angulus Astra.

Artist is more peculiarly used by Paracelsus and other adepts, for a chemist or alchemist. We find frequent mention, in authors of this class, of Elias Artista, or Elias the artist, who is to come some time before the dissolution of the world, and restore and make perfect all arts and sciences, but especially the gold-making art; and usher in a truly golden age, or millennium. The lower and meaner things in this sublime art, Paracelsus observes, God has permitted to be already discovered; but for the greater and more important matters, as the transmutation of other metals into gold, they are reserved to the coming of Elias the artist.

ARTOBRIGA, a town of Vindelicia (Ptolemy): Now *Altzburg*, in Bavaria, on the Danube, below Ingolstadt (Aventinus); but Cluverius supposes it to be *Lebenau*, on the Saltzbach, below Lauffen, in the archbishopric of Saltzburg.

Artocarpus

ARTOCARPUS (from αρτος, *bread*, and καρπος, *fruit*), the Bread-fruit Tree: A genus of the monandria order, belonging to the monœcia class of plants. It has a cylindric amentum or catkin, which thickens gradually, and is covered with flowers; the male and female in different amentum. In the *male*, the calyx is two-valved, and the corolla is wanting. In the *female*, there is no calyx or corolla; the stylus is one, and the drupa is many-celled.

Though this tree has been mentioned by many voyagers, particularly Dampier, by Rumphius, and by Lord Anson, yet very little notice seems to have been taken of it till the return of Captain Wallace from the South Seas, and since that time by others who have touched at Otaheite and some countries in the East Indies. Captain Dampier relates, that in Guam, one of the Ladrone islands, "there is a certain fruit called the *bread-fruit*, growing on a tree as big as our large apple-trees, with dark leaves. The fruit is round, and grows on the boughs like apples, of the bigness of a good penny loaf: when ripe, it turns yellow, soft, and sweet; but the natives take it green, and bake it in an oven till the rind is black: this they scrape off, and eat the inside, which is soft and white, like the inside of new-baked bread, having neither seed nor stone; but if it is kept above 24 hours it is harsh. As this fruit is in season eight months in the year, the natives feed upon no other sort of bread during that time. They told us that all the Ladrone islands had plenty of it. I never heard of it in any other place."

Rumphius, after describing the tree, observes, that "the fruit is shaped like a heart, and increases to the size of a child's head. Its surface or rind is thick, green, and covered every where with warts of a quadragonal or hexagonal figure, like cut diamonds, but without points. The more flat and smooth these warts are, the fewer seeds are contained in the fruit, and the greater is the quantity of pith, and that of a more glutinous nature. The internal part of the rind, or peel consists of a fleshy substance, full of twisted fibres, which have the appearance of fine wool; these adhere to, and in some measure form it. The fleshy part of this fruit becomes softer towards the middle, where there is a small cavity formed without any nuts or seeds, except in one species, which has but a small number, and this sort is not good unless it is baked, or prepared some other way: but if the outward rind be taken off, and the fibrous flesh dried and afterwards boiled with meat as we do cabbage, it has then the taste of artichoke bottoms. The inhabitants of Amboyna dress it in the liquor of cocoa-nuts: but they prefer it roasted on coals till the outward part or peel is burnt. They afterwards cut it into pieces, and eat it with the milk of the cocoa-nut. Some people make fritters of it, or fry it in oil; and others, as the Sumatrians, dry the internal soft part, and keep it to use instead of bread with other food. It affords a great deal of nourishment, and is very satisfying, therefore proper for hard-working people; and being of a gentle astringent quality, is good for persons of a laxative habit of body.

It

Artocarpus Artois.

It is more nourishing boiled in our manner with fat meat than roasted on coals. The milky juice which distils from the trunk, boiled with the cocoa-nut oil, makes a very strong bird-lime. This tree is to be found on the eastern parts of Sumatra, and in the Malay language is called *soccus* and *soccum capas*. It grows likewise about the town of Bantam in Java, and in Balega and Madura, and is known there by the name of *soccum*."

In Anson's voyage we are informed, "that the rima, or bread-fruit tree, is common in all the Ladrone islands and some of the Philipines. It is somewhat larger than our apple-tree, and bears a broad dark-coloured leaf with five indentures on each side. The fruit hangs on boughs like apples; and is of the size of a penny loaf, with a thick tough rind, which when full ripe turns yellow. The natives gather it before it is quite ripe, and bake it till the crust is pretty black; then they rasp it, and there remains a pretty loaf, with a tender yellow crust, and the crumb of it is soft and sweet as a new-baked roll: it is without any seeds or stones. This fruit the inhabitants enjoy for about seven months; during which they never eat any other kind of bread: but they are obliged to bake it every day; for when it grows a little stale, it becomes harsh and husky, somewhat like the potatoe-bread made in the west of England. There is, however, a remedy for this; which is cutting the loaf into slices when it is new, and drying it in the sun, by which it is changed into the pleasantest rusk that can be eaten."

Captain Cook, in his voyage, observes, that this fruit not only serves as a substitute for bread among the inhabitants of Otaheite * and the neighbouring islands, but also, variously dressed, composes the principal part of their food. It grows on a tree that is about the size of a middling oak; its leaves are frequently a foot and an half long, of an oblong shape, deeply sinuated like those of the fig-tree, which they resemble in colour and consistence, and in the exsuding of a milky juice upon being broken. The fruit is about the size and shape of a new-born child's head; and the surface is reticulated †, not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small knife. The eatable part lies between the skin and the core; it is as white as snow, and somewhat of the consistence of new bread; it must be roasted before it is eaten, being first divided into three or four parts; its taste is insipid, with a slight sweetness somewhat resembling that of the crumb of wheaten bread mixed with a Jerusalem artichoke. This fruit is also cooked in a kind of oven, which renders it soft, and something like a boiled potatoe; not quite so farinaceous as a good one, but more so than those of the middling sort. Of the bread-fruit they also make three dishes, by putting either water or the milk of the cocoa-nut to it, then beating it to a paste with a stone pestle, and afterwards mixing it with ripe plantains, bananas, or the sour paste which they call *mahie*.

* *Hawkesworth's account of Captain Cooke's voyage.*

† Plate LVIII.

The mahie, which is likewise made to serve as a succedaneum for ripe bread-fruit before the season comes on, is thus made: The fruit of the bread-tree is gathered just before it is perfectly ripe; and being laid in heaps, is closely covered with leaves: in this state it undergoes a fermentation, and becomes disagreeably sweet; the core is then taken out entire, which is done by gently pulling out the stalk, and the rest of the fruit is thrown into a hole which is dug for that purpose generally in the houses, and neatly lined in the bottom and sides with grass: the whole is then covered with leaves and heavy stones laid upon them; in this state it undergoes a second fermentation, and becomes sour, after which it will suffer no change for many months. It is taken out of the hole as it is wanted for use; and being made into balls, it is wrapped up in leaves and baked: after it is dressed, it will keep five or six weeks. It is eaten both cold and hot; and the natives seldom make a meal without it, though to Europeans the taste is as disagreeable as that of a pickled olive generally is the first time it is eaten. The fruit itself is in season eight months in the year, and the mahie supplies the inhabitants during the other four.

To procure this principal article of their food (the bread-fruit), costs these happy people no trouble or labour except climbing up a tree: the tree which produces it does not indeed grow spontaneously; but if a man plants ten of them in his life-time, which he may do in about an hour, he will as completely fulfil his duty to his own and future generations, as the native of our less temperate climate can do by ploughing in the cold of winter, and reaping in the summer's heat, as often as these seasons return; even if, after he has procured bread for his present household, he should convert a surplus into money, and lay it up for his children.

There are two species of artocarpus, viz. the incisus, with gashed leaves; and the integrifolia, with entire leaves. There is also said to be another distinction, into that which bears fruit with stones or seeds, and that in which the fruit has none. The parts of fructification of that tree which bears the fruit without stones are defective. The amentum, or catkin, which contains the male parts, never expands. The styli, or female part of the fruit, are likewise deficient. From which it follows, that there can be no stones or seeds, and therefore that this tree can be propagated only by suckers or layers; although it is abundantly evident, that it must originally have proceeded from the seed-bearing bread-fruit tree. Instances of this kind we sometimes find in European fruits; such as the barberry, and the Corinthian grape from Zant commonly called currants, which can therefore be increased only by layers and cuttings. Dr Solander was assured by the oldest inhabitants of Otaheite and the adjoining islands, that they well remember there was formerly plenty of the seed-bearing bread-fruit; but they had been neglected upon account of the preference given to the bread-fruit without seeds, which they propagate by suckers.

ARTOIS, a province of France, and one of the finest and most fertile in the whole kingdom; formerly it was one of the 17 provinces of the Netherlands, but now belongs entirely to France. The names of *Artois*, and *Arras* its capital, are derived from the Atrebates, a people of Gallia Belgica, mentioned by Julius Cæsar. Its greatest length from north to south is about 24 leagues, and its breadth about 12, being bounded to the south and west by Picardy, to the east by Hainault, and to the north by Flanders. A considerable trade is carried on in the province in grain, flax, hops, wool, and linen cloth. The states, who meet regularly once a-year, consist of the clergy, nobility, and commoners; and sit generally a fortnight at Arras: their chief business is to deliberate on the ways and means to raise the money which the king demands of them, and which usually amounts to about 400,000 livres, exclusive of forage-money. The most considerable places in Artois are, Arras the capital, Bapaume, Bethune, St Venant, and St Omer.

ARTOLICA (anc. geog.), a town of the Salassii, in Gallia Cispadana, (Antonine); at the foot of the Alps: now called *la Tuile* by the inhabitants, a hamlet of Savoy, in the duchy of Aoust, at the foot of mount St Bernard the Less.

ARTOTYRITES, a Christian sect, in the primitive church, who celebrated the eucharist with bread and cheese, saying, that the first oblations of men were not only of the fruit of the earth, but of their flocks. The word is derived from αρτος, *bread*, and τυρος, *cheese*.

The Artotyrites admitted women to the priesthood and episcopacy; and Epiphanius tells us, it was a common thing to see seven girls at once enter into their church, robed in white, and holding a torch in their hand; where they wept, and bewailed the wretchedness of human nature, and the miseries of this life.

ARUA (anc. geog.), a town of Bætica, of the resort of the Conventus Hispalensis, (Pliny): now *Alcclea*, a citadel of Andalusia, on the Bætis, or Guadalquiver, seven leagues above Seville.

ARVALES FRATRES, in Roman antiquity, a college of 12 priests, instituted by Romulus, and chosen out of the most noble families, himself being one of that body: they assisted in the sacrifices of the ambervalia annually offered to Ceres and Bacchus, for the prosperity of the fruits of the earth; when they wore on their heads crowns made of ears of corn.—The original of this institution was as follows: Acca Laurentia, Romulus's nurse, was accustomed once a-year to make a solemn sacrifice for a blessing on the fields, her 12 sons always assisting her in the solemnity; but at last losing one of her sons, Romulus offered himself to supply his place, and gave this small society the name of *Arvales fratres*. This order was in great repute at Rome; they held the dignity for life, and never lost it upon account of imprisonment, banishment, or any other accident.

ARUBA, a small island on the coast of Terra Firma, subject to the Dutch, and situated in W. Long. 69. 30. N. Lat. 12. 30.

ARUCI (anc. geog.), a town of the Celtici, in the north of Lusitania, (Antonine, inscription); called also *Aruci Novem*, to distinguish it from the following: Now supposed to be *Moura*, a small city of Portugal, near the confluence of the Ardila and Guadalquiver.

ARUCI VETUS (anc. geog.), a small city of the Turdetani, in Bætica, (Ptolemy); now *Aroche*, a hamlet of Andalusia, on the confines of Portugal and Estramadura, on the river Gama, seven leagues to the east of Aruci Novum or Moura. From it a mountain, in its neighbourhood, takes the name *Arucitanus*. Now *la Sierra de Aroche*.

ARUCIA (anc. geog.), a town of Illyria, in the inland part of Liburnia, (Ptolemy): Now *Bregna*; according to some; but *Ottoschatz*, according to others; a citadel of Morlachia.

ARVERNI, an appellation early used for the capital of the Arverni, according to the custom of the latter ages of naming towns from the people; it was formerly called *Nemossus*, (Strabo). The *Arverni*, a brave and ancient people, and one of the most powerful nations of Gaul, claimed affinity with the Romans, as descendants from Antenor, (Lucan): and after their conquest by the Romans, their ancient liberty was preserved to them on account of their bravery, (Pliny). Above 1000 years ago the town was called *Clarus Mons*, from its situation, (Valesius.) Now *Clermont*, in Auvergne, E. Long. 3. 20. N. Lat. 45. 42.

ARVIL-SUPPER, a feast or entertainment made at funerals, in the north part of England. Arvil-bread is the bread delivered to the poor at funeral solemnities: and *arvil*, *arval*, *arfal*, are used for the burial or funeral rites, as,

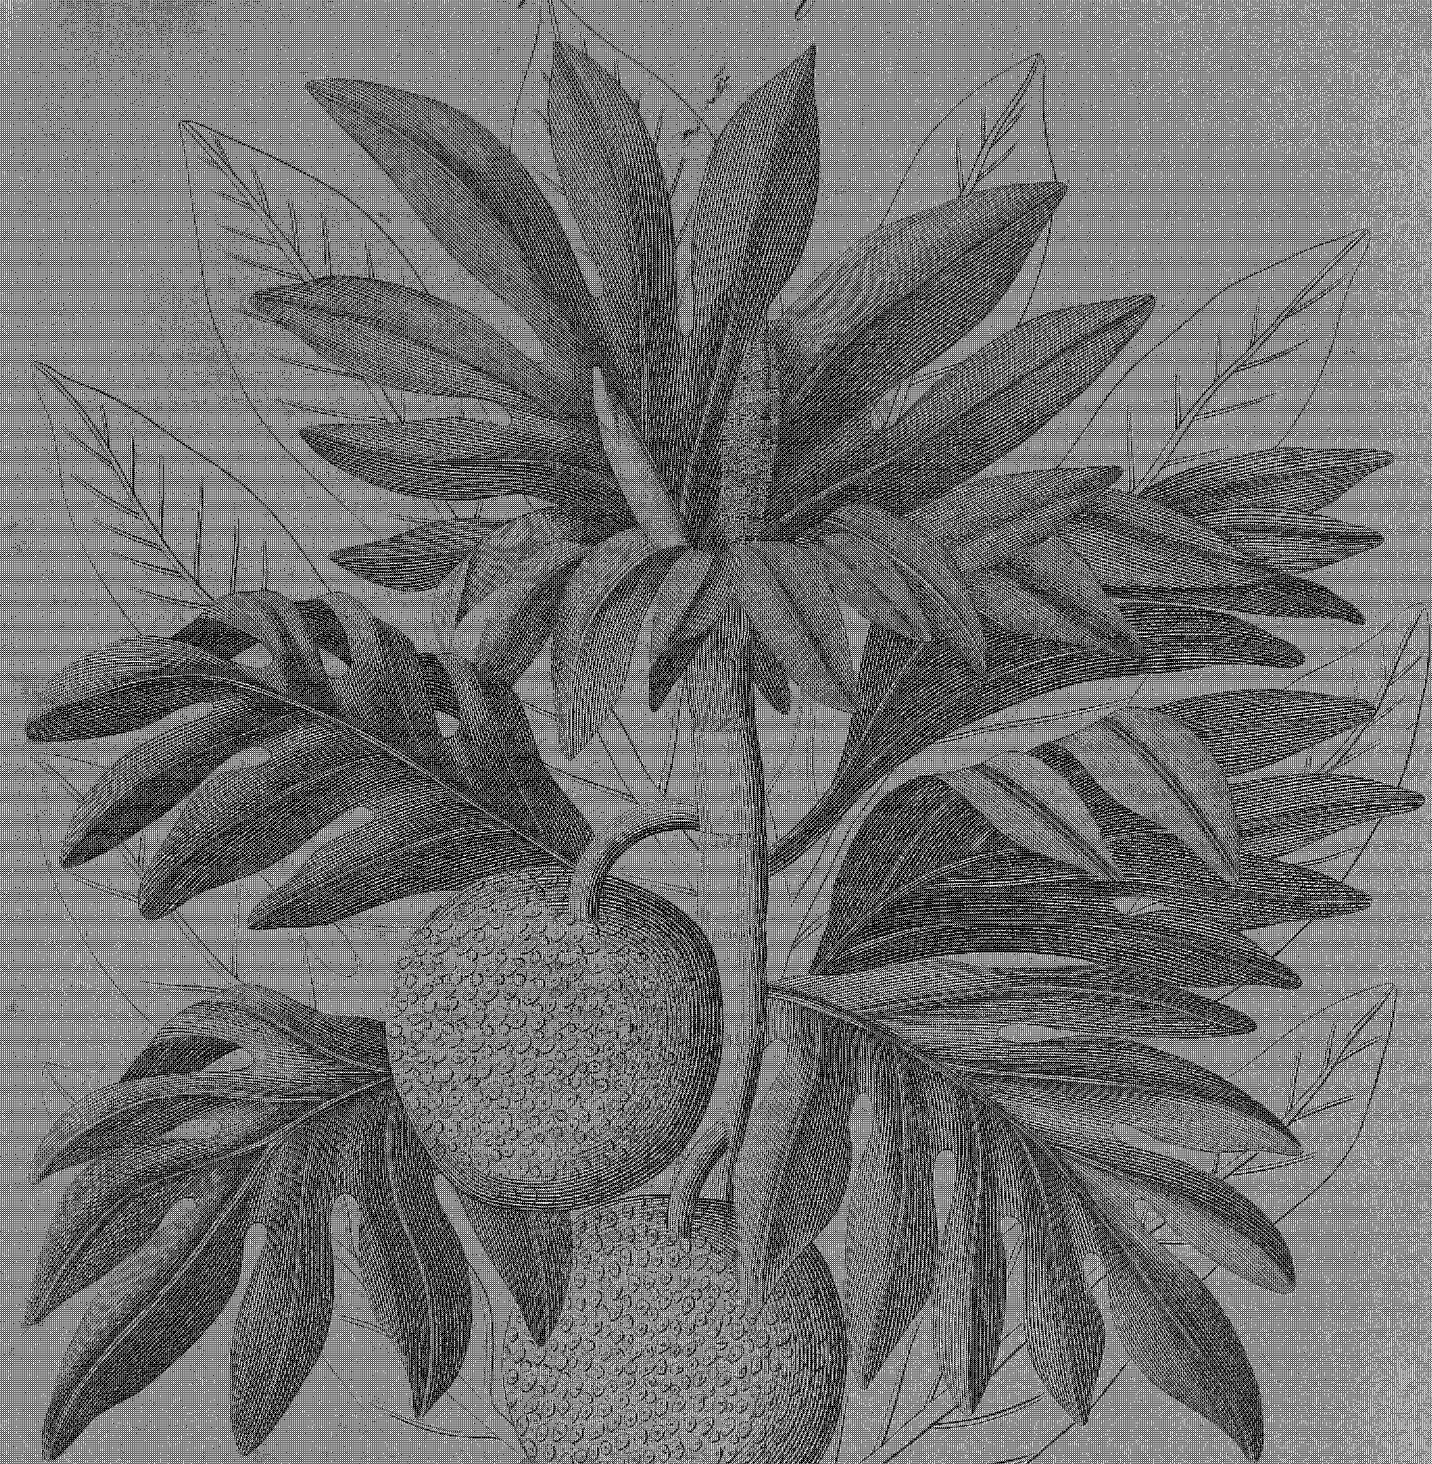
> Come, bring my jerkin, Tibb, I'll to the *arvil*;
> Yon man's dea scuy seoun, it makes me marvil.
>
> *Yorksh. Dial.* p. 58.

ARVIRAGUS, an ancient British king who flourished in the time of the emperor Domitian. He gained a complete victory over Claudius: but being soon after besieged in the city of Winchester, he made a treaty with the Romans, and married the emperor's daughter Genuissa. This monarch lived to a good old age: he confirmed the ancient laws, enacted new ones, and liberally rewarded persons of merit.

ARUM, WAKEROBIN, or CUCKOW-PINT: A genus of the polyandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 2d order, *Piperitæ*. The spatha is monophyllous, and cowl-shaped; the spadix is naked above, female below, and stamen'd in the middle.—The

Species are 22; of which the most remarkable are the following. 1. The maculatum, or common wakerobin, grows naturally in woods and on shady banks in most parts of Britain. The leaves are halberd-shaped, very entire, and spotted; the berries numerous, growing in a naked cluster. The flowers appear in April; and their wonderful structure hath given rise to many disputes among the botanists. The receptacle is long, in the shape of a club, with the seed-buds surrounding its base. The chives are fixed to the receptacle amongst the seed-buds, so that there is no occasion for the tips to be supported upon threads, and therefore they have none; but they are fixed to the fruit-stalk, and placed between two rows of tendrils: the point in dispute is what is the use of those tendrils? 2. The proboscidium. 3. The arisarum. 4. The tenuifolium. These three species have usually been separated from this genus, and distinguished by the general name of *arisarum*, or *friar's cowl*, on account of the resemblance of their flowers to the shape of the cowls worn by friars. The flowers appear in April. 5. The italicum, is a native of Italy, Spain, and Portugal. The leaves rise a foot and an half high, terminating in a point; they are very large, and finely veined with white, interspersed with black spots, which, together with the fine shining green, make a pretty variety. The flowers grow near a foot high;

Artocarpus The Bread fruit Tree Plate LVIII



and have very long upright ſpathas, which are of a pale green. They appear in the end of April, or beginning of May. 6. The dracunculus, or common dragons, grows naturally in moſt of the ſouthern parts of Europe. It hath a ſtraight ſtalk three or four feet high, which is ſpotted like the belly of a ſnake: at the top it is ſpread out into leaves, which are cut into ſeveral narrow ſegments almoſt to the bottom, and are ſpread open like a hand; at the top of the ſtalk the flower is produced, which is in ſhape like the common arum, having a long ſpatha of a dark purple colour, ſtanding erect, with a large piſtil of the ſame colour, ſo that when it is in flower it makes no unpleaſing appearance; but the flower hath ſo ſtrong a ſcent of carrion, that few people can endure it, for which reaſon it hath been baniſhed moſt gardens. 7. The trilobatum, or arum of Ceylon, is a native of that iſland and ſome other parts of India; ſo is very impatient of cold. It is a low plant; the flower riſes immediately from the root, ſtanding on a very ſhort footſtalk: the ſpatha is long, erect, and of a fine ſcarlet colour, as is alſo the piſtil. 8. The colocaſia. 9. The divaricatum, with ſpear-ſhaped leaves. 10. The peregrinum, or elder. 11. The eſculentum, or eatable arum. 12. The ſagittifolium, or greateſt Egyptian arum. All theſe ſpecies have mild roots, which are eaten by the inhabitants of the hot countries, where they grow naturally; and ſome of them are cultivated by the inhabitants of the ſugar colonies, where their roots are conſtantly eaten, as alſo the leaves of ſome of them, particularly thoſe of the eſculentum, which they call *Indian kale;* and which, in thoſe countries where many of the eſculent vegetables of England are with difficulty produced, proves a good ſuccedaneum. 13. The arboreſcens, or dumb cane, is a native of the ſugar iſlands and warm parts of America, where it grows chiefly on low grounds. All the parts of it abound with an acrid juice; ſo that if a leaf or part of the ſtalk is broken and applied to the tip of the tongue, it occaſions a very painful ſenſation and a great defluxion of ſaliva. The ſtalks of this plant are ſometimes applid to the mouths of the negroes by way of puniſhment.

Culture. All the ſpecies of this plant are hardy, except the trilobatum and the arboreſcens. The former muſt be kept conſtantly in a ſtove, and the laſt in a moderate hot-bed. The arboreſcens is propagated by cutting off the ſtalks into lengths of three or four joints, which muſt be left to dry ſix weeks or two months; for if the wounded part is not perfectly healed over before the cuttings are planted, they will rot and decay. They are then to be planted in ſmall pots filled with light ſandy earth, and plunged in a moderate hot-bed of tan, obſerving to let them have little water till they have taken good root.

Medicinal Uſes. The roots of the maculatum and dracunculus are uſed in medicine, and differ in nothing but that the latter is ſomewhat ſtronger than the former. All the parts of the arum, particularly the root, have an extremely pungent, acrimonious taſte; if the root be but lightly chewed, it continues to burn and vellicate the tongue for ſome hours, occaſioning at the ſame time a conſiderable thirſt: theſe ſymptoms are alleviated by butter, milk, or oily liquors. Dried and kept for ſome time, it loſes much of its acrimony, and becomes at length an almoſt inſipid farinaceous ſubſtance.

This root is a powerful ſtimulant and attenuant. It is reckoned a medicine of great efficacy in ſome cachectic and chlorotic caſes, in weakneſs of the ſtomach occaſioned by a load of viſcid phlegm. Great benefit has been obtained from it in rheumatic pains, particularly thoſe of the fixed kind, and which were ſeated deep. In theſe caſes it may given from ten grains to a ſcruple of the freſh root twice or thrice a-day, made into a bolus or emulſion with unctuous and mucilaginous ſubſtances, which cover its pungency, and prevent its making any painful impreſſion on the tongue. It generally excites a ſlight tingling ſenſation through the whole habit, and, when the patient is kept warm in bed, produces a copious ſweat.

The arum was formerly an ingredient in an officinal preparation, the compound powder; but in that form its virtues are very precarious. Some recommended a tincture of it drawn with wine; but neither wine, water, nor ſpirits, extract its virtues.

ARUNDA, a town of Hiſpania Bætica, on the Annas, or Guadiana, (Ptolemy, Pliny): Now ſaid to be *Ronda,* in the province of Granada, on the confines of Andaluſia. W. Long. 5. 40. Lat. 36. 26.

ARUNDEL (Thomas), archbiſhop of Canterbury in the reign of Richard II. Henry IV. and Henry V. He was the ſecond ſon of Robert Earl of Arundel and Warren, and brother of Richard Earl of Arundel who was beheaded. At 22 years of age, from being archdeacon of Taunton he was raiſed to the biſhopric of Ely, the 6th of April 1375, in the reign of Edward III. He was a great benefactor to the church and palace of this ſee; among other donations he gave a curious table of maſſy gold, adorned with precious ſtones, which had been given to prince Edward by the king of Spain, and ſold by the latter to Biſhop Arundel. In 1386, he was appointed lord chancellor of England; two years after, he was tranſlated to the ſee of York; and, in 1316, was advanced to the archipiſcopal ſee of Canterbury, when he reſigned the chancellorſhip. This was the firſt inſtance of the tranſlation of an archbiſhop of York to the ſee of Canterbury. Scarcely was he fixed in this ſee, when he had a conteſt with the univerſity of Oxford about the right of viſitation. The affair was referred to king Richard, who determined it in favour of the archbiſhop. At his viſitation in London, he revived an old conſtitution, by which the inhabitants of the reſpective pariſhes were obliged to pay to their rector one-half-penny in the pound out of the rent of their houſes. In the ſecond year of his tranſlation, a parliament being held at London, the commons with the king's leave impeached the archbiſhop, together with his brother the earl of Arundel, and the Duke of Gloceſter, of high treaſon. The archbiſhop was ſentenced to be baniſhed, and within forty days to depart the kingdom on pain of death. He retired firſt to France; and then to the court of Rome, where Pope Boniface IX. gave him a kind reception. About this time the Duke of Lancaſter (afterwards Henry IV.) was in France, having been baniſhed by king Richard. The nobility and others, tired with the oppreſſions of Richard, ſolicited the Duke to take the crown. This their requeſt they drew up in a

Arundel. letter, and sent it over by faithful messengers to archbishop Arundel, desiring him to be their advocate on this occasion with the Duke. The archbishop, being a fellow-sufferer, gladly accepted the office; and went with the messengers to the Duke at Paris, where they delivered the letters from the nobles and commons of England, and the archbishop seconded them with the best arguments he could invent. The inviting offer, after some objections which were easily obviated, the Duke accepted; and upon his accession to the throne, Arundel, who had returned with him to England, was restored to his see. In the first year of this prince's reign. Arundel summoned a synod which sat at St Paul's. The next year the commons moved that the revenues of the church might be applied to the service of the public; but Arundel opposed the motion with such vigour, that it was thrown aside. In the year 1408, Arundel began to exert himself against the Lollards, or Wickliffites; and his zeal for suppressing that sect carried him to several unjustifiable severities against the heads of it, particularly against Sir John Oldcastle and Lord Cobham. He also procured a synodical constitution, which forbad the translation of the Scriptures into the vulgar tongue. This prelate died at Canterbury, Feb. 20th, 1413, of an inflammation in his throat, with which he was seized (as it is pretended) whilst he was pronouncing sentence upon Lord Cobham. The Lollards asserted this to be a judgment from God; and indeed Bishop Goodwin speaks in the same manner, saying "He who had with-held from the people the word of God, the food of the soul, by the just judgement of God had his throat so closed, that he could not speak a single word, nor swallow meat or drink, and was so starved to death." He was buried in the cathedral church of Canterbury, near the west end, under a monument erected by himself in his lifetime. To this church he was a considerable benefactor: for he built the lantern-tower and great part of the nave; gave a ring of five bells, called from him *Arundel's ring*; several rich vestments, a mitre enchased with jewels, a silver gilt crosier, and two golden chalices.

Arundel, a borough and market town in Sussex, seated on the north-west side of the river Arun, over which there is a bridge. It had a harbour, wherein a ship of 100 ton burthen might ride; but the sea had ruined it so far, that, in 1733, an act passed for repairing it, and for erecting new piers, locks, &c. The castle, which gives the title of *earl* to its possessors, is seated on the east of the Tame, and is reputed to be a mile in compass. It sends two members to parliament; and is 55 miles south-west-by-south of London, and 10 miles east of Chichester. Arundel is the premier earldom in England, belonging to the illustrious family of Norfolk; and is the only title in England that goes along with the lands. W. Long. 0. 25. N. Lat. 50. 45.

Arundel Oil, in the materia medica. At Bombay, Gambroon, and Surat, in the East Indies, there grows a tree which bears a nut inclosed in a rough husk, which resembles much the horse-chesnut; and the kernel of the nut yields an oil by expression, which is of a purgative nature. A tea-spoonful of it is reckoned a dose. The tree goes by the name of the *Arundel tree* at Bombay, and its oil by that of the *Arundel oil*. Mr. Sinclair, one of the surgeons belonging to the royal regiment of artillery, who was formerly surgeon to an East India ship, gave Dr Monro of London a small bottle full of this oil, which he said was much used for the cure of the dysentery in India, and that he had given it in four recent cases of dysentery with success.—Dr Monro thinks it probable that this is the oil of the purging nuts mentioned in Dale's Pharmacologia, which are got from the tree called *Lignum Moluccense, Pavana dictum, fructu avellanæ,* J. B. 1. 342; and *pinus Indica, nucleo purgante,* C. B. 492; and the *palma Christi Indica,* Turnefort, Mat. Med.

Arundelian. ARUNDELIAN Marbles, Oxford Marbles, or Parian Chronicle, are ancient stones (as has been supposed), whereon is inscribed a chronicle of the city of Athens, engraven in capital letters in the island of Paros, one of the Cyclades, 264 years before Jesus Christ. They take their first name from Thomas Earl of Arundel, who procured them out of the East, or from Henry his grandson, who presented them to the University of Oxford.

The Arundelian Marbles, in their perfect state, contained a chronological detail of the principal events of Greece during a period of 1318 years, beginning with Cecrops, before Christ 1582 years, and ending with the archonship of Diognetus, before Christ 264. But the chronicle of the last 90 years is lost; so that the part now remaining ends at the archonship of Diotimus, 354 years before the birth of Christ: and in this fragment the inscription is at present so much corroded and effaced, that the sense can only be discovered by very learned and industrious antiquaries; or, more properly speaking, supplied by their conjectures.

This chronicle, and many other relics of antiquity, real or pretended, were purchased in Asia Minor, in Greece, or in the islands of the Archipelago, by Mr William Petty, who in the year 1624 was sent by Thomas Earl of Arundel for the purpose of making such collections for him in the East. They were brought into England about the beginning of the year 1627, and placed in the gardens belonging to Arundel-house in London.

Soon after their arrival they excited a general curiosity, and were viewed by many inquisitive and learned men; among others by Sir Robert Cotton, who prevailed upon Selden to employ his abilities in explaining the Greek inscriptions. Selden and two of his friends, Patrick Young, or, as he styled himself in Latin, *Patricus Junius*, and Richard James, immediately commenced their operations, by cleaning and examining the marble containing the Smyrnean and Magnesian league, and afterwards proceeded to the Parian Chronicle. The following year Selden published a small volume in quarto, including about 39 inscriptions copied from the marbles.

In the turbulent reign of Charles I. and the subsequent usurpation, Arundel-house was often deserted by the illustrious owners; and, in their absence, some of the marbles were defaced and broken, and others either stolen or used for the ordinary purposes of architecture. The chronological marble, in particular, was unfortunately broken and defaced. The upper part, containing 31 epochas, is said to have been worked up in repairing a chimney in Arundel-house.

In the year 1667, the Hon. Henry Howard, afterwards

Arundelian.

wards Duke of Norfolk, the grandson of the first collector, presented these supposed remains of antiquity to the university of Oxford.

Selden's work becoming very scarce, Bishop Fell engaged Mr. Prideaux to publish a new edition of the inscriptions, which was printed at Oxford in 1676. In 1732 Mr Maittaire obliged the public with a more comprehensive view of the marbles than either of his predecessors. Lastly, Dr Chandler published a new and improved copy of the marbles in 1763, in which he corrected the mistakes of the former editors; and in some of the inscriptions, particularly that of the Parian chronicle, supplied the *lacunæ* by many ingenious conjectures.

The Arundelian marbles have generally been regarded as a curious monument of antiquity. They were, however, discovered in some instances to be inconsistent with the most authentic historical accounts; Sir Isaac Newton and several other modern philosophers paid little or no regard to them; and of late their absolute authenticity has been severely questioned in an express dissertation upon the subject, entitled, *The Parian Chronicle*. In this dissertation much ingenuity as well as judgment and a great extent of ancient learning are displayed. His doubts, the author observes, arise from the following considerations.

I. "The characters have no certain or unequivocal marks of antiquity." The Π and Z, which frequently occur in the form supposed to be the most ancient (viz. the perpendicular line of the Π on the right hand only half as long as that on the left, and the Z in the form of a prostrate Ξ), are so well known, that any modern fabricator of a Greek inscription, which he intends to impose upon the world as a relic of antiquity, would most probably use them in preference to the more common and ordinary forms. But the letters in the Parian Chronicle have no appearance of antiquity except this very equivocal one. They do not in the least resemble the Sigean, the Nemean, or the Delian inscriptions, which are supposed to be of a more ancient date. They differ in many respects from the letters on the Marmor Sandvicense, which, according to the learned editor of that inscription, was engraved in the year before Christ 374. They bear no sort of resemblance to the characters on the Farnesian pillars, to those of the Alexandrian manuscript, or others of a later date. They seem, continues our author, to resemble perhaps more than any other the letters of the alphabet taken by Montfaucon from the Marmor Cyzicenum at Venice. They are plain and simple in their form, and such as an ordinary stone-cutter of the present age would probably make, if he were employed to engrave a Greek inscription according to the alphabet now in use. The small letters intermixed among the larger have, in the opinion of our author, an air of affectation and artifice, rather than genuine antiquity; and he is persuaded, that the antiquity of an inscription can never be proved by the mere form of the letters, because the most ancient characters may be as easily counterfeited as those which compose our present alphabets.

That the learned reader may form a competent idea of the characters in the Parian Chronicle, the author has compared them with those of other inscriptions, and given what is usually termed a *fac simile*.

In regard to several *archaisms*, as they are called, in this chronicle, and which our author specifies, he contends, that no conclusion can be drawn from them in favour of its antiquity. What reason could there be, he asks, for introducing these into the Parian chronicle? We do not usually find them in Greek writers of the same age, or even in those of the most early date. The reign of Ptolemy Philadelphus, with the 21st year of which the date of the chronicle coincides, was not an age of rude antiquity with respect to the Greek language; being only 130 years after the time of Xenophon and Plato, when the Greek was spoken and written in its utmost purity and elegance: and we can scarcely suppose, that even a stone-cutter, in that refined age, would have been permitted to disgrace a superb and learned monument with such barbarisms as occur in the chronicle. The archaisms, however, he remarks are not uniformly observed in this inscription. He adduces six instances of deviation; and adds, he is almost tempted to suspect that εμ Παρω εμ Μαραθωνι, and other pretended archaisms, are owing to a mere affectation of antiquity, or to a corrupted dialect and pronunciation in later ages. These archaisms, our author acknowledges, appear on other marbles; but he thinks, that, for that very reason, they would naturally be adopted by the fabricator of a supposititious inscription; and the authenticity of those inscriptions in which they appear must be established before they can be urged in opposition to the present argument.

II. "It is not probable that the chronicle was engraved for *private use*."—Our author thinks it an impossible supposition that such an expensive and cumbersome work could have been executed by a private citizen, either for his own amusement, or for the benefit of his fellow-citizens. In the first place, a long inscription could not be engraved in marble without such an expence as few learned Greeks were able to afford. Or, if its author, by an uncommon felicity, was able to erect such a literary monument, the scheme would have been useless and imprudent; as all the contents of the inscription might have been published more commodiously and effectually by the common mode of writing in use at that time.

A variety of arguments is adduced, illustrating the superiority of a manuscript to such an inscription as the chronicle, in a number of respects; and enforcing the improbability of its having ever been executed, either for public or private use. Much evidence from ancient history is likewise produced in support of the assertion, that the common mode of writing, in the reign of Ptolemy Philadelphus, was not on stones. It is not, however, necessary to prove, by the testimony of ancient authors, that books were written on parchment, or paper made of the Egyptian papyrus, or any such materials, before the date of the Parian chronicle. This is sufficiently evinced by the very existence of the writings of Moses, David, Solomon, and the Jewish prophets; the works of Homer, Hesiod, Anacreon, Pindar, Eschylus, Sophocles, Euripides, Herodotus, Hippocrates, Aristophanes, Thucydides, Xenophon, Plato, Demosthenes, Aristotle, &c. And it is still more incontestibly proved by the libraries which were collected in preceding ages, or about that time, such as those of Polycrates in Samos, Pisistratus and Euclides at Athens, Nicocrates in Cyprus, Euripides the poet,

Aristotle

Arundelian.

Ariſtotle the philoſopher, Clearchus at Heraclea Pontica, and the moſt extenſive and magnificent library of Ptolemy Philadelphus in Egypt, founded in or before the year 284, which in his time is ſaid to have contained 100,000 volumes, and to have been enlarged by his ſucceſſors to the amount of almoſt 700,000. Not long afterwards a library was founded at Pergamus by Attalus and Eumenes, which, according to Plutarch, contained 200,000. Theſe are clear and deciſive proofs, that the common mode of writing in the time of Ptolemy Philadelphus was not on ſtones.

III. "The chronicle does not appear to have been engraved by *public authority*."

1. The firſt argument in ſupport of this opinion is, that inſcriptions of that kind uſually begin with a particular form; as, Η ΒΟΤΛΗ ΚΑΙ Ο ΔΗΜΟΣ, 'The ſenate and the people;' or thus, ΕΔΟΞΕΝ ΤΗΙ ΒΟΤΛΗΙ ΚΑΙ ΤΟΙ ΔΗΜΩΙ, 'It pleaſed the ſenate and the people, &c.' But the Parian chronicle begins in the manner of a private man, ſpeaking of his own performance in the firſt perſon ſingular. This argument, our author remarks, cannot be much affected by obſerving, that the beginning of the inſcription is obliterated; for it is neceſſarily implied by the words now remaining.

2. The facts, and dates, which are mentioned in this chronicle, do not appear to have been extracted from any public records, or calculated to anſwer the purpoſe of authentic documents; as many eminent princes and magiſtrates are paſſed over without notice; in ſeveral inſtances, the tranſactions of whole centuries are omitted: and the facts, chiefly ſpecified are not matters of general or national importance.

3. The Parian inſcription is ſuch a one as we can hardly ſuppoſe the magiſtrates of the people of Paros would have ordered to be engraved. Stately ſepulchres, pillars, triumphal arches, and the like, were erected to perpetuate the glory of eminent men. The remembrance of events in which nations were intereſted, the ſucceſſion of princes, &c. were preſerved in the ſame manner. Leagues, decrees, and laws, were likewiſe engraved on marble or braſs, and fixed to a pillar, the walls of a temple, or other public buildings; becauſe ſuch inſcriptions were deſigned for the inſpection of the people, as they eſſentially concerned their conduct, their property, their liberty, or their lives. But, our author aſks, for whom could the chronicle of Paros be intended? It contains no encomiums on any of the patriots, the heroes, or the demigods of the country, no decrees of the magiſtrates, no public records, no laws of ſtate. On the contrary, it is a work of mere ſpeculation and learning, in which the inhabitants of that iſland, eſpecially the common people, had not the leaſt intereſt or concern.

Theſe words at the beginning, *αρχον τος εμ Παρω*, would naturally lead us to ſuppoſe, that the inſcription related to Paros. And, if ſo, it would have been natural for the author to have mentioned ſome of the moſt important occurrences in the hiſtory of that iſland. But, ſays this acute and learned critic, what ſcheme does our chronologer purſue on this occaſion? Does he record the events and revolutions of his own country? Does he mention any of the battles, ſieges, and treaties of the Parians? any of their public inſtitutions? any of their poets, patriots, or warriors? Does he mention Archilochus, who was honoured by his countrymen, and diſtinguiſhed as a poet in a general aſſembly of the Greeks?—Not a ſyllable on any of theſe ſubjects! On the contrary, he rambles from place to place, and records the tranſactions of Athens, Corinth, Macedon, Lydia, Crete, Cyprus, Sicily, Perſia, and other foreign countries with which Paros had no connection.

In this view the inſcription ſeems to have been as impertinent in the iſland of Paros, as a marble monument would be in this country, recording the antiquities of France or Spain, or one in Jamaica recording the revolutions of England. But upon ſuppoſition that the inſcription is a forgery, it is eaſy to account for this extraordinary circumſtance. A few chronological occurrences in the ancient hiſtory or Paros, would not have been ſo intereſting to the generality of readers, or ſo valuable in the eſtimation of every lover of antiquities, or, in ſhort, ſo profitable to the compiler, as a general ſyſtem of Grecian chronology.

IV. "The Greek and Roman writers, for a long time after the date of this work, complain that they had no chronological account of the affairs of ancient Greece." This poſition is confirmed by the teſtimony of Julius Africanus, Juſtin Martyr, Plutarch, Joſephus, Varro, Diodorus Siculus, and others; and the following ſeries of interrogatories is ſubjoined: 'Thucydides, I know, lived 140 years before the chronicle is ſaid to have been written; but if Thucydides, as well as other writers, complained that there was nothing but uncertainty in the earlier period of Grecian hiſtory, from whence can we ſuppoſe the author of this inſcription collected ſuch a clear, determinate, and comprehenſive ſyſtem of chronology? If we had any ſources of information, which were unknown to ſucceeding writers, how happens it, that they ſhould all of them overlook this moſt conſiderable, moſt exact, moſt creditable author? Why did they omit this ancient account of their early ages? Why did they not copy his moſt memorable epochas? Why did they not produce his authority? or, at leaſt, why did they not mention his opinion? Surely nothing, to all appearance, could be more elaborate, more important, or of higher authority, than a chronological table, which was thought worthy of being engraved on marble.

V. "The chronicle is not once mentioned by any writer of antiquity." This indeed appears a ſtrong argument againſt its authenticity. Apollodorus, an Athenian, the diſciple of Ariſtarchus the grammarian, and Panætius the philoſopher, wrote a genealogical and hiſtorical work on the early ages of Greece; but, though compoſed 120 years after the date of the Parian chronicle, it does not contain the ſmalleſt traces of a ſyſtematical chronology. It is remarkable too that the chronicle of Apollodorus is quoted by Diodorus Siculus, Strabo, Plutarch, A. Gellius, Lucian, and many other writers of antiquity; while the Parian chronicle, which comprehends a more extenſive period, is entirely unnoticed. It contains, however, ſuch wonderful diſcoveries in ancient hiſtory, that if it had exiſted 264 years before the Chriſtian æra, it muſt have excited a general attention, and been referred to as an authority by writers of ſucceeding times. But we do not find, in any author of antiquity, either poet or hiſtorian, geographer or chronologer, mythologiſt or ſcholiaſt, the moſt diſtant alluſion to the Parian chronicle; though it was ſuch a common practice among the

the ancients to mention the works of their predeceſſors, that in many books we find references and alluſions to three, four, five, ſix, or ſevent hundred different authors of every denomination.

VI. "Some of the facts mentioned in the chronicle ſeem to have been taken from writers of a later date." Our inquirer collates ſeveral paſſages in the Parian chronicle with parallel paſſages in Greek authors, to evince that there is, in the former, an appearance of imitation, or a ſtronger reſemblance than ſuch as may be ſuppoſed to ariſe from accident; that there are likewiſe ſome improbabilities attending the account of Deucalion, as related in the Parian chronicle; and that the names of ſix, and, if the lacunæ are properly ſupplied, the names of 12 cities appear to have been engraved on the marble, exactly as we find them in Ælian's Various Hiſtory. But there is not, our author obſerves, any imaginable reaſon for this particular arrangement. It does not correſpond with the time of their foundation, with their ſituation in Ionia, with their relative importance, or with the order in which they are placed by other eminent hiſtorians. The argument by which our author endeavours to prove that the Parian chronicle has, in this inſtance, copied Ælian's Various Hiſtory, ſeems deciſive of the fact. He obſerves, that ſix names may be tranſpoſed 720 different ways; and that 12 names admit of 479,001,600 different tranſpoſitions. Suppoſing then, there is no particular reaſon for one arrangement rather than another, it will follow, that the chance of two authors, placing them in the ſame order, is, in the former caſe, as 1 to 720; and in the latter, as 1 to 479,001,600. It is therefore, ſays he, utterly improbable, that theſe names would have been placed in this order on the marble, if the author of the inſcription had not tranſcribed them from the hiſtorian.

It may indeed be urged, with regard to this ſimilarity of arrangement in the Parian chronicle and Ælian's Various Hiſtory, that the inference might be the very inverſe of that which is ſpecified by our author. But that Ælian ſhould have ſeen the Parian chronicle, without once mentioning it; or that he ſhould have exactly copied a liſt of towns, arranged neither according to chronological nor topographical order; is indeed a ſuppoſition equally improbable with the other.

VII. "Parachroniſms appear in ſome of the epochas, which we can ſcarcely ſuppoſe a Greek chronologer in the 129th Olympiad would be liable to commit." After ſpecifying theſe, our inquirer aſks, Would a writer of reputation and learning, in one of the moſt poliſhed and enlightened æras of ancient Greece, commit ſuch miſtakes, in oppoſition to the poſitive atteſtations of the moſt accurate hiſtorians, in events of public notoriety? Would a private citizen, or a magiſtrate of Paros, order a crude and inaccurate ſeries of epochas to be engraved, at a great expence, and tranſmitted to poſterity on a marble moument? It is hardly probable.

VIII. "The hiſtory of the diſcovery of the Parian chronicle is obſcure and unſatisfactory. Our author obſerves, that it is attended with ſome ſuſpicious circumſtances, and without any of thoſe clear and unequivocal evidences which always diſcriminate truth from falſehood. There are no data in the inſcription by which to diſcover the place where the marble was erected. The place likewiſe where it was found is not aſcertained; though the generality of writers who have had occaſion to mention it have ſuppoſed that it was found in the iſland of Paros. If it was erected at Smyrna, as ſome imagine, our author aſks, for what purpoſe does the writer mention Aſtyanax the archon of Paros, and not one circumſtance relative to Smyrna? If, adds he, it was erected at Paros, why does he not mention more archons of that city than one? Or how ſhall we account for his profound ſilence with reſpect to all the events and revolutions which muſt have happened in that iſland, and have been infinitely more intereſting to the natives than the tranſactions of any foreign country?

The train of circumſtances by which the Parian chronicle came into the poſſeſſion of Mr Petty, whom Lord Arundel had ſent into the eaſt for the purpoſe of collecting antiquities, as well as the ſubſequent conduct of Peireſc, its former owner, affords our author a ſtrong preſumption, that, "the inſcription was actually fabricated, with the view of obtaining for it a high price, upon the pretence that it was a relic of great antiquity. It is certain, that there is ſomething myſterious in the conduct of the firſt oſtenſible proprietors. Theſe marbles had been totally unknown, or unnoticed, for almoſt 1900 years, and at laſt they are dug out of the ground—no body can tell us when or where!"

IX. "The literary world has been frequently impoſed upon by ſpurious books and inſcriptions; and therefore we ſhould be extremely cautious with regard to what we receive under the venerable name of antiquity." This propoſition is illuſtrated by a great variety of examples, and very properly expoſes the forgeries which have diſgraced the republic of letters in different ages; and although one of the more recent ones cited, namely, Oſſian's poems, be a point very far indeed from being eſtabliſhed, yet that deceptions of this kind have been practiſed is an unqueſtionable fact.

In endeavouring, towards the end of his diſſertation to inveſtigate the time of the ſuppoſed forgery, he obſerves, That the 16th century, and the prior part of the 17th, produced a multitude of grammarians, critics, and commentators, deeply verſed in Grecian literature, and amply qualified for the compilation of ſuch a chronological ſyſtem as that of the Arundelian marbles. Above all, the ſcience of chronology was particularly ſtudied and inveſtigated about that time: "Nunc fervet chronologia," ſays Scaliger in the year 1605, "omnes hoc ferrum excalfaciunt." Cauſabon treats thoſe perſons with contempt who were unacquainted with the improvements which had been made in that department of learning after the revival of letters. Innumerable ſyſtems of chronology had been publiſhed before the year 1625; from which it was eaſy to extract a ſeries of memorable events, and give the compilation a Grecian dreſs. "The avidity," ſays our author, "with which all relics of antiquity were then collected, and the high price at which they were purchaſed, were ſufficient inducements to any one, whoſe avarice or whoſe neceſſity was ſtronger than his integrity, to engrave his labours on marble, and tranſmit them to Smyrna, as a commodious emporium for ſuch rarities."

The preciſe period of the fabrication, however, muſt ſtill

Arundo.

still be reckoned apocryphal and uncertain. The sum of fifty guineas, which Peiresc gave to the supposed fabricator, was inadequate to such a laborious and expensive work. Upon the whole, perhaps, it would be too hasty to pronounce decisively that this famous Chronicle so long respected, is an imposition upon the public. It may, however, be safely affirmed, that the suspicions against it are extremely strong, and the objections already cited of a nature very difficult to be removed. No attempts have yet been made with this view: But under some future article, as CHRONOLOGY, MARBLES, or PARIAN *Chronicle*, we may possibly have an opportunity of resuming the subject with additional information.

ARUNDO, the REED: A genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx consists of two valves, and the flosculеs are thick and downy.

Species and properties. 1. The phragmitis, or common marsh-reed, grows by the sides of rivers and in standing waters. 2. The debax, or manured reed, is a native of warm countries, but will bear the cold of moderate winters in the open air. It dies to the surface in autumn, but appears again in the spring, and if kept supplied with water, will grow 10 or 12 feet high in one summer. The stalks of this are brought from Spain and Portugal; and are used by the weavers, as also for making fishing-rods. 3. The versicolor, or Indian variegated reed, is supposed to be a variety of the second, differing from it only in having variegated leaves. 4. The bambos, or bamboo *, is a native of the East Indies and some parts of America; where it frequently attains the height of 60 feet. The main root is long, thick, jointed, spreads horizontally, and sends out many cylindrical woody fibres, of a whitish colour, and many feet long. From the joints of the main root spring several round jointed stalks to a prodigious height, and at about 10 or 12 feet from the ground send out at their joints several stalks joined together at their base: these run up in the same manner as those they shoot out from. If any of these be planted with a piece of the first stalk adhering to them, they will perpetuate their species. They are armed at their joints with one or two sharp rigid spines, and furnished with oblong oval leaves, eight or nine inches long, seated on short footstalks. The flowers are produced in large panicles from the joints of the stalk, placed three in a parcel close to their receptacles: they resemble those of the common reed, and are succeeded by seeds of the same form surrounded with down.

* See *Bamboo*.

The young shoots are covered with a dark-green bark; these when very tender are put up in vinegar, salt, garlic, and the pods of capsicum, and thus afford a pickle, which is esteemed a valuable condiment in the Indies, and is said greatly to promote the appetite and assist digestion (see ACHIAR). The stalks in their young state are almost solid, and contain a milky juice: this is of a sweet nature; and as the stalks advance in age, they become hollow, except at the joints, where they are stopped by a woody membrane, upon which this liquor lodges, and concretes into a substance called *Tabaxir*, or sugar of *Mombu*, which was held in such esteem by the ancients, in some particular disorders, that it was equal in value to its weight in silver. The old stalks grow to five or six inches diameter, are then of a shining yellow colour, and so hard and durable that they are used in buildings, and for making all sorts of houshold furniture. These, when bored through the membranes at their joints, are converted into water-pipes. They serve also to make the sticks and poles with which the slaves or other persons carry those sorts of litters which are called *palanquins*, and are so common and convenient in all the East. The smaller stalks are used for walking-sticks. The inhabitants of Otaheite make flutes of them, about a foot long, with two holes only, which they stop with the first finger of the left hand and the middle one of the right, and they blow through their nostrils. 5. The arborea, with a tree-like stalk, differs from the former only in having narrower leaves. 6. The orientalis is what the Turks use as writing-pens; it grows in a valley near mount Athos, as also on the banks of the river Jordan. None of these plants are at present to be found in Britain.

Arundo, Arusini.

Culture. As all these plants grow naturally in low marshy lands, they must be supplied with plenty of water. The second kind requires little care; the third is more delicate, and requires to be kept in pots. The fourth, fifth, and sixth sorts must be preserved in stoves. They are to be planted in tubs filled with rich earth, and plentifully supplied with water. When the tubs decay, they may be suffered to grow into the tan, which will encourage them to grow to a larger size: but care must be taken, when the bed is refreshed with new tan, to leave a sufficient quantity of old tan about the roots of the plants; for if they are too much bared and the new tan laid near them, when that heats, it will scorch their roots, so that the plants are sometimes destroyed by it.

ARUNDO Saccharifera, or *Sugar-cane*. See SACCHARUM.

ARUSINI CAMPI (erroneously written *Taurasini* by Cluverius), plains in Lucania famous for the last battle fought between the Romans and Pyrrhus. That prince being at Tarentum, and hearing that the two new consuls Curius Dentatus and Cornelius Lentulus had divided their forces, the one including Lucania and the other Samnium; he likewise divided a chosen detachment of his army into two bodies, marching with his Epirots against Dentatus, in hopes of surprising him in his camp near Beneventum. But the consul, having notice of his approach, marched out of his entrenchments with a strong detachment of legionaries to meet him, repulsed his van-guard, put many of the Epirots to the sword, and took some of their elephants. Curius, encouraged by this success, marched into the Arusian fields, and drew up his army in a plain, which was wide enough for his troops, but too narrow for the Epirot phalanx to act with its full effect. But the king's eagearness to try his strength and skill with so renowned a commander, stimulated him to engage at that great disadvantage. Upon the first signal the action began; and one of the kings wings giving way, victory seemed to incline to the Romans. But that wing where the king fought in person repulsed the enemy, and drove them to their intrenchments. This advantage was in great part owing to the elephants; a circumstance which Curius perceiving, commanded a body of reserve, which he had posted near the

the camp, to advance and attack those animals with burning torches; which frightened and annoyed them to such a degree, that they wheeled about, broke into the phalanx, and put that body into the utmost disorder. The Romans taking advantage of this confusion, charged with such fury that the enemy were entirely broken and defeated. Pyrrhus retired to Tarentum, attended only by a small body of horse, leaving the Romans in full possession of his camp; which they so much admired, that they made it a model which they followed ever after.

ARUSPICES, or HARUSPICES, in Roman antiquity, an order of priests who pretended to fortel future events by inspecting the intrails of victims killed in sacrifice; they were also consulted on occasion of portents and prodigies. The haruspices were always chosen from the best families; and as their employment was of the same nature as that of the augurs, they were as much honoured. Their college, as well as those of the other religious orders, had its particular registers and records.

ARX, in the ancient military art, a town, fort, or castle, for defence of a place.

The arx in ancient Rome was a distinct edifice from the capitol, though some have confounded the two. According to Ryckius, the arx, properly speaking, was a place on the highest part of the Capitoline Mount, stronger and better fortified than the rest, with towers and pinnated walls: in which was also the temple of Jupiter Capitolinus.

ARX also denoted a consecrated place on the Palatine Mount, where the augurs publicly performed their office. Some will have the arx to have been the augural temple; but Varro expresly distinguishes between the two.

ARX was particularly used for a public place in Rome, set apart for the operations of the augurs. In which sense arx amounts to the same with what is otherwise called *auguraculum* and *auguratorium*, and in the camp *augurale*. Out of this arx it was that the *feciales*, or heralds, gathered the grass used in the ceremony of making leagues and treaties.

ARX Britannica, a citadel of Batavia, whose foundation is seen at low water, near the old mouth of the middle Rhine: some imagine it the pharos or high tower of Caligula, as Suetonius calls it; a monument of Caligula's sham conquest of Britain. Others, that it was built by Drusus, with an altar afterwards by Claudius, on his expedition into Britain. But the usual passage was from Gessoriacum; and Suetonius expresly says, Claudius passed over thence. The ancient name of this citadel, now covered by the sea, is no where expressed: Now commonly called *'t Huis Britten*, or *Brittenburg*; that is, *Arx Britannica*; but from what authority does not appear.

ARYTENOIDES, in anatomy, the name of two cartilages which, together with others, constitute the head of the larynx. It is also applied to to some muscles of the larynx.

ARYTHMUS, in medicine, the want of a just modulation in the pulse. It is opposed to *eurythmus*, a pulse modulated agreeably to nature.

ARZILLA, a very ancient maritime town of Africa, in the kingdom of Fez, about five leagues from Tangiers. It is built at the mouth of a river, and inhabited by Moors and Jews, who carry on no trade. It was formerly a Roman colony; afterwards fell under the government of the Goths, and was next taken by the Mahometans. Alphonso of Portugal, surnamed the African, took it by assault in 1471, and brought away the presumptive heir of the crown. After that prince came to the throne, he besieged it, in 1508, with 100,000 men; but was obliged to abandon the undertaking. However, at length the Portuguese forsook it of their own accord. W. Long. 5. 30. N. Lat. 35. 30.

AS, in antiquity, a particular weight, consisting of 12 ounces; being the same with *libra*, or the Roman pound. The word is derived from the Greek *αις*, which in the Doric dialect is used for *εις*, *one*, q. d. an entire thing; though others will have it named *as* quasi *æs*, because made of brass.

As was also the name of a Roman coin, which was of different weights and different matter in different ages of the commonwealth.—Under Numa Pompilius, according to Eusebius, the Roman money was either of wood, leather, or shells. In the time of Tullus Hostilius it was of brass: and called *as*, *libra*, *libella*, or *pondo*, because actually weighing a pound or 12 ounces. Four hundred and twenty years after, the first Punic war having exhausted the treasury, they reduced the *as* to two ounces. In the second Punic war, Hannibal pressing very hard upon them, they reduced the *as* to half its weight, viz. to one ounce. And lastly, by the Papirian law, they took away half an ounce more, and consequently reduced the *as* to the diminutive weight of half an ounce: and it is generally thought that it continued the same during the commonwealth, and even till the reign of Vespasian. The *as* therefore was of four different weights in the commonwealth. Its original stamp was that of a sheep, ox, or sow: but from the time of the emperors, it had on one side a Janus with two faces, and on the reverse the rostrum or prow of a ship.

As was also used to denote any integer or whole. Whence the English word *ace*.—Thus *as* signified the whole inheritance; whence *hæres ex asse*, the heir to the whole estate.

ASA, king of Judah, succeeded his father Abijam. He pulled down the altars erected to idols, restored the worship of the true God, and, with the assistance of Benhadad king of Syria, took several tows from the king of Israel. He died 917 years before the Christian æra, and was succeeded by Jehoshaphat.

ASA, among naturalists. The writers of the later ages have formed this word *asa* from the lasar of the ancients, and attributed it to a gum very different from that anciently known by the name they have thus corrupted.

The asa of the ancients was an odoriferous and fragrant gum; and the asa of the after-ages had so little title to this epithet, that they distinguished it by one, expressing its being of an offensive or stinking smell. The Arabian writers, according to this distinction, describe two kinds of asa, the one stinking, the other aromatic; and the modern Greeks preserved the name *asa*, or *lasa*, to the stinking gum the Latins called by that name, but added a distinctive epithet to express its smell, and called it *scardolasarum*.

Asa or Assa, in the materia medica, a name given to two very different substances, called *asa-dulcis* and *asa-fœtida*.

Asa-Dulcis is the same with Benzoin.

Asa-Fœtida is the concrete juice of a large umbelliferous plant growing in several parts of Asia; the properties of which are described under the article Ferula.

ASAPH (St), a city in Flintshire, with a bishop's see; on which account principally it deserves notice, being in itself but a poor place. As a bishoprick, it is of great antiquity, and was founded about the year 560, by Kentigern, a Scotsman, bishop of Glasgow. He began the church on the banks of the river Elwy, whence it is called by the Welsh *Land Elwy*, and in Latin *Elwensis*. Kentigern returning into Scotland, left a holy man his successor, St Asaph. Who was his successor is uncertain, as there are no records that mention it; and it seems rather probable that the religious settled here had been necessitated to remove to some more peaceful abode, as the country was frequently the seat of war between the English and the Welsh. This see was formerly a very wealthy one; but its revenues were greatly lessened by the profusion of bishop Parfew, who alienated much of the lands belonging to this bishoprick.

This diocese doth not contain any one whole county; but consists of part of Denbigh, Flint (where its church is), Montgomery, and Merioneth shires, and a small part of Shropshire; wherein are 121 parishes, and 131 churches and chapels, most of which are in the immediate patronage of the bishop. This see hath but one archdeaconry, viz. that of St Asaph, which is united to the bishoprick, for the better maintenance thereof. This see is valued in the king's books at L. 187 : 11, 6, but computed to the worth annually L. 1500. The tenth of the clergy comes to L. 186 : 19 : 6¾. To this cathedral belongs a bishop, a dean, archdeacon, chancellor, &c.

ASAPPES, or Azapes, an order of soldiers in the Turkish army, whom they always expose to the first shock of the enemy; to the end that the enemy being thus fatigued, and their swords blunted, the spahis and janisaries may fall on and find an easy conquest. The word is derived from the Turkish *saph*, which signifies *rank*, from whence they have formed *asphaph*, "to range in battle." The asappes are said to be held of so little value, that they frequently serve as bridges for the cavalry to pass over in bad roads, and as fascines to fill up the ditches of places besieged. They travel on foot, and have no pay but the plunder they can get from the enemy.

ASAR-addon, or Esar-Haddon, the son of Sennacherib, succeeded his father about 712 years before the Christian æra, and united the kingdoms of Nineveh and Babylon. He rendered himself master of Syria; sent a colony to Samaria; and his generals took king Manesses, and carried him loaded with chains to Babylon. Asar-Addon died after a reign of 12 years.

ASARINA. See Chelone.

ASAROTA, ασαρωτα, from α and σαιρω, *I sweep*, a kind of painted pavements in use before the invention of mosaic work. The most celebrated was that at Pergamus, painted by Sesus, and exhibiting the appearance of crumbs, as if the floor had not been swept after dinner, whence, according to Pliny, the denomination. Perrault supposes them to have been a black kind of pavements of a spongy matter.

ASARUM, asarabacca: A genus of the monogynia order, belonging to the dodecandria class of plants. The calyx is trifid or quadrifid, and rests on the germen; there is no corolla; the capsule is leathery and crowned.—The species are three; the Europeum, the Canadense, and Virginicum. The first species grows naturally in some parts of England. It hath thick fleshy jointed roots; the leaves grow singly upon short foot-stalks, which arise immediately from the root: the flowers grow upon very short foot-stalks close to the ground, so are hid under the leaves. They have a bell-shaped impalement, of a worn-out purple colour, which is cut in three at the top, where it turns backward. It delights in a moist shady place, and may be propagated by parting the roots in autumn. The two other species have no remarkable properties.

Medicinal Uses. The dried roots of this plant have been generally brought from the Levant; those of our own growth being supposed weaker. Both the roots and leaves have a nauseous, bitter, acrimonious, hot taste; their smell is strong, and not very disagreeable. Given in substance from half a dram to a dram, they evacuate powerfully both upwards and downwards. It is said, that tinctures made in spirituous menstrua, possess both the emetic and cathartic virtues of the plant; that the extract obtained by inspissating these tinctures, acts only by vomit, and with great mildness; that an infusion in water proves cathartic, rarely emetic; that aqueous decoctions made by long boiling, and the watery extract, have no purgative or emetic quality, but prove notable diaphoretics, diuretics, and emmenagogues.

The principal use of this plant among us is as a sternutatory. The root of asarum is perhaps the strongest of all the vegetable errhines, white hellebore itself not excepted. Snuffed up the nose, in the quantity of a grain or two, it occasions a large evacuation of mucus, and raises a plentiful spitting. The leaves are considerably milder, and may be used to the quantity of three, four, or five grains. Geoffroy relates, that after snuffing up a dose of this errhine at night, he has frequently observed the discharge from the nose to continue for three days together; and that he has known a paralysis of the mouth and tongue cured by one dose. He recommends this medicine in stubborn disorders of the head proceeding from viscid tenacious matter, in palsies, and in soporific distempers. The leaves are the principal ingredient in the *pulvis sternutatorius* or *pulvis asari compositus*, as it is now called, of the shops.

ASBAMEA, a fountain of Cappadocia, near Tyana, sacred to Jupiter, and to an oath. Though this fountain bubbled up, as in a state of boiling, yet its water was cold; and never ran over, but fell back again: (Philostratus, Ammian).

ASBESTOS, a sort of native fossile stone, which may be split into threads and filaments, from one inch to ten inches in length, very fine, brittle, yet somewhat tractable, silky, and of a greyish colour, not unlike talc of Venice. It is almost insipid to the taste, indissoluble in water, and endued with the wonderful property of remaining unconsumed in the fire, which only whitens it. There are some sorts of asbestos whose

whose filaments are rigid and brittle; others more flexible.

The industry of mankind has found a method of working this untoward mineral, and employing it in divers manufactures, chiefly cloth and paper. The manufacture is undoubtedly difficult enough. Pliny calls the asbestos *inventu rarum, textu difficilimum*. Wormius assures us, that the method of making cloth of asbestos is now entirely unknown. And indeed one would scarce imagine the thing practicable, without the mixture of some other pliant matter, as wool, hemp, or flax, along with the asbestos, the filaments of this latter appearing too coarse and brittle to make any tolerable fine work. However this be, Bapt. Porta assures us, that in his time the spinning of asbestos was a thing known to every body at Venice. Sig. Castagnatta, superintendant of some mines in Italy, is said to have carried the manufacture to such perfection, that his asbestos was soft and tractable, much resembling lamb-skin dressed white: he could thicken and thin it at pleasure, and thus either make it into a very white skin or a very white paper.

This kind of linen cloth was chiefly esteemed by the ancients; though then better known and more common than among us, being held equally precious with the richest pearls: nor is it now of mean value, even in the country where it is most generally made, a China cover (i. e. a piece of 23 inches and three-quarters long) being worth 80 tale, i. e. L. 36 : 13 : 4. Pliny says, he himself had seen napkins thereof, which, being taken foul from the table after a feast, were thrown into the fire, and by that means were better scoured than if they had been washed in water, &c. But its principal use, according to Pliny, was for the making of shrouds for royal funerals, to wrap up the corpse, so that the ashes might be preserved distinct from those of the wood, &c. whereof the funeral pile was composed: and the princes of Tartary, according to the accounts in the Philosophical Transactions, still use it at this day in burning their dead. Some of the ancients are said to have made themselves clothes of it, particularly the Brachmans among the Indians. The wicks for their perpetual lamps, according to Dr Lister, were also made of it: some to this day use it for the wicks of such lamps as they would not have any trouble with; because the asbestos never wasting, there is no occasion for shifting the wick. Septalla, canon of Milan, had thread, rope, nets, and paper, made of the asbestos. A handkerchief or pattern of this linen was long since presented to the Royal Society, a foot long and half a foot broad. This gave two proofs of its resisting fire; though, in both experiments, it lost above three drams in its weight. When taken out red-hot, it did not burn a piece of white paper on which it was laid. Mr. Villette pretends that his large burning concave usually vitrifies the asbestos.

The method of preparing the incombustible paper and cloth is thus described by Ciampini: The stone is laid to soak in warm water; then opened and divided by the hands, that the earthy matter may be washed out. The ablution being several times repeated, the flax-like filaments are collected and dried; and they are most conveniently spun with an addition of flax. Two or three filaments of the asbestos are easily twisted along with the flaxen thread, if the operator's fingers are kept oiled. The cloth also, when woven, is best preserved by oil from breaking or wasting. On exposure to the fire, the flax and the oil burn out, and the cloth remains pure and white. Probably from the dissipation of some extraneous matter of this kind proceeded the diminution of weight in the handkerchief just recited; for pure asbestos leaves nothing. The shorter filaments which separate in washing the stone may be made into paper in the common manner.

The asbestos is found in Crete and Cyprus; in Tartary; at Namur in the Low Countries; in Thuringia among the mines; in the Old Noricum; in Egypt; in the mountains of Arcadia; at Puteoli; in the island of Corsica; in the island of Anglesey in Wales; in Aberdeenshire in Scotland: at Montauban in France; and in the kingdom of Siberia.

ASCALON, an ancient city, and one of the five satrapies or principalities of the Philistines; situated on the Mediterranean, 43 miles to the south-west of Jerusalem (Antonine), between Azotus to the north and Gaza to the south. The birth-place of Herod the Great, thence surnamed *Ascalonita* (Stephanus). Famous for its scallions, which take name from this town (Strabo, Pliny). Now *Scalona*. E. Long. 34. 30. Lat. 31. 30.

ASCANIUS, the son of Æneas and Creusa, succeeded his father in the kingdom of the Latins, and defeated Mezentius king of the Tuscans, who had refused to conclude a peace with him. At length he founded Alba Longa; and died about 1139 years before the Christian æra, after a reign of 38 years.

ASCARIS, in zoology, a genus of insects belonging to the order of vermes intestina. The body of the ascaris is cylindrical, filiform, and tapers at both ends. The species are two, viz. 1. The vermicularis, with faint annular rugæ, and the mouth transverse, is about a quarter of an inch long, and thicker at one end than the other. It is found in boggy places, in the roots of putrid plants, and very frequently in the rectum of children and horses. It emaciates children greatly, and is sometimes vomited up. 2. The lumbricoides is about the same length with the lumbricus terrestris, or common earth-worm; but it wants the protuberant ring towards the middle of the body, the only mark by which they can properly be distinguished. The body of the lumbricoides is cylindrical, and subulated at each extremity; but the tail is somewhat triangular. The lumbricoides is the worm which is most commonly found in the human intestines. It is viviparous, and produces vast numbers. For the method of expelling these two kinds of insects, see MEDICINE-*Index*.

Plate LV.

ASCENDANT, in astrology, denotes the horoscope, or the degree of the ecliptic which rises upon the horizon at the time of the birth of any one. This is supposed to have an influence on the person's life and fortune, by giving him a bent and propensity to one thing more than another.

In the celestial theme, this is also called the *first house*, the *angle of the East* or *Oriental angle*, and the *significator of life*.—Such a planet ruled in his *ascendant*: Jupiter was in his *ascendant*, &c.—Hence the word is also used in a moral sense, for a certain superiority which one man has over another, from some unknown cause.

ASCENDANTS, in law, are opposed to descendants in

Ascending, Ascension. in ſucceſſion; i. e. when a father ſucceeded his ſon, or an uncle his nephew, &c. heritage is ſaid to aſcend, or go to aſcendants.

ASCENDING, in aſtronomy, is ſaid of ſuch ſtars as are riſing above the horizon in any parallel of the equator.

Ascending Latitude, is the latitude of a planet when going towards the north pole.

Ascending Node, is that point of a planet's orbit wherein it paſſes the ecliptic, to proceed northward. This is otherwiſe called the *northern node*, and repreſented by this character ☊.

Ascending Veſſels, in anatomy, thoſe which carry the blood upwards; as the aörta aſcendens. See Anatomy, n° 123.

ASCENSION, in aſtronomy, is either right or oblique. Right aſcenſion of the ſun, or a ſtar, is that degree of the equinoctial, counted from the beginning of aries, which riſes with the ſun or ſtar in a right ſphere. Oblique aſcenſion is an arch of the equator intercepted betwen the firſt point of aries and that point of the equator which riſes together with a ſtar in an oblique ſphere.

Ascension Day, a feſtival of the Chriſtian church, held ten days before Whitſuntide, in memory of our Saviour's aſcenſion into heaven after his reſurrection.

Ascension Iſland, a barren iſland on the coaſt of Africa, lying in W. Long. 17. 20. S. Lat. 7. 5. The following account is given of it by Mr Forſter. "This iſland was firſt diſcovered in 1501, by Joaõ de Nova Galego, a Portugueſe navigator, who named it *Ilha de Noſſa Senhora de Conceiçao*. The ſame admiral, on his return to Portugal in 1502, diſcovered the iſland of St Helena, which obtained that name from the day of the diſcovery. Aſcenſion was ſeen a ſecond time by Alfonſo d'Albuquerque on his voyage to India in 1503, and then received the name it now bears; but was already at that time in the ſame deſolate condition as at preſent. "We ſent ſeveral parties on ſhore, who paſſed the night on the watch for turtles, which came to lay their eggs on the ſandy ſhores. The drearineſs of this iſland ſurpaſſed all the horrors of Eaſter Iſland and Tierra del Fuego, even without the aſſiſtance of ſnow. It was a ruinous heap of rocks, many of which, as far as we could diſcern from the ſhip, ſeemed to be totally changed by the fire of a volcano. Nearly in the centre of the iſland riſes a broad white mountain of great height, on which we diſcerned ſome verdure by the help of our glaſſes, from whence it has obtained the name of *Green Mountain*.

"We landed early in the morning among ſome rocks, the ſurf being always immenſely high on the great beach; which conſiſts of minute ſhell-ſand, chiefly of a ſnowy white, very deep, dry, and intolerable to the eyes when the ſun ſhines. We aſcended among heaps of black cavernous ſtone, which perfectly reſembles the moſt common lavas of Veſuvius and Iceland, and of which the broken pieces looked as if they had been accumulated by art. The lava currents cooling very ſuddenly, may eaſily be imagined to produce ſuch an effect. Having aſcended about 12 or 15 yards perpendicular, we found ourſelves on a great level plain of ſix or eight miles in circuit; in the different corners of which we obſerved a large hill of an exact conical ſhape, and of reddiſh colour, ſtanding perfectly inſulated. Part of the plain between theſe conic hills was covered with great numbers of ſmaller hillocks, conſiſting of the ſame wild and ragged lava as that near the ſea, and ringing like glaſs when two pieces are knocked together. The ground between the heaps of lava was covered with a black earth, on which we walked very firmly; but when theſe heaps did not appear, the whole was a red earth, which was ſo looſe, and in ſuch dry minute particles, that the wind raiſed clouds of duſt upon it. The conic hills conſiſted of a very different ſort of lava, which was red, ſoft, and crumbling into earth. One of theſe hills ſtands directly in front of the bay, and has a wooden croſs on its ſummit, from whence the bay is ſaid to take its name. Its ſides are very ſteep, but a path near three quarters of a mile long winds round it to the ſummit. After examining this remarkable country a little longer, we concluded, with a great degree of probability on our ſide, That the plain on which we ſtood was once the crater or ſeat of a volcano, by the accumulation of whoſe cinders and pumice-ſtones the conic hills had been gradually formed: that the currents of lava which we now ſaw divided into many heaps, had perhaps been gradually buried in freſh cinders and aſhes; and the waters coming down from the interior mountain in the rainy ſeaſon had ſmoothened every thing in their way, and filled up by degrees the cavity of the crater. The rocky black lava was the reſidence of numberleſs men-of-war birds and boobies, which ſat on their eggs, and ſuffered us to come cloſe to them.

"About eight in the evening, it being then quite dark, a ſmall veſſel came into the bay, and anchored directly within us. Captain Cook having hailed her repeatedly, received in anſwer that ſhe was the Lucretia, a New-York ſloop, which had been at Sierra Leon, and was now come to catch turtles, in order to ſell them at the windward iſlands of the Weſt Indies. A lieutenant was ſent on board, who learned from the maſter, that he had taken our ſhip to be a French Indiaman, and was very deſirous of trading with Engliſh India-ſhips, in which he was diſappointed by the company's regulations. He dined with our officers the next day, but on the 31ſt at day-break left the iſland. On the 30th in the morning, we landed a ſecond time; and croſſing the plain, arrived at a prodigious lava-current, interſected by many channels from ſix to eight yards deep, which bore ſtrong marks of being worn by vaſt torrents of water, but were at preſent perfectly dry, the ſun being in the northern hemiſphere. In theſe gullies we found a ſmall quantity of ſoil conſiſting of a black volcanic earth, mixed with ſome whitiſh particles gritty to the touch. Here we ſaw ſome ſmall bunches of purſlane, and a ſpecies of graſs (*panicum ſanguineum*) which found ſufficient nutriment in the dry ſoil. Having at laſt, with great fatigue, climbed over this extenſive and tremendous current of lava, which was much more ſolid than the heaps nearer to the ſea, we came to the foot of the Green Mountain, which even from the ſhip's place in the bay we had plainly diſtinguiſhed to be a different nature from all the reſt of the country. Thoſe parts of the lava which ſurrounded it were covered with a prodigious quantity of purſlane, and a kind of new fern (*lonchites Adſcenſionis*), where ſeveral flocks of wild goats were feeding. The great mountain is divided in its extremities, by by various clefts, into ſeveral bodies; but in the centre they all run together, and form one broad maſs of great height. The whole appears to conſiſt of a gritty tophaceous lime-ſtone, which has never been attacked by the volcano, but probably exiſted prior to its eruption; its ſides are covered with a kind of graſs, peculiar to the iſland, which Linnæus has named *ariſtida Adſcenſionis*. We likewiſe obſerved ſeveral flocks of goats feeding on it; but they were all exceſſively ſhy, and ran with ſurpriſing velocity along tremendous precipices, where it was impoſſible to follow them. The maſter of the New-York ſloop acquainted us, that there is a ſpring of water on one part of this mountain, which falls down a great precipice, and is afterwards abſorbed in the ſand. I am almoſt perſuaded, that with a little trouble, Aſcenſion might ſhortly be made fit for the reſidence of men. The introduction of furze (*ulex Europæus*), and of a few other plants which thrive beſt in a parched ſoil, and are not likely to be attacked by rats or goats, would ſoon have the ſame affect as at St Helena. The moiſture attracted from the atmoſphere by the high mountains in the centre of the iſland, would then no longer be evaporated by the violent action of the ſun, but collect into rivulets, and gradually ſupply the whole iſland. A ſod of graſſes would every where cover the ſurface of the ground, and annually increaſe the ſtratum of mould, till it could be planted with more uſeful vegetables.

"We returned gradually to Croſs Bay, in the heat of noon, over the plain; having a ſpace of more than five miles to traverſe, where the ſun burnt and bliſtered our faces and necks, and heated the ſoil to ſuch a degree, that our feet were likewiſe extremely ſore. About three o'clock we arrived at the water's ſide; and after bathing in a ſmall cove among a few rocks, we made the ſignal for a boat, and were taken on board. The next forenoon we made another ſmall excurſion, in company with Captain Cook, towards the Green Mountain; but we were all of us ſo much fatigued, that we could not reach it. We made no new obſervations in the courſe of this day, the nature of the iſland being dreary beyond deſcription in its outſkirts."

ASCENSIONAL DIFFERENCE, the difference between the right and oblique aſcenſion of the ſame point to the ſurface of the ſphere.

ASCENT, in a general ſenſe, implies the motion of a body upwards, or the continual receſs of a body from the earth. The Peripatetics attribute the ſpontaneous *aſcent* of bodies to a principle of levity inherent in them. The moderns deny any ſuch thing as ſpontaneous levity; and ſhew, that whatever *aſcends*, does it in virtue of ſome external impulſe or extruſion. Thus it is that ſmoke and other rare bodies *aſcend* in the atmoſphere; and oil, light woods, &c. in water; not by any external principle of levity, but by the ſuperior gravity or tendency downwards of the parts of the medium wherein they are. The *aſcent* of light bodies in heavy mediums is produced after the ſame manner as the *aſcent* of the lighter ſcale of a balance. It is not that ſuch ſcale has an internal principle whereby it immediately tends upwards; but it is impelled upwards by the preponderancy of the other ſcale; the exceſs of the weight of the one having the ſame effect, by augmenting its impetus downwards, as ſo much real levity in the other; by reaſon the tendencies mutually oppoſe each other, and that action and reaction are always equal.

Ascent of Bodies on Inclined Planes, the reader will find explained under MECHANICS; *Aſcent of Fluids*, under HYDROSTATICS; and *Aſcent of Vapours*, under the article EVAPORATION.

ASCESIS, properly denotes exerciſe of the body. It is formed from the verb ασκειν, uſed by the ancients in ſpeaking of the ſports and combats of the athletæ.

ASCESIS is alſo uſed by philoſophers, to denote an exerciſe, conducive to virtue, or to the acquiring a greater degree of virtue. This is particularly denominated the *philoſophical aſceſis*, becauſe practiſed chiefly by philoſophers, who make a more peculiar profeſſion of improving themſelves in virtue; on the model whereof, the ancient Chriſtians introduced a religious Aſceſis.

ASCETERIUM, in eccleſiaſtical writers, is frequently uſed for a monaſtery, or place ſet apart for the exerciſes of virtue and religion. The word is formed from *aſceſis*, "exerciſe;" or *aſcetra*, "one who performs exerciſe." Originally is ſignified a place where the athletæ or gladiators performed their exerciſes.

ASCETIC, an ancient appellation given to ſuch perſons as, in the primitive times, devoted themſelves more immediately to the exerciſes of piety and virtue, in a retired life; and particularly to prayer, abſtinence, and mortification. The word is derived from ασκεω, *exercio*, "I exerciſe." Afterwards, when the monks came in faſhion, this title was beſtowed upon them; eſpecially upon ſuch of them as lived in ſolitude.

ASCETIC is alſo a title of ſeveral books of ſpiritual exerciſes.—As, the *Aſciatics*, or devout exerciſes of St Baſil, archbiſhop of Cæſarea in Cappadocia.

We alſo ſay the *aſcetic* life, meaning the exerciſe of prayer, meditation, and mortification.

ASCHAFENBURG, a town of Germany, ſeated on the river Maine, in the circle of the Lower Rhine, and territory of the elector of Mentz, who has a palace there. It is memorable for being the place where the king of Great Britain took up his quarters the night before the battle of Dettingen. E. Long. 9. 35. N. Lat. 50. 14.

ASCHAM (Roger), was born at Kirby-Wiſke, near North-Allerton in Yorkſhire, in the year 1516. His father was ſteward to the noble family of Scroop. Our author Roger was educated in the family of Sir Anthony Wingfield, who, about the year 1530, ſent him to St John's College, Cambridge, where he was ſoon diſtinguiſhed for his application and abilities. He took his degree of Bachelor of Arts at the age of 18, was ſoon after elected fellow of his college, and in 1536 proceeded Maſter of Arts. In 1544, he was choſen univerſity orator; and, in 1548, was ſent for to court, to inſtruct the lady Elizabeth (afterwards queen) in the learned languages. In the year 1550, he attended Sir Richard Moryſine, as ſecretary, on his embaſſy to the emperor Charles V. at whoſe court he continued three years, and in the mean time was appointed Latin ſecretary to King Edward VI. But, upon the death of that prince, he loſt his preferment and all his hopes, being profeffedly of the reformed religion; yet, contrary to his expectations, he was foon after, by the intereft of his friend lord Paget, made Latin fecretary to the king and queen. In June 1554, he married Mrs Margaret How, a lady of a good family, with whom he had a confiderable fortune. It is very remarkable of Mr Afcham, that, tho' he was known to be a Proteftant, he continued in favour not only with the miniftry of thofe times, but with queen Mary herfelf. Upon the acceffion of queen Elizabeth, he was not only confirmed in his poft of Latin fecretary, but was conftantly employed as preceptor to her Majefty in the Greek and Latin languages. He died in the year 1568, much regretted, efpecially by the queen, who faid fhe had rather have loft L. 10,000. Camden and fome other writers tell us, that he had a great propenfity to dice and cock-fighting. He certainly died poor.—He wrote,

1. Toxophilus. The fchole or partitions of fhooting, contayned in two bookes, written by Roger Afcham, 1544, and now newly perufed. Pleafaunt for all gentlemen and yeomen of England, &c. Lond. 1571. Whilft at the univerfity he was fond of archery by way of exercife and amufement, for which he was cenfured; and on that account he fat down to write this book, which was dedicated to Henry VIII. who fettled a penfion of L. 10 per annum, on the author. It is rather whimfical; but is admirably well written, and full of learning. 2. A report and difcourfe, written by Roger Afcham, of the affairs and ftate of Germany, and the emperor Charles his court, &c. 4to. A valuable curiofity. 3. The fchoolmafter. Firft printed in 1573, 4to. Mr Upton publifhed an edition with notes in 1711. It has uncommon merit; abounding in great good fenfe, as well as knowledge of ancient and modern hiftory: it is alfo expreffive of the great humanity of the author, who was for making the paths of knowledge as level and pleafant as poffible, and for trying every gentle method of enlarging the mind and winning the heart. 4. Latin epiftles. Firft publifhed by Mr Grant in 1576; have fince paffed many editions: the beft is that of Oxford in 1703. Much admired on account of the ftyle, and efteemed almoft the only claffical work of that kind written by an Englifhman. 5. Apologia contra miffam. 1577, 8vo.

ASCIBURGIUM (anc. geog.), mentioned by Tacitus, fuppofed to be one of the 50 citadels built on the Rhine; who adds, fome imagined it was built by Ulyffes. Here was a Roman camp and a garrifon. To its fituation on the banks of the Rhine anfwers a fmall hamlet, now called *Afburg*, not far from Meurs, in the duchy of Cleves.

ASCIDIA, a genus of animals belonging to the order of vermes Mollufca. The body is cylindrical, and fixed to a fhell, rock, &c. It has two appertures; one on the fummit, the other lower, forming a fheath. There are fix fpecies of this animal, viz. the papillofum, gelatinofum, inteftinalis, quadridentata, ruftica, and echinata; only one of which, viz. the ruftica*, is found in the Britifh feas. Animals of this genus have the faculty of fquirting out the water they take in. The expanfion and contraction of their bodies occafion their affuming various forms.

*Pl. LVI.

ASCII, among geographers, an appellation given to thofe inhabitants of the earth who, at certain feafons of the year, have no fhadow; fuch are all the inhabitants of the torrid zone, when the fun is vertical to them.

ASCITÆ (from ασκος, a *bag* or *bottle*), in antiquity, a fect or branch of Montanifts, who appeared in the fecond century, they were fo called, becaufe they introduced a kind of Bacchanals into their affemblies, who danced round a bag or fkin blowed up; faying, they were thofe new bottles filled with new wine whereof our Saviour makes mention, Matth. ix. 17.—They are fometimes alfo called *Afcodrogitæ*.

ASCITES, in medicine, the dropfy of the abdomen. See MEDICINE-*Index*.

ASCLEPIA, a feftival of Æfculapius the god of phyfic, obferved particularly at Epidaurus, where it was attended with a conteft between the poets and muficians, whence it was likewife called Ιερος Αγων, *the facred contention*.

ASCLEPIAD, in ancient poetry, a verfe compofed of four feet, the firft of which is a fpondee, the fecond a choriambus, and the two laft dactyls; or of four feet and a cæfura, the firft a fpondee, the fecond a dactyl, after which comes the cæfura, then the two dactyls; as, *Mæcenas atavis edite regibus*

ASCLEPIADES, one of the moft celebrated phyficians among the ancients, was a native of Prufa, in Bithynia; and practifed phyfic at Rome, under Pompey, 96 years before the Chriftian æra. He was the head of a new fect; and, by making ufe of wine and cold water in the cure of the fick, acquired a very great reputation. He wrote feveral books, which are frequently mentioned by Galen, Celfus, and Pliny; but they are now loft.

ASCLEPIADES, a famous phyfician under Hadrian, of the fame city with the former. He wrote feveral books concerning the compofition of medicines, both internal and external.

ASCLEPIAS, SWALLOW-WORT; A genus of the digynia order, belonging to the pentandria clafs of plants; and in the natural method ranking under the 30th order, *Contortæ*. The generic character is taken from five oval, concave, horn-like nectaria which are found in the flower. The

Species are 19; of which the following are the moft remarkable. 1. The alba, or common fwallow-wort, has a root compofed of many ftrong fibres connected at top like thofe of afparagus, from whence arife many ftalks, in number proportional to the fize of the roots, which grow two feet high, and are very flender at the top: the leaves are placed oppofite by pairs; the flowers are white, growing in umbels near the top of the ftalk, from whence are fent out fmaller umbels. After the flower is paft, the two germens become long pointed pods, inclofing many compreffed feeds lying imbricatim, which are crowned with a foft white down. It flowers in June, and the feeds ripen in September. It is a native of the fouth of France, Spain, and Italy. 2. The Syriaca, or greater Syrian dogfbane, is a perennial plant, which fends up feveral upright ftalks in the fpring, about two feet high, garnifhed with oval leaves growing oppofite; at the top of the ftalks the umbels of flowers are produced, which are of a bright purple colour, making a pretty appearance, but are not fucceeded by pods in England. 3. The curraffavica, or baftard ipecacuanha, is a native of the warm parts of of America. It rises to the height of five or six feet, with upright stems, and smooth oblong leaves placed opposite. Toward the top of the branches the umbels of flowers come out, which stand erect: the petals of the flowers are of a scarlet colour, and the horny nectariums in the middle are of a bright saffron colour, which make a pretty appearance; and there is a succession of flowers on the same plant from June to October. The flowers are succeeded by long taper pods, filled with seeds crowned with soft down, which ripen late in autumn. The first two species are hardy; but the last one is tender, and therefore must be preserved in a stove.

Medicinal Uses, &c. The root of the first species is used in medicine. It is reckoned by botanists a species of dogsbane; from all the poisonous sorts of which it may be distinguished, by yielding a limpid juice, whilst that of the others is milky. The root has a strong smell, especially when fresh, approaching to that of Valerian, or nard; the taste is at first sweetish and aromatic, but soon becomes bitterish, subacrid, and nauseous. This root is esteemed sudorific, diuretic, and emmenagogue: it is also frequently employed by the French and German physicians as an alexipharmic, and sometimes as a succedaneum to contrayerva, whence it has received the name of *contrayerva Germanorum*. Among us it is very rarely made use of: it appears from its sensible qualities to be a medicine of much the same kind with valerian, which is indisputably preferable to it. The root of the third species has been sometimes sent over from America instead of that of ipecacuanha, and mischievous effects have been produced by it. Those who cultivate this plant ought to be careful that none of its milky juice mix with any thing which is taken inwardly.

ASCODUTÆ, in antiquity, a sect of heretics, in the second century, who rejected the use of symbols and sacraments, on this principle, That incorporeal things cannot be communicated by things corporeal, nor divine mysteries by any thing visible.

ASCOLI, formerly *Asculum Apulum*, a pretty large and populous town of Italy, in the marche of Ancona, and territory of the church; it is a bishop's see, and seated on a mountain, at the bottom of which runs the river Fronto. E Lon. 15. 20. N. Lat. 42. 47.

Ascoli de Satriano, formerly *Asculum Picenum*, an episcopal city of Italy, in the kingdom of Naples; seated on a mountain. E. Long. 15. 5. N. Lat. 42. 8.

ASCOLIA, in Grecian antiquity, a festival celebrated by the Athenian husbandmen in honour of Bacchus, to whom they sacrifice a he-goat, because it destroys the vines (*Ovid Fast*. i. 357); and, to shew the greater indignity to an animal hated by Bacchus, the peasants, after having killed him, made a foot-ball of his skin. Virgil has beautifully described the occasion of the sacrifice, and manner of celebrating the festival, *Georg*. ii. 380.

ASCRIPTITII, or ADSCRIPTITII, were a kind of villains, who, coming from abroad, settle in the lands of some new lord, whose subjects or servants they commence; being so annexed to the lands, that they may be transferred and sold with the same. Ascriptitii is sometimes also used in speaking of aliens or foreigners newly admitted to the freedom of a city or country.

ASCRIPTITII was also used in the military laws for the recruits appointed to supply the losses of the legions, called also *Accensi*.

ASCRIVIUM (anc. geog.), a town of Dalmatia, on the Sinus Rhizicus (Pliny, Ptolemy): Now *Cattaro* (Harduin); the capital of the territory of Cattaro, in Venetian Dalmatia. E. Long. 19. 20. Lat. 45. 25.

ASCULUM APULUM (anc. geog.) a town of Apulia, much mentioned in the war with Pyrrhus (Florus, Plutarch): Now called *Ascoli*; a city of the Capitanata, in the kingdom of Naples. E. Long. 16. 30. Lat. 41. 15.

Asculum Picenum (anc. geog.), a town of the Piceni (Cæsar); and the capital (Florus): Now *Ascoli*, in the marche of Ancona, on the river Tronto. E. Long. 15. 5. Lat. 42 50.

ASCYRUM, PETER'S-WORT: A genus of the polyandria order, belonging to the polydelphia class of plants; and in the natural method ranking under the 20th order, *Rotaceæ*. The calyx consists of four leaves; the corolla has four petals; the filaments are numerous, and divided into four bundles. There are three species, the crux andreæ, the hypericoides, and the villosum, all natives of the West Indies or America, but possessing no property worthy of notice.

ASDRUBAL, the name of several Carthaginian generals. See CARTHAGE.

ASEKI, or ASEKAI, the name which the Turks give to the favourite sultanesses who have brought forth sons. These are greatly distinguished above others in their apartments, attendants, pensions, and honours. They have sometimes shared the government. The sultana who first presents the emperor with a male child, is reckoned the chief favourite, is called *buyuk aseki*, and ranks as a legitimate wife: though, from the time of Bajazet I. the sultans are forbid to marry by a public law, which Solyman II. violated in favour of Roxalana.

ASELLUS, in zoology, the trivial name of a species of oniscus. See ONISCUS.

ASGILL, (John), a late humorous writer, was bred to the law, and practised in Ireland with great success. He was there elected a member of the house of commons, but was expelled for writing a treatise on the possibility of avoiding death; and being afterwards chosen a member for the borough of Bramber in Sussex, he was also on the same account expelled the parliament of England. After this he continued 30 years a prisoner in the Mint, Fleet, and King's-bench; during which time he published a multitude of small political pamphlets, several of which were in defence of the succession of the house of Hanover, and against the Pretender. He died in the rules of the King's-bench, in the year 1738, when he was upwards of fourscore.

ASH, in botany. See FRAXINUS.

Ash-Hole, among chemists, is the lowest part of a furnace; and is intended to receive the ashes falling from the fire, and to give a passage to the air which is to be introduced into the furnace, to keep up the combustion.

Ash-Wednesday, the first day of Lent; supposed to have been so called from a custom in the church, of sprinkling ashes that day on the heads of penitents then admitted to penance. See LENT.

ASHBORN, a town in Derbyshire, seated between the rivers Dove and Compton, over which there is a stone bridge, in a rich soil. It is a pretty large town, though not so flourishing as formerly. W. Long. 1. 35. N. Lat. 53. 0.

ASHBURTON, a town in Devonshire. It sends two members to parliament, and is one of the four stannery towns. It is seated among the hills, which are remarkable for tin and copper; and has a very handsome church; as also a chapel, which is turned into a school. It gives title of Baron to Dunning the late solicitor-general, whose son now enjoys it. W. Long. 3. 10. N. Lat. 50. 30.

ASHBY DE LA ZOUCH a market-own in Leicestershire, situated in W. Long. 1. 20. N. Lat. 52. 40. It had a castle, which was long in the possession of the family of de la Zouch. It afterwards fell into the hands of Edward IV. who granted it to Sir Edward Hastings, created baron Hastings, with licence to make a castle of the manorhouse, to which he adjoined a very high tower. It was demolished in 1648; but a great part of the tower is still standing. It now belongs to the Earl of Huntingdon.

ASHDOD, or AZOTUS. See AZOTUS.

ASHES, the earthy particles of combustible substances after they have been burnt.

If the ashes are produced from vegetable bodies, they contain a considerable quantity of fixed salt, blended with the terrene particles: and from these ashes the fixed alkaline salts called *pot-ash*, *pearl-ash*, &c. are extracted. See POTASH, &c.

The ashes of all vegetables are vitrefiable, and found to contain iron. They are also excellent manure for cold and wet grounds. See AGRICULTURE, n° 20.

Several religious ceremonies depend upon the use of ashes. St Jerome relates, that the Jews in his time rolled themselves in ashes, as a sign of mourning. To repent in sackcloth and ashes, is a frequent expression in Scripture for mourning and being afflicted for our sins. There was a sort of lye and lustral water made with the ashes of an heifer sacrificed upon the great day of expiation; the ashes whereof were distributed to the people, and this water was used in purifications as often as any touched a dead body, or was present at funerals, (Numb. xix. 17.) Tamar after the injury received from her brother Amnon, covered her head with ashes, (2 Sam. xiii. 19.) The Psalmist in great sorrow says, that he had eaten ashes as if it were bread, (Ps. cii. 9.); which, however is to be considered as an hyperbole. He sat on ashes, he threw ashes on his head; his food, his bread, was spoiled with the ashes wherewith he was covered.

The ancient Persians had a sort of punishment for some great criminals, which consisted in executing them in ashes. The criminal was thrown headlong from a tower 50 cubits high, which was filled with ashes to a particular height, (2 Mac. xiii. 5, 6.) The motion which the criminal used to disengage himself from this place, plunged him still deeper into it, and this agitation was farther increased by a wheel which stirred the ashes continually about him till at last he was stifled.

ASHFORD, a market-town of Kent, situated about 12 miles south-west of Canterbury, in E. Long. 45. and N. Lat. 51. 15.

ASHLAR, a term used among builders, by which they mean common or free stones, as they come out of the quarry, of different lengths and thicknesses.

ASHLERING, among builders, signifies quartering, to lath to, in garrets, about two and a half, or three feet high, perpendicular to the floor, up to the under side of the rafters.

ASHMOLE (Elias), a great antiquary and herald, founder of the Ashmolean musæum at Oxford, was born at Litchfield in Staffordshire, 1617. In the early part of his life, he practised in the law; and in the civil war had a captain's commission under the king, and was also comptroller of the ordnance. He married the lady Mainwaring in 1649, and settled at London; where his house was frequented by all the learned and ingenious men of the time. Mr Ashmole was a diligent and curious collector of manuscripts. In the year 1650, he published a treatise written by Dr Arthur Dee, relating to the philosopher's stone; together with another tract on the same subject, by an unknown author. About the same time he was busied in preparing for the press a complete collection of the works of such English chemists as had till then remained in manuscript. This undertaking cost him great labour and expence; and at length the work appeared, towards the close of the year 1652. He proposed at first to have carried it on to several volumes; but he afterwards dropped this design, and seemed to take a different turn in his studies. He now applied himself to the study of antiquity and records: he was at great pains to trace the Roman road, which in Antoninus's Itinerary is called *Bennevanna*, from Weedon to Litchfield, of which he gave Mr Dugdale an account in a letter. In 1658, he began to collect materials for his history of the order of the garter, which he lived to finish, and thereby did no less honour to the order than to himself. In September following, he made a journey to Oxford, where he set about giving a full and particular description of the coins presented to the public library by Archbishop Laud.

Upon the restoration of King Charles II. Mr Ashmole was introduced to his majesty, who received him very graciously; and on the 18th of June 1660, bestowed on him the place of Windsor herald A few days after, he appointed him to give a description of his medals, which were accordingly delivered into his possession, and King Henry VIII's closet was assigned for his use. On the 15th of February Mr Ashmole was admitted a fellow of the royal society: and, on the 9th of February following, the king appointed him secretary of Surinam, in the West Indies. On the 19th of July 1699, the university of Oxford, in consideration of the many favours they had received from Mr Ashmole, created him Dr of physic by diploma, which was presented to him by Dr Yates, principal of Brazen Nose college. On the 8th of May 1672, he presented his "Institution, laws, and ceremonies of the most noble order of the garter," to the king; who received it very graciously, and, as a mark of his approbation, granted him a privy seal for L.400 out of the custom of paper. On the 26th of January 1679, a fire broke out in the Middle Temple, in the next chamber to Mr. Ashmole's, by which he lost a noble library, with a collection of 9000 coins, ancient and modern, and a vast repository of seals, charters, and other antiquities and curiosities; but

Asia. but his manuscripts and his most valuable gold medals were luckily at his house at Lambeth. In 1683, the university of Oxford having finished a magnificent repository near the theatre, Mr Ashmole sent thither his curious collection of rarities; which benefaction was considerably augmented by the addition of his manuscripts and library at his death, which happened at Lambeth, the 18th of May, in the 76th year of his age. He was interred in the church of Great-Lambeth, in Surry, on the 26th of May 1692, and a black marble stone laid over his grave, with a Latin inscription.

Besides the works which we have mentioned, Mr Ashmole left several which were published since his death, and some which remain still in manuscript.

ASIA, is one of the three general parts of our continent, and one of the four of the whole earth. It is separated from Europe by the Mediterranean sea, the Archipelago, the Black Sea, the Palus Meotis, the Don, and the Dwina, which fall into the White Sea; and from Africa, by the Arabic Gulph or Red Sea, and the Istmus of Suez. All the other parts are surrounded by the ocean. The late discoveries show that it does not join to America, though it extends very near it: (See America, n° 105.). It is situated between 44 and 196 degrees of east longitude, and 1 and 74 degrees of north latitude. From the Dardanelles to the most eastern shore of Tartary, it is 4740 miles in length; and from the most southern point of Malacca to the most northern point of Nova Zembla, it is 4380 miles in breadth.

This vast extent of territory was successively governed in past times by the Assyrians, the Medes, the Persians, and the Greeks; but the immense regions of India and China were little known to Alexander, or the conquerors of the ancient world. Upon the decline of those empires, great part of Asia submitted to the Roman arms; and afterwards, in the middle ages the successors of Mahomet, or, as they are usually called, Saracens, founded in Asia, in Africa, and in Europe, a more extensive empire than that of Cyrus, Alexander, or even the Roman when in its height of power. The Saracen greatness ended with the death of Tamerlane; and the Turks, conquerors on every side, took possession of the middle regions of Asia, which they still enjoy. Besides the countries possessed by the Turks and Russians, Asia contains at present three large empires, the Chinese, the Mogul, and the Persian; upon which the lesser kingdoms and sovereignties of Asia generally depend. The prevailing form of government in this division of the globe is absolute monarchy. If any of them can be said to enjoy some share of liberty, it is the wandering tribes, as the Tartars and Arabs. Many of the Asiatic nations, when the Dutch first came among them, could not conceive how it was possible for any people to live under any other form of government than that of a despotic monarchy. Turkey, Arabia, Persia, part of Tartary, and part of India, profess Mahometanism. The Persian and Indian Mahometans are of the sect of Hali, and the others of that of Omar; but both own Mahomet for their law-giver, and the Koran for their rule of faith and life. In the other parts of Tartary, India, China, Japan, and the Asiatic Islands, they are generally heathens and idolaters. Jews are to be found every where in Asia. Christianity, though planted here with wonderful rapidity by the apostles and primitive fathers, suffered an almost total eclipse by the conquests of the Saracens, and afterwards of the Turks. Incredible indeed have been the hazards, perils, and sufferings of popish missionaries, to propagate their doctrines in the most distant regions and among the grossest idolaters; but their labours have hitherto failed of success, owing in a great measure to their own avarice, and the avarice and profligacy of the Europeans, who resort thither in search of wealth and dominion.

Asia may be divided into the following parts: Turkey in Asia, Arabia, Persia, the Mogul's Empire, with the two peninsulas of the Indies; Tibet, China, and Corea; Great and Little Buckaria, with Korasin; Tartary, Siberia, and the islands. The principal languages spoken in Asia are, the modern Greek, the Turkish, the Russian, the Tartarian, the Persian, the Arabic, the Malayan, the Chinese, and the Japanese. The European languages are also spoken upon the coasts of India and China.

Asia is looked upon as that part of the world which, of all others, has been most peculiarly distinguished by heaven. There it was the first man was created; there the patriarchs lived, the law was given to Moses, and the greatest and most celebrated monarchies were formed; from thence the first founders of cities and nations in other quarters of the world brought their colonies. Lastly, in Asia, Jesus Christ appeared: there it was that he wrought the salvation of mankind, that he died and rose again; and from thence it is that the light of the gospel was diffused over all the world. Laws, arts, sciences, and religion, almost all had their original in Asia.

As Asia exceeds the other two parts of our continent, Europe and Africa, so it is superior to them in the serenity of its air, the fertility of its soil, the deliciousness of its fruits, the fragrancy and balsamic qualities of its plants, spices, and gums; the salubrity of its drugs; the quantity, variety, beauty, and value of gems; the richness of its metals, and the fineness of its silks and cottons. A great change indeed hath happened in that part of it called Turkey, which hath lost much of its ancient splendor, and from the most populous and best cultivated spot in Asia, is become a wild and uncultivated desart. The other parts of Asia continue much in their former condition; the soil being as remarkable for its fertility, as most of the inhabitants for their indolence, effeminacy, and luxury. This effeminacy is chiefly owing to the warmth of the climate, though in some measure heightened by custom and education; and the symptoms of it are more or less visible as the several nations are seated nearer or farther from the north. Hence the Tartars, who live near the same latitudes with us, are as brave, hardy, strong, and vigorous, as any European nation. What is wanting in the robust frame of their bodies among the Chinese, Mogul-Indians, and all the inhabitants of the more southern regions, is in a great measure made up to them by the vivacity of their minds, and ingenuity in various kinds of workmanship, which our most skilful mechanics have in vain endeavoured to imitate.

The chief rivers of Asia are, the Euphrates and Tigris,

gris, in Turkey; the Indus and Ganges, in India; the Kiang and Hoang-ho, in China: the Sir Amu and Wolga, in Western Tartary; the Saghalia Ula or Amur, in Eastern Tartary; the Irtish, Oby, Jenisea, and Lena, in Siberia. The lakes are, that prodigious one called the *Caspian Sea*; and near that another very large one, but lately known to us, called *Aral*, or the lake of eagles. The Baykal is in Siberia, the Kokonor near Tibet, and the Tong Ping in China. The chief mountains are, the Taurus in Turkey and Persia; the Imaus, between India and Tibet; and the Altay, in Tartary.

The Asiatic islands are very numerous, insomuch that some reckon 150,000; but of this there is no certainty. However, they may be divided into those of the east, west, south, and south-east. Those that lie on the east of Asia are, the islands of Jesso or Yedso, and Japan, with several small ones on the coast of Korea, the island of Formosa, and the Phillippines. Those on the west are, the island of Cyprus, in the Mediterranean; Scanderoon, off Natolia, and the isle of Rhodes, off Phischio, on the same coast. Those on the south are, the isles of the Maldives, in the Indian Sea; the isle of Ceylon, off cape Komorin; with a great many small ones in the gulph of Bengal. Those on the south-east are, the isles of Sandi, as Sumatra, the isles of Java, Borneo, &c. the Moluccas, the isles of Kumbava, Timor, &c.

Asia Minor, or *Lesser Asia*; the same with Natolia. See Natolia.

ASIARCHÆ, (termed by St Paul, *Chief of Asia*, Acts xix. 31.) were the Pagan Pontiffs of Asia, chosen to superintend and have the care of the public games; which they did at their own expence: for which reason they were always the richest and most considerable men of the towns.

ASIDE, in the drama, something said by an actor, which some, or even all the other actors present, are supposed not to hear; a circumstance justly condemned as being unnatural and improbable.

ASIITO, a town of Italy, in Perugia, and in the Pope's territories. E. Long. 23. 40. N. Lat. 43. 0.

ASILIUS, or Honey-fly, a genus of insects belonging to the order of insecta diptera. It has two wings; and a horny, strait, two-valved beak. There are 17 species of this insect. Many of them wound in a very painful manner, and are particularly troublesome to cattle in low meadows; others of them are quite harmless. See Plate LVI.

ASINARA, an island of Italy, on the western coast of Sardinia. E. Long. 8. 30. N. Lat. 41. 0.

ASINIUS (Pollio), consul and Roman orator, distinguished himself under Augustus by his exploits and his literary works. He is frequently mentioned with praises by Horace and Virgil, and is said to have collected the first library at Rome. He died at Frescati, at 80 years of age.

ASIONGABER, Esiongeber, or Eziongeber a town of Arabia Petræa, on the bay of Elath, a part of the Arabian Gulf; the dock or station of the ships of Solomon and Jehosaphat; an ancient town, mentioned also by Moses. It was afterwards called *Berenice* (Josephus).

ASISIA, or Assisia, a town of Liburnia (Ptolemy, Antonine), now in ruins, but exhibiting many monuments of antiquity. It is the Assesia or Asseria of Pliny. This author, after having specified the Liburnian cities that were obliged to attend the congress or diet of Scardona, adds to the catalogue the free Asserians, *immunesque Asseriates*; and this people, who created their own magistrates, and were governed by their own municipal laws, were no doubt more rich and powerful than their neighbours.

The vestiges of the walls of Asseria that still remain, are a sufficient proof of this; for their circumference is clearly distinguishable above ground, and measures 3600 Roman feet. The space inclosed by them forms an oblong polygon, and they are built with common Dalmatian marble; but not taken from the hill on which they stand, for that furnishes only soft stone. The walls are invested, both inside and out, with this marble: some of the stones are ten feet long, and they are all of considerable dimensions. The thickness of these fortifications is commonly about eight feet: but at the narrowest extremity, which falls towards the foot of the hill, they are eleven feet thick; and, in some parts, their height still above ground reaches to near 30 feet. An antiquary, or even a simple lover of the fine arts, or of erudition, the Abbe Fortis observes, cannot help wishing at Podgraje (the modern name of Asseria), that some powerful hand *quicquid sub terra est in apricum proferit*: and such a wish becomes stronger when he reflects, that since the destruction of that city no search has ever been made under ground, with a view to discover any thing curious; and yet these walls without doubt inclose a valuable deposite of antiquities, thrown down in heaps, who knows by what cause; perhaps naturally, by an earthquake, or perhaps by a sudden inundation of barbarians, which is still worse. The gate now demolished, the considerable height of the walls to be seen in several places from without, some pieces of thick walls that still appear levelled to the ground among the bushes, are circumstances which give ground to hope that many costly monuments might be recovered out of these ruins. The magnificence of the remaining wall, and the many pieces of well-cut stone and fine marble scattered over the contiguous fields, afford sufficient proof that both good taste and grandeur once flourished in that country. In the midst of the rubbish which covers the remains of Asseria, the parish church of the little village stands insolated; it is built of broken pieces of ancient ruins, taken as they happened to be nearest, mixed with mutilated inscriptions, and fragments of noble cornices.

ASKELON. See Ascalon.

ASKERON, a place five miles from Doncaster, noted for a medicinal spring. It is a strong sulphureous water, and is slightly impregnated with a purging salt. It is recommended internally and externally in strumous and other ulcers, scabs, leprosy, and similar complaints. It is good in chronic obstructions, and in cases of worms and foulness of the bowels.

ASISIO, or Asitio, a city of the Pope's territories in Italy, situated about 16 miles east of Perugia. E. Long. 13. 35. N. Lat. 43.

ASKRIG, a town in the N. Riding of Yorkshire. W. Long. 0. 5. N. Lat. 53. 50.

ASLANI, in commerce, a silver coin, worth from 115 to 120 aspers. See Asper.

ASMONEUS, or ASSAMONEUS, the father of Simon, and chief of the Asmoneans, a family that reigned over the Jews during 126 years.

ASNA, or ESNA, a town in Upper Egypt, seated upon the Nile, believed by some authors to be the ancient Syena, though others say the ruins of it are still to be seen near Assuan. It is so near the cataracts of the Nile, that they may be heard from thence. It contains several monuments of antiquity; and among the rest an ancient Egyptian temple, pretty entire, all painted throughout, except in some places that are effaced by time. The columns are full of hieroglyphic figures. This superb structure is now made use of for a stable, wherein they put oxen, camels, and goats. A little way from thence are the ruins of an ancient nunnery, said to be built by St Helena, surrounded with tombs.—Asna is the principal town in these parts, and the inhabitants are rich in corn and cattle. They drive a considerable trade into Lower Egypt and Nubia, by means of the Nile, and also by the caravans that pass over the Desart. The inhabitants are all Arabs, except about 200 Copts, the ancient inhabitants, and a sort of Christians. They are under the government of the Turks, who have a cadi, and the Arabs have two sheriffs of their own nation. E. Long. 31. 40. N. Lat. 28. 15.

ASOLA, a town of the Bressan in Italy, belonging to the republic of Venice. E. Long. 14. 18. N. Lat. 45. 15.

ASOLO, a town of Italy, in the Trevisan, seated on a mountain 17 miles north-west of Trevisan, and 10 north-east of Bassano. E. Long. 12. 2. N. Lat. 45. 49.

ASOPH, a town of Coban Tartary, in Asia, seated on the river Don, near its mouth, a little to the east of the Palus Mœotis, or Sea of Azoph. It has been several times taken and retaken of late years; but in 1739, the contending powers agreed that the fortifications should be demolished, and the town remain under the dominion of Russia. E. Long. 41. 30. N. Lat. 47. 18.

ASOPUS, a river of Phrygia Major, which, together with the Lycus, washes Laodicea, (Pliny).—Another of Bœotia, which running from mount Cithæron, and watering the territory of Thebes, separates it from the territory of Platæa, and falls with an east course into the Euripus, at Tanagra. On this river Adrastus king of Sicyon built a temple to Nemesis, thence called *Adrasteia*. From this river Thebae came to be surnamed *Asopides*, (Strabo). It is now called *Asopo*.—A third Asopus, a river of Peloponnesus, which runs by Sicyon, (Strabo); and with a north-west course falls into the Sinus Corinthiacus, to the west of Corinth.—A fourth, a small river of the Locri Epicnemidii, on the borders of Thessaly, (Pliny); rising in Mount Oeta, and falling into the Sinus Maliacus.

ASOPUS, a town of Laconica, (Pausanias); on the Sinus Laconicus, with a port in a peninsula, between Boæ to the east, and the mouth of the Eurotas to the west. The citadel only remains standing, now called by the sailors *Castel Rampano*.

ASOR, or HAZOR (anc. geog.), a town of the tribe of Judah, to the south-west, on the borders of Ascalon, (Joshua); as also Hasor-Hadata, translated by the seventy Ασωρη Καινη (id).—Another Asor, Asorus, or Hazor, a town of Galilee; called the capital of all the kingdoms to the north of Palestine. It was taken by Joshua; the inhabitants were put to the sword, and their houses burnt. It was afterwards rebuilt (Judges, 1 Sam.); but remained still in the hands of the Canaanites, though in the lot of the tribe of Naphthali, (Joshua). It lay to the north of the Lacus Samachonites, called in Scripture the *Waters of Merom*, (Josephus).

ASOW, a celebrated and important fortress of Russia, once a place of considerable trade, but now demolished. It was situated in the district of Bachmut, near the place where the Greeks many centuries ago built the city of Tanais, which was very famous for its trade, and underwent many vicissitudes. The Genoese, who settled a trade with Russia soon after the discovery of Archangel by Captain Chancellor, became masters of this place, and gave it the name of *Tana*, or *Catana*: but the Tartars, who were very powerful in these parts, seem to have been in possession of it long before; for, as Busching informs us, there are Asow coins yet extant, on which is the name of *Taktamyss-Kan*. From the Genoese it fell into the hands of the Turks, lost its trade, and became an inconsiderable town. In 1637, it was taken by the Cossacks, who defended it against the Turks in 1641, and next year set fire to it, and blew it up. The Turks rebuilt it with strong fortifications. The Russians laid claim to it in 1672, and took it in 1696; but, by the treaty of Pruth in 1711, it was restored to the Turks. In 1736, the Russians became masters of Asow; but by the treaty of Belgrade they were obliged to relinquish it, and entirely destroy the place.

ASP, in natural history, a small poisonous kind of serpent, whose bite gives a speedy but easy death. It is said to be thus denominated from the Greek ασπις, *shield*, in regard to the manner of its lying convolved in a circle, in the centre of which is the head, which it exerts, or raises, like the umbo or umbilicus of a buckler. This species of serpent is very frequently mentioned by authors; but so carelessly described, that it is not easy to determine which, if any of the species known at present, may properly be called by this name. It is said to be common in Africa, and about the banks of the Nile; and Bellonius mentions a small species of serpent which he had met with in Italy, and which had a sort of callous excrescence on the forehead, which he takes to have been the aspis of the ancients. It is with the asp that Cleopatra is said to have dispatched herself, and prevented the designs of Augustus, who intended to have carried her captive to adorn his triumphal entry into Rome. But the fact is contested: Brown places it among his vulgar errors. The indications of that queen's having used the ministry of the asp, were only two almost insensible pricks found in her arm; and Plutarch says it is unknown what she died of. At the same time, it must be observed, that the slightness of the pricks found in her arm furnishes no presumption against the fact; for no more than the prick of a needle-point dipt in the poison was necessary for the purpose. See the article SERPENT.

Lord Bacon makes the asp the least painful of all the instruments of death. He supposes it to have an affinity to opium, but to be less disagreeable in it operation; and his opinion seems to correspond with the

 account,

accounts of most writers, as well as with the effects described to have been produced upon Cleopatra; for which see the article already referred to.

The ancients had a plaster called δι Ασπιδων, made of this terrible animal, of great efficacy as a discutient of strumæ and other indurations, and used likewise against pains of the gout. The flesh and skin, or exuviæ, of the creature, had also their share in the ancient materia medica.

ASPA, a town of Parthia, (Ptolemy); now *Ispahan*, (Holstenius). In Ptolemy the latitude seems to agree, being 33°; but whether the longitude does, is a question. E. Long. 51. Lat. 32. 30.

ASPALATHUS, AFRICAN BROOM: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method raking under the 32d order, *Papilionaceæ*. The calyx consists of 5 divisions: the pod is oval, and contains 2 seeds. Of this genus there are 19 species; all of which are natives of warm climates, and must be preserved in stoves by those who would cultivate them here. The rose-wood, whence the oleum rhodii is obtained, is one of the species, but of which we have yet had no particular description. The wood is heavy, oleaginous, somewhat sharp and bitter to the taste, of a strong smell and purple colour. It is called *rose-wood* or *lignum Rhodium*, either on account of its sweet smell, or of its growth in the island of Rhodes. It was anciently in much repute as an astringent, strengthener, and drier; but it is now disused in internal practice. It affords an oil of an admirable scent, reputed one of the best of perfumes: it is chiefly used in scenting pomatums and liniments.

ASPARAGUS, SPARAGUS, SPERAGE, or SPARROWGRASS: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 11th order, *Sarmentaceæ*. The calyx is quinquepartite, and erect; the 3 inferior petals are bent outwards; the berry has 3 cells, and contains 2 seeds.—The species are 10; but the only one cultivated in the gardens is that with an upright herbaceous stalk, bristly leaves, and equal stipula, or the common asparagus. The other species are kept only in the gardens of the curious for the sake of variety.

Culture. The garden asparagus is with great care cultivated for the use of the table. The propagation of this useful plant is from seed; and as much of the success depends upon the goodness of the seed, it is much better to save it than to buy it at the shops. The manner of saving it is this: Mark with a stick some of the fairest buds; and when they are run to berry, and the stalks begin to dry and wither, cut them up; rub off the berries into a tub, and pouring water upon them, rub them about with your hands; the husks will break and let out the seed, and will swim away with the water in pouring it off; so that in repeating this two or three times, the seeds will be clean washed, and found at the bottom of the tub. These must be spread on a mat to dry, and in the beginning of February must be sown on a bed of rich earth. They must not be sown too thick, and must be trod into the ground, and the earth raked over them smooth: the bed is to be kept clear of weeds all the summer; and in October, when the stalks are withered and dry, a little rotten dung must be spread half an inch thick over the whole surface of the bed. The spring following, the plants will be fit to plant out for good; the ground must therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, so that it may lie at least six inches below the surface of the ground: when this is done, level the whole plot exactly, taking out all the loose stones. This is to be done just at the time when the asparagus is to be planted out; which must be in the beginning of March, if the soil is dry and the season forward; but in a wet soil it is better to wait till the beginning of April, which is about the season that the plants are beginning to shoot. The season being now come, the roots must be carefully taken up with a narrow-pronged dunk-fork, shaking them out of the earth, separating them from each other, and observing to lay all their heads even for the more convenient planting them; which must be done in this manner. Lines must be drawn, at a foot distance each, straight across the bed; these must be dug into small trenches of six inches deep, into which the roots must be laid, placing them against the sides of the trench with their buds in a right position upwards, and so that, when the earth is raked over them, they may be two inches under the surface of the ground. Between every four rows a space of two feet and a half should be left for walking in, to cut the asparagus. When the asparagus is thus planted, a crop of onions may be sown on the ground, which will not at all hurt it. A month after this, the asparagus will come up, when the crop of onions must be thinned, and the weeds carefully cleared away. About August the onions will be fit to pull up. In October following, cut off the shoots of the asparagus within two inches of the ground, clear well all weeds away, and throw up the earth upon the beds, so as to leave them five inches above the level of the alleys. A row of colworts may be planted in the middle of the alleys, but nothing must be now sown on the beds. In the spring the weeds must be hoed up, and all the summer the beds kept clear of weeds. In October they must be turned up, and earthed again, as the preceeding season. The second spring after planting, some of the young asparagus may be cut for the table. The larger shoots should only be taken, and these should be cut at two inches under ground, and the beds every year managed as in the second year. But as some people are very fond of early asparagus, the following directions are given by which it may be obtained any time in winter: Plant some good roots at one year old in a moist rich soil, about eight inches apart; the second and third years after planting, they will be ready to take up for the hot-beds; these should be made pretty strong, about three feet thick, with new stable-dung that has fermented a week or more; the beds must be covered with earth six inches thick; then against a ridge made at one end, begin to lay in your plants, without trimming or cutting the fibres, and between every row lay a little ridge of fine earth, and proceed thus till the bed is planted; then cover the bed two inches thick with earth, and encompass it with a straw-band, and in a week, or as the bed is in the temper, put on the frames and glasses, and lay on three inches thick of fresh

fresh earth over the beds, and give them air and add fresh heat to them as it requires. These beds may be made from November till March, which will last till the natural grass comes on.

Medicinal Uses. The roots have a bitterish mucilaginous taste, inclining to sweetness; the fruit has much the same kind of taste; the young shoots are more agreeable than either. Asparagus promotes appetite, but affords little nourishment. It gives a strong ill smell to the urine in a little time after eating it, and for this reason chiefly is supposed to be diuretic: it is likewise esteemed aperient and deobstruent; the root is one of the five called *opening roots*. Some suppose the shoots to be most efficaceous; others, the root; and others the bark of the root. Stahl is of opinion that none of them have any great share of the virtues usually ascribed to them. Asparagus appears from experience to contribute very little either to the exciting of urine when suppressed, or increasing its discharge; and in cases where aperient medicines generally do service, this has little or no effect.

ASPASIA *of* MILETUS, a courtezan, who settled at Athens under the administration of Pericles, and one of the most noted ladies of antiquity. She was of admirable beauty; yet her wit and eloquence, still more than her beauty, gained her extraordinary reputation among all ranks in the republic. In eloquence she surpassed all her contemporaries, and her conversation was so entertaining and instructive, that notwithstanding the dishonourable commerce she carried on in female virtue, persons of the first distinction, male and female, resorted to her house as to an academy: she even numbered Socrates among her hearers and admirers. She captivated Pericles in such a manner, that he dismissed his own wife, in order to espouse her; and, by her universal knowledge, irresistible elocution, and intriguing genius, she in a great measure influenced the administration of Athens. She was accused of having excited, from motives of personal resentment, the war of Peloponnesus; yet, calamitous as that long and obstinate conflict proved to Greece, and particularly to Athens, it may be suspected that Aspasia occasioned still more incurable evils to both. Her example, and still more her instructions, formed a school at Athens, by which her dangerous profession was reduced into a system. The companions of Aspasia served as models for painting and statuary, and themes for poetry and panegric. Nor were they merely the objects, but the authors of many literary works, in which they established rules for the behaviour of their lovers, particularly at table; and explained the art of gaining the heart and captivating the affections. The dress, behaviour, and artifices of this class of women, became continually more seductive and dangerous; and Athens thenceforth remained the chief school of vice and pleasure, as well as of literature and philosophy.

ASPASIA, among ancient physicians, a constrictive medicine for the *pudenda muliebria*. It consisted only of wool, moistened with an infusion of unripe galls.

ASPATICUM, (from ασπαζομαι, "I salute," in ecclesiastical writers), a place, or apartment, adjoining to the ancient churches, wherein the bishop and Presbyters sat, to receive the salutations of the persons who came to visit them, desire their blessing, or consult them on business.—This is also called *aspaticum diaconicum, receptorium, metatorium,* or *mesatorium,* and *salutatorium;* in English, "greeting-house."

ASPECT, in astronomy, denotes the situation of the planets and stars with respect to each other.

There are five different aspects. 1. Sextile aspect is when the planets or stars are 60° distant, and marked thus ✱. 2. The quartile, or quadrate, when they are 90° distant, marked □. 3. Trine, when 120° distant, marked △. 4. Opposition, when 180° distant, marked ☍. And, 5. Conjunction, when both in the same degree, marked ☌.

Kepler, who added eight new ones, defines aspect to be the angle formed by the rays of two stars meeting on the earth, whereby their good or bad influence is measured: for it is to be observed, that these aspects being first introduced by astrologers, were distinguished into benign, malignant, and indifferent; the quartile and opposition being accounted malign; the trine and sextile, benign or friendly; and the conjunction indifferent.

ASPEN-TREE, in botany. See POPULUS.

ASPER, in grammar, an accent peculiar to the Greek language, marked thus (ʽ); and importing, that the letters over which it is placed ought to be strongly aspirated, or pronounced as if an *h* were joined with them.

ASPER, or *Aspre*, in commerce, a Turkish coin, three of which make a MEDINE.

ASPERA ARTERIA, in anatomy, the same with the windpipe or trachea. See ANATOMY, n° 116.

ASPERIFOLIATE, or ASPERIFOLIOUS, among botanists, such plants as are rough-leaved, having their leaves placed alternately on their stalks, and a monopetalous flower divided into five parts.—They constitute an order of plants in the *Fragmenta methodi naturalis* of Linnæus, in which are these genera, viz. tournefortia, cerinthe, symphytum, pulmonaria, anchusa, lithospermum, myosotis, heliotropium, cynoglossum, asperugo, lycopsis, echium, borrago: *magis minusve oleraceæ, mucilaginosæ, & glutinosæ sunt.* Lin. In the present system, these are among the pentandria monogynia.

ASPERIFOLIÆ PLANTÆ, rough-leaved plants. The name of a class in Hermanus, Boerhaave, and Ray's methods, consisting of plants which have four naked seeds, and whose leaves are rough to the touch.

In Tournefort's System, these plants constitute the third section or order of the second class; and in Linnæus's Sexual Method, they make a part of the pentandria monogynia.

ASPERITY, the inequality of the surface of any body, which hinders the hand from passing over it freely.—From the testimony of some blind persons, it has been supposed that every colour hath its particular degree of asperity: though this has been denied by others. See the article BLIND.

ASPEROSA, a town of Turkey, in Europe; it is a bishop's see, situated on the coast of the Archipelago. E. Long. 25. 20. N. Lat. 40. 58.

ASPERUGA, SMALL WILD BUGLOSS, in botany: A genus of the pentandria mongynia class; and in the natural method ranking under the 49th order, *Asperifoliæ*. The calyx of the fruit is compressed, with folds flatly parallel, and sinuous. There are two species, viz. the procumbens, or wild buglofs, a native of Bri-

Asperula, Asphaltites

Britain; and the Egyptiaca, a native of Egypt. Horses, goats, sheep, and swine eat the first species; cows are not fond of it.

ASPERULA, WOODROOF: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 47th order, *Stellatæ*. The corolla is infundibuliform; and the capsule contains two globular seeds. There are two species, the cynanchica and the odorata. Both of them grow wild in Britain, so are seldom admitted into gardens. The first is found on chalky hills. The latter is a low umbelliferous plant, growing wild in woods and copses, and flowering in May. It has an exceeding pleasant smell, which is improved by moderate exsiccation; the taste is subsaline, and somewhat austere. It imparts its flavour to vinous liquors. Asperula is supposed to attenuate viscid humours, and strengthen the tone of the bowels; it is recommended in obstructions of the liver and biliary ducts, and by some in epilepsies and palsies; modern practice has nevertheless rejected it. The smell of it is said to drive away ticks and other insects. The roots of the first are used in Sweden to dye red.

ASPHALTITES, so called from the great quantity of bitumen it produces; called also the *Dead Sea*, and from its situation, the *East Sea*; the *Salt Sea*, the *Sea of Sodom*, the *Sea of the Desart*, and the *Sea of the Plain*, by the sacred writings: A lake of Judea.

Many things have been said and written of this famed, or, if they were indeed true, rather infamous lake; such as that it arose from the submersion of the vale of Siddim, where once stood, as is commonly reported, the three cities which perished in the miraculous conflagration, with those of Sodom and Gomorrah, for their unnatural and detestable wickedness: on which account this lake has been looked upon as a lasting monument of the just judgment of God, to deter mankind from such abominations. Hence it is added, that the waters of the lake are so impregnated with salt, sulphur, and other bituminous stuff, that nothing will sink or live in it; and that it casts such stench and smoke, that the very birds die in attempting to fly over it. The description likewise of the apples that grew about, fair without, and only ashes and bitterness within, were looked upon as a farther monument of God's anger. So likewise the description which many travellers give not only of the lake, but of all the country round about, of the whole appearing dreadful to behold, all sulphureous, bituminous, stinking, and suffocating: and lastly, what hath been farther affirmed of the ruins of the five cities being still to be seen in clear weather, and having been actually seen in these latter times; all these surprising things, and ill-grounded notions, tho' commonly, and so long, received among Christians, have been of late so much exploded, not only by the testimony of very credible witnesses, but even by arguments drawn from Scripture, that we must give them up as inventions, unless we will suppose the face and nature of all these to have been entirely changed. Those, in particular, of bodies not sinking in the water, and of birds being stifled by the exhalations of it, appear now false in fact. It is true, the quantity of salt, alum and sulphur, with which it is impregnated, render it so much specifically heavier (Dr Pococke says one-fifth) than fresh water, that bodies will not so easily sink: yet that author and others, assure us, they have swam and dived in it; and, as to the birds, we are told likewise, that they will fly over it without any harm. To reconcile these things with the experiments which Pliny * tells us had been made by Vespasian, is impossible, without supposing that those ingredients have been since much exhausted, which is not at all improbable; such quantities of them, that is, of the bitumen and salt, having been all along, and being still taken off, and such streams of fresh water continually pouring into it, as may reasonably be supposed to have considerably diminished its gravity and denseness. For, with respect to its salt, we are told, the Arabs made quantities of it from that lake, in large pits about the shores, which they fill with that water, and leave to be christalized by the sun. This salt is in some cases much commended by Galen, as very wholesome, and a strengthener of the stomach, &c. on account of its unpleasant bitterness.

* *Nat. Hist.* lib. v. cap. 15.

What likewise relates to the constant smoke ascending from the lake, its changing the colour of its water three times a-day, so confidently affirmed by Josephus† and other ancients, and confirmed by prince Radziville and other moderns, who pretend to have been eye-witnesses of it, is all now in the same manner exploded by others of more modern date, and of at least equal candour. The unhealthiness of the air about the lake was affirmed by Josephus and Pliny, especially on the west: the monks that live in the neighbourhood confirm the same, and would have dissuaded Dr Pococke from going to it on that account; and, as he ventured to go and bath in it, and was, two days after, seized with a dizziness, and violent pain in the stomach, which lasted near three weeks, they made no doubt but it was occasioned by it; and he doth not seem to contradict them. As to the water, it is, though clear, so impregnated with salt, that those who dive into it come out covered with a kind of saline matter. There is one remarkable thing relating to this lake, generally agreed on by all travellers and geographers; viz. that it receives the waters of Jordan, a considerable river, the brooks of Jabbok, Kishon, Arnon, and other springs, which flow into it from the adjacent mountains, and yet never overflows, though there is no visible way to be found by which it discharges that great influx. Some naturalists have been greatly embarrassed to find a discharge for these waters, and have therefore been inclined to suspect the lake had a communication with the Mediterranean. But, besides that we know of no gulph to corroborate this supposition, it has been demonstrated by accurate calculations, that evaporation is more than sufficient to carry off the waters brought by the river. It is, in fact, very considerable; and frequently becomes sensible to the eye, by the fogs with which the lake is covered at the rising of the sun, and which are afterwards dispersed by the heat. It is inclosed on the east and west with exceeding high mountains, many of them craggy and dreadful to behold. On the north it has the plains of Jericho; or, if we take in both sides of the Jordan, it has the Great Plain, properly so called, on the south; which is open, and extends beyond the reach of the eye. Josephus gives this lake 580 furlongs in length, from the mouth of the Jordan to the town of Segor, on the opposite end, that is about 22 leagues; and about 150 furlongs,

† *Bel. Jud.* lib. v. cap. 5.

Asphaltites

furlongs, or five leagues, in its largest breadth: but our modern accounts commonly give it 24 leagues in length and 6 or 7 in breadth. On the west side of it is a kind of promontory, where they pretend to show the remains of Lot's metamorphosed wife. Josephus says it was still standing in his time; but when Prince Radziville inquired after it, they told him there was no such salt pillar or statue to be found in all that part. However, they have found means, about a century after him, to recover, as they pretended to assure Mr Maundrell, a block or stump of it, which may in time grow up, with a little art, into its ancient bulk.

It is to be observed here, that the name of *Dead Sea* is not to found in the sacred writings; but hath been given to this lake because no creature will live in it, on account of its excessive saltness, or rather bituminous quality; for the Hebrews rank sulphur, nitre, and bitumen, under the general name of *salt*. However, some late travellers have found cause to suspect the common report of its breeding no living creature; one of them having observed, on the shore, two or three shells of fish like those of an oyster, and which he supposes to have been thrown up by the waves, at two hours distance from the mouth of the Jordan, which he there takes notice of, lest they should be suspected to have been brought into the lake by that way. And Dr Pococke, though he neither saw fish nor shells, tells us, on the authority of a monk, that some sort of fish had been caught in it; and gives us his opinion, that as so many sorts live in salt-water, some kind may be so formed as to live in a bituminous one. Mr Volney, however, affirms, that it contains neither animal nor vegetable life. We see no verdure on its banks, nor a fish to be found within its waters. But he adds, that it is not true that its exhalations are pestiferous, so as to destroy birds flying over it. "It is very common (says he) to see swallows skimming its surface, and dipping for the water necessary to build their nests. The real cause which deprives it of vegetables and animals is the extreme saltness of the water, which is infinitely stronger than that of the sea. The soil around it, equally impregnated with this salt, produces no plants; and the air itself, which becomes loaded with it from evaporation, and which receives also the sulphureous and bituminous vapours, cannot be favourable to vegetation: hence the deadly aspect which reigns around this lake. In other respects, the ground about it, however, is not marshy; and its waters are limpid and incorruptible, as must be the case with a dissolution of salt. The origin of this mineral is easy to be discovered; for on the south-west shore are mines of fossil salt, of which I have brought away several specimens. They are situated in the side of the mountains which extend along that border; and, for time immemorial, have supplied the neighbouring Arabs, and even the city of Jerusalem. We find also on this shore fragments of sulphur and bitumen, which the Arabs convert into a trifling article of commerce; as also hot fountains, and deep crevices, which are discovered at a distance by little pyramids built on the brink of them. We likewise find a sort of stone, which, on rubbing, emits a noxious smell, burns like bitumen, receives a polish like white alabaster, and is used for the paving of courtyards. At intervals, we also meet with unshapen blocks, which prejudiced eyes mistake for mutilated statues, and which pass with ignorant and superstitious pilgrims for monuments of the adventure of Lot's wife; though it is no where said she was metamorphosed into stone like Niobe, but into salt, which must have melted the ensuing winter."

Asphaltite Asphaltum

It is on account of this bitumen that it hath had the name of *Asphaltite Lake*, it being reported to have thrown up great quantities of that drug, which was much in use among the Egyptians, and other nations, for embalming of dead bodies. Josephus assures us, that in his days it rose in lumps as big as an ox without its head, and some even larger. But, whatever it may have formerly done, we are assured by Mr Maundrell and others, that it is now to be found but in small quantities along the shore, though in much greater near the mountains on both sides the lake. But the contrary is since affirmed by two or more late* travellers; the one of whom tells us, that it is observed to float on the surface of the water, and to come on the shore, after windy weather, where the Arabians gather it, and put it to all the uses that common pitch is used for, even in the compositions of some medicines: and another † tells us, he was there informed, that it was raised at certain times from the bottom, in large hemispheres, which, as soon as they touch the surface, and are acted upon by the external air, burst at once, with great noise and smoke, like the *pulvis fulminans* of the chemists, dispersing themselves about in a thousand pieces. From both these judicious authors we may conclude the reason of Mr Maundrell's mistake, both as to the lake's throwing it up only on certain seasons (that reverend gentleman might chance to be there at the wrong time); and likewise as to his not observing it about the shores, seeing the Arabs are there ready to gather it as soon as thrown up; all of them describe it as resembling our black pitch, so as not to be distinguished from it but by its sulphureous smoke and stench when set on fire; and it hath been commonly thought to be the same with that which our druggists sell under the name of *bitumen Judaicum*, or *Jewish pitch*, though we have reason to think that this last is factitious, and that there is now none of the asphaltum brought from Judea.

* *Pococke's Travels*, p. 56.

† *Shaw's Travels*, p. 374.

It hath, moreover, been confounded with a sort of blackish combustible stone thrown on the shore, and called by some *Moses's* stone, which, being held in the flame of a candle, will soon burn, and cast a smoke and intolerable stench; but with this extraordinary property, that though it loses much of its weight and colour, it becoming in a manner white, yet it diminishes nothing of its bulk. But these, Dr Pococke tells us, are found about two or three leagues from the shore. He concludes, however, from it, that a *stratum* of that stone under the lake is probably one part of the matter that feeds the subterraneous fire, and causes the bitumen to boil up out of it.

ASPHALTUM, BITUMEN JUDAICUM, or JEWS PITCH, is a light solid bitumen, of a dusky colour on the outside, and a deep shining black within; of very little taste; and having scarcely any smell, unless heated, when it emits a strong pitchy one. It is found in a soft or liquid state on the surface of the Dead Sea, and by age grows dry and hard. The same kind of bitumen is met with likewise in the earth, in other parts of the world, in China, America, and in some places of Europe, as the Carpathian hills, France, Neufchatel,

&c.

&c. There are feveral kinds of Jews pitch in the fhops: but none of them are the genuine fort, and have little other title to their name, than their being artificially compounded by Jews; and as they are a medley of we know not what ingredients, their medicinal ufe begins to be defervedly laid afide, notwithftanding the difcutient, refolvent, practoral, and other virtues, attributed to this bitumen by the ancients. The true afphaltum was formerly ufed in embalming the bodies of the dead. The thick and folid afphalta are at prefent employed in Egypt, Arabia, and Perfia, as pitch for fhips; as the fluid ones, for burning in lamps, and for varnifhes. Some writers relate, that the walls of Babylon, and the temple of Jerufalem, were cemented with bitumen inftead of mortar. Thus much is certain, that a true natural bitumen, that for inftance, which is found in the diftrict of Neufchatel, proves an excellent cement for walls, pavements, and other purpofes, uncommonly firm, very durable in the air, and not penetrable by water. The watch and clock makers ufe a compofition of afphaltum, fine lamp-black, and oil of fpike or turpentine, for drawing the black figures on dial-plates: this compofition is prepared chiefly by certain perfons at Augfburg and Nuremberg. See the preceding article.

ASPHODELUS, ASPHODEL, or KING'S SPEAR: A genus of the monogynia order, belonging to the hexandria clafs of plants. The calyx is divided into fix parts; and the nectarium confifts of fix valves covering the nectarium.—The

Species are five. 1. The luteus, or common yellow afphodel, hath roots compofed of many thick flefhy fibres, which are yellow, and joined into a head at the top; from whence arife ftrong round fingle ftalks near three feet high, garnifhed on the upper part with yellow ftar-fhaped flowers, which appear in June, and the feeds ripen in autumn. 2. The ramofus, or branching afphodel, hath roots compofed of flefhy fibres, to each of which is faftened an oblong bulb as large as a fmall potatoe; the leaves are long and flexible, having fharp edges; between thefe come out the flower-ftalks, which arife more than three feet high, fending forth many lateral branches. The upper parts of thefe are adorned with many white ftar-fhaped flowers, which grow in long fpikes flowering gradually upward. They come out in the beginning of June, and the feeds ripen in autumn. 3. The ramofus, or unbranched afphodel, hath roots like the fecond, but the leaves are longer and narrower; the ftalks are fingle, never putting out any fide branches. The flowers appear at the fame time with the former, are of a purer white, and grow in longer fpikes. 4. The albus, with keel-fhaped leaves, hath roots compofed of fmaller fibres than the two laft, nor are the knobs at bottom half fo large; the leaves are long, almoft triangular, and hollow like the keel of a boat; the ftalks feldom rife above two feet high, and divide into feveral fpreading branches; thefe are terminated by loofe fpikes of white flowers fmaller than thofe of the former. 5. The ftulofus, or annual branching fpiderwort, hath roots compofed of many yellow flefhy fibres: the leaves are fpread out from the crown of the root, clofe to the ground, in a large clufter; thefe are convex on their under fide, but plain above. The flower-ftalks rife immediately from the root, and grow about two feet high, dividing into three or four branches upward, which are adorned with white ftarry flowers, with purple lines on the outfide. Thefe flower in July and Auguft, and their feeds ripen in October.

Culture. The way to increafe thefe plants is by parting their roots in Auguft, before they fhoot up their frefh green leaves. They may alfo be raifed from feeds fown in Auguft; and the Auguft following the plants produced from thefe may be tranfplanted into beds, and will produce flowers the fecond year. They muft not be planted in fmall borders, among tender flowers; for they will draw away all the nourifhment, and ftarve every thing elfe.

The Lancafhire afphodel is thought to be very noxious to fheep, whenever, through poverty of pafture, they are neceffitated to eat it; although they are faid to improve much in their flefh at firft, they afterwards die with fymptoms of a difeafed liver. This is the plant of which fuch wonderful tales have been told by Pauli, Bartholine, and others, of its foftening the bones of fuch animals as fwallow it; and which they thence called *gramen offifragum*. Horned cattle eat it without any ill effect.

ASPHURELATA, in natural hiftory, are femimetallic foffils, fufible by fire, and not malleable in their pureft ftate, being in their native ftate intimately mixed with fulphur and other adventitious matter, and reduced to what are called *ores*.

Of this feries of foffils, there are only five bodies, each of which makes a diftinct genus; viz. antimony, bifmuth, cobalt, zinc, and quickfilver.

ASPICUETA (Martin de), commonly called the Doctor of Navarre, or *Doctor Navarrus*, was defcended of a noble family, and born the 13th of December 1491, at Varafayn, a fmall city of Navarre, not far from Pampeluna. He entered very young into the monaftery of Regular canons at Roncevaux, where he took the habit which he continued to wear after he left the convent. He ftudied claffical learning, natural and moral philofophy, and divinity, at Alcala, in New-Caftile, adopting chiefly the fyftem of Petrus Lombardus, commonly called the *Mafter of the Sentences*. He applied to the ftudy of the law at Ferrara, and taught it with applaufe at Touloufe and Cahors. After being firft profeffor of canon low at Salamanca for 14 years, he quitted that place to be profeffor of law at Coimbra, with a larger falary. The duties of this office he difcharged for the fpace of 20 years, and then refigned it to retire into his own country, where he took care of his nieces, the daughters of his deceafed brothers. Having made a journey to Rome to plead the caufe of Bartholomeo de Caranza archbifhop of Toledo, who had been accufed of herefy before the tribunal of the inquifition in Spain, and whofe caufe was, by the Pope's order, to be tried in that city, Afpiceuta's writings, which were well known, procured him a moft honourable reception. Pope Pius V. made him affiftant to cardinal Francis Aciat, his vice-penitentiary; and Gregory XIII. never paffed by his door without calling for him, and ftopped fometimes a whole hour to talk with him in the ftreet. His name became fo famous, that even in his lifetime the higheft encomium on a learned man was to call him a *Navarrus*. He was confulted as an oracle. By temperance he prolonged his life to a great length. His œconomy enabled him to give fubsubstantial proofs of his charity. Being very old, he used to ride on a mule through the city, and relieved all the poor he met; to which his mule was so well accustomed, that it stopped of its own accord at the sight of every poor man till its master had relieved him. He refused several honourable posts in church and state, that he might have leisure to correct and improve the works he had already written, and compose others. He died at the age of 94, on the 21st of June 1586. He wrote a vast number of treatises, all which are either on morality or canon law.

ASPIRATE, in grammar, denotes words marked with the spiritus asper. See ASPER.

ASPIRATION, among grammarians, is used to denote the pronouncing a syllable with some vehemence.

ASPLENIUM, CETERACH: A genus of the order of filices, belonging to the cryptogamia class of plants. The parts of fructification are situated in the small sparse line under the disk of the leaves. There are 24 species. Two of these are natives of Britain, and grow upon old walls or moist rocks; one is called *scolopendrium*, or *hart's tongue*: the other is properly *ceterach*, also called *spleenwort*. It has an herbaceous, somewhat mucilaginous, roughish taste: it is recommended as a pectoral, and for promoting urine in nephritic cases. The virtue which it has been most celebrated for is that which it has the least title to, viz. diminishing the spleen.

ASS, in zoology, is ranked as a species of equus, or horse. See EQUUS.

Coronation of the Ass, in antiquity, was a part of the ceremony of the feast of Vesta, wherein the bakers put bread crowns on the heads of these quadrupeds; *Ecce coronatis panis dependet asellis* *. Hence, in an ancient calendar, the ides of June are thus denoted: *Festum est Vestæ. Asinus coronatur!*—This honour, it seems was done the beast, because, by its braying, it had saved Vesta from being ravished by the Lampsacan god. Hence the formula, *Vestæ delicium est asinus*.

* Ovid Fast. vi. 311.

ASSAI, in music, signifies quick; and, according to others, that the motion of the piece be kept in a middle degree of quickness or slowness. As, *Assai allegro, assai presto*. See ALLEGRO and PRESTO.

ASSANCALA, a strong town in Armenia, near the river Arras, in the road between Erzerum and Erivan, and noted for its hot baths. It stands on a high hill; the walls are built in a spiral line all round the rock and strengthened with square towers. The ditches are about two fathoms over, cut out of hard rock. E. Long. 41. 30. N. Lat. 39. 46.

ASSANCHIF, a town of Asia, in Diarbekir, seated on the river Tigris. E. Long. 42. 30. N. Lat. 37. 20.

ASSANS. See ASSENS.

ASSARIUM, in antiquity, denotes a small copper coin, being a part or diminutive of the *as*. The word ασσαριον is used by Suidas indifferently with οβολος and νομισμα, to denote a small piece of money; in which he is followed by Cujacius, who defines ασσαριον by *Minimus æris nummus*. We find mention of the assarion in the gospel of St Matthew, chap. x. verse 29.

ASSARON, or OMER, a measure of capacity, in use among the Hebrews, containing five pints. It the measure of manna which God appointed for every Israelite.

ASSASIN, or ASSASSIN, a person who kills another with the advantage either of an inequality in the weapons, or by means of the situation of the place, or by attacking him at unawares.

The word *assassin* is said by some to have been brought from the Levant, where it took its rise from a certain prince of the family of the *Arsacidæ*; popularly called *Assassins*, living in a castle between Antioch and Damasco, and bringing up a number of young men, ready to pay a blind obedience to his commands; whom he employed in murdering the princes with whom he was at enmity. But according to Mr Volney, the word *Hassassin* (from the root *hass*, "to kill, assassinate, to listen, to surprise,") in the vulgar Arabic signifies "Robbers of the night," persons who *lie in ambush to kill*; and is universally understood in this sense at Cairo and in Syria. Hence it was applied to the *Batenians*, who slew by surprise. See the next article.

There was a certain law of nations, an opinion received in all the republics of Greece and Italy, whereby he that assassinated an usurper of the supreme power was declared a virtuous man. At Rome especially, after the expulsion of the kings, the law was formal and solemn, and instances of it admitted. The commonwealth armed the hand of any citizen, and created him magistrate for that moment.

ASSASSINS, a tribe or clan in Syria, called also *Ismaelians* and *Batanists* or *Batenians*. These people probably owed their origin to the Kirmatians, a famous heretical sect among the Mahometans, who settled in Persia about the year 1090; whence, in process of time, they sent a colony into Syria, where they became possessed of a considerable tract of land among the mountains of Lebanon, extending itself from the neighbourhood of Antioch to Damascus.

The first chief and legislator of this remarkable tribe appears to have been Hassan Sabah, a subtle impostor, who by his artifices made fanatical and implicit slaves of his subjects. Their religion was compounded of that of the Magi, the Jews, the Christians, and the Mahometans: but the capital article of their creed was to believe that the Holy Ghost resided in their chief; that his orders proceeded from God himself, and were real declarations of his divine pleasure. To this monarch the orientals gave the name of *Scheik*: but he is better known in Europe by the name of the *Old Man of the Mountain*. His dignity, instead of being hereditary, was confirmed by election; where merit, that is, a superior multiplicity and enormity of crimes, was the most effectual recommendation to a majority of suffrages.

This chief, from his exalted residence on the summit of mount Lebanon, like a vindictive deity, with the thunderbolt in his hand, sent inevitable death to all quarters of the world; so that from one end of the earth to the other, kalifs, emperors, sultans, kings, princes, Christians, Mahometans, and Jews, every nation and people, execrated and dreaded his sanguinary power, from the strokes of which there was no security. At the least suggestion or whisper that he had threatened the death of any potentate, all immediately doubled their guards, and took every other precaution in their power.

power. It is known that Philip Auguftus king of France, on a premature advice that the Scheik intended to have him affaffinated, inftituted a new body-guard of men diftinguifhed for their activity and courage, called *fergens d'Armes*, with brafs clubs bows and arrows; and he himfelf never appeared without a club, fortified either with iron or gold. Moft fovereigns paid fecretly a penfion to the Scheik, however fcandalous and derogatory it might be to the luftre of majefty, for the fafety of their perfons. The Knights Templars alone dared to defy his fecret machinations and open force. Indeed they were a permanent difperfed body, not to be cut off by maffacres or affaffinations.

This barbarous prince was furnifhed with refources unknown to all other monarchs even to the moft abfolute defpotic tyrant. His fubjects would proftrate themfeves at the foot of his throne, requefting to die by his hand or order, as a favour by which they were fure of paffing in paradife. On them if danger made any impreffion, it was an emulation to prefs forward; and if taken in any enterprife, they went to the place of execution with a magnanimity unknown to others. Henry count of Champaigne, who married Ifabella daughter of Amaury king of Jerufalem, paffing over part of the territory of the Affaffins in his way to Syria, and talking highly of his power, their chief came to meet him, "Are your fubjects (faid the old man of the mountain) as ready in their fubmiffion as mine?" and, without ftaying for an anfwer, made a fign with his hand, when ten young men in white, who were ftanding on an adjacent tower, inftantly threw themfelves down. On another occafion, Sultan Malek-Shah fummoning the Scheik to fubmit himfelf to his government, and threatening him with the power of his arms, fhould he hefitate to comply; the latter, very compofedly turning himfelf towards his guards, faid to one of them, "Draw your dagger and plunge it into your breaft;" and to another, "Throw yourfelf headlong from yonder rock." His orders were no fooner uttered than they were joyfully obeyed: and all the anfwer he deigned to give the fultan's envoy was, "Away to thy mafter, and let him know I have many thoufand fubjects of the fame difpofition." Men fo ready to deftroy themfelves were equally alert and refolute in being the minifters of death to others. At the command of their fovereign, they made no difficulty of ftabbing any prince, even on his throne; and being well verfed in the different dialects, they conformed to the drefs and even the external religion of the country, that they might with lefs difficulty ftrike the fatal blow required by their chief. With the Saracens they were Mahometans; with the Franks, Chriftians; in one place they joined with the Mamaluks; in another, with the ecclefiaftics or religious; and under this difguife feized the firft opportunity of executing their fanguinary commiffion. Of this we meet with an inftance in the hiftory of Saladin, while he was befieging Manbedge, the celebrated Hieropolis of antiquity. Being one day, with a few attendants, and they at fome diftance, reconnoitring the place for the better difpofition of the attack, a man rufhed on him with a dagger in his hand, and wounded him in the head; but the fultan, as he was endeavouring to repeat his ftroke, wrefted the dagger from him, and, after receiving feveral wounds, laid him dead at his feet. Before the fultan had well recovered himfelf, a fecond encountered him to finifh the treachery of the former; but he met with the fame fate: he was fucceeded with equal fury by a third, who alfo fell by the hand of that magnanimous prince whom he was fent to affaffinate. And it was obferved, that thefe wretches dealt about their fruitlefs blows as they lay in the agonies of death. With fuch rapidity was this tranfacted, that it was over before Saladin's guards could come to his affiftance. He retired to his tent, and in great perturbation throwing himfelf on his fopha, ordered his fervants to take a ftrict view of his houfehold, and to cafhier all fufpected perfons; at the fame time afking with great earneftnefs, "Of whom have I deferved fuch treacherous ufage?" But it afterwards appeared, that thefe villains had been fent by the old man of the mountain; of whom the vizir Kamfchlegin had purchafed the murder of Saladin, to free himfelf from fo great a warrior whom he could not meet in the field. To animate them in their frantic obedience, the Scheik, before their departure on fuch attempts, ufed to give them a fmall foretafte of fome of the delights which he affured them would be their recompenfe in paradife. Delicious foporific drinks were given them; and while they lay afleep, they were carried into beautiful gardens, where very allurement invited their fenfes to the moft exquifite gratifications. From thefe feats of voluptuoufnefs, inflamed with liquor and enthufiaftic views of perpetual enjoyments, they fallied forth to perform affaffinations of the blackeft dye.

This people once had, or atleaft they feigned to have, an intention of embracing the Chriftian religion. They reigned a long time in Perfia and on Mount Lebanon. Hulaku, a khan of the Mogul Tartars, in the year 655 of the Hegira, or 1254 of the Chriftian æra, entered their country and difpoffeffed them of feveral places; but it was not till the year 1272 that they were totally conquered. This atchievement was owing to the conduct and intrepidity of the Epyptian forces fent againft them by the fultan Bibaris. It has, however, been thought that the Drufes, who ftill refide among the eminences of Mount Lebanon, and whofe religion and cuftoms are fo little known, are a remnant of thofe barbarians.

ASSAULT, in law, is an attempt or offer to beat another, without touching him: as if one lifts up his cane or his fift in a threatening manner at another; or ftrikes at him, but miffes him; this is an affault, *infultus*, which Finch defcribes to be "an unlawuful fetting upon one's perfon." This alfo is an inchoate violence, amounting confiderably higher than bare threats; and therefore, though no actual fuffering is proved, yet the party injured may have redrefs by action of *trefpafs vi et armis*, wherein he fhall recover damages as a compenfation for the injury.

ASSAULT, in the military art, a furious effort made to carry a fortified poft, camp, or fortrefs, wherein the affailants do not fcreen themfelves by any works: while the affault continues, the batteries ceafe, for fear of killing their own men.—The *enfans perdus* march firft to the affault. See *ENFANS Perdus*.

ASSAY, ESSAY, or SAY, in metallurgy, the proof or trial of the goodnefs, purity, value, &c. of metals and metalline fubftances. See ESSAY.

In ancient statutes this is called *touch;* and those who had the care of it, *Keepers of the touch.*—Under Henry VI. divers cities were appointed to have touch for wrought silver-plate, 2 Hen. VI. c. 14.—By this, one might imagine they had no better method of assaying than the simple one by the touch-stone; but the case is far otherwise. In the time of King Henry II. the bishop of Salisbury, then treasurer, considering that though the money paid into the king's exchequer for his crown-rents did answer *numero et pondere*, it might nevertheless be mixed with copper or brass: wherefore a constitution was made, called the *trial by combustion*; which differs little or nothing from the present method of assaying silver. See a description of it in the Black Book in the Exchequer, written by Gervase of Tilbury, c. xxi. This trial is also there called *essaium*, and the officer who made it is named *fusor*. The method still in use of assaying gold and silver was first established by an act of the English parliament 1354.

Assaying, *ars docimastica*, in its extent, comprehends particular manners of examining every ore, or mixed metal, according to its nature, with the best-adapted fluxes; so as to discover, not only what metals, and what proportions of metal, are contained in ores; but likewise how much sulphur, vitriol, alum, arsenic, smelt, &c. may be obtained from every one respectively. See Blow-pipe, Metallurgy, and Mineralogy.

Assaying is more particularly used by moneyers and goldsmiths, for the making a proof or trial by the cuppel, or test, of the fineness or purity of the gold and silver to be used in the coining of money, and manufacture of plate, &c. or that have been already used therein.

There are two kinds of assaying; the one before metals are melted, in order to bring them to their proper fineness; the other after they are struck, to see that the species be standard. For the first assay, the assayers use to make 14 or 15 grains of gold, and half a dram of silver, if it be for money; and 18 grains of the one, and a dram of the other, if for other occasions. As to the second assay, it is made of one of the pieces of money already coined, which they cut in four parts. The quantity of gold for an assay among us is six grains: In France, nearly the same; and in Germany, about three times as much.

The proper spelling of that word, however, is essay; under which article, therefore, the reader will find the subject more particularly treated.

Assay-Balance, or *Essay-Balance*, the flat pieces of glass often placed under the scales of an assay-balance, seem, by their power of electricity, capable of attracting, and thereby making the lighter scale preponderate, where the whole matter weighed is so very small. See *Essay-Bala*nce.

The electricity of a flat surface of about three inches square has been known to hold down one scale, when there were about 200 grains weight in the other. See Balance.

Assay-Master, or *Essay-Master*, an officer under certain corporations entrusted with the care of making true touch, or assay, of the gold and silver brought to him; and giving a just report of the goodness or badness thereof. Such is the assay-master of the mint in the Tower, called also *assayer of the king*.

The assay-master of the goldsmiths company is a sort of assistant-warden, called also a *touch-warden*, appointed to survey, assay, and mark all the silver-work, &c. committed to him. There are also assay-masters appointed by statute at York, Exeter, Bristol, Chester, Norwich, Newcastle, and Birmingham, for assaying wrought plate. The assay-master is to retain eight grains of every pound Troy of silver brought to him; four whereof are to be put in the pix, or box of deal, to be re-assayed the next year, and the other four to be allowed him for his waste and spillings.

Note, The number of pennyweights set down in the assay-master's report, is to be accounted as per pound, or so much in every pound of 12 ounces Troy. For every 20 penny-weight, or ounce Troy, the silver is found by the assay to be worse than standard, or sterling, sixpence is to be deducted; because every ounce will cost so much to reduce it to standard goodness, or to change it for sterling.

In gold, for every carat it is set down to be worse than standard, you must account that in the ounce Troy it is worse by so many times 3 s. 8 d.; and for every grain it is set down worse, you must account it worse by so many times 11 d. in the ounce Troy; and for every half grain 5¼d.: for so much it will cost to make it of standard goodness, &c.

ASSELYN (John), a famous Dutch painter, was born in Holland, and became the disciple of Isaiah Vandevelde, the battle-painter. He distinguished himself in history-paintings, battles, landscapes, animals, and particularly horses. He travelled into France and Italy; and was so pleased with the manner of Bambochio, that he always followed it. He painted many pictures at Lyons, where he married the daughter of a merchant of Antwerp, and returned with her to Holland. Here he first discovered to his countrymen a fresh and clear manner of painting landscapes, like Claude Lorraine; upon which all the painters imitated his style, and reformed the dark brown they had hitherto followed. Asselyn's pictures were so much admired at Amsterdam, that they sold there at a high price. He died in that city in 1660. Twenty-four pieces of landscapes and ruins, which he painted in Italy, have been engraved by Perelle.

ASSEMBLAGE, the uniting or joining of things together; or the things themselves so united or joined. It is also used, in a more general sense, for a collection of various things so disposed and diversified, that the whole produces some agreeable effect.

ASSEMBLY, the meeting of several persons, in the same place, upon the same design.

Assembly, in the beau monde, an appointed meeting of fashionable persons of both sexes, for the sake of play, dancing, gallantry, conversation, &c.

Assembly, in the military art, the second beating of a drum before a march; at which the soldiers strike their tents, roll them up, and stand to arms.

Assemblies of the clergy are called *convocations, synods, councils*. The annual meeting of the church of Scotland is called a *General Assembly:* In this assembly his Majesty is represented by his Commissioner, who dissolves one meeting, and calls another, in the name of the *King*, while the Moderator does the same in the name of the *Lord Jesus Christ*.

Assemblies of the Roman people were called *comitia*.

Under the Gothic governments, the supreme legislative power was lodged in an assembly of the states of the kingdom, held annually for the like purposes as the British parliament. Some feeble remains of this usage still subsist in the annual assemblies of the states of Languedoc, Bretagne, and a few other provinces of France; but these are no more than shadows of the ancient assemblies. It is only in Great Britain, Sweden, and Poland, that such assemblies retain their ancient powers and privileges.

ASSENS, a sea-port town of Denmark, situated upon the Little Belt, a strait of the Baltic, which separates the isle of Funen from the continent. It is the common passage from the duchy of Sleswick to Copenhagen. E. Long. 10. 30. N. Lat. 55. 15.

ASSENT, in a general sense, implies an agreement to something proposed or affirmed by another.

Royal Assent, the approbation given by the king to a bill in parliament, after which it becomes a law.

ASSER (John), or Asserius Menevensis, that is, *Asser of St David's*, bishop of Shirburn in the reign of Alfred the Great. He was born in Pembrokeshire, in South Wales; and educated in the monastery of St David's by the archbishop Asserius, who, according to Leland, was his kinsman. In this monastery he became a monk, and by his assiduous application soon acquired universal fame as a person of profound learning and great abilities. Alfred, the munificent patron of genius, about the year 880, sent for him to court. The king was then at Dean in Wiltshire. He was so charmed with Asser, that he made him his preceptor and companion. As a reward for his services, he appointed him abbot of two or three different monasteries; and at last promoted him to the episcopal see of Shirburn, where he died and was buried in the year 910. He was, says Pits, a man of a happy genius, wonderful modesty, extensive learning, and great integrity of life. He is said to have been principally instrumental in persuading the king to restore the university of Oxford to its pristine dignity and lustre.—He wrote, *De vita et rebus gestis Alfredi*, &c. Lond. 1574, published by Archbishop Parker, in the old Saxon character, at the end of *Walsinghami hist.*——Francf. 1602. fol. Oxf. 1722, 8vo. Many other works are ascribed to this author by Gale, Bale, and Pits, but all doubtful.

ASSERIA. See Asisia.

ASSERTION, in the language of the schools, a proposition advanced by the assertor, who avows the truth of it, and is ready to defend it.

ASSESSOR, an inferior officer of justice, appointed chiefly to assist the ordinary judge with his opinion and advice.

Assessor is also one who assesses or settles taxes and other public dues.

ASSETS, in law, signifies goods enough to discharge that burden which is cast upon the executor or heir, in satisfying the debts and legacies of the testator or ancestor. Assets are real or personal. Where a man hath lands in fee simple, and dies seised thereof, the lands which come to his heir are assets real; and where he dies possessed of any personal estate, the goods which come to the executors are assets personal. Assets are also divided into *assets per descent*, and *assets inter maines*. Assets by descent is where a person is bound in an obligation, and dies seised of lands which descend to the heir, the land shall be assets, and the heir shall be charged as far as the land to him descended will extend. *Assets inter maines* is when a man indebted makes executors, and leaves them sufficient to pay his debts and legacies; or where some commodity or profit ariseth to them in right of the testator, which are called *assets in their hands*.

ASSEVERATION, a positive and vehement affirmation of something.

ASSHETON (William), doctor of divinity, and rector of Beckenham, in Kent, was born in the year 1641, and was educated at Brazen-nose college, Oxford. After entering into orders, he became chaplain to the Duke of Ormond, and was admitted doctor of divinity in 1673. Soon after, he was nominated to a prebend in the church of York, presented to the living of St Antholin, London, and to the rectory of Beckenham in Kent. He was the first projector of the scheme for providing for clergymens widows, and others, by a jointure payable out of the mercers company. He wrote several pieces against the Papists and Dissenters, and some devotional tracts. He died at Beckenham in September 1711, in the 70th year of his age.

ASSIDEANS, or Chassidæans, (from the Hebrew *chasidim*, "merciful, pious"); those Jews who resorted to Mattathias to fight for the law of God and the liberties of their country. They were men of great valour and zeal, having voluntarily devoted themselves to a more strict observation of the law than other men. For, after the return of the Jews from the Babylonish captivity, there were two sorts of men in their church; those who contented themselves with that obedience only which was prescribed by the law of Moses, and who were called *Zadikim*, i. e. the *righteous*; and those who, over and above the law, superadded the constitutions and traditions of the elders, and other rigorous observances: these latter were called *Chasidim*, i. e. the *pious*. From the former sprung the Samaritans, Sadducees, and Caraites; from the latter, the Pharisees and the Essenes.

ASSIDENT signs, in medicine, are symptoms which usually attend a disease but not always; hence differing from *pathognomic* signs, which are inseparable from the disease: *e. gr.* In the pleurisy, a pungent pain in the side; in an acute fever, difficulty of breathing, &c. collectively taken, are pathognomic signs; but that the pain extends to the hypochondrium or clavicle, or that the patient lies with more ease on one side than on the other, are *assident* signs.

ASSIDUUS, or Adsiduus, among the Romans, denoted a rich or wealthy person. The word in this sense is derived from *as assis*, q. d. a monied man. Hence we meet with *assiduous* sureties, *assidui fidejussores*; answering to what the French now call city sureties or securities, *cautions bourgeois*.

When Servius Tullius divided the Roman people into five classes, according as they were assessed or taxed to the public, the richer sort who contributed asses were denominated *assidui*; and as these were the chief people of business who attended all the public concerns, those who were diligent in attendances came to be denominated *assidui*.

ASSIENTO, a Spanish word signifying a *farm*, in commerce, is used for a bargain between the king of Spain

Spain and other powers, for importing negroes into the Spanish dominions in America, and particularly to Buenos Ayres. The first assiento was made with the French Guinea-company; and, by the treaty of Utrecht, transferred to the English, who were to furnish 4800 negroes annually.

ASSIGN, in common law, a person to whom a thing is assigned or made over.

ASSIGNATION, an appointment to meet. The word is generally understood of love-meetings.

ASSIGNEE, in law, a person appointed by another to do an act, transact some business, or enjoy a particular commodity.

ASSIGNING, in a general sense, implies the making over the right of one person to another. In a particular sense, it signifies the pointing out of something; as, an error, false judgment, or waste.

ASSIGNMENT, the transferring the interest one has in a lease, or other thing, to another person.

ASSIMILATION, in physics, is that motion by which bodies convert other bodies related to them, or at least such as are prepared to be converted, into their own substance and nature. Thus, flame multiplies itself upon oily bodies, and generates new flame; air upon water, and produces new air; and all the parts, as well similar as organical, in vegetables and animals, first attract with some election or choice, nearly the same common or not very different juices for aliment, and afterwards assimilate or convert them to their own nature.

ASSISE, in old English law-books, is defined to be an assembly of knights, and other substantial men, together with a justice, in a certain place, and at a certain time: but the word, in its present acceptation, implies a court, place or time, when and where the writs and processes, whether civil or criminal, are decided by judge and jury.

All the counties of England are divided into six circuits; and two judges are assigned by the king's commission, who hold their assises twice a-year in every county (except London and Middlesex, where courts of *nisi prius* are holden in and after every term, before the chief or other judge of the several superior courts; and except the four northern counties, where the assises are taken only once a year) to try by a jury of the respective counties the truth of such matters of fact as are then under dispute in the courts of Westminster-hall. These judges of assise came into use in the room of the ancient justices in eyre, *justiciarii in itinere:* who were regularly established, if not first appointed, by the parliament of Northampton, A. D. 1176, 22 Hen. II. with a delegated power from the king's great court or *aula regia*, being looked upon as members thereof: and they afterwards made their circuit round the kingdom once in seven years for the purpose of trying causes. They were afterwards directed by *magna charta*, c. 12. to be sent into every county once a-year to take or try certain actions then called *recognitions* or *assises;* the most difficult of which they are directed to adjorn into the court of common pleas to be there determined. The itinerant justices were sometimes mere justices of assise, or of dower, or of gaol-delivery, and the like; and they had sometimes a more general commission, to determine all manner of causes, *justiciarii ad omnia placita:* but the present justices of assise and *nisi prius* are more immediately derived from the statute Westm. 2, 13 Edw. I. c. 30. explained by several other acts, particularly the statute 14 Edw. III. c. 16. and must be two of the king's justices of the one bench or the other, or the chief baron of the exchequer, or the king's serjeants sworn. They usually make their circuits in the respective vacations after Hilary and Trinity terms; assises being allowed to be taken in the holy time of Lent by consent of the bishops at the king's request, as expressed in statute Westm. 1. 3 Edw. I. c. 51. And it was also usual, during the times of Popery, for the prelates to grant annual licenses to the justices of assise to administer oaths in holy times: for oaths being of a sacred nature, the logic of those deluded ages concluded that they must be of ecclesiastical cognizance. The prudent jealousy of our ancestors ordained that no man of law should be judge of assise in his own county: and a similar prohibition is found in the civil law, which has carried this principle so far, that it is equivalent to the crime of sacrilege, for a man to be governor of the province in which he was born, or has any civil connection.

The judges upon their circuits now sit by virtue of five several authorities. 1. The commission of the *peace*, in every county of the circuits; and all justices of the peace of the county are bound to be present at the assises; and sheriffs are also to give their attendance on the judges, or they shall be fined. 2. A commission of *oyer* and *terminer*, directed to them and many other gentlemen of the county, by which they are empowered to try treasons, felonies, &c. and this is the largest commission they have. 3. A commission of general *gaol-delivery*, directed to the judges and the clerk of assise associate, which gives them power to try every prisoner in the gaol committed for any offence whatsoever, but none but prisoners in the gaol; so that one way or other they rid the gaol of all the prisoners in it. 4. A commission of *assise*, directed to the judges and clerk of assise, to take assises; that is, to take the verdict of a peculiar species of jury called *an assise*, and summoned for the trial of *landed* disputes. The other authority is, 5. That of *nisi prius*, which is a consequence of the commission of *assise*, being annexed to the office of those justices by the statute of Westm. 2. 13 Edw. I. c. 30. And it empowers them to try all questions of fact issuing out of the courts of Westminster, that are then ripe for trial by jury. The original of the name is this: all causes commenced in the courts of Westminister-hall are by the course of the courts appointed to be there tried, on a day fixed in some Easter or Michaelmas term, by a jury returned from the county wherein the cause of action arises; but with this proviso, *nisi prius justiciarii ad assisas capiendas venerint; unless before* the day prefixed the judges of assise come into the county in question. This they are sure to do in the vacations preceding each Easter and Michaelmas term, and there dispose of the cause; which saves much expence and trouble, both to the parties, the jury, and the witnesses.

The word *assise* (from the French *assis*, seated, settled, or established, and formed of the Latin verb *assideo*, I sit by) is used in several different senses. It is sometimes taken for the sittings of a court; sometimes for its regulations or ordinances, especially those that fix the

the ſtandard of weights and meaſures; and ſometimes it ſignifies a jury, either becauſe juries conſiſted of a fixed determined number, or becauſe they continued ſitting till they pronounced their verdict. In Scots law, an aſſiſe or jury conſiſts of fifteen ſworn men *(juratores)*, picked out by the court from a greater number, not exceeding 45, who have been ſummoned for that purpoſe by the ſheriff, and given in liſt to the defender, at ſerving him with a copy of his libel.

ASSISIO, an epiſcopal town of Italy, in the duchy of Spoleto, built on the ſide of a very high mountain. The cathedral of St Francis is very magnificent, and compoſed of three churches one above another. E. Long. 13. 35. N. Lat. 43. 4.

ASSITHMENT, a wiregeld, or compenſation, by a pecuniary mulct; from the prepoſition *ad*, and the Sax. *ſithe, vicè: quod vicè ſupplicii ad expiandum delictum ſolvitur.*

ASSOCIATION, the act of aſſociating, or conſtituting a ſociety, or partnerſhip, in order to carry on ſome ſcheme or affair with more advantage.—The word is Latin, *aſſociatio;* and compounded of *ad*, to, and *ſocio*, to join.

Association of Ideas, is where two or more ideas conſtantly and immediately follow or ſucceed one another in the mind, ſo that one ſhall almoſt infallibly produce the other whether there be any natural relation between them or not. See Metaphysics.

Where there is a real affinity or connection in ideas, it is the excellency of the mind to be able to collect, compare, and range them in order, in its inquiries: but where there is none, nor any cauſe to be aſſigned for their accompanying each other, but what is owing to mere accident or habit; this unnatural aſſociation becomes a great imperfection, and is, generally ſpeaking, a main cauſe of error, or wrong deductions in reaſoning. Thus the idea of goblins and ſprights, it has been obſerved, has really no more affinity with darkneſs than with light; and yet let a fooliſh maid inculcate theſe ideas often on the mind of a child, and raiſe them there together, it is poſſible he ſhall never be able to ſeparate them again ſo long as he lives, but darkneſs ſhall ever bring with it thoſe frightful ideas. With regard to this inſtance, however, it muſt at the ſame time be obſerved, that the connection alluded to appears far from being either unnatural or abſurd. See the article Apparition.

Such wrong combinations of ideas, Mr Locke ſhows, are a great cauſe of the irreconcileable oppoſition between the different ſects of philoſophy and religion: for we cannot imagine, that all who hold tenets different from, and ſometimes even contradictory to, one another, ſhould wilfully and knowingly impoſe upon themſelves, and refuſe truth offered by plain reaſon: but ſome looſe and independent ideas are by education, cuſtom, and the conſtant din of their party, ſo coupled in their minds that they always appear there together: theſe they can no more ſeparate in their thoughts, than if they were but one idea, and they operate as if they were ſo. This gives ſenſe to jargon, demonſtration to abſurdities, conſiſtency to nonſenſe, and is the foundation of the greateſt, and almoſt of all, the errors in the world.

Aſſociation forms a principal part of Dr Hartley's mechanical theory of the mind. He diſtinguiſhes it into ſynchronous and ſucceſſive; and aſcribes our ſimple and complex ideas to the influence of this principle or habit. Particular ſenſations reſult from previous vibrations conveyed through the nerves to the medullary ſubſtance of the brain; and theſe are ſo intimately aſſociated together, that any one of them, when impreſſed alone, ſhall be able to excite in the mind the ideas of all the reſt. Thus we derive the ideas of natural bodies from the aſſociation of the ſeveral ſenſible qualities with the names that expreſs them, and with each other. The ſight of part of a large building ſuggeſts the idea of the reſt inſtantaneouſly, by a ſynchronous aſſociation of the parts; and the ſound of the words, which begin a familiar ſentence, brings to remembrance the remaining parts, in order, by ſucceſſive aſſociation. Dr Hartley maintains, that ſimple ideas run into complex ones by aſſociation; and apprehends, that by purſuing and perfecting this doctrine, we may ſome time or other be enabled to analyſe thoſe complex ideas that are commonly called the *ideas of reflection*, or *intellectual ideas*, into their ſeveral component parts, i. e. into the ſimple idea of ſenſation of which they conſiſt; and that this doctrine may be of conſiderable uſe in the art of logic, and in explaining the various phenomena of the human mind.

Association of Parliament. In the reign of king William III. the Britiſh parliament entered into a ſolemn aſſociation to defend his majeſty's perſon and government againſt all plots and conſpiracies; and all perſons bearing offices civil or military, were enjoined to ſubſcribe the aſſociation to ſtand by king William, on pain of forfeitures and penalties, &c. by ſtat. 7 and 8 W. III. c. 27.

ASSOILZIE, in law, to abſolve or free.

ASSONANCE, in rhetoric and poetry, a term uſed where the words of a phraſe or a verſe have the ſame ſound or termination, and yet make no proper rhyme. Theſe are uſually accounted vicious in Engliſh; though the Romans ſometimes uſed them with elegancy: as, *Militem comparavit, exercitum ordinavit, aciem luſtravit.*

ASSONANT rhymes, is a term particularly applied to a kind of verſes among the Spaniards, where a reſemblance of ſound ſerves inſtead of a natural rhyme. Thus, *ligera, cubierta, tierra, meſa*, may anſwer each other in a kind of *aſſonant* rhyme, having each an *e* in the penult ſyllable, and *a* in the laſt.

ASSUAN. See Syene.

ASSUMPSIT, in the law of England, a voluntary or verbal promiſe, whereby a perſon aſſumes, or takes upon him to perform or pay any thing to another.

A promiſe is in the nature of a verbal covenant, and wants nothing but the ſolemnity of writing and ſealing to make it abſolutely the ſame. If therefore it be to do any explicit act, it is an expreſs contract, as much as any covenant: and the breach of it is an equal injury. The remedy indeed is not exactly the ſame: ſince, inſtead of an action of covenant, there only lies an action upon the caſe, for what is called an *aſſumpſit* or undertaking of the defendant; the failure of performing which is the wrong or injury done to the plaintiff, the damages whereof a jury are to eſtimate and ſettle. As, if a builder promiſes, undertakes, or aſſumes to Caius, that he will build and cover his houſe within a time limited, and fails to do it; Caius has an action on the caſe againſt the builder for this breach

Assumpsit. breach of his express promise, undertaking, or assumpsit; and shall recover a pecuniary satisfaction for the injury sustained by such delay. So also in the case of a debt by simple contract, if the debtor promises to pay and does not, this breach of promise intitles the creditor to his action on the case, instead of being driven to an action of debt. Thus likewise a promissory note, or note of hand not under seal to pay money at a day certain, is an express assumpsit; and the payee at common law, or by custom and act of parliament the indorsee, may recover the value of the note in damages, if it remains unpaid. Some agreements indeed, though never so expresly made, are deemed of so important a nature, that they ought not to rest in verbal promise only which cannot be proved but by the memory (which sometimes will induce the perjury) of witnesses. To prevent which, the statute of frauds and perjuries, 29 Car. II. c. 3. enacts, that in the five following cases no verbal promise shall be sufficient to ground an action upon, but at the least some note or memorandum of it shall be made in writing, and signed by the party to be charged therewith: 1. When an executor or administrator promises to answer damages out of his own estate. 2. Where a man undertakes to answer for the debt, default, or miscarriage, of another. 3. Where any agreement is made upon consideration of marriage. 4. Where any contract or sale is made of lands, tenements, or hereditaments, or any interest therein. 5. And lastly, where there is any agreement that is not to be performed within a year from the making thereof. In all these cases, a mere verbal assumpsit is void.

From these express contracts the transition is easy to those that are only implied by law. Which are such as reason and justice dictate, and which therefore the law presumes that every man has contracted to perform; and, upon this presumption, makes him answerable to such persons as suffer by his non-performance.

Thus, 1. If I employ a person to transact any business for me, or perform any work, the law implies that I undertook, or assumed, to pay him so much as his labour deserved: and if I neglect to make him amends, he has a remedy for this injury by bringing his action on the case upon this implied assumpsit; wherein he is at liberty to suggest that I promised to pay him so much as he reasonably deserved, and then to aver that his trouble was really worth such a particular sum, which the defendant has omitted to pay. But this valuation of his trouble is submitted to the determination of a jury; who will assess such a sum in damages as they think he really merited. This is called an *assumpsit* on a *quantum meruit*.

2. There is also an implied assumpsit on a *quantum valebat*, which is very similar to the former; being only where one takes up goods or wares of a tradesman, without expresly agreeing for the price. There the law concludes, that both parties did intentionally agree that the real value of the goods should be paid; and an action on the case may be brought accordingly, if the vendee refuses to pay that value.

3. A third species of implied assumpsit is when one has had and received money belonging to another without any valuable consideration given on the receiver's part; for the law construes this to be money had and received for the use of the owner only; and implies that the person so receiving, promised and undertook to account for it to the true proprietor. And, if he unjustly detains it, an action on the case lies against him for the breach of such implied promise and undertaking; and he will be made to repair the owner in damages, equivalent to what he has detained in such violation of his promise. This is a very extensive and beneficial remedy, applicable to almost every case where the defendant has received money which *ex æquo et bono* he ought to refund. It lies for money paid by mistake, or on a consideration which happens to fail, or through imposition, extortion, or oppression, or where undue advantage is taken of the plaintiff's situation. Assumpsit.

4. Where a person has laid out and expended his own money for the use of another at his request, the law implies a promise of repayment, and an action will lie on this assumpsit.

5. Likewise, fifthly, upon a stated account between two merchants, or other persons, the law implies that he against whom the balance appears has engaged to pay it to the other; though there be not any actual promise. And from this implication it is frequent for actions on the case to be brought, declaring that the plaintiff and defendant had settled their accounts together, *insimul computassent*, (which gives name to this species of assumpsit); and that the defendant engaged to pay the plaintiff the balance, but has since neglected to do it. But if no account has been made up, then the legal remedy is by bringing a writ of *account de computo*; commanding the defendant to render a just account to the plaintiff, or shew the court good cause to the contrary. In this action, if the plaintiff succeeds, there are two judgments; the first is, that the defendant do account *(quod computet)* before auditors appointed by the court; and when such account is finished, then the second judgment is, that he do pay the plaintiff so much as he is found in arrear.

6. The last class of contracts, implied by reason and construction of law, arises upon this supposition, that every one who undertakes any office, employment, trust, or duty, contracts with those who employ or entrust him, to perform it with integrity, diligence, and skill: and if by his want of either of those qualities any injury accrues to individuals, they have therefore their remedy in damages, by a special action on the case. A few instances will fully illustrate this matter. If an officer of the public is guilty of neglect of duty, or a palpable breach of it, of non-feasance or of mis-feasance; as, if the sheriff does not execute a writ sent to him, or if he wilfully makes a false return thereof; in both these cases, the party aggrieved shall have an action *on the case*, for damages to be assessed by a jury. If a sheriff or goaler suffers a prisoner who is taken upon mesne process (that is, during the pendency of a suit) to escape, he is liable to an action *on the case*. But if after judgment, a goaler or a sheriff permits a debtor to escape, who is charged in execution for a certain sum; the debt immediately becomes his own, and he is compellable by action of *debt*, being for a sum liquidated and ascertained, to satisfy the creditor in his whole demand. An advocate or attorney that betray the cause of their client, or, being retained, neglect to appear at the trial, by which the cause miscarries, are liable to an action on the case, for a reparation to their injured client. There is also in law always an

implied

implied contract with a common innkeeper, to secure his guest's goods in his inn; with a common carrier or barge-master, to be answerable for the goods he carries; with a common farrier, that he shoes a horse well, without laming him; with a common taylor, or other workman, that he performs his business in a workmanlike manner; in which if they fail, an action on the case lies to recover damages for such breach of their general undertaking. Also if an innkeeper, or other victualler, hangs out a sign and opens his house for travellers, it is an implied engagement to entertain all persons who travel that way; and upon this universal *assumpsit* an action on the case will lie against him for damages, if he without good reason refuses to admit a traveller. In contracts likewise for sales, if the seller doth upon the sale warrant it to be good, the law annexes a tacit contract to this warranty, that if it be not so, he shall make compensation to the buyer: else it is an injury to good faith, for which an action on the case will lie to recover damages.

ASSUMPTION, a festival in the Romish church, in honour of the miraculous ascent of the Virgin Mary into heaven: the Greek church, who also observe this festival, celebrate it on the 15th of August with great ceremony.

Assumption, in logic, is the minor or second proposition in a categorical syllogism.

Assumption is also used for a consequence drawn from the propositions whereof an argument is composed.

Assumption, an island of North-America, in the gulph of St Lawrence, at the mouth of the great river of the same name. It is covered with trees. W. Long. 60. 40. N. Lat. 49. 30.

Assumption, a large and handsome town of Proper Paraguay, on the river of the same name in South America. It is a bishop's see, is well peopled, and seated in a country fruitful in corn and fruits, whose trees are always green. There is likewise a quantity of pasture, and the air is temperate and salutary. W. Long. 60. 40. S. Lat. 34. 10.

ASSUMPTIVE arms, in heraldry, are such as a person has a right to assume, with the approbation of his sovereign, and of the heralds: thus, if a person, who has no right by blood, and has no coat of arms, shall captivate, in any lawful war, any gentleman, nobleman, or prince, he is, in that case, entitled to bear the shield of that prisoner, and enjoy it to him and his heirs for ever.

ASSURANCE, or Insurance, in commerce. See Insurance.

ASSUROR, a merchant, or other person, who makes out a policy of assurance, and thereby insures a ship, house, or the like.

ASSUS, or Assos (anc. geog.), a town of Troas (though by others supposed to be of Mysia), and the same with Apollonia (Pliny); but different from the Apollonia on the river Rhyndacus. Ptolemy places it on the sea-coast, but Strabo more inland; if he does not mean the head of an inland bay, as appears from Diodorus Siculus. It was the country of Cleanthes the stoic philosopher, who succeeded Zeno. St Luke and others of St Paul's companions in his voyage (Acts xx. 13. 14), went by sea from Troas to Assos: but St Paul went by land thither, and meeting them at Assos, they all went together to Mytelene. It is still called *Assos*. E. Long. 27. 30. Lat. 38. 30.

ASSYRIA, an ancient kingdom of Asia, concerning the extent, commencement, and duration of which, historians differ greatly in their accounts. Several ancient writers, in particular Ctesias and Diodorus Siculus, have affirmed, that the Assyrian monarchy, under Ninus and Semiramis, comprehended the greater part of the known world. Had this been the case, it is not likely that Homer and Herodotus would have omitted a fact so remarkable. The sacred records intimate, that none of the ancient states or kingdoms were of considerable extent; for neither Chederlaomer, nor any of the neighbouring princes, were tributary or subject to Assyria; and we find nothing of the greatness or power of this kingdom in the history of the Judges and succeeding kings of Israel, though the latter kingdom was oppressed and enslaved by many different powers in that period. It is highly probable, therefore, that Assyria was originally of small extent. According to Ptolemy, it was bounded on the north by Armenia Major; on the west by the Tigris; on the south by Susiana; and on the east by Media.

It is probable, that the origin and revolutions of the Assyrian monarchy were as follows.—The founder of it was Ashur, the second son of Shem, who went out of Shinar, either by the appointment of Nimrod, or to elude the fury of a tyrant; conducted a large body of adventurers into Assyria, and laid the foundation of Nineveh (Gen. x. 11.) These events happened not long after Nimrod had established the Chaldæan monarchy, and fixed his residence at Babylon. The Persian historians suppose that the kings of Persia of the first dynasty were the same with the kings of Assyria, of whom Zohah, or Nimrod, was the founder of Babel (Herbelot Orient. Bibl. v. *Bagdad*). It does not, however, appear, that Nimrod reigned in Assyria. The kingdoms of Babylon and Assyria, were originally distinct and separate (Micah v. 6.), and in this state they remained until Ninus conquered Babylon, and made it tributary to the Assyrian empire. Ninus, the successor of Ashur (Gen. x. 11. Diod. Sic. L. 1.), seized on Chaldæa, after the death of Nimrod, and united the kingdoms of Assyria and Babylon. This great prince is said to have subdued Asia, Persia, Media, Egypt, &c. If he did so, the effects of his conquests were of no duration; for, in the days of Abraham, we do not find that any of the neighbouring kingdoms were subject to Assyria. He was succeeded by Semiramis; a princess of an heroic mind; bold, enterprising, fortunate; but of whom many fabulous things have been recorded. It appears, however, that there were two princesses of the same name, who flourished at very different periods. One of them was the consort of Ninus; and the other lived five generations before Nitocris queen of Nebuchadnezzar (Euseb. Chron. p. 58. Herod. L. i. c. 184.) This fact has not been attended to by many writers.

Playfair's Chronology.

Whether there was an uninterrupted series of kings from Ninus to Sardanapalus, or not, is still a question. Some suspicion has arisen, that the list which Ctesias has given of the Assyrian kings is not genuine; for many names in it are of Persian, Egyptian, and Grecian extraction.

Nothing memorable has been recorded concerning the successors of Ninus and Semiramis. Of that effeminate race of princes it is barely said, that they ascended the throne, lived in indolence, and died in their palace at Nineveh. Diodorus (L. ii.) relates, that, in the reign of Teutames, the Assyrians, solicited by Priam their vassal, sent to the Trojans a supply of 20,000 foot and 200 chariots, under the command of Memnon, son of Tithonus president of Persia: But the truth of this relation is rendered doubtful by the accounts of other writers.

Sardanapalus was the last of the ancient Assyrian kings. Contemning his indolent and voluptuous course of life, Arbaces, governor of Media, withdrew his allegiance, and rose up in rebellion against him. He was encouraged in this revolt by the advice and assistance of Belesis, a Chaldean priest, who engaged the Babylonians to follow the example of the Medes. These powerful provinces, aided by the Persians and other allies, who despised the effeminacy, or dreaded the tyranny of their Assyrian lords, attacked the empire on all sides. Their most vigorous efforts were, in the beginning, unsuccessful. Firm and determined, however, in their opposition, they at length prevailed, defeated the Assyrian army, besieged Sardanapalus in his capital, which they demolished, and became masters of the empire, B. C. 821.

After the death of Sardanapalus, the Assyrian empire was divided into three kingdoms, viz. the Median, Assyrian, and Babylonian. Arbaces retained the supreme power and authority, and fixed his residence at Ecbatana in Media. He nominated governors in Assyria and Babylon, who were honoured with the title of *kings*, while they remained subject and tributary to the Median monarchs. Belesis received the government of Babylon as the reward of his services; and Phul was entrusted with that of Assyria. The Assyrian governor gradually enlarged the boundaries of his kingdom, and was succeeded by Tiglath-pilefer, Salmanasar, and Sennacherib, who asserted and maintained their independency. After the death of Assar-haddon, the brother and successor of Senacherib, the kingdom of Assyria was split, and annexed to the kingdoms of Media and Babylon. Several tributary princes afterwards reigned in Nineveh; but no particular account of them is found in the annals of ancient nations. We hear no more of the kings of Assyria, but of those of Babylon. Cyaxares king of Media, assisted Nebuchadnezzar king of Babylon, in the siege of Nineveh, which they took and destroyed, B. C. 606. The Chaldean or Babylonish kingdom was transferred to the Medes, after the reign of Nabonadius, son of Evilmerodach, and grandson of Nebuchadnezzar. He is styled Belshazzar in the sacred records, and was conquered by Cyrus, B. C. 538.

ASSYTHMENT. See ASSITHMENT.

ASTA, an inland town of Liguria, a colony, (Ptolemy); on the river Tanarus: Now *Asti*. E. Long. 8. 15. Lat. 44. 40.

Asta Regia, a town of Bætica, (Pliny); situated at that mouth of the Bætis which was choaked up with mud, to the north of Cadiz; 16 miles distant from the port of Cadiz, (Antonine). Its ruins show its former greatness. Its name is Phœnician, denoting a *frith* or arm of the sea, on which it stood. It is said to be the same with XERA; which see.

ASTABAT, a town of Armenia, in Asia, situated near the river Aras, 12 miles south of Nakshivan. The land about it is excellent, and produces very good wine. There is a root peculiar to this country, called *ronas*; which runs in the ground like liquorice, and serves for dyeing red. It is very much used all over the Indies, and for it they have a great trade. E. Long. 46. 30. N. Lat. 39. 0.

ASTANDA, in antiquity, a royal courier or messenger, the same with ANGARUS.—King Darius of Persia is said by Plutarch, in his book on the fortune of Alexander, to have formerly been an *astanda*.

ASTAROTH, or ASHTAROTH, in antiquity, a goddess of the Sidonians.—The word is Syriac, and signifies *sheep*, especially when their udders are turgid with milk. From the fecundity of these animals, which in Syria continue to breed a long time, they formed the notion of a deity, whom they called *Astaroth*, or *Astarte*. See ASTARTE.

ASTAROTH, (anc. geog.) the royal residence of Og king of Bashan; whether the same with Astaroth Carnaim, is matter of doubt: if one and the same, it follows from Eusebius's account, that it lay in Bashan, and to the east of Jordan, because in the confines of Arabia.

ASTARTE, in Pagan mythology (the singular of Astaroth), a Phœnician goddess, called in Scripture the *queen of heaven*, and the *goddess of the Sidonians.*—Solomon, in complement to one of his queens, erected an alter to her. In the reign of Ahab, Jezebel caused her worship to be performed with much pomp and ceremony: she had 400 priests; the women were employed in weaving hangings or tabernacles for her; and Jeremiah observes, that "the children gathered the "wood, the fathers kindled the fire, and the women "kneaded the dough, to make cakes for the queen of "heaven."

ASTARTE, (anc. geog.) a city on the other side Jordan; one of the names of Rabbath Ammon, in Arabia Petræa, (Stephanus).

ASTEISM, in rhetoric, a genteel irony, or handsome way of deriding another. Such, *e. gr.* is that of Virgil:

Qui Bavium non odit, amet tua carmina, Mævi, &c.

Diomed places the characteristic of this figure, or species of irony, in that it is not gross and rustic, but ingenious and polite.

ASTELL (Mary), the great ornament of her sex and country, was the daughter of —— Astell, an opulent merchant of Newcastle upon Tyne, where she was born about the year 1668. She was educated in a manner suitable to her station; and, amongst other accomplishments, was mistress of the French, and had some knowledge of the Latin tongue. Her uncle, a clergyman, observing in her some marks of a promising genius, took her under his tuition, and taught her mathematics, logic, and philosophy. She left the place of her nativity when she was but 20 years of age, and spent the remaining part of her life at London and at Chelsea. Here she pursued her studies with great assiduity, made great proficiency in the abovementioned sciences, and acquired a more complete knowledge of many classic authors. Among these Seneca, Epictetus, Hierocles, Antoninus, Tully, Plato, and Xenophon, were her principal favorites.

Her life was spent in writing for the advancement of learning, religion, and virtue; and in the practice of those religious duties which she so zealously and pathetically recommended to others, and in which perhaps no one was ever more sincere and devout. Her sentiments of piety, charity, humility, and other Christian graces, were uncommonly refined and sublime; and religion sat gracefully upon her, unattended with any forbidding airs of sourness or of gloom. Her mind was generally calm and serene; and her conversation was innocently facetious, and highly entertaining. She would say, "The good Christian only hath reason, and he always ought, to be cheerful;" and, "That dejected looks and melancholy airs were very unseemly in a Christian." But these subjects she hath treated at large in some of her excellent writings.

She was remarkably abstemious; and seemed to enjoy an uninterrupted state of health till a few years before her death; when, having one of her breasts cut off, it so much impaired her constitution, that she did not long survive it. This painful operation she underwent without discovering the least timidity, or so much as uttering a groan; and showed the same resolution and resignation during her whole illness. When she was confined to her bed by a gradual decay, and the time of her dissolution drew near, she ordered her shroud and coffin to be made and brought to her bedside; and there to remain in her view, as a constant memento of her approaching fate, and to keep her mind fixed on proper contemplation. She died in the year 1731, in the 63d year of her age, and was buried at Chelsea. She wrote, 1. A Serious Proposal to the Ladies. 2. An Essay in Defence of the Female Sex. 3. Letters concerning the Love of God. 4. Reflections upon Marriage. 5. Moderation truly stated. 6. The Christian Religion, as professed by a Daughter of the Church of England; and some other works.

ASTER, STARWORT: A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ discoides*. The receptacle is naked; the papus is simple; the rays of the corolla are 10; and the calyx is imbricated. There are above 30 species. All of them may be raised from seed sown either in autumn or spring: but the greatest part of them being perennial plants, and increasing greatly at the roots, are generally propagated by parting their roots early in the spring, and they will grow in almost any soil or situation; and the larger sorts increase so fast, that, if not prevented, they will in a little time run over a large space of ground. They grow best in the shade: the lower kinds do not run so much at the root, but should be taken up and transplanted every other year; which will make them produce much fairer flowers. Some few sorts, which are natives of warm climates, will require artificial heat to raise them, if not to preserve them.

ASTER, or *Stella Marina*, in zoology. See ASTERIAS.

ASTERABAD, a province in the north-east part of Persia, having Tabristan on the west, part of the Caspian Sea and part of Jorjan on the north, Korasan on the west, and Koumas on the south. It is a mountainous country, except near the banks of the rivers that almost surround it, where it is pleasant, and fruitful, producing grapes of a prodigious size. In other parts the soil is sandy and barren. Asterabad is the chief town, which gives name to a gulph in the Persian Sea, at the bottom of which it stands. E. Long. 54. 35. N. Lat. 36. 50.

ASTERIA, in zoology, a name by which some authors have called the *falco palumbarius*, or *goshawk*. See FALCO.

ASTERIA is also the name of a gem, usually called the *cat's eye*, or *oculus cati*. It is a very singular and very beautiful stone, and somewhat approaches to the nature of the opal, in having a bright included colour, which seems to be lodged deep in the body of the stone, and shifts about, as it is moved, in various directions: but it differs from the opal in all other particulars, especially in its want of the great variety of colours seen in that gem, and in its superior hardness. It is usually found between the size of a pea and the breadth of a sixpence; is almost always of a semicircular form, broad and flat at the bottom, and rounded and convex at the top; and is naturally smooth and polished. It has only two colours, a pale brown and a white; the brown seeming the ground, and the white playing about in it, as the fire colour in the opal. It is considerably hard, and will take a fine polish, but is usually worn with its native shape and smoothness. It is found in the East and West Indies, and in Europe. The island of Borneo affords some very fine ones, but they are usually small; they are very common in the sands of rivers in New Spain; and in Bohemia they are not unfrequently found immersed in the same masses of jasper with the opal.

ASTERIA is also the name of an extraneous fossil, called in English the *star-stone*. These fossils are small, short, angular, or sulcated columns, between one and two inches long, and seldom above a third of an inch in diameter: composed of several regular joints; when separated, each resembles a radiated star. They are, not without reason, supposed to be a part of some sea-fish petrified, probably the asterias or sea-star. The asteria is also called *astrites*, *astroites*, and *asteriscus*. They may be reduced to two kinds: those whose whole bodies make the form of a star; and those which in the whole are irregular, but are adorned as it were with constellations in the parts. Dr Lister, for distinction's sake, only gives the name *asteria* to the former sort, distinguishing the latter by the appellation of *astroites*; other naturalists generally use the two indiscriminately. The asteria spoken of by the ancients appears to be of this latter kind. The quality of moving in vinegar, as if animated, is scarce perceivable in the astroites, but is signal in the asteria. The former must be broken in small pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. The curious frequently meet with these stones in many parts of England: at Cleydan in Oxfordshire they are found rather larger than common, but of a softer substance; for, on being left a small space of time in a strong acid, they may easily be separated at the joints in small plates.

ASTERIAS, STAR-FISH, or SEA-STAR, in zoology, a genus of insects of the order of vermes mollusca. It has a depressed body, covered with a coriaceous coat; is composed of five or more segments, running out from a central part, and furnished with numerous tentacula; and has the mouth in the centre.—The conformation of the mouth is this: The under part of each lobe runs towards a point with the rest at the centre of the body; and these several productions of the rays make a sort of lips, the ends of each of which are armed with a number of sharp teeth, which serve to take and convey the food into the body. From this mouth there goes a separate canal to all or many of the rays, which runs through their whole length, and becomes gradually narrower as it approaches the extremity. The tentacula resembles the horns of snails, but serve the animal to walk with. They are capable of being contracted or shortened: and it is only at the creature's moving that they are seen of their full length; at other times, no part of them is seen but the extremity of each, which is formed like a sort of button, being somewhat larger than the rest of the horn.

Most of the species of asterias are found in the British seas. 1. The glacialis, with five rays, depressed, broad at the base, yellow, and having a round striated operculum on the back, is the most common; it feeds on oysters, and is very destructive to the beds. 2. The clathatra, or cancellated sea-star, with five short thick rays, hirsute beneath, cancellated above, is found with the former, but more rare. 3. The oculata, with five smooth rays, dotted or punctured, is of a fine purple colour, and is found about Anglesea. 4. The hispida, with five rays, broad, angulated at top, and rough with short bristles, is of a brown colour, and likewise found about Anglesea. 5. The placenta, with five very broad and membranaceous rays, extremely thin and flat, is found about Weymouth. 6. The spherulata, with a pentagonal indented body; a small globular bead between the base of each ray; the rays slender, jointed, taper, and hirsute on their sides; found off Anglesea. 7. The caput medusæ, or aborescent sea-star, with five rays issuing from an angular body; the rays dividing into innumerable branches, growing slender as they recede from the base. These the animal, in swimming, spreads like a net to their full length; and when he perceives any prey within them, draws them in again, thus catching it with all the dexterity of a fisherman. It is an inhabitant of every sea, and is called by some the *Magellanic star-fish* and *basket-fish*. When it extends its rays fully, it forms a circle of three feet diameter. The fragments of these rays furnish the fossile entrochi. If we drown this animal in brandy or spirits of wine, and keep the rays flat and expanded in the execution, it is easy to extract, by means of a pair of forceps, the stomach of the animal whole and entire through the mouth. The decacnemos, has ten slender rays, with numbers of long beards on the sides: the body is small, and surrounded beneath with ten small filiform rays. It inhabits the western coasts of Scotland.—There are several other species mentioned by authors; some of them of 10, 12, 13, or even 14 rays.

Aristotle and Pliny called this genus αστηρ, and *stella marina*, from their resemblance to the pictured form of the stars of heaven; and they asserted that they were so exceedingly hot, as instantly to consume whatsoever they touched.

The fossil world has been greatly enriched by the fragments and remains of the several pieces of star-fish which have been converted into stones. See ASTERIA.

ASTERIAS, the ancient name of the bittern. See ARDEA.

ASTERISK, a mark in form of a star (*), placed over a word or sentence, to refer the reader to the margin, or elsewhere, for a quotation, explanation, or the like.

ASTERIUS, or ASTURIUS, a Roman consul, in 449. We have under his name, *A Conference on the Old and New Testament*, in Latin verse: in which each strophe contains, in the first verse, an historical fact in the Old Testament; and in the second, an application of that fact to some point in the New.

ASTERN, a sea-phrase, used to signify any thing at some distance behind the ship, being the opposite of AHEAD, which signifies the space before her. See AHEAD.

ASTEROPODIUM, a kind of extraneous fossil, of the same substance with the asteriæ or star-stones, to which they serve as a base. See ASTERIA and STAR-STONE.

ASTHMA, See the *Index* subjoined to MEDICINE.

ASTI, a city of Montferrat in Italy, seated on the Tanaro, and capital of the county of the same name. It is a bishop's see, and well fortified with strong walls and deep ditches; and is divided into the city, borough, citadel, and castle. There are a great many churches and convents, as well as other handsome buildings; and its territory is well watered, abounding with groves, pleasant hills, and spacious fields. It was taken by the French in 1745, and retaken by the king of Sardinia in 1746. E. Long. 8. 15. N. Lat. 54. 50.

ASTIGI, (anc. geog.), a colony, and conventus juridicus, of Bætica, surnamed *Augusta Firma*, situated on the Singulus, which falls into the Bætis; called also *Colonia Astigitana* (Pliny): Now *Ecya*, midway between Seville and Corduba. W. Long. 5°. Lat. 37. 20.

ASTOMI, in anthropology, a people feigned without mouths. Pliny speaks of a nation of Astomi in India, who lived only by the smell or effluvia of bodies taken in by the nose.

ASTORGA, a very ancient city of Spain, in the kingdom of Leon, with a bishop's see, is seated on the river Tuerta, and well fortified both by art and nature. It stands in a most agreeable plain, about 150 miles north-west of Madrid. There are excellent trouts in the river. W. Long. 6. 20. N. Lat. 42. 20.

ASTRACAN, a province of Russia, and the most easterly part of Europe; bounded on the north by Bulgaria, and Baskiria; on the south, by the Caspian Sea; on the west, by the Volga, which divides it from the Nagayan Tartars and Don Cossacks; and on the east, by the great ridge of mountains which part it from Great Tartary. The province extends from the 46th to the 52d degree of latitude. The summer is long, and intensely hot: the winter continues about three months so severe, that the Volga is frozen hard enough to bear loaded sledges. The soil is rich and fertile; but the Tartars who inhabit it are strangers to agriculture. On the western and southern sides of the Volga are heaths of a prodigious extent, sandy, desert, and uncultivated: these, however, produce vast quantities of fine transparent salt in pits, where the sun bakes and incrustates it to the thickness of an inch on the surface of

Astracan the water. There are pits in the neighbourhood of Aſtracan which yield this excellent ſalt in ſuch abundance, that any perſon may carry it off, paying at the rate of one farthing a pooſt, which is equal to forty pounds. The metropolis Aſtracan, is ſituated within the boundaries of Aſia, on the iſland called *Dolgoi*, about 60 Engliſh miles above the place where the Volga diſembogues itſelf into the Caſpian Sea. The city derives its name from Hadgee Tarken, a Tartar, by whom it was founded. It was conquered by Iwan Baſilowitz, recovered by the Tartars in the year 1668, and retaken by the Czar, who employed for this purpoſe a great number of flat-bottomed veſſels, in which he tranſported his forces down the Volga from Caſan.

The city of Aſtracan is about two miles and a half in circumference, ſurrounded by a brick-wall, which is now in a ruinous condition: but if we comprehend the ſuburbs, the circuit will be near five miles. The number of inhabitants amounts to 70,000, including Armenians and Tartars, as well as a few Perſians and Indians. The garriſon conſiſts of ſix regiments of the beſt Ruſſian troops, who, when this place was alarmed from the ſide of Perſia, had in the adjacent plain erected a great number of ſmall batteries to ſcour the fields, and obſtruct the approach of the enemy. The houſes of Aſtracan are built of wood, and generally mean and inconvenient. The higher parts of the city command a proſpect of the Volga, which is here about three miles in breadth, and exhibits a noble appearance. The marſhy lands on the banks of it render the place very ſickly in the ſummer: the earth being impregnated with ſalt is extremely fertile, and produces abundance of fruit, the immoderate uſe of which is attended with epidemical diſtempers. Sickneſs is likewiſe the conſequence of thoſe annual changes in the atmoſphere produced by the floods in ſpring and autumn. All round the city of Aſtracan, at the diſtance of two miles, are ſeen a vaſt number of gardens, orchards, and vineyards, producing all ſorts of herbs and roots. The grapes are counted ſo delicious, that they are preſerved in ſand, and tranſported to court by land-carriage at a prodigious expence: yet the wine of Aſtracan is very indifferent. The ſummer being generally dry, the inhabitants water their gardens by means of large wheels worked by wind or horſes, which raiſe the water to the higheſt part of the garden, from whence it runs in trenches to refreſh the roots of every ſingle tree and plant. The neighbouring country produces hares and partridges, plenty of quails in ſummmer, with wild and water fowl of all ſorts in abundance.

About ten miles below Aſtracan is a ſmall iſland called *Boſmaiſe*, on which are built large ſtorehouſes for the ſalt, which is made about twelve miles to the eaſtward, and, being brought hither in boats, is conveyed up the Volga, in order to ſupply the country as far as Moſcow and Twere. The quantity of ſalt annually dug for theſe purpoſes amounts to ſome millions of pounds, the excluſive property of which is claimed by the crown, and yields a conſiderable revenue; for the ſoldiers and bulk of the people live almoſt entirely on bread and ſalt. The neighbourhood of theſe ſalt-works is of great advantage to the fiſheries, which extend from hence to the Caſpian Sea, and reach to the ſouth-eaſt as far as Yack, and even 100 miles above Zaritzen. The principal fiſh here caught are ſturgeon and belluga. Theſe being ſalted, are put on board of veſſels, and ſent away in the ſpring, for the uſe of the whole empire, even as far as Peterſburgh: but as fiſh may be kept freſh as long as it is frozen, the winter is no ſooner ſet in than they tranſport great quantities of it by land through all the provinces of Ruſſia. Of the roes of the fiſh called *belluga*, which are white, tranſparent, and of an agreeable flavour, the fiſhers here prepare the caviare, which is in ſo much eſteem all over Europe. Theſe fiſheries were firſt eſtabliſhed by one Tikon Demedoff, a carrier, who ſettled in this place about 60 years ago, his whole wealth conſiſting of two horſes. By dint of ſkill and induſtry, he ſoon grew the richeſt merchant in this country: but his ſucceſs became ſo alluring to the crown, that of late years it hath engroſſed ſome of the fiſheries as well as the ſalt-works. Aſtracan.

From the latter end of July to the beginning of October, the country about Aſtracan is frequently infeſted with myriads of locuſts, which darken the air in their progreſſion from the northward to the ſouthward; and, wherever they fall, conſume the whole verdure of the earth. Theſe inſects can even live for ſome time under water; for when the wind blows acroſs the Volga, vaſt numbers of them fall in cluſters and are rolled aſhore; and their wings are no ſooner dry, than they riſe and take flight again.

Heretofore the inhabitants of Aſtracan traded to Khuva and Bokhara; but at preſent theſe branches are loſt, and their commerce is limited to Perſia and the dominions of Ruſſia. Even the trade of Perſia is much diminiſhed by the troubles of that country: nevertheleſs, the commerce of Aſtracan is ſtill conſiderable. Some years ago the city maintained about 40 veſſels, from 100 to 200 tons burden, for the Caſpian traffic. Some of theſe belong to the government, and are commanded by a commodore, under the direction of the admiralty. This office is generally well ſtocked with naval ſtores, which are ſold occaſionally to the merchants. The trading ſhips convey proviſions to the frontier towns of Terkie and Kiſlar, ſituated on the Caſpian Sea; and tranſport merchandize to ſeveral parts of Perſia. The merchants of Aſtracan export to Perſia, chiefly on account of the Armenians, red leather, linens, woollen cloths, and other European manufactures. In return, they import the commodities of Perſia, particularly thoſe manufactured at Caſan; ſuch as ſilk ſaſhes intermixed with gold, for the uſe of the Poles; wrought ſilks and ſtuffs mixed with cotton; rice, cotton; rhubarb, and a ſmall quantity of other drugs; but the chief commodity is raw ſilk. The government has engroſſed the article of rhubarb, the greater part of which is brought into Ruſſia by the Tartars of Yakutſki, bordering on the eaſtern Tartars belonging to China. They travel through Siberia to Samura, thence to Caſan, and laſtly to Moſcow. The revenue of Aſtracan is computed at 150,000 rubles, or 33,000 pounds, ariſing chiefly from ſalt and fiſh. The city is ruled by a governor, under the check of a chancery. He is nevertheleſs arbitrary enough, and exerciſes oppreſſion with impunity. The officers of the admiralty and cuſtom-houſe having

very

very small salaries, are open to corruption, and extremety rapacious. At christening-feasts which are attended with great intemperance, the guests drink a kind of cherry-brandy out of large goblets; and every person invited throws a present of money into the bed of the mother, who sits up with great formality to be saluted by the company.

The Indians have a Pagan temple at Astracan, in which they pay their adoration, and make offerings of fruit to a very ugly deformed idol. The priests of this pagod use incense, beads, cups, and prostrations. The Tartars, on the contrary, hold idol-worship in the utmost abomination.

ASTRÆA, in astronomy, a name which some give to the sign Virgo, by others called *Erigone*, and sometimes *Isis*. The poets feign that justice quitted heaven to reside on earth, in the golden age; but growing weary of the iniquities of mankind, she left the earth, and returned to heaven, where she commenced a constellation of stars, and from her orb still looks down on the ways of men.

ASTRAGAL, in architecture, a little round moulding, which in the orders surround the top of the shaft or body of the column. It is also called the *talon* and *tondino*; it is used at the bottoms as well as tops of columns, and on other occasions: it properly represents a ring, on whatever part of a column it is placed; and the original idea of it was that of a circle of iron put round the trunk of a tree, used to support an edifice to prevent its splitting. See Plate XXXVI. fig. 2. The astragal is often cut into beads and berries, and is used in the ornamented entablatures to separate the several faces of the architrave.

Astragal, in gunnery, a round moulding encompassing a cannon, about half a foot from its mouth.

ASTRAGALOMANCY, a species of divination performed by throwing small pieces, with marks corresponding to the letters of the alphabet; the accidental disposition of which formed the answer required. This kind of divination was practised in a temple of Hercules, in Achaia. The word is derived from ἀςραγαλος, and μαντεια, *divination*.

ASTRAGALLUS, Milk-vetch, or Liquorice-vetch: A genus of the decandria order, belonging to the diadelphia class of plants: and in the natural method ranking under the 32d order, *Papilionaceæ*. The pod is gibbous and billocular. Of this genus there are 39 species. The common sort grows wild upon dry uncultivated places, and is recommended by Mr Anderson to be cultivated as proper food for cattle (See Agriculture, nº 60, 61.). The other species deserving notice is the tragagantha, a thorny bush growing in Crete, Asia, and Greece, which yields the gum tragracanth. This is of so strong a body, that a dram of it, will give a pint of water the consistence of a syrup, which a whole ounce of gum Arabic is scarce sufficient to do. Hence its use for forming torches, and the like purposes, in preference to the other gums.

Astragalus, in anatomy. See there nº 65.

ASTRANTIA, Masterwort: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The involucrum is lanceolated, open, equal, and coloured. The species are two, the major and minor, both natives of the Alps, and possessing no remarkable properties.

ASTRICTION, in law. See Thirlage.

Astriction, among physicians, denotes the operation of astringent medicines.

ASTRINGENTS, in the materia medica, substances distinguished by a rough austere taste, and changing solutions of iron, especially those made in the vitriolic acid, into a dark purple or black colour; such are galls, tormentil root, bistort root, balaustines, terra Japonica, acacia, &c. See Materia Medica.

ASTROGNOSIA, the science of the fixed stars, or the knowledge of their names, constellations, magnitudes, &c. See Astronomy.

ASTROITES, or Star-Stone, in natural history. See the articles Asteria and Star-Stone; and Plate LVI.

ASTROLABE, the name of a stereographic projection of the sphere, either upon the plane of the equator, the eye being supposed to be in the pole of the world; or upon the plane of the meridian, when the eye is supposed in the point of the intersection of the equinoxial and horizon.

Astrolabe is also the name of an instrument formerly used for taking the altitude of the sun or stars at sea.

Astrolabe, among the ancients, was the same as our armillary sphere.

ASTROLOGY, a conjectural science, which teaches to judge of the effects and influences of the stars, and to foretel future events by the situation and different aspects of the heavenly bodies.

This science has been divided into two branches, *natural* and *judiciary*. To the former belongs the predicting of natural effects; as the changes of weather, winds, storms, hurricanes, thunder, floods, earthquakes, &c. This art properly belongs to natural philosophy; and is only to be deduced *a posteriori*, from phenomena and observations. Judiciary or judicial astrology, is that which pretends to foretel moral events, i. e. such as have a dependence on the free will and agency of man; as if they were directed by the stars. This art, which owed its origin to the practices of knavery on credulity, is now universally exploded by the intelligent part of mankind.

The professors of this kind of astrology maintain, "That the heavens are one great volume or book, wherein God has written the history of the world; and in which every man may read his own fortune, and the transactions of his time. The art, say they, had its rise from the same hands as astronomy itself: while the ancient Assyrians, whose serene unclouded sky favoured their celestial observations, were intent on tracing the paths and periods of the heavenly bodies, they discovered a constant settled relation of analogy between them and things below; and hence were led to conclude these to be the Parcæ, the Destinies, so much talked of, which preside at our births, and dispose of our future fate.

"The laws therefore of this relation being ascertained by a series of observations, and the share each planet has therein; by knowing the precise time of any person's nativity, they were enabled, from their knowledge in astronomy, to erect a scheme or horoscope of the situation of the planets at that point of time; and hence, Astrology Astronomy

hence, by considering their degrees of power and influence, and how each was either strengthened or tempered by some other, to compute what must be the result thereof."

Thus the astrologers.—But the chief province now remaining to the modern professors, is the making of kalendars or almanacks.

Judicial astrology is commonly said to have been invented in Chaldea, and thence transmitted to the Egyptians, Greeks, and Romans; though some will have it of Egyptian origin, and ascribe the invention to Cham. But it is to the Arabs that we owe it. At Rome, the people were so infatuated with it, that the astrologers, or, as they were then called, the *mathematicians*, maintained their ground in spite of all the edicts of the emperors to expel them out of the city. See GENETHLIACI.

Add, that the Bramins, who introduced and practised this art among the Indians, have hereby made themselves the arbiters of good and evil hours, which gives them great authority: they are consulted as oracles; and they have taken care never to sell their answers but at good rates.

The same superstition has prevailed in more modern ages and nations. The French historians remark, that in the time of queen Catharine de Medicis, astrology was in so much vogue, that the most inconsiderable thing was not to be done without consulting the stars. And in the reigns of king Henry III. and IV. of France, the predictions of astrologers were the common theme of the court conversation. This predominant humour in that court was well rallied by Barclay, in his *Argenis*, lib. ii. on occasion of an astrologer, who had undertaken to instruct king Henry in the event of a war then threatened by the faction of the Guises.

Astronium || Astronomy

ASTRONIUM, in botany: A genus of the pentandria order, belonging to the diœcia class of plants. The male calyx consists of five leaves, and the corolla is quinquepetalous: Of the female the calyx and corolla are the same as in the male; the styli are three, and the seed is single. There is but one species, the graveolens, a native of Jamaica.

ASTRONOMICAL, something relating to ASTRONOMY.

ASTRONOMICAL Calendar, an instrument engraved on copper plates, printed on paper, and pasted on a board, with a brass slider carrying a hair: it shows by inspection the sun's meridian altitude, right ascension, declination, rising, setting, amplitude, &c. to a greater degree of exactness than the common globes.

ASTRONOMICAL Sector, a very useful mathematical instrument, made by the late ingenious Mr Graham; a description of which is given in the course of the following article.

A S T R O N O M Y,

IS a knowledge of the heavenly bodies, with regard to their magnitudes, motions, distances, &c. whether real or apparent; and of the natural causes on which their phenomena depend.

History of Astronomy.

The antiquity of this science may be gathered from what was spoken by the Deity at the time of creating the celestial luminaries, "Let them be for signs and seasons," &c. whence it is thought probable that the human race never existed without some knowledge of astronomy among them. Indeed, besides the motives of mere curiosity, which of themselves may be supposed to have excited people to a contemplation of the glorious celestial canopy, as far as that was possible, it is easily to be seen that some parts of the science answer such essential purposes to mankind, that they could not possibly be dispensed with.

1 Astronomy supposed to be understood by Adam and the Antediluvians.

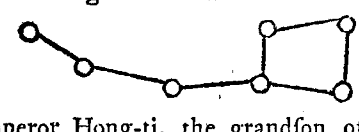
By some of the Jewish rabbins, Adam, in his state of innocence, is supposed to have been endowed with a knowledge of the nature, influence and uses of the heavenly bodies; and Josephus ascribes to Seth and his posterity an extensive knowledge of astronomy. But whatever may be in this, the long lives of the Antediluvians certainly afforded such an excellent opportunity for observing the celestial bodies, that we cannot but suppose the science of astronomy to have been considerably advanced before the flood. Josephus says, that longevity was bestowed upon them for the very purpose of improving the sciences of geometry and astronomy. The latter could not be learned in less that 600 years: "for that period (says he) is the *grand year*." By which it is supposed he meant the period wherein the sun and moon came again into the same situation as they were in the beginning thereof, with regard to the nodes, apogee of the moon, &c. "This period (says Cassini), whereof we find no intimation in any monument of any other nation, is the finest period that ever was invented: for it brings out the solar year more exactly than that of Hipparchus and Ptolemy; and the lunar month within about one second of what is determined by modern astronomers. If the Antediluvians had such a period of 600 years, they must have known the motions of the sun and moon more exactly than their descendants knew them some ages after the flood."

2 Astronomical knowledge of the Chinese.

On the building of the tower of Babel, Noah is supposed to have retired with his children born after the flood, to the north-eastern part of Asia, where his descendants peopled the vast empire of China. "This (says Dr Long) may perhaps account for the Chinese having so early cultivated the study of astronomy; their being so well settled in an admirable police, and continuing so many hundred years as they did in the worship of the true God." The vanity of that people indeed has prompted them to pretend a knowledge of astronomy almost as early as the flood itself. Some of the Jesuit missionaries have found traditional accounts among the Chinese, of their having been taught this science by their first emperor Fo-hi, supposed to be Noah; and Kempfer informs us, that this personage discovered the motions of the heavens, divided time into years and months, and invented the twelve signs into which they divide the zodiac, which they distinguish by the following

3 Their names for the ſigns of the zodiac.

following names. 1. The mouſe. 2. The ox or cow. 3. The tiger. 4. The hare. 5. The dragon. 6. The ſerpent. 7. The horſe. 8. The ſheep. 9. The monkey. 10. The cock or hen. 11. The dog; and, 12. The boar. They divide the heavens into 28 conſtellations, four of which are aſſigned to each of the ſeven planets; ſo that the year always begins with the ſame planet; and their conſtellations anſwer to the 28 manſions of the moon uſed by the Arabian aſtronomers. Theſe conſtellations in the Chineſe books of aſtronomy, are not marked by the figures of animals, as was in uſe among the Greeks, and from them derived to the other European nations, but by connecting the ſtars by ſtraight lines: and Dr Long informs us, that in a Chineſe book in thin 4to, ſhown him by Lord Pembroke, the ſtars were repreſented by ſmall circles joined by lines; ſo that the great bear would be marked thus,



To the emperor Hong-ti, the grandſon of Noah, they attribute the diſcovery of the pole-ſtar, the invention of the mariner's compaſs, of a period of 60 years, and ſome kind of ſphere. This extraordinary antiquity, however, is with good reaſon ſuſpected, as is likewiſe their knowledge in the calculation of eclipſes; of which Du Halde aſſures us, that 36 are recorded by Confucius himſelf, who lived 551 years before Chriſt; and P. Trigault, who went to China in 1619, and read more than 100 volumes of their annals, ſays, "It is certain that the Chineſe began to make aſtronomical obſervations ſoon after the flood; that they have obſerved a great number of eclipſes, in which they have noted down the hour, day, month, and year, when they happened, but neither the duration nor the quantity; and that theſe eclipſes have been made uſe of for regulating their chronology."

"But out of this abundance (ſays Dr Long), it is much to be regretted, that ſo very few of their obſervations have been particularized; for beſide what has been mentioned above, we meet with no very ancient obſervations of the Chineſe, except a winter ſolſtice in the year 1111, and a ſummer ſolſtice in the year 882, before Chriſt. Martini indeed ſpeaks of a ſummer ſolſtice 2342 years before that period. But M. Caſſini, who calculated it, found that there muſt have been an error in the Chineſe computation of 500 years at leaſt. An error of equal magnitude appears to have been committed in the conjunction of the five planets, which it is pretended they obſerved between the years 2513 and 2435 before Chriſt. In ſhort, ſome have ſuppoſed, that none of theſe are real obſervations, but the reſult of bungling calculations: and it has been hinted, but ſurely on too ſlight a foundation, that even thoſe good fathers themſelves were greatly to be ſuſpected. But let us come to things which are not conteſted.

"P. Gaubil informs us, that at leaſt 120 years before Chriſt, the Chineſe had determined by obſervation the number and extent of their conſtellations as they now ſtand; the ſituation of the fixed ſtars with reſpect to the equinoctial and ſolſtitial points; and the obliquity of the ecliptic. He farther ſays, he cannot tell by what means it is that they foretel eclipſes: but this is certain, that the theory by which they do predict them was ſettled about the ſame time; and that they were acquainted with the true length of the ſolar year, the method of obſerving meridian altitudes of the ſun by the ſhadow of a gnomon, and of learning from thence his declination and the height of the pole, long before. We learn, moreover, from the ſame miſſionary, that there are yet remaining among them ſome treatiſes of aſtronomy, which were written about 200 years before Chriſt; from which it appears, that the Chineſe had known the daily motion of the ſun and moon, and the times of the revolutions of the planets, many years before that period.

"We are informed by Du Halde, that, in the province of Honan, and city Teng-ſoang, which is nearly in the middle of China, there is a tower, on the top of which it is ſaid that *Toheou-cong*, the moſt ſkilful aſtronomer that ever China produced, made his obſervations. He lived 1200 years before Ptolemy, or more than 1000 years before Chriſt, and paſſed whole nights in obſerving the celeſtial bodies and arranging them into conſtellations. He uſed a very large braſs table placed perfectly horizontal, on which was fixed a long upright plate of the ſame metal, both of which were divided into degrees, &c. By theſe he marked the meridian altitudes; and from thence derived the times of the ſolſtices, which were their principal epocha."

Dr Long repreſents the ſtate of aſtronomy in China as at preſent very low; occaſioned, he ſays, principally by the barbarous decree of one of their emperors*, to have all the books in the empire burnt, * See *China*
excepting ſuch as related to agriculture and medicine. We are informed, however, by the Abbe Groſier, in his deſcription of China, that aſtronomy is cultivated in Peking in the ſame manner as in moſt of the capital cities of Europe. A particular tribunal is eſtabliſhed there, the juriſdiction of which extends to every thing relating to the obſervation of celeſtial phenomena. Its members are, an inſpector; two preſidents, one of them a Tartar and the other a Chineſe; and a certain number of mandarins who perform the duty of aſſeſſors; but for near a century and an half the place of the Chineſe preſident has been filled by an European. Since that time particular attention has been paid to the inſtruction of the aſtronomical pupils; and the preſidents have always conſidered it as their duty to make them acquainted with the ſyſtem and method of calculation made uſe of in Europe. Thus two-thirds of the aſtronomical pupils, maintained at the emperor's expence, in all about 200, have a tolerable notion of the ſtate of the heavens, and underſtand calculation ſo well as to be able to compoſe ephemerides of ſufficient exactneſs. The miſſionaries have never been the authors of any of theſe ephemerides: their employment is to reviſe the labours of the Chineſe mathematicians, verify their calculations, and correct any errors into which they have fallen. The Portugueſe miſſion ſtill continues to furniſh aſtronomers for the academy as it did at the firſt.

The aſtronomical tribunal is ſubordinate to that of ceremonies. When an eclipſe is to be obſerved, information muſt be given to the emperor of the day and hour, the part of the heavens where it will be, &c. and this intelligence muſt be communicated ſome months before it happen; the eclipſe muſt alſo be calculated for the longitude and latitude of the capital city of

every

every province of the empire. These observations, as well as the diagram which represents the eclipse, are preserved by the tribunal of ceremonies, and another called the *calao*, by whom it is transmitted to the different provinces and cities of the empire. Some days before the eclipse, the tribunal of ceremonies causes to be fixed up in a public place, in large characters, the hour and minute when the eclipse will commence; the quarter of the heavens in which it will be visible, with the other particulars relating to it. The mandarins are summoned to appear in state at the tribunal of astronomy, and to wait there for the moment in which the phenomenon will take place. Each of them carries in his hand a sheet of paper, containing a figure of the eclipse and every circumstance attending it. As soon as the observation begins to take place, they throw themselves on their knees, and knock their heads against the earth, and a horrid noise of drums and cymbals immediately commences throughout the whole city: a ceremony proceeding from an ancient superstitious notion, that by such noise they prevented the luminary from being devoured by the celestial dragon; and tho' this notion is now exploded in China, as well as every where else, such is the attachment of the people to ancient customs, that the ceremonial is still preserved. While the mandarins thus remain prostrated in the court, others, stationed on the observatory, examine, with all the attention possible, the beginning, middle, and end of the eclipse, comparing what they observe with the figure and calculations given. They then write down their observations, affix their seal to them, and transmit them to the Emperor; who on his part has been no less assiduous to observe the eclipse with accuracy. A ceremonial of this kind is observed throughout the whole empire.

The Japanese, Siamese, and inhabitants of the Mogul's empire, have also, from time immemorial, been acquainted with astronomy; and the celebrated observatory at BENARES, is a monument both of the ingenuity of the people and of their skill in this science.

4 Indian astronomy.

Mr. Bailly has been at great pains to investigate the progress of the Indians in astronomical knowledge, and gives a splendid account of their proficiency in the science, as well as of the antiquity of their observations. He has examined and compared four different astronomical tables of the Indian philosophers. 1. Of the Siamese, explained by M. Cassini in 1689. 2. Those brought from India by M. le Gentil of the Academy of Sciences. 3. and 4. Two other manuscript tables found among the papers of the late M. de Lisle. All of these tables have different epochs, and differ in form, being also constructed in different ways; yet they all evidently belong to the same astronomical system: the motions attributed to the sun and the moon are the same, and the different epochs are so well connected by the mean motions, as to demonstrate that they had only one, whence the others were derived by calculation. The meridians are all referred to that of Benares above mentioned. The fundamental epoch of the Indian astronomy is a conjunction of the sun and moon, which took place at no less a distance of time than 3102 years before the Christian æra. Mr Bailly informs us, that, according to our most accurate astronomical tables, a conjunction of the sun and moon actually did happen at that time. But though the bramins pretend to have ascertained the places of the two luminaries at that time, it is impossible for us at this time to judge of the truth of their assertions, by reason of the unequal motion of the moon; which, as shall afterwards be more particularly taken notice of, now performs its revolution in a shorter time than formerly.

Our author informs us, that the Indians at present calculate eclipses by the mean motions of the sun and moon observed 5000 years ago; and with regard to the solar motion, their accuracy far exceeds that of the best Grecian astronomers. The lunar motions they had also settled by computing the space through which that luminary had passed in 1,600,984 days, or somewhat more than 4383 years. They also make use of the cycle of 19 years attributed by the Greeks to Meton; and their theory of the planets is much better than that of Ptolemy, as they do not suppose the earth to be the centre of the celestial motions, and they believe that Mercury and Venus turn round the sun. Mr Bailly also informs us, that their astronomy agrees with the most modern discoveries of the decrease of the obliquity of the ecliptic, the acceleration of the motion of the equinoctial points, with many other particulars too tedious to enumerate in this place.

5 Astronomy of the Americans.

It appears also, that even the Americans were not unacquainted with astronomy, though they made use only of the solar, and not of the lunar motions, in their division of time. The Mexicans have had a strange predilection for the number 13. Their shortest periods consisted of 13 days; their cycle of 13 months, each containing 20 days; and their century of four periods of 13 years each. This excessive veneration for the number 13, according to Siguenza, arose from its being supposed the number of their greater gods. What is very surprising, though asserted as a fact by Abbé Clavigero, is that having discovered the excess of a few hours in the solar above the civil year, they made use of intercalary days, to bring them to an equality: but with this difference in regard to the method established by Julius Cæsar in the Roman kalendar, that they did not interpose a day every four years, but 13 days (making use here even of this favorite number) every 52 years, which produces the same regulation of time.

6 Of the Chaldeans and Egyptians.

Among those nations who first began to make any figure in ancient history, we find the Chaldeans and Egyptians most remarkable for their astronomical knowledge. Both of them pretended to an extravagant antiquity, and disputed the honour of having been the first cultivators of the science. The Chaldeans boasted of their temple of Belus; and of Zoroaster whom they placed 5000 years before the destruction of Troy: the Egyptians boasted of their colleges of Priests, where astronomy was taught; and of the monument of Osymandyas, in which we are told was a golden circle 365 cubits in circumference and one cubit thick. The upper face was divided into 365 equal parts, answering to the days of the year; and on every division were written the name of the day, and the heliacal rising of the several stars for that day, with the prognostications from their rising, principally, as Long conjectures, for the weather.

The Chaldeans certainly began to make observations very soon after the confusion of languages; for when Alexander the Great took Babylon, Callisthenes, by

Fig. 2

The motion of Saturn Jupiter and Mars in respect of the Earth

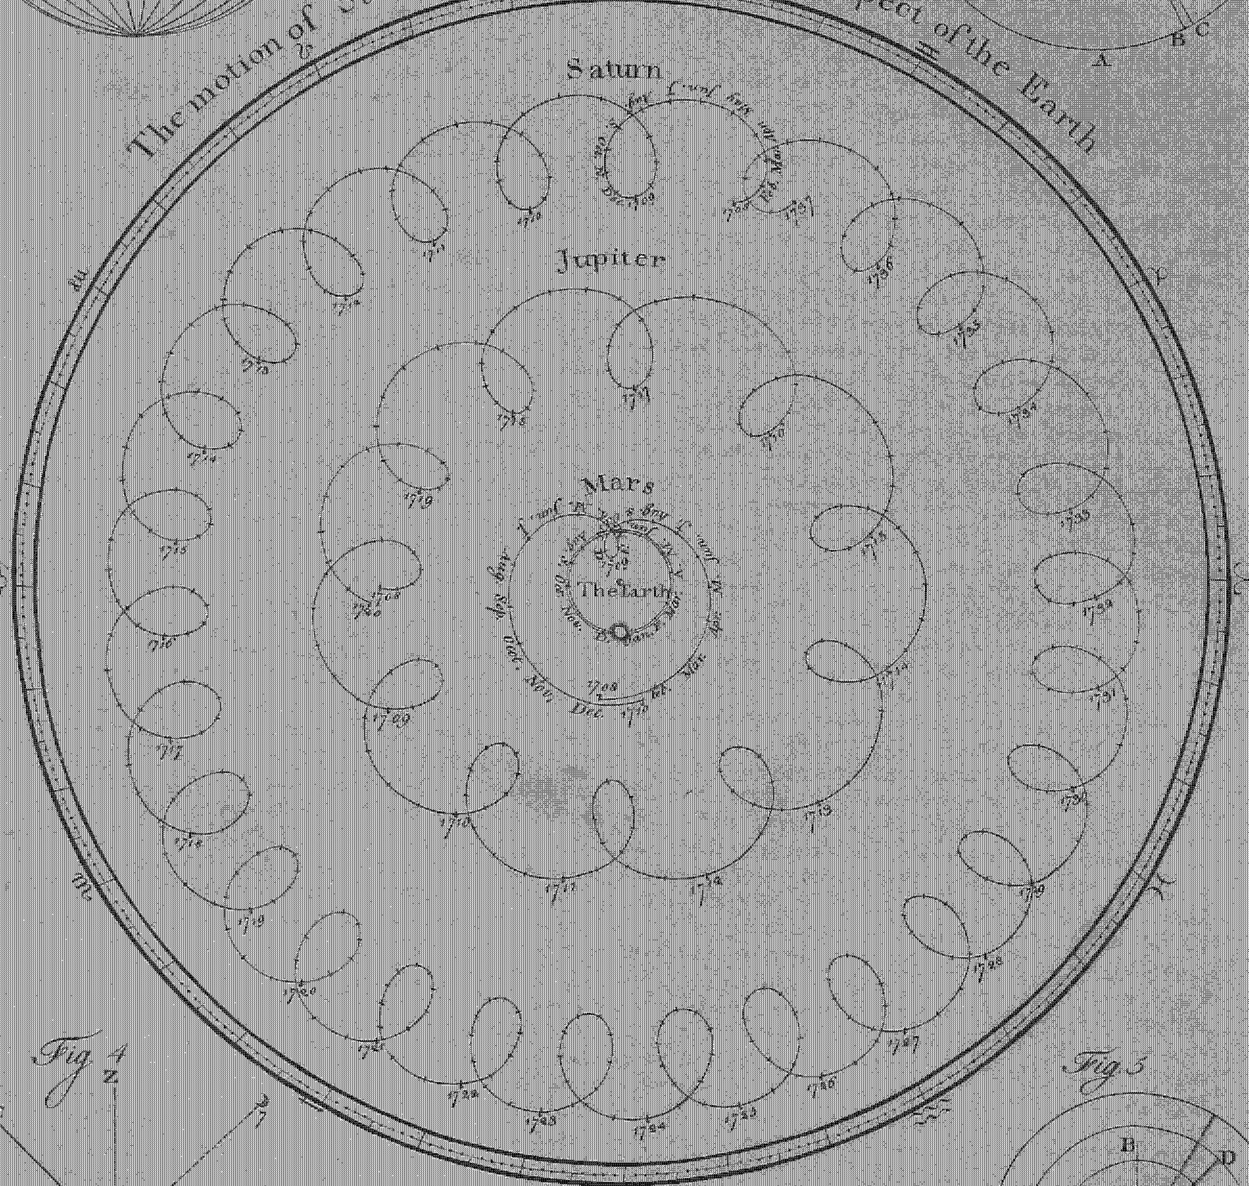

Fig. 4

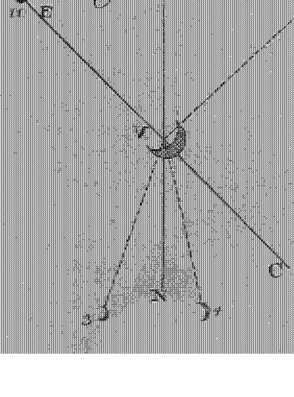

Fig. 5

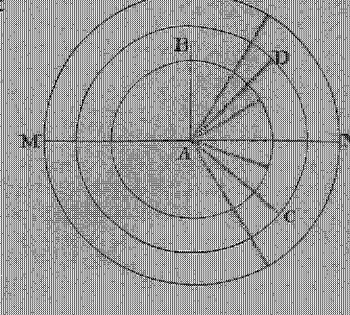

Scot Philad^a

by his order, inquired after the aſtronomical obſervations recorded in that city, and obtained them for 1903 years back. Nothing, however, now remains of the Chaldean aſtronomy, excepting ſome periods of years which they had formed for the more ready computation of the heavenly bodies. But though they muſt have laboured under great diſadvantages, for want of proper inſtruments, in thoſe early ages, Gemina, as quoted by Petavius in his Uranologion, informs us, that they had determined, with tolerable exactneſs, the length both of a ſynodical and periodical month. They had alſo diſcovered, that the motion of the moon was not uniform, and even attempted to aſſign thoſe parts of her orbit in which it was quicker or ſlower. Ptolemy alſo aſſures us, that they were not unacquainted with the motion of the moon's nodes, and that of her apogee, ſuppoſing that the former made a complete revolution in 6585$\frac{1}{3}$ days, or 18 years 15 days and 8 hours; which period, containing 223 complete lunations, is called the Chaldean *Saros*. The ſame author alſo gives us, from Hipparchus, ſeveral obſervations of lunar eclipſes which had been made at Babylon about 720 years before Chriſt; but though he might very probably meet with many of a more ancient date, it was impoſſible to mention them particularly, on account of the imperfect ſtate of the Chaldean chronology, which commenced only with the æra of Nabonaſſar, 747 years before Chriſt. Ariſtotle likewiſe informs us, that they had many obſervations of the occultations of fixed ſtars and planets by the moon; and from hence, by a very natural and eaſy inference, they were led to conclude that the eclipſes of the ſun were occaſioned alſo by the moon, eſpecially as they conſtantly happened when the latter was in the ſame part of the heavens with the ſun. They had alſo a conſiderable ſhare in arranging the ſtars into conſtellations. Nor had the comets, by which aſtronomers in all ages have been ſo much perplexed, eſcaped their obſervation: for both Diodorus Siculus and Appollinus Myndius, in Seneca, informs us, that many of the Chaldeans held theſe to be laſting bodies, which have ſtated revolutions as well as the planets, but in orbits vaſtly more extenſive; on which account they are only ſeen by us while near the earth, but diſappear again when they go into the higher regions. Others of them were of opinion, that the comets were only meteors raiſed very high in the air, which blaze for a while, and diſappear when the matter of which they conſiſt is conſumed or diſperſed. Dialling was alſo known among them long before the Greeks were acquainted with any ſuch thing.

It is evident, indeed, that the countries both of Chaldea and Egypt were exceedingly proper for aſtronomical obſervations, on account of the general purity and ſerenity of the air. The tower or temple of Belus, which was of an extraordinary height, with ſtairs winding round it up to the top, is ſuppoſed to have been an aſtronomical obſervatory; and the lofty pyramids of Egypt, whatever they were originally deſigned for, might poſſibly anſwer the ſame purpoſe. Indeed theſe very ancient monuments ſhow the ſkill of this people in practical aſtronomy, as they are all ſituated with their four fronts exactly facing the cardinal points. Herodotus aſcribes the Egyptian knowledge in aſtronomy to Seſoſtris, whom Sir Iſaac Newton makes cotemporary with Solomon: but if this was the caſe, he could not be the inſtructor of the Egyptians in aſtronomical matters, ſince we find that Moſes, who lived 500 years before Solomon, was ſkilled in all the wiſdom of the Egyptians, in which we are undoubtedly to include aſtronomy.

From the teſtimony of ſome ancient authors, we learn that they believed the earth to be ſpherical, that they knew the moon was eclipſed by falling into its ſhadow, and that they made their obſervations with the greateſt exactneſs. They even pretended to foretel the appearance of comets, as well as earthquakes and inundations; which extraordinary knowledge is likewiſe aſcribed to the Chaldeans. They attempted to meaſure the magnitude of the earth and ſun; but the methods they took to find out the latter were very erroneous. It does not indeed appear with certainty that they had any knowledge of the true ſyſtem of the univerſe; and by the time of the Emperor Auguſtus, their aſtronomical knowledge was entirely loſt.

7 Of the Phenicians.

From Chaldea the ſcience of aſtronomy moſt probably paſſed into Phenicia; though ſame are of opinion that the Phenicians derived their knowledge of this ſcience from the Egyptians. They ſeem, however, to have been the firſt who applied aſtronomy to the purpoſes of navigation; by which they became maſters of the ſea, and of almoſt all the commerce in the world. They became adventurous in their voyages, ſteering their ſhips by one of the ſtars of the Little Bear; which being near the immoveable point of the heavens called the *Pole* is the moſt proper guide in navigation. Other nations made their obſervations by the Great Bear; which being too diſtant from the pole could not guide them in long voyages; and for this reaſon they never durſt venture far from the coaſts.

8 Aſtronomy of the Greeks.

The firſt origin of aſtronomical knowledge among the Greeks is unknown. Sir Iſaac Newton ſuppoſes that moſt of the conſtellations were invented about the time of the Argonautic expedition: but Dr Long is of opinion that many of them muſt have been of a much older date; and that the ſhepherds, who were certainly the firſt obſervers, gave names to them according to their fancy; from whence the poets invented many of their fables. Several of the conſtellations are mentioned by Heſiod and Homer, the two moſt ancient writers among the Greeks, who lived about 870 years before Chriſt; Heſiod deſiring the farmer to regulate the time of ſowing and harveſt by the riſing and ſetting of the Pleiades; and Homer informing us, that obſervations from the Pleiades, Orion, and Arcturus, were uſed in navigation. Their aſtronomical knowledge, however, was greatly improved by Thales the Mileſian, who travelled into Egypt, and brought from thence the firſt principles of the ſcience. He is ſaid to have determined the height of the pyramids by meaſuring their ſhadows at the time the ſun was 45 degrees high, and when of conſequence the lengths of the ſhadows of objects are equal to their perpendicular heights. But his reputation was raiſed to the higheſt pitch among his countrymen, by the prediction of an eclipſe, which happened juſt at the time that the armies of Alyattes king of Lydia, and Cyaxares the Mede, were about to engage; and being regarded as an evil omen by both parties, inclined them to

9 Improved by Thales.

to peace. To him Callimachus attributes the forming of the constellation of the little bear; the knowledge of which he certainly introduced into Greece. He also taught the true length of the year; determined the cosmical setting of the Pleiades in his time to have been 25 days after the autumnal equinox; divided the earth into five zones by means of the polar circles and tropics; taught the obliquity of the ecliptic; and showed that the equinoctial is cut by the meridians at right angles, all of which intersect each other at the poles. He is also said to have observed the exact time of the solstices, and from thence to have deduced the true length of the solar year; to have observed eclipses of the sun and moon; and to have taught that the moon had no light but what she borrowed from the sun. According to Stanley, he also determined the diameter of the sun to be one-720th part of his annual orbit. "But (says Dr Long) these things should be received with caution. There are some reasons which might be assigned for supposing that the knowledge of Thales in these matters was much more circumscribed: and indeed it is not unreasonable to suppose, that that veneration for the ancients which leads authors to write professedly on the history of ancient times, may have induced them to ascribe full as much knowledge to those who lived in them as was really their due."

10 By Anaximander, &c.

The successors of Thales, Anaximander, Anaximanes, and Anaxagoras, contributed considerably to the advancement of astronomy. The first is said to have invented or introduced the gnomon into Greece; to have observed the obliquity of the ecliptic; and taught that the earth was spherical, and the centre of the universe, and that the sun was not less than it. He is also said to have made the first globe, and to have set up a sun-dial at Lacedemon, which is the first we hear of among the Greeks; though some are of opinion that these pieces of knowledge were brought from Babylon by Pherycides, a cotemporary of Anaximander. Anaxagoras also predicted an eclipse which happened in the fifth year of the Peloponnesian war; and, taught that the moon was habitable, consisting of hills, valleys, and waters, like the earth. His cotemporary

11 Doctrines of Pythagoras.

Pythagoras, however, greatly improved not only astronomy and mathematics, but every other branch of philosophy. He taught that the universe was composed of four elements, and that it had the sun in the centre; that the earth was round, and had antipodes; and that the moon reflected the rays of the sun; that the stars were worlds, containing earth, air, and ether; that the moon was inhabited like the earth; and that the comets were a kind of wandering stars, disappearing in the superior parts of their orbits, and becoming visible only in the lower part of them. The white colour of the milky-way he ascribed to the brightness of a great number of small stars; and he supposed the distances of the moon and planets from the earth to be in certain harmonic proportions to one another. He is said also to have exhibited the oblique course of the sun in the ecliptic and the tropical circles, by means of an artificial sphere; and he first taught that the planet Venus is both the evening and morning star. This philosopher is said to have been taken prisoner by Cambyses, and thus to have become acquainted with all the mysteries of the Persian magi; after which he settled at Crotona in Italy, and founded the Italian sect.

About 440 years before the Christian æra, Philolaus, a celebrated Pythagorean, asserted the annual motion of the earth round the sun; and soon after Hicetas, a Syracusan, taught its diurnal motion on its own axis. About this time also flourished Meton and Euctemon at Athens, who took an exact observation of the summer solstice 432 years before Christ; which is the oldest observation of the kind we have, excepting what is delivered by the Chinese. Meton is said to have composed a cycle of 19 years, which still bears his name; and he marked the risings and settings of the stars, and what seasons they pointed out: in all which he was assisted by his companion Euctemon. The science, however, was obscured by Plato and Aristotle, who embraced the system afterwards called the *Ptolemaic*, which places the earth in the centre of the universe.

Eudoxus the Cnidian was a cotemporary with Aristotle, though considerably older, and is greatly celebrated on account of his skill in astronomy. He was the first who introdced geometry into the science, and he is supposed to be the inventor of many propositions attributed to Euclid. Having travelled into Egypt in the earlier part of his life, and obtained a recommendation from Agesilaus to Nectanebus king of Egypt, he, by his means, got access to the priests, who had the knowledge of astronomy entirely among them, after which he taught in Asia and Italy. Seneca tells us that he brought the knowledge of the planetary motions from Egypt into Greece; and Archimedes, that he believed the diameter of the sun to be nine times that of the moon. He was also well acquainted with the method of drawing a sun-dial upon a plane; from whence it may be inferred that he understood the doctrine of the projection of the sphere: yet, notwithstanding what has been said concerning the observations of Eudoxus, it is not certain that his sphere was not taken from one much more ancient, ascribed to Chiron the Centaur. The reason given for this supposition is, that had the places of the stars been taken from his own observations, the constellations must have been half a sign farther advanced than they are said to be in his writings.

Soon after Eudoxus, Calippus flourished, whose system of the celestial sphere is mentioned by Aristotle; but he is better known from a period of 76 years, containing four corrected metonic periods, and which had its beginning at the summer solstice in the year 330, before Christ. But about this time, or rather earlier, the Greeks having begun to plant colonies in Italy, Gaul, and Egypt, these became acquainted with the Pythagorean system, and the notions of the ancient Druids concerning astronomy. Julius Cæsar informs us, that the latter were skilled in this science; and that the Gauls in general were able sailors, which at that time they could not be without a competent knowledge of astronomy: and it is related of Pythoas, who lived at Marseilles in the time of Alexander the Great, that he observed the altitude of the sun at the summer solstice by means of a gnomon. He is also said to have travelled as far as Thule to settle the climates.

12 State of astronomy in Egypt after the death of Alexander.

After the death of Alexander the Great, sciences flourished in Egypt more than in any other part of the world; and a famous school was set up at Alexandria under the auspices of Ptolemy Philadelphus, a prince instructed in all kinds of learning, and the patron of all

all thoſe who cultivated them; and this ſchool continued to be the ſeminary of all kinds of literature, till the invaſion of the Saracens in 650. Timocharis and Aryſtillus, who firſt cultivated the aſtronomical ſcience in this ſchool, began to put it on a new footing; being much more careful in their obſervations, and exact in noting down the times when they were made, than their predeceſſors. Ptolemy aſſures us, that Hipparchus made uſe of their obſervations, by means of which he diſcovered that the ſtars had a motion in longitude of about one degree in an hundred years; and he cites many of their obſervations, the oldeſt of which is before the erection of this ſchool, in the year 295, when the moon juſt touched the northern ſtar in the forehead of the ſcorpion; and the laſt of them was in the 13th year of Philadelphus, when Venus hid the former ſtar of the four in the left wing of Virgo.

From this time the ſcience of aſtronomy continued greatly to advance. Ariſtarchus, who lived about 270 years before Chriſt, ſtrenuouſly aſſerted the Pythagorean ſyſtem, and gave a method of determining the diſtance of the ſun by the moon's dichotomy. Eratoſthenes, born at Cyrene in 271 B. C. determined the meaſure of a great circle of the earth by means of a gnomon. His reputation was ſo great, that he was invited from Athens to Alexandria by Ptolemy Euergetes, and made by him keeper of the royal library at that place. At his inſtigation the ſame prince ſet up thoſe armillas or ſpheres, which Hipparchus and Ptolemy the aſtronomer afterwards employed ſo ſucceſsfully in obſerving the heavens. He alſo found the diſtance between the tropics to be eleven ſuch parts as the whole meridian contains eighty-three. About the ſame time Beroſus, a native of Chaldea, flouriſhed at Athens. He is by ſome ſaid to have brought many obſervations from Babylon, which are aſcribed to the Greeks; while others contend, that the latter owe little or nothing of their aſtronomical knowledge to the Babylonians.

13 Diſcoveries of Archimedes.

The celebrated Archimedes, who next to Sir Iſaac Newton holds the firſt place among mathematicians, was nothing inferior as an aſtronomer to what he was as a geometrician. He determined the diſtance of the moon from the earth, of Mercury from the moon, of Venus from Mercury, of the ſun from Venus, of Mars from the ſun, of Jupiter from Mars, and of Saturn from Jupiter; as likewiſe the diſtance of the fixed ſtars from the orbit of Saturn. That he made aſtronomical obſervations, is not to be doubted; and it appears from an epigram of the poet Claudian, that he invented a kind of planetarium, or orrery, to repreſent the phenomena and motions of the heavenly bodies.

14 Of Hipparchus.

Hipparchus was the firſt who applied himſelf to the ſtudy of every part of aſtronomy, his predeceſſors having chiefly conſidered the motions and magnitudes of the ſun and moon. Ptolemy alſo informs us, that he firſt diſcovered the orbits of the planets to be eccentric, and on this hypotheſis wrote a book againſt Eudoxus and Calippus. He gives many of his obſervations; and ſays, that by comparing one of his with another made by Ariſtarchus 145 years before, he was enabled to determine the length of the year with great preciſion. Hipparchus alſo firſt found out the anticipation of the moon's nodes, the eccentricity of her orbit, and that ſhe moved ſlower in her apogee than in her perigee. He collected the accounts of ſuch ancient eclipſes as had been obſerved by the Chaldeans and Egyptians. He formed hypotheſes concerning the celeſtial motions, and conſtructed tables of thoſe of the ſun and moon, and would have done the ſame with thoſe of the other planets if he could have found ancient obſervations ſufficient for the purpoſe; but, theſe being wanting, he was obliged to content himſelf with collecting fit obſervations for that purpoſe, and endeavouring to form theories of the five planets. By comparing his own obſervations on the ſpica virginis with thoſe of Timochares at Alexandria made 100 years before, he diſcovered that the fixed ſtars changed their places, and had a ſlow motion of their own from weſt to eaſt. He corrected the Calippic period, and pointed out ſome errors in the method laid down by Eratoſthenes for meaſuring the circumference of the earth. By means of geometry, which was now greatly improved, he was enabled to attempt the calculation of the ſun's diſtance in a more correct manner than any of his predeceſſors; but unhappily it required ſo much accuracy in obſervation as was found impracticable.

15 Makes the firſt catalogue of fixed ſtars.

His greateſt work, however, was his catalogue of the fixed ſtars, which he was induced to attempt by the appearance of a new ſtar. The catalogue is preſerved by Ptolemy, and contains the longitudes and latitudes of 1022 ſtars, with their apparent magnitudes. He wrote alſo concerning the intervals between eclipſes both ſolar and lunar, and is ſaid to have calculated all that were to happen for no leſs than 600 years from his time.

16 Syſtem of Ptolemy.

Little progreſs was made in aſtronomy from the time of Hipparchus to that of Ptolemy, who flouriſhed in the firſt century. The principles on which his ſyſtem is built are indeed erroneous; but his work will always be valuable on account of the number of ancient obſervations it contains. It was firſt tranſlated out of the Greek into Arabic in the year 827, and into Latin from the Arabic in 1230. The Greek original was unknown in Europe till the beginning of the 15th century, when it was brought from Conſtantinople, then taken by the Turks, by George a monk of Trapezond, who tranſlated it into Latin. Various editions were afterwards publiſhed; but little or no improvement was made by the Greeks in this ſcience.

17 Aſtronomy of the Arabians.

During the long period from the year 800 to the beginning of the 14th century, the weſtern parts of Europe were immerſed in deep ignorance and barbarity. However, ſeveral learned men aroſe among the Arabians. The caliph Al Manſur was the firſt who introduced a taſte for the ſciences in his empire. His grandſon Al Mamun, who aſcended the throne in 814, was a great encourager of the ſciences, and devoted much of his own time to the ſtudy of them. He made many aſtronomical obſervations himſelf, and determined the obliquity of the ecliptic to be 23° 35′. He employed many able mechanics in conſtructing proper inſtruments, which he made uſe of for his obſervations; and under his auſpices a degree of the earth was meaſured a ſecond time in the plain of Singar, on the border of the Red Sea. From this time aſtronomy was ſtudiouſly cultivated by the Arabians; and Elements of Aſtronomy were written by Alferganus, who was partly cotemporary with the caliph Al Mamun. But the moſt celebrated of all their aſtronomers is Albategnius,

nius, who lived about the year of Christ 880. He greatly reformed astronomy, by comparing his own observations with those of Ptolemy. Thus he calculated the motion of the sun's apogee from Ptolemy's time to his own; determined the precession of the equinoxes to be one degree in 70 years; and fixed the sun's greatest declination at 23.35′. Finding that the tables of Ptolemy required much correction, he composed new ones of his own fitted to the meridian of Aracta, which were long held in estimation by the Arabians. After his time, though several eminent astronomers appeared among the Saracens, none made any very valuable observations for several centuries, excepting Ebn Younis astronomer to the caliph of Egypt: who observed three eclipses with such care, that by means of them we are enabled to determine the quantity of the moon's acceleration since that time.

Other eminent Saracen astronomers were, Arzachel a Moor of Spain, who observed the obliquity of the ecliptic, and constructed tables of sines, or half chords of double arcs, dividing the diameter into 300 parts; and Alhazen, his cotemporary, who first showed the importance of the theory of refractions in astronomy; writing also upon the twilight, the height of the clouds, and the phenomenon of the horizontal moon.

Ulug Beg, a grandson of the famous Tartar prince Timur Beg, or Tamerlane, was a great proficient in practical astronomy. He is said to have had very large instruments for making his observations; particularly a quadrant as high as the church of Sancta Sophia at Constantinople, which is 180 Roman feet. He composed astronomical tables from his own observations for the meridian of Samarcand his capital, so exact as to differ very little from those afterwards constructed by Tycho Brache; but his principal work is his catalogue of the fixed stars, made from his own observations in the year of Christ 1437. The accuracy of his observations may be gathered from his determining the height of the pole at Samarcand to be 39° 37′ 23″.

Besides these improvements, we are indebted to the Arabians for the present form of trigonometry. Manelaus, indeed, an eminent Greek astronomer who flourished about the year 90, had published three books of Spherics, in which he treated of the geometry necessary to astronomy, and which show great skill in the sciences; but his methods were very laborious, even after they had been improved and rendered more simple by Ptolemy: but Geber the Arabian, instead of the ancient method, proposed three or four theorems, which are the foundation of our modern trigonometry. The Arabians also made the practice still more simple, by using sines instead of the chords of double arcs. The arithmetical characters they had from the Indians.

18 Revival of astronomy in Europe.

During the greatest part of this time, almost all Europe continued ignorant not only of astronomy but of every other science. The emperor Frederick II. first began to encourage learning in 1230; restoring some universities, and founding a new one in Vienna. He also caused the works of Aristotle, and the Almagest or Astronomical Treatise of Ptolemy, to be translated into Latin; and from the translation of this book we may date the revival of astronomy in Europe. Two years after this publication, John de Sacro Bosco, or of Halifax, an Englishman, wrote his four books *De Sphæra*, which he compiled from Ptolemy Albategnius, Alferganus, and other Arabian astronomers: this work was so much celebrated, that for 300 years it was preferred in the schools to every other; and has been thought worthy of several commentaries, particularly by Clavius in 1531. In 1240, Alphonso king of Castile caused the tables of Ptolemy to be corrected: for which purpose he assembled many persons skilled in astronomy, Christians, Jews, and Moors; by whom the tables called *Alphonsine* were composed, at the expence of 40,000, or according to others 400,000 ducats. About the same time Roger Bacon, an English monk, published many things relative to astronomy; particularly of the places of the fixed stars, solar rays, and lunar aspects. Vitellio, a Polander, wrote a treatise on Optics about 1270, in which he showed the use of refractions in astronomy.

19 Improvements of Purbach.

From this time to that of Purbach; who was born in 1423, few or no improvements were made in astronomy. He wrote a commentary on Ptolemy's Almagest, some treatises on Arithmetic and Dialling, with tables for various climates. He not only used spheres and globes, but constructed them himself; and formed new tables of the fixed stars, reduced to the middle of that age. He composed also new tables of sines for every ten minutes, which Regiomontanus afterwards extended to every single minute, making the whole sine 60, with 6 ciphers annexed. He likewise corrected the tables of the planets, making new equations to them, because the Alphonsine tables were very faulty in this respect. In his solar tables he placed the sun's apogee in the beginning of Cancer; but retained the obliquity of the ecliptic 23° 33½′, to which it had been reduced by the latest observations. He made new tables for computing eclipses, of which he observed some, and had just published a theory of the planets, when he died in 1461.

20 Of Regiomontanus.

John Muller of Monteregio (Coningsberg), a town of Franconia, from whence he was called *Regiomontanus*, was the scholar and successor of Purbach. He completed the epitome of Ptolemy's Almagest which Purbach had begun; and after the death of the latter, went to Rome, where he made many astronomical observations. Having returned to Nuremberg in 1471, he was entertained by a wealthy citizen named *Bernard Walther*, who having a great love for astronomy, caused several instruments to be made under the direction of Regiomontanus, for observing the altitude of the sun and stars, and other celestial phenomena. Among these was an armillary astrolabe, like that which had been used by Hipparchus and Ptolemy at Alexandria, and with which many observations were made. He also made ephemerides for 30 years to come, showing the lunations, eclipses, &c. He wrote the Theory of the Planets and Comets, and a Treatise of Triangles yet in repute for several extraordinary cases. He is said to have been the first who introduced the use of tangents into trigonometry; and to have published in print (the art of printing having been lately invented) the works of many of the most celebrated ancient astronomers. After his death, which happened at Rome, Walther made a diligent search for all his instruments and papers which could be found; and continued his observations with the instruments he had till his death. The observations of both were collected by order of the senate of Nuremberg, and published there

there by John Schoner in 1544; afterwards by Snellius at the end of the observations made by the Landgrave of Hesse in 1618; and lastly, in 1666, with those of Tycho Brache. Walther, however, as we are told by Snellius, found fault with his armilla, not being able to give any observation with certainty to less than ten minutes. He made use of a good clock, which also was a late invention in those days.

21 Of Werner

John Werner, a clergyman, succeeded Walther as astronomer at Nuremberg; having applied himself with great assiduity to the study of that science from his infancy. He observed the motion of the comet in 1500; and published several tracts, in which he handled many capital points of geometry, astronomy, and geography, in a masterly manner. He published a translation of Ptolemy's Geography, with a commentary, which is still extant. In this he first proposed the method of finding the longitude at sea by observing the moon's distance from the fixed stars; which is now so successfully put in practice. He also published many other treatises on mathematics and geography; but the most remarkable of all his treatises, are those concerning the motion of the eighth sphere or of the fixed stars, and a short theory of the same. In this he shewed by comparing his own observations of the stars regulus, spica virginis, and the bright star in the southern scale of the balance, made in 1514, with the places assigned to the same stars by Ptolemy, Alphonsus, and others, that the motion of the fixed stars, now called *the precession of the equinoctial points*, is one degree ten minutes in 100 years, and not one degree only, as former astronomers had made it. He made the obliquity of the ecliptic 23° 28′, and the first star of Aries 26° distant from the equinoctial point. He also constructed a planetarium representing the celestial motions according to the Ptolemaic hypothesis, and made a great number of meteorological observations with a view towards the prediction of the weather. The obliquity of the ecliptic was settled by Dominic Maria, the friend of Copernicus, at 23° 29′, which is still held to be just.

22 Pythagorean system restored by Copernicus

The celebrated Nicholaus Copernicus next makes his appearance, and is undoubtedly the great reformer of the astronomical science. He was originally bred to the practice of medicine, and had obtained the degree of Doctor in that faculty: but having conceived a great regard for the mathematical sciences, especially astronomy, he travelled into Italy, where he for some time was taught by Dominic Maria, or rather assisted him in his astronomical operations. On his return to his own country, being made one of the canons of the church, he applied himself with the utmost assiduity to the contemplation of the heavens, and to the study of the celestial motions. He soon perceived the deficiency of all the hypotheses by which it had been attempted to account for these motions; and for this reason he set himself to study the works of the ancients, with all of whom he also was dissatisfied excepting Pythagoras; who, as has been already related, placed the sun in the centre, and supposed all the planets, with the earth itself, to revolve round him. He informs us, that he began to entertain these notions about the year 1507; but not being satisfied with stating the general nature of his hypothesis, he became desirous of determining the several periodical revolutions of the planets, and thence of constructing tables of their motions which might be more agreeable to truth than those of Ptolemy and Alphonsus. The observations he was enabled to make, however, must have been extremely inaccurate; as he tells us, that if with the instruments he made use of he should be able to come within ten minutes of the truth, he would rejoice no less than Pythagoras did when he discovered the proportion of the hypothenuse to the other two sides of a right-angled triangle. His work was completed in the year 1530; but he could not be prevailed upon to publish it till towards the end of his life, partly through diffidence, and partly through fear of the offence which might be taken at the singularity of the doctrines set forth in it. At last, overcome by the importunities of his friends, he suffered it to be published at their expence, and under the inspection of Schoner and Osiander, with a dedication to Pope Paul III. and a preface, in which it was attempted to palliate as much as possible the extraordinary innovations it contained. During the time of its publication, the author himself was attacked by a bloody flux, succeeded by a palsy; so that he received a copy only a few hours before his death, which happened on the 23d of May 1543.

After the death of Copernicus, the astronomical science was greatly improved by Schoner, Nonius, Appian, and Gemma Frisius. Schoner survived Copernicus only four years; however, he greatly improved the methods of making celestial observations, reformed and explained the kalendar, and published a treatise of cosmography. Nonius had applied himself very early to the study of astronomy and navigation; but finding the instruments at that time in use excessively inaccurate, he applied himself to the invention of others which should be less liable to inconvenience. Thus he invented the astronomical quadrant, in which he divided the degrees into minutes by a number of concentric circles. The first of these was divided into 90 equal parts, the second into 89, the third into 88, and so on, as low as 46; and thus, as the index of the quadrant would always fall upon one or other of the divisions, or very near it, the minutes might be known by computation. He published many treatises on mathematical subjects, particularly one which detected the errors of Orontius, who had imagined that he could square the circle, double the cube, &c. by finding two mean proportionals betwixt two right lines. Appian's chief work was intitled *The Cæsarian Astronomy;* and was published at Ingoldstadt in 1540, dedicated to the emperor Charles V. and his brother Ferdinand. In this he showed how to resolve astronomical problems by means of instruments, without either calculations or tables; to observe the places of the stars and planets by the astrolabe; and to foretel eclipses and describe the figures of them; the whole illustrated with proper diagrams. In his second book he describes the method of dividing an astronomical quadrant, and of using it properly. His treatise concludes with the observation of five comets. Gemma Frisius wrote a commentary on a work of Appian, intitled his *Cosmography*, with many observations of eclipses. He invented also the astronomical ring, and several other instruments, which, though they could not boast of much exactness superior to others, were yet of considerable utility in taking observations

at

at ſea; and he is alſo memorable for being the firſt who propoſed a time-keeper for determining the longitude at ſea.—George Joachim Rheticus was a ſcholar of Copernicus, to attend whoſe lectures he gave up his profeſſorſhip of mathematics at Wittemberg. For the improvement of aſtronomical calculations, he began to conſtruct a table of ſines, tangents, and ſecants, for every minute and ten ſeconds of the quadrant. In this work he firſt ſhowed the uſe of ſecants in trigonometry, and greatly enlarged the uſe of tangents, firſt invented by Regiomontanus; but he aſſigned for the radius a much larger number of places than had been done before, for the greater exactneſs of calculation. This great work he did not live to accompliſh; but it was completed by his diſciple Valentine Otho, and publiſhed at Heidelberg in 1594.

23 Several illuſtrious perſons apply to the ſtudy of aſtronomy.

During this century, the liſt of aſtronomers was dignified by ſome very illuſtrious names. About the year 1561, William IV. Landgrave of Heſſe Caſſel, applied himſelf to the ſtudy of aſtronomy. With the aſſiſtance of Rothman and Burgius, the former an aſtronomer, the latter an excellent mathematical inſtrument maker, he erected an obſervatory on the top of his palace at Caſſel, and furniſhed it with ſuch inſtruments as were then in uſe, made in the beſt manner the artiſts of that age could execute. With theſe he made a great number of obſervations, which were by Hevelius preferred to thoſe of Tycho-Brache, and which were publiſhed by Snellius in 1618. From theſe obſervations he determined the longitudes and latitudes of 400 ſtars, which he inſerted in a catalogue where their places are rectified to the beginning of the year 1593.

24 Obſervations of Tycho-Brache.

Tycho-Brache began his obſervations about the ſame time with the Landgrave of Heſſe, already mentioned. He obſerved the great conjunction of Saturn and Jupiter in 1563; and finding the inſtruments he could procure very inaccurate, he made a quadrant capable of ſhewing ſingle minutes, and likewiſe a ſextant four cubits radius. In 1571, he diſcovered a new ſtar in the chair of Caſſiopeia; which induced him, like Hipparchus, to make a catalogue of the ſtars. This contained the places of 777 ſtars, rectified to the year 1600; but inſtead of the moon, which was uſed by the ancients to connect the places of the ſun and ſtars, Tycho ſubſtituted Venus as having little or no parallax, and yet being like the moon viſible both day and night. By the recommendation of the Landgrave of Heſſe, he obtained from the king of Denmark the iſland of Huenna, oppoſite to Copenhagen, where an obſervatory was built.

25 Account of Uraniburg, his obſervatory.

The firſt ſtone of this building, afterwards called *Uraniburg*, was laid in the year 1576. It was of a ſquare form, one ſide of it being about 60 feet in length; and on the eaſt and weſt ſides were two round towers of 32 feet diameter each. The inſtruments were more large and ſolid than had ever been ſeen before by any aſtronomer. They conſiſted of quadrants, ſextants, circles, ſemicircles, armillæ both equatorial and zodiacal, parallactic rulers, rings, aſtrolabes, globes, clocks, and ſun-dials. Theſe inſtruments were ſo divided as to ſhow ſingle minutes; and in ſome the arch might be read off to 10 ſeconds. Moſt of the diviſions were diagonal: but he had one quadrant divided according to the method invented by Nonius; that is, by 47 concentric circles. The whole expence is ſaid to have amounted to 200,000 crowns. The method of dividing by diagonals, which Tycho greatly admired, was the invention of Mr Richard Chanceller, an Engliſhman: Tycho, however, ſhows, that it is not accurately true when ſtraight lines are employed, and the circles at equal diſtances from each other; but that it may be corrected by making circular diagonals, which if continued would paſs through the centre.

Tycho employed his time at Uraniburg to the beſt advantage; but falling into diſcredit on the death of the king, he was obliged to remove to Holſtein, and at laſt found means to get himſelf introduced to the emperor, with whom he continued to his death. He is well known to have been the inventor of a ſyſtem of aſtronomy, which bears his name; and which he vainly endeavoured to eſtabliſh on the ruins of that of Copernicus; but the ſimplicity and evident conſonancy to the phenomena of nature, diſplayed in all parts of the Copernican ſyſtem, ſoon got the better of the unnatural and complicated ſyſtem of Tycho. His works, however, which are very numerous, diſcover him to have been a man of vaſt abilities. After his death the caſtle of Uraniburg quickly fell to decay, and indeed ſeems to have been purpoſely pulled down; for, in 1652, when Mr Huet went to Sweden, it was almoſt level with the ground, and few traces of the walls could be diſcerned. None of the neighbouring inhabitants had ever heard of the name of Tycho or Uraniburg, excepting one old man, whom Mr Huet found out with great difficulty, and who had been a ſervant in the family! All the diſcoveries of Purback, Regiomontanus, and Tycho, were collected and publiſhed in the year 1621, by Longomontanus, who had been Tycho's favourite ſcholar.

26 Diſcoveries of Kepler.

While Tycho reſided at Prague with the emperor, he invited thither John Kepler, afterwards ſo famous for his diſcoveries. Under the tuition of ſo great an aſtronomer, the latter quickly made an amazing progreſs. He found that his predeceſſors had erred in ſuppoſing the orbits of the planets to be circular, and their motions uniform: on the contrary, he perceived from his own obſervations, that they were elliptical, and their motions unequal, having the ſun in one of the foci of their orbits; but that, however, they varied in abſolute velocity, a line drawn from the centre of the ſun to the planet, and revolving with it, would always deſcribe equal areas in equal times. He diſcovered, in the year 1618, that the ſquares of the periodical times are as the cubes of the diſtances of the planets; two laws which have been of the greateſt importance to the advancement of aſtronomy. He ſeems to have had ſome notion of the extenſive power of the principle of gravity: for he tells us, that gravity is a mutual power betwixt two bodies; that the moon and earth tend towards each other, and would meet in a point nearer the earth than the moon in the proportion of the ſuperior magnitude of the former, were they not hindered by their projectile motions. He adds alſo, that the tides ariſe from the gravitation of the waters towards the moon: however, he did not adhere ſteadily to theſe principles, but afterwards ſubſtituted others as the cauſes of the planetary motions.

Cotemporary with Kepler were Mr Edward Wright, and Napier baron of Merchiſton. To the former we owe ſeveral very good meridional obſervations of the ſun's sun's altitude, made with a quadrant of six feet radius, in the years 1594, 1595, and 1596; from which he greatly improved the theory of the sun's motion, and computed more exact tables of his declination than had been done by any person before. He published also in 1599, an excellent Treatise, entitled, "Certain Errors in Navigation discovered and detected." To the latter we are indebted for the knowledge of logarithms; a discovery, as was justly observed by Dr Halley, one of the most useful ever made in the art of numbering. John Bayer, a German, who lived about the same time, will ever be memorable for his work, entitled, *Uranometria*, which is a very complete celestial atlas, or a collection of all the constellations visible in Europe. To this he added a nomenclature, in which the stars in each constellation are marked with the letters of the Greek alphabet; and thus every star in the heavens may be referred to with the utmost precision and exactness. About the same time also, astronomy was cultivated by many other persons; abroad, by Maginus, Mercator, Maurolycus, Homelius, Schultet, Stevin, &c.; and by Thomas and Leonard Digges, John Dee, and Robert Flood, in England; but none of them made any considerable improvement.

27 Invention of telescopes and consequent discoveries.

The beginning of the 17th century was distinguished not only by the discovery of logarithms, but by that of telescopes, a sort of instruments by which astronomy was brought to a degree of perfection utterly inconceivable by those who knew nothing of them. The question concerning the inventor is discussed under the article OPTICS; but whoever was entitled to this merit, it is certain that Galileo was the first who brought them to such perfection as to make any considerable discoveries in the celestial regions. With instruments of his own making, Galileo discovered the inequalities in the moon's surface, the satellites of Jupiter, and the ring of Saturn; though this last was unknown to him after he had seen it, and the view he got made him conclude that the planet had a threefold body, or that it was of an oblong shape like an olive. He discovered spots on the sun, by means of which he found out the revolution of that luminary on his axis; and he discovered also that the milky way and nebulæ were full of small stars. It was not, however, till some time after these discoveries were made that Galileo and others thought of applying the observations on Jupiter's satellites to the purpose of finding the longitude of places on the surface of the earth; and even after this was thought of, astronomers found it so difficult to construct tables of their motions, that it was not till after many observations had been made in distant places of the world, that Cassini was able to determine what positions of the satellites were most proper for finding out the longitude. At last he perceived that the entrance of the first satellite into the shadow of Jupiter, and the exit of it from the same, were the most proper for this purpose: that next to these the conjunctions of the satellites with Jupiter, or with one another, may be made use of; especially when any two of them, moving in contrary directions, meet with each other: and lastly, that observations on the shadows of the satellites, which may be seen on the disk of Jupiter, are useful, as also the spots which are seen upon his face, and are carried along it with greater velocity than has hitherto been discovered in any of the other heavenly bodies.

28 Logarithmic tables composed.

While astronomers were thus busy in making new discoveries, the mathematicians in different countries were no less earnestly employed in constructing logarithmic tables to facilitate their calculations. Benjamin Ursinus, an excellent mathematician of Brandenburg, calculated much larger tables of logarithms than had been done by their noble inventor, and published them in 1625. They were improved by Henry Briggs, Savilian professor of Oxford; who by making unity the logarithm of ten, thus rendered them much more convenient for the purposes of calculation. Logarithmic tables of sines and tangents were also composed by Mr Briggs and Adrian Vlacq at Goude, so that the business of calculation was now rendered nearly as easy as possible.

29 Transit of Venus first discovered by Mr Horrox.

In 1633, Mr Horrox, a young astronomer of very extraordinary talents, discovered that Venus would pass over the disk of the sun on the 24th of November 1639. This event he announced only to one friend, a Mr Crabtree; and these two were the only persons in the world who observed this transit the first time it had ever been viewed by human eyes. Mr Horrox made many useful observations at the time; and had even formed a new theory of the moon, so ingenious as to attract the notice of Sir Isaac Newton; but the hopes of astronomers from the abilities of this excellent young man were blasted by his death in the beginning of January 1640.

30 Foundation of the academy of sciences at Paris and Royal Society at London.

About the year 1638 many learned men began to assemble at Paris in order to hold conferences on different scientific subjects, which was the first foundation of the Royal Academy of Sciences in that capital. This practice was introduced in France by Mersennus, and soon after at London by Oldenburg; which laid the foundation of the Royal Society there. About this time also the celebrated astronomer Hevelius flourished at Dantzic, building an observatory in his own house, and furnishing it with excellent instruments of his own construction; particularly octants and sexants of brass of three and four feet radius, as well as telescopes, with which he constantly observed the spots and phases of the moon, and from which observations he afterwards compiled his excellent and beautiful work intitled *Selenographia*. This noble building, together with all the books and instruments it contained, was consumed by fire on the 26th of September 1679; but the memory, as well as the form and construction of the instruments, is preserved in a curious work of the ingenious inventor, intitled *Machina Cœlestis*; though almost the whole impression of this book was involved in the same fate with the instruments it describes. The damage sustained on this occasion was estimated at 30,000 crowns.

The celebrated English mechanic Dr Hooke, who was cotemporary with Hevelius, had in the mean time invented instruments with telescopic sights, which he preferred to those used by Hevelius so much, that a dispute commenced, which procured Hevelius a visit from Dr Halley. The latter had at that time taken a voyage to St Helena at the desire of the Royal Society, in order to observe and form a catalogue of the stars in the southern hemisphere. The result of his observations with Hevelius's instruments was, that three several observations on the Spica Virginis and Regulus differed only a few seconds from each other. They were the invention of Tyco-Brache, and are described

deſcribed under the article Optics. At this viſit Halley and Hevelius obſerved on occultation of Jupiter by the moon, and determined the diameter of the latter to be 30′. 33″.

In 1671 the Royal Obſervatory in Paris was finiſhed, and the uſe of it aſſigned to Mr Caſſini, after it had been furniſhed with inſtruments at a very great expence: and the obſervatory at Greenwich being likewiſe built five years after, Mr Flamſtead was appointed aſtronomer-royal. The obſervations in both theſe places, however, have been ſo numerous, that it is in vain to attempt any account of them.

31 Improvements in teleſcopes.

Before the middle of the 17th century the conſtruction of teleſcopes had been greatly improved, particularly by Fontana and Huygens. The latter conſtructed one of 123 feet, which is ſtill preſerved in the muſeum of the Royal Society at London. With this he obſerved the moon and planets for a long time, and diſcovered that Saturn was encompaſſed with a ring. The French, however, ſtill outdid the Engliſh artiſts; and by means of teleſcopes of 200 and 300 feet focus, M. Caſſini was enabled to ſee all the five ſatellites of Saturn, his belts, and the ſhadows of Jupiter's ſatellites paſſing over his body. In 1666 M. Azout applied a micrometer to teleſcopes for the purpoſe of meaſuring the diameters of the planets, and ſmall diſtances in the heavens; however an inſtrument of this kind had been before invented by Mr Gaſcoine, though it was but little known abroad.

Notwithſtanding all theſe diſcoveries by means of teleſcopes, it was evident that they ſtill continued in a very imperfect ſtate, and their imperfections at the time appeared to be without remedy. One defect was the enormous length requiſite to admit of any very conſiderable magnifying power; and another was the incorrectneſs of the image ariſing from the aberration of the rays, as was then ſuppoſed, by the ſpherical figure of the glaſs. To obviate theſe inconveniences, Merſennus is ſaid to have firſt propoſed, in a letter to Deſcartes, the uſe of reflectors inſtead of lenſes in the conſtruction of teleſcopes; but this he did in ſuch an obſcure manner, that the latter laboured to perſuade him of the falſehood of the principle on which his ſcheme was founded. In 1663, however, James Gregory of Aberdeen ſhowed how ſuch a teloſcope might be conſtructed. He ſhowed alſo, that in order to form a perfect image of an object in this manner, the figure of the ſpeculum ought to be parabolic; but Sir Iſaac Newton, who applied himſelf to the framing of teleſcopes of the reflecting kind, found it impracticable to grind them of the deſired figure. Laying aſide the idea of reflecting teleſcopes, therefore, he applied himſelf to the execution of a ſcheme formed by Deſcartes, viz. that of grinding lenſes of the figure of one of the conic ſections. In proſecuting this plan, he diſcovered, that the greateſt errors to which teleſcopes were ſubject aroſe from the different refrangibility of the rays of light, for which he could not then find any remedy. He therefore returned to the ſcheme he had juſt abandoned; and, in the year 1672, preſented to the Royal Society two reflectors which were conſtructed with ſpherical ſpeculums, as he could not procure any other. The inconveniences ariſing from the different refrangibility of the rays of light, have ſince been in the fulleſt manner corrected by Mr Dolland, the excellency of whoſe achromatic teleſcopes are too well known to need any encomium.

About the beginning of the preſent century, the practical part of aſtronomy ſeemed to languiſh for want of proper inſtruments. Roemer, indeed, had invented ſome new ones, and Dr Hooke had turned his attention towards this ſubject in a very particular manner; but either through want of ſkill in the artiſts, or ſome other unfortunate circumſtance, it happened that nothing effectual was done. But at the very time when this was the caſe with practical aſtronomy, the ſpeculative part was carried in a manner to its utmoſt pitch by the labours of the immortal Newton, whoſe Principia gave an entire new face to the ſcience. It was not, however, for many years reliſhed by the foreign philoſophers, though almoſt immediately adopted at home, and has continued ever ſince to ſpread its reputation farther and farther, ſo that now it is in a manner eſtabliſhed all over the world. "But (ſays Dr. Long) that, after Newton's ſyſtem had for ſo long a time been neglected, it ſhould all at once be univerſally received and approved of, is not to be attributed to chance, or the caprice of faſhion, as ſome who are ignorant of it are apt to think; and from thence to expect that ſome other ſyſtem will hereafter take its place and bury it in oblivion. The ſyſtem of Newton, like that of Copernicus, is ſo agreeable to the phenomena of nature, and ſo well put together, that it *muſt* laſt as long as truth and reaſon endure, although time may perhaps bring the word attraction into diſuſe; and though it may no longer be thought inherent in matter, yet the laws of gravitation, as they are now called, and on which this ſyſtem is founded, will never be forgotten.".

32 Aſtronomical inſtruments firſt improved in England

It was alſo in Britain that the firſt improvements in aſtronomical inſtruments took place. The celebrated mechanic and watchmaker Graham, carried the accuracy of his inſtruments to a degree which ſurpriſed every one. He alſo greatly improved the principles of watchwork, and made clocks to go with much greater regularity than before. The old eight feet mural arch at Greenwich was alſo conſtructed by him; as was a ſmall equatorial ſector for making obſervations out of the meridian: but he is chiefly remarkable for contriving the zenith ſector of 24 feet radius, and afterwards one of 12½ feet, by which Dr Bradley diſcovered the aberration of the fixed ſtars. The reflecting teleſcope which had been invented by Gregory, and executed by Newton, was greatly improved by Mr Hadley, and a very complete and powerful inſtrument of that kind was preſented to the Royal Society in 1719. The ſame gentleman has alſo immortalized his memory by the invention of the reflecting quadrant, which he preſented to the Society in 1731, which is now in univerſal uſe at ſea; and without which all improvements of the lunar theory would have been uſeleſs for determining the longitude, through the want of an inſtrument proper to make the obſervations with. It however appears, that an inſtrument, exactly ſimilar to this in its principles, had been invented by Sir Iſaac Newton; and a deſcription of it, together with a drawing, given by the inventor to Dr Halley, when he was preparing for his voyage to diſcover the variation of the needle

needle in 1701. About the middle of this century, the constructing and dividing of large astronomical instruments was carried to a great degree of perfection by Mr John Bird: reflecting telescopes were equally improved by Mr Short, who first executed the divided object-glass micrometer. This had indeed been thought of by M. Louville, and several other persons long before; and a description of one nearly agreeing with that of Mr Short had been published in the Philosophical Transactions for 1753: but had it not been for the great skill of Mr Short in figuring and centering glasses of this kind, it is very probable the scheme might never have been executed. About this time also Mr Dollond brought refracting telescopes to such perfection, that they became superior to reflectors of equal length; though all of them are now excelled by those of Mr Herschel, whose Telescopic discoveries have been far more numerous and surprising than those of any other astronomer.

33 Improvements within this last century

We shall close this history with a short account of the labours of the principal astronomers since the building the Royal Observatories at Paris, Greenwich, and the appointment of Mr Flamstead to the office of astronomer royal. This gentleman not only made observations on the sun, moon, planets, and comets which appeared in his time, but on the fixed stars also, of which he gave a catalogue of 3000: many of them so small that they cannot be discerned without the help of a telescope: he also published new solar tables, and a theory of the moon according to Horrox. He published a very curious tract on the doctrine of the sphere, in which he showed how to construct eclipses of the sun and moon, as well as occultations of the fixed stars by the moon geometrically; and it was upon his observations that Halley's tables and Newton's theory of the moon were constructed. Mr Cassini also distinguished himself very considerably. He erected the gnomon, and drew the famous meridian line in the church of Petronia at Borunia. He enjoyed his office more than 40 years, making many observations on the sun, moon, planets, and comets, and greatly amended the elements of their motions. The office was continued in his family, and his grandson still enjoys it. Rœmer, a celebrated Danish astronomer, first discovered the progressive motion of light by observing the eclipses of Jupiter, and read a dissertation upon it before the Royal Academy of Sciences at Paris in the year 1675. He was also the first who made use of a meridional telescope.

Mr Flamstead was succeeded in 1719 by Dr Halley, "the greatest astronomer (says M. de la Lande) without contradiction in England;" and, adds Dr Long, "I believe he might have said in the whole world." He had been sent, at the age of 21, by King Charles II. to the island of St Helena, in order to make a catalogue of the southern stars, which was published in 1679. In 1705, he published his *Synopsis Astronomiæ Cometicæ*, in which, after immense calculation, he ventured to predict the return of one in 1758 or 1759. He also published many learned dissertations in the Philosophical Transactions concerning the use that might be made of the next transit of Venus in determining the distance of the sun from the earth. He was the first who discovered the acceleration of the moon, and gave a very ingenious method of finding her parallax by three observed phases of a solar eclipse. He composed tables of the sun, moon, and all the planets; and, in the nine years in which he was at Greenwich, made near 1500 observations of the moon; all which he compared with the tables, and noted the differences; and these, he thought, would return in about 18 years. He recommended the method of determining the longitude by means of the moon's distance from the sun and certain fixed stars. He was convinced of its superior excellence; and it has since been adopted by all the most eminent astronomers in Europe. It is at present the only sure guide to the mariner; and the great perfection to which it is now brought is much owing to the industry and exertions of Dr Maskelyne, the present astronomer-royal, to whom we are indebted for the publication of the Nautical Almanac, the Requisite Tables, and other works of the utmost service to practical astronomy.

34 True figure of the earth discovered.

In the mean time an attempt was made in France to measure a degree of the earth, which occasioned a very warm dispute concerning the figure of it. Cassini, from Picart's measure, concluded that the earth was an oblong spheroid; but Newton, from a consideration of the laws of gravity and the diurnal motion of the earth, had determined the figure of it to be an oblate spheroid, and flatted at the poles. To determine this point, Lewis XV. resolved to have two degrees of the meridian measured; one under, or very near the equator; and the other as near the pole as possible. For this purpose the Royal Academy of Sciences sent M. Maupertuis, Clairault, Camus, and Le Monier, to Lapland. They were accompanied by the Abbé Outhier, a correspondent of the same academy. They were joined by M. Celsius professor of anatomy at Upsal; and having set out from France in the spring of the year 1736, returned to it in 1737, after having fully accomplished their errand. On the southern expedition were dispatched M. Godin, Condamine, and Bouguer, to whom the king of Spain joined Don George Juan and Don Anthony de Ulloa, two very ingenious gentlemen and officers of the marine. They left Europe in 1735; and after enduring innumerable hardships and difficulties in the execution of their commission, returned to Europe at different times, and by different ways, in the years 1744, 1745, and 1746. The result of this arduous task was a confirmation of Newton's investigation. Picart's measure was revised by Cassini and De la Caille; and, after his errors were corrected, it was found to agree very well with the other two. On this occasion too it was discovered, that the attraction of the great mountains of Peru had an effect on the plumb-line of one of their largest instruments, drawing it seven or eight seconds from the true perpendicular.

Dr Halley, dying in 1742, was succeeded by Dr Bradley, who, though inferior as a mathematician, greatly exceeded him as a practical astronomer. He was the first who made observations with an accuracy sufficient to detect the lesser inequalities in the motions of the planets and fixed stars. Thus he discovered the aberration of light, the nutation of the earth's axis, and was able to make the lunar tables much more perfect than they had ever been. He also observed the places, and computed the elements of the comets which appeared

peared in the years 1723, 1736, 1743, and 1757. He made new and most accurate tables of the motions of Jupiter's satellites, from his own observations and those of Dr Pound; and from a multitude of observations of the sun, moon, and stars, was enabled to give the most accurate table of mean refractions yet extant, as well as the best methods of computing the variations of those refractions arising from the different states of the air as indicated by the thermometer and barometer. In 1750, having procured a very large transit instrument made by Mr Bird, and a new mural quadrant of brass eight feet radius, he began to make observations with redoubled industry; so that betwixt this time and his death, which happened in 1762, he made observations for settling the places of all the stars in the British catalogue, together with near 1500 places of the moon, much the greater part of which he compared with the tables of Mr Mayer.

35 Improvements by the French astronomers.

In the mean time the French astronomers were assiduous in their endeavours to promote the science of astronomy. The theory of the moon, which had been given in a general way by Sir Isaac Newton, began to be particularly considered by Messrs Clairault, D'Alembert, Euler, Mayer, Simpson, and Walmsly; tho' Clairault, Euler, and Mayer, distinguished themselves beyond any of the rest, and Mr Euler has been particularly happy in the arrangement of his tables for the ease and expedition of computation. He was excelled in exactness, however, by Mayer, who published his tables in the Gottingen Acts for 1753. In these the errors in longitude never exceeded two minutes; and having yet farther improved them, he sent a copy to the lords of the British admiralty in 1755; and it was this copy which Dr Bradley compared with his observations, as already mentioned. His last corrections of them were afterwards sent over by his widow; for which she and her children received a reward of L.3000. Accurate tables for Jupiter's satellites were also composed by Mr Wargentin a most excellent Swedish astronomer, and published in the Upsal Acts in 1741; which have since been corrected by the author in such a manner as to render them greatly superior to any ever published before.

36 Of M. de la Caille.

Amongst the many French astronomers who contributed to the advancement of the science, we are particularly indebted to M. de la Caille, for a most excellent set of solar tables, in which he has made allowances for the attractions of Jupiter, Venus, and the moon. In 1750 he went to the Cape of Good Hope, in order to make observations in concert with the most celebrated astronomers in Europe, for determining the parallax of the moon, as well as of the planet Mars, and from thence that of the sun; from whence it appeared that the parallax of the sun could not greatly exceed 10 seconds. Here he re-examined and adjusted the places of the southern stars with great accuracy, and measured a degree of the meridian at that place. In Italy the science was cultivated with the greatest assiduity by Signior Bianchini, father Boscovich, Frisi, Manfredi, Zanotti, and many others; in Sweden by Wargentin already mentioned, Blingenstern, Mallet, and Planman; and in Germany, by Euler elder and younger, Mayer, Lambert, Grischow, &c. In the year 1760 all the learned societies in Europe began to prepare for observing the transit of Venus over the sun, foretold by Dr Halley upwards of 80 years before it happened, showing at the same time the important use which might be made of it. Unfortunately, however, for the cause of science, many of the astronomers sent out to observe this phenomenon were prevented by unavoidable accidents from reaching the places of their destination, and others were disappointed by the badness of the weather. It happened also, that the circumstances of the phenomenon were much less favourable for the purpose of determining the sun's parallax than had been expected by Dr Halley, owing to the faults of the tables he made use of: so that, notwithstanding all the labours of astronomers at that time, they were not able to determine the matter; and even after their observations in 1769, when the circumstances of the transit were more favourable, the parallax of the sun remained still uncertain.

Dr Bradley was succeeded in his office of astronomer-royal by Mr Bliss Savilian professor of astronomy at Oxford; who being in a very declining state of health at the time of his accession to the office, did not enjoy it long. He was succeeded by the learned Nevil Maskelyne, D. D. the present astronomer-royal, whose name will be rendered immortal by his assiduity and success in bringing the lunar method of determining the longitude at sea into general practice.

Such was the general state of astronomy, when Mr Herschel's great discovery of augmenting the power of telescopes, beyond the most sanguine hopes of astronomers, opened at once a scene altogether unlooked for. By this indefatigable observer we are made acquainted with a new primary planet attended by two secondaries belonging to our solar system; so that the latter now appears to have double the bounds formerly assigned to it; this new planet being at least twice the distance of Saturn from the sun. In the still farther distant celestial regions, among the fixed stars, his observations are equally surprising; of which we shall only say with Dr Priestley *, "Mr Herschel's late discoveries in and beyond the bounds of the solar system, the great views that he has given of the arrangement of the stars, their revolutions, and those of the immense systems into which they are formed, are peculiarly calculated to inspire an ardent desire of seeing so great a scene a little more unfolded. Such discoveries as these give us a higher idea of the value of our being, by raising our ideas of the system of which we are a part; and with this an earnest wish for the continuance of it."

* *Exper. and Observ.* vol. vi. Pref.

Sect. I. *Of the apparent Motions, Magnitudes, and Changes, in the celestial Bodies, as seen by the naked eye.*

As the true motions of bodies at a great distance are to be gathered only from a careful observation of their apparent ones, it is absolutely necessary for those who want to become acquainted with the true motions of the heavenly bodies, to know perfectly the different changes which take place in the heavens as seen from this earth, the only place from which any observation can

Apparent Motion, &c.

can be made. By carefully attending to these, a little knowledge of optics will enable us to understand with great certainty not only the true system of nature, but also what appearance the heavens would make to a spectator placed in any part of the visible creation.

37 **Apparent motion of the sun.**

The first and most obvious phenomenon is the daily rising of the sun in the east, and his setting in the west; after which the moon and stars appear, still keeping the same westerly course, till we lose sight of them altogether. This cannot be long taken notice of before we must likewise perceive that neither the sun nor moon always rise exactly in the same point of the heavens. If we begin to observe the sun, for instance, in the beginning of March, we will find that he seems to rise almost every day sensibly more to the northward than he did the day before, to continue longer above the horizon, and to be more vertical at mid-day. This continues till towards the end of June, when he is observed to move backward in the same manner; and this retrograde motion continues to the end of December, or near it, when he begins again to move forwards, and so on.

38 **Of the moon.**

The motion of the moon through the heavens, as well as her appearance at different times, is still more remarkable than those of the sun. When she first becomes visible at the time she is called the *new moon*, she appears in the western part of the heavens, and seems to be at no great distance from the sun himself. Every night she not only increases in size, but removes to a greater distance from the sun; till at last she appears in the eastern part of the horizon, just at the time the sun disappears in the western. After this she gradually moves farther and farther eastward, and therefore rises every night later and later, till at last she seems to approach the sun as nearly in the east as she did in the west, and rises only a little before him in the morning, as in the first part of her course she set in the west not long after him. All these different appearances are completed in the space of a month; after which they begin in the same order as before. They are not, however, at all times regular; for at some seasons of the year, particularly in harvest, the moon for several days rises nearly at the same hour every night.

39 **Of the stars.**

In contemplating the stars, it is observed that some of them have the singular property of neither rising in the east nor setting in the west; but seem to turn round one immoveable point, near which is placed a single star called the *pole*, or *pole-star*. This point is more or less elevated according to the different parts of the earth from which we take our view. The inhabitants of Lapland, for instance, see it much more elevated above the horizon, or more vertical, than we do; we see it more vertical than it appears to the inhabitants of France and Spain; and they, again, see it more elevated than the inhabitants of Barbary. By continually travelling south, this star would at length seem depressed in the horizon, and another point would appear directly opposite to it, round which the stars in the southern part of the horizon would seem to turn. In this part of the heavens, however, there is no star so near the pole as there is in the northern part; neither is the number of stars in the southern part of the heavens so great as in the northern. Supposing us still to travel southward, the north-pole would then entirely disappear, and the whole hemisphere would appear to turn round a single point in the south, as the northern hemisphere appears to us to turn round the pole-star.—The general appearance of the heavens, therefore, is that of a vast concave sphere, turning round two points fixed in the north and south parts of it, once in 24 hours.

40 **Fixed stars and planets**

When we further consider the stars, we will find the greatest part of them to keep their places with respect to one another; that is, if we observe two stars having a certain apparent distance from each other this night, they will seem to have the same to-morrow, and every other succeeding night; but we will by no means observe them to have the same places either with respect to the sun or moon, as must be easily understood from what we have already said. Neither do all the stars in the heavens appear to be of this fixed kind. Some of them, on the contrary, change their places very remarkably with regard to the fixed stars, and with regard to one another. Of these, five were only observed formerly; but Mr Herschel has now discovered a sixth. They are distinguished by the appellation of *planets*, (from πλανω, to *err* or *wander*); and called by the names of *Mercury*, *Venus*, *Mars*, *Jupiter*, *Saturn*, and the *Georgium Sidus*. The fixed stars are likewise distinguished from the planets by their continually exhibiting that appearance which is called the *scintillation* or *twinkling of the stars*. This is said to arise from the exceeding minuteness of their apparent diameter; so that the interposition of any little substance, of which there are many floating in the atmosphere, continually deprives us of the sight of them; but the interposing body soon changing its place, we again see the star, and thus the twinkling is produced.

Mercury is a small star, but emits a very bright white light; though by reason of his always keeping near the sun, he is seldom to be seen; and when he does makes his appearance, his motion towards the sun is so swift, that he can only be discerned for a short time. He appears a little after sunset, and again a little before sunrise.

Venus, the most beautiful star in the heavens, known by the names of the *morning* and *evening star*, likewise keeps near the sun, though she recedes from him almost double the distance of mercury. She is never seen in the eastern quarter of the heavens when the sun is in the western; but always seems to attend him in the evening, or to give notice of his approach in the morning.

Mars is of a red fiery colour, and always gives a much duller light than Venus, though sometimes he equals her in size. He is not subject to the same limitation in his motions as Mercury or Venus; but appears sometimes very near the sun, and sometimes at a great distance from him; sometimes rising when the sun sets, or setting when he rises. Of this planet it is remarkable, that when he approaches any of the fixed stars, which all the planets frequently do, these stars change their colour, grow dim, and often become totally invisible, though at some little distance from the body of the planet: but Mr Herschel thinks this has been exaggerated by former astronomers.

Jupiter and Saturn likewise often appear at great distances from the sun. The former shines with a bright white light, and the latter with a pale faint one: and

Apparent Motion, &c.

the motion of Saturn among the fixed stars is so slow, that, unless carefully observed, he will not be thought to move at all.

41 Apparent magnitudes of the planets different at different times.

Besides the motions which we observe in all these planets, their apparent magnitudes are very different at different times. Every person must have observed that Venus, though she constantly appears with great splendor is not always equally big; and this apparent difference of magnitude is so remarkable, that she appears no less than 32 times larger at some seasons than at others. This increase of magnitude is likewise very remarkable in Mars and Jupiter, but less so in Saturn and Mercury.

42 Their irregular motion.

Though we have thus described the motions of the planets with respect to their apparent distances from the sun, they by no means appear to us to move regularly in the heavens; but, on the contrary, in the most complex and confused manner that can be imagined, sometimes going forward, sometimes backward, and sometimes seeming to be stationary. They all seem to describe looped curves; but it is not known when any of these curves would return into themselves, except that of Venus, which returns nearly into itself every eighth year. On each side of the loops they appear stationary; in that part of each loop near the earth, retrograde; and in every other part of their path direct.

43 Comets.

These, however, are not the only moving bodies which are to be observed in the celestial regions. The six abovementioned are indeed the only ones which appear almost constantly, or disappear only at certain intervals, and then as certainly return. But there are others which appear at uncertain intervals, and with a very different aspect from the planets. These are very numerous, and no fewer than 450 are supposed to belong to our solar system. They are called *Comets*, from their having a long tail, somewhat resembling the appearance of hair. This, however, is not always the case; for some comets have appeared which were as well defined and as round as planets: but in general they have a luminous matter diffused around them, or projecting out from them, which to appearance very much resembles the Aurora Borealis. When these appear, they come in a direct line towards the sun, as if they were going to fall into his body; and after having disappeared for some time in consequence of their proximity to that luminary, they fly off again on the other side as fast as they came, projecting a tail much greater and brighter in their recess from him than when they advanced towards him; but, getting daily at a farther distance from us in the heavens, they continually lose of their splendor, and at last totally disappear. Their apparent magnitude is very different: sometimes they appear only of the bigness of the fixed stars; at other times they will equal the diameter of Venus, and sometimes even of the sun or moon. So, in 1652, Hevelius observed a comet which seemed not inferior to the moon in size, though it had not so bright a splendor, but appeared with a pale and dim light, and had a dismal aspect. These bodies will also sometimes lose their splendor suddenly, while their apparent bulk remains unaltered. With respect to their apparent motions, they have all the inequalities of the planets; sometimes seeming to go forwards, sometimes backwards, and sometimes to be stationary.

44 Fixed stars seemingly destructible and generable.

Though the fixed stars are the only marks by which astronomers are enabled to judge of the courses of the moveable ones, and though they have never been observed to change their places; yet they seem not to be endued with the permanency even of the earth and planets, but to be perishable or destructible by accident, and likewise generable by some natural cause. Several stars observed by the ancients are now no more to be seen, but are destroyed; and new ones have appeared, which were unknown to the ancients. Some of them have also disappeared for some time, and again become visible.

We are also assured from the observations of astronomers, that some stars have been observed which never were seen before, and for a certain time they have distinguished themselves by their superlative lustre; but afterwards decreasing, they vanished by degrees, and were no more to be seen. One of these stars being first seen and observed by Hipparchus, the chief of the ancient astronomers, set him upon composing a catalogue of the fixed stars, that by it posterity might learn whether any of the stars perish, and others are produced afresh.

45 Dr Halley's history of new stars.

After several ages another new star appeared to Tycho Brache and the astronomers who were cotemporary with him; which put him on the same design with Hipparchus, namely, the making a catalogue of the fixed stars. Of this, and other stars which have appeared since that time, we have the following history by Dr Halley: "The first new star in the chair of Cassiopeia, was not seen by Cornelius Gemma on the 8th of November 1572, who says, he that night considered that part of the heaven in a very serene sky, and saw it not: but that the next night, November 9, it appeared with a splendor surpassing all the fixed stars, and scarce less bright than Venus. This was not seen by Tycho Brache before the 11th of the same month: but from thence he assures us that it gradually decreased and died away, so as in March 1574, after sixteen months, to be no longer visible; and at this day no signs of it remain. The place thereof in the sphere of fixed stars, by the accurate observations of the same Tycho, was $0^s\ 9^\circ\ 17'$ *a* 1^{ma} ✱ ♈^{is}, with $53^\circ\ 45'$ north latitude.

"Such another star was seen and observed by the scholars of Kepler, to begin to appear on Sept. 30. *st. vet.* anno 1604, which was not to be seen the day before: but it broke out at once with a lustre surpassing that of Jupiter; and like the former, it died away gradually, and in much about the same time disappeared totally, there remaining no footsteps thereof in January 1605—6. This was near the ecliptic, following the right leg of Serpentarius; and by the observations of Kepler and others, was in $7^s\ 20^\circ\ 00'$ *a* 1^{ma} ✱ ♈, with north latitude $1^\circ\ 56'$. These two seem to be of a distinct species from the rest, and nothing like them has appeared since.

"But between them, viz. in the year 1596, we have the first account of the wonderful star in Collo Ceti, seen by David Fabricius on the third of August, *st. vet.* as bright as a star of the third magnitude which has been since found to appear and disappear periodically, its

Apparent Motion, &c.

its period being preciſely enough ſeven revolutions in ſix years, though it returns not always with the ſame luſtre. Nor is it ever totally extinguiſhed, but may at all times be ſeen with a ſix-feet tube. This was ſingular in its kind, till that in Collo Cygni was diſcovered. It precedes the firſt ſtar in Aries 1° 40′, with 15° 57′ ſouth latitude.

"Another new ſtar was firſt diſcovered by William Janſonius in the year 1600, *in pectore*, or rather *in eductione*, Colli Cygni, which exceeded not the third magnitude. This having continued ſome years, became at length ſo ſmall, as to be thought by ſome to have diſappeared entirely: but in the years 1657, 1658, and 1659, it again aroſe to the third magnitude; tho' ſoon after it decayed by degrees to the fifth or ſixth magnitude, and to this day is to be ſeen as ſuch in 9^s 18° 38′ *a* 1^{ma} * ♈, with 55° 29′ north latitude.

"A fifth new ſtar was firſt ſeen by Hevelius in the year 1670, on July 15. *ſt. vet.* as a ſtar of the third magnitude, but by the beginning of October was ſcarce to be perceived by the naked eye. In April following it was again as bright as before, or rather greater than of the third magnitude, yet wholly diſappeared about the middle of Auguſt. The next year, in March 1672, it was ſeen again, but not exceeding the 6th magnitude: ſince when, it has been no further viſible, though we have frequently ſought for its return; its place is 9^s 3° 17′ *a* 1^{ma} * ♈, and has lat. north 47° 28′.

"The ſixth and laſt is that diſcovered by Mr G. Kirch in the year 1686, and its period determined to be of 404½ days; and though it rarely exceeds the fifth magnitude, yet it is very regular in its returns, as we found in the year 1714. Since then we have watched, as the abſence of the moon and clearneſs of the weather would permit, to catch the firſt beginning of its appearance in a ſix-feet tube, that, bearing a very great aperture, diſcovers moſt minute ſtars. And on June 15, laſt, it was firſt perceived like one of the very leaſt teleſcopical ſtars: but in the reſt of that month and July, it gradually increaſed, ſo as to become in Auguſt viſible to the naked eye; and ſo continued all the month of September. After that, it again died away by degrees; and on the eighth of December, at night, was ſcarce diſcernible by the tube; and, as near as could be gueſſed, equal to what it was at its firſt appearance on June 25th: ſo that this year it has been ſeen in all near ſix months, which is but little leſs than half its period; and the middle, and conſequently the greateſt brightneſs, falls about the 10th of September."

46 Mr Montanere's account of changes among the fixed ſtars.

Concerning the changes which happen among the fixed ſtars, Mr Montanere, profeſſor of mathematics at Bononia, gave the following account, in a letter to the Royal Society, dated April 30th, 1670. "There are now wanting in the heavens two ſtars of the ſecond magnitude in the ſtern of the ſhip Argo, and its yard; Bayerus marked them with the letters β and γ. I and others obſerved them in the year 1664, upon the occaſion of the comet that appeared that year: when they diſappeared firſt, I know not: only I am ſure that in the year 1668, upon the 10th of April, there was not the leaſt glimpſe of them to be ſeen; and yet the reſt about them, even of the third and fourth magnitudes, remained the ſame. I have obſerved many more changes among the fixed ſtars, even to the number of an hundred, though none of them are ſo great as thoſe I have ſhowed."

The late improvements in aſtronomy, and particularly thoſe in the conſtruction of teleſcopes, have now given aſtronomers an opportunity of obſerving the changes which take place among the ſtars with much greater accuracy than could be formerly done. In a paper in the 76th volume of the Philoſophical Tranſactions, Mr Edward Pigot gives a diſſertation on the ſtars ſuſpected by the aſtronomers of laſt century to be changeable. For the greater accuracy in the inveſtigation of his ſubject, he divides them into two claſſes; one containing thoſe which are undoubtedly changeable, and the other thoſe which are only ſuſpected to be ſo. The former contains a liſt of 12 ſtars, from the firſt to the fourth magnitudes; including the new one which appeared in Caſſiopeia in 1572, and that in Serpentarius in 1604: the other contains the names of 38 ſtars of all magnitudes, from the firſt to the ſeventh. He is of opinion, that the celebrated new ſtar in Caſſiopeia is a periodical one, and that it returns once in 150 years. Mr Keill is of the ſame opinion; and Mr Pigot thinks, that its not being obſerved at the expiration of each period is no argument againſt the truth of that opinion; "ſince (ſays he), perhaps, as with moſt of the variable, it may at different periods have different degrees of luſtre, ſo as ſometimes only to increaſe to to the ninth magnitude; and if this ſhould be the caſe, its period is probably much ſhorter." For this reaſon, in September 1782, he took a plan of the ſmall ſtars near the place where it formerly appeared, but in four years had obſerved no alteration.

47 Mr Pigot's remarks on the accounts of variable ſtars.

48 Star in Collo Celi.

The ſtar in the neck of the Whale had alſo been examined by Mr Pigot from the end of 1782 to 1786, but he never found it exceed the ſixth magnitude; though Mr Goodricke had obſerved it on the 9th of Auguſt to be of the ſecond magnitude, and on the 3d of September the ſame year it was of the third magnitude. Mr Pigot deduced its period from its apparent equality with a ſmall ſtar in the neighbourhood, and thence found it to be 320, 328, and 337 days.

49 Algol.

The moſt remarkable of theſe changeable ſtars is that called *Algol*, in the head of Meduſa. It had long been known to be variable; but its period was firſt aſcertained by Mr Goodricke of York, who began to obſerve it in the beginning of 1783. It changes continually from the firſt to the fourth magnitude; and the time taken up from its greateſt diminution to its leaſt is found, at a mean, to be 2 days 20 hours 49 minutes and 3 ſeconds. During four hours it gradually diminiſhes in luſtre, which it recovers during the ſucceeding four hours; and in the remaining part of the period it invariably preſerves its greateſt luſtre, and after the expiration of the term its diminution again commences. According to Mr Pigot, the degree of brightneſs of this ſtar when at its *minimum* is variable in different periods, and he is of the ſame opinion with regard to its brightneſs when at its full; but whether theſe differences return regularly or not, has not been determined.

The 420th of Mayer's catalogue in Leo, has lately been ſhewn to be variable by Mr. Koch. Some years before 1782, that gentleman perceived it undoubtedly ſmaller than the 419th of the ſame catalogue. In February

bruary that year, it was of the same brightness with the 419th, that is, of the seventh magnitude. In April 1783, it was of the ninth magnitude; and in the same month 1784, it was of the tenth. Mr Pigot could never observe this star, though he frequently looked for it with a night-glass, and on the fifth of April 1785 with a three-feet achromatic transit instrument.

50 Variable star in Hydra.

In 1704, Maraldi observed a variable star in Hydra, whose period he settled at about two years, though with considerable variations: but from the observations even of Maraldi, Mr Pigot concludes, that its period was then only 494 days; and from some others made by himself, he thinks that now it is only 487 days; so that since the time of Maraldi it has shortened seven days. The particulars relating to this star are as follow. 1. When at its full brightness it is of the fourth magnitude, and does not perceptibly change for a fortnight. 2. It is about six months in increasing from the tenth magnitude and returning to the same; so that it may be considered as invisible during that time. 3. It is considerably more quick, perhaps one half more so, in its increase than in its decrease. 4. Though when at its full it may always be styled a star of the fourth magnitude, it does not constantly attain the same degree of brightness, but the differences are very small. This star is the 30th of Hydra in Hevelius's catalogue, and is marked by him of the sixth magnitude.

51 Swan's head.

The new star in Serpentarius, observed by Kepler, seems to have been of the same nature with that of Cassiopeia; and Mr. Pigot therefore looks upon it also to be a periodical one, though, after taking a plan of the nearest stars in that part of the heavens, in the year 1782, he could, in four years time, perceive no alteration.

The variation of the star β Lyræ was discovered by Mr Goodricke abovementioned, who suspects its period to be six days nine hours; which coincides with the opinion of Mr Pigot.

The new star near the Swan's Head, observed by Don Anthelme in December 1669, soon became of the third magnitude, and disappeared in 1672. Mr Pigot has constantly looked for it since November 1781, but without success. He is of opinion, that had it only increased to the 10th or 11th magnitude, he would have seen it, having taken a plan of all the neighbouring small stars.

The next variable star in Mr Pigot's catalogue is the η Antinoi, whose variation and period he discovered in 1785. From his corrected observations, he concludes that it continues at its greatest brightness 40 hours without decreasing; it is 66 hours after it begins to decrease before it comes to its full diminution; after which it continues stationary for 30 hours more, and then increases for 36 hours. In every period it seems to acquire its full brightness, and to be equally decreased.

52 Swan's neck.

The variable star in the Swan's Neck was observed for three years. The period of this star had been settled by Maraldi and Cassini at 405, and by M. Le Gentil at 405.3 days; but from a mean of the observations of Mr Pigot, it appears to be only 329. "Perhaps (says he) its period is irregular; to determine which several intervals of 15 years ought to be taken; and I am much inclined to believe that it will be found only 396 days 21 hours." The particulars relating to this star are: 1. When at its full brightness it undergoes no perceptible change for a fortnight. 2. It is about three months and an half in increasing from the 11th magnitude to its full brightness, and the same in decreasing; for which reason it may be considered as invisible during six months. 3. It does not always attain the same degree of lustre, being sometimes of the fifth and sometimes of the seventh magnitude.

53 Swan's breast.

In 1600, G. Jansonius discovered a variable star in the breast of the Swan, which was afterwards observed by different astronomers, and supposed to have a period of about ten years. The results of Mr Pigot's calculations from the observations of former astronomers are, 1. That it continues in full lustre for five years. 2. It decreases rapidly for two years. 3. It is invisible to the naked eye for four years. 4. It increases slowly during seven years. 5. All these changes are completed in 18 years. 6. It was at its *minimum* at the end of the year 1663. 7. It does not always increase to the same degree of brightness, being sometimes of the third, and at others only of the sixth magnitude. "I am entirely ignorant (says Mr. Pigot) whether it is subject to the same changes in this century, having not met with any series of observations on it; but if the above conjectures are right, it will be at its minimum in a very few years. Since November 1781 I have constantly seen it of the sixth magnitude. Sometimes I have suspected that it has decreased within these two last years, though in a very small degree."

The last star in Mr. Pigot's first class is the δ Cephei, whose variation was discovered by Mr. Goodricke. Its changes are very difficult to be seen, unless it is observed at the times of its greatest and least brightness. The result of the observations hitherto made upon it are, that its period consists of 5 days 8 hours 37′ on a mean. The following observations relate to some stars of the second class.

54 Stars, the variation of which is less certain.

1. Hevelius's 6th Cassiopeæ was missing in 1782, nor could Mr Pigot find it in 1783 and 1784.

2. ξ or 46th Andromedæ, said to be variable, but the evidence is not convincing to Mr Pigot.

3. Flamstead's 50, 52, Andromedæ, and Hevelius's 41 Andromedæ. The position and characters of these stars differ considerably in different catalogues, and some of them are said by Cassini to have disappeared and reappeared. Mr Pigot therefore gives their comparative brightness as observed in the years 1783, 1784, and 1785, during which time he does not mention any particular change.

4. Tycho's 20th Cœti. "This (says Mr Pigot) must be the star which Hevelius said had disappeared, being Tycho's second in the Whale's Belly. There can hardly be any doubt that it is the χ, misplaced by Tycho. This χ is of the fourth or fifth magnitude."

5. σ, or the 17th Eridani of Ptolemy and Ulug Beigh. Flamstead says he could not see this star in 1691 and 1692; but in 1782, 1783, and 1784, Mr Pigot observed in that place one of the seventh magnitude, which appeared always of the same lustre.

6. Flamstead's 41 Tauri was supposed by Cassini to be either a new or variable star; but Mr Pigot thinks there is no reason to be of that opinion. "That it is not

Apparent Motion, &c.

not new (ſays he) is evident, ſince it is Ulug Beigh's 26th and Tycho's 43d.

7. A ſtar about 2½ north of 53 Eridani, and 47 Eridani. Caſſini ſuppoſed the firſt of theſe ſtars to be a new one, and that it was not viſible in 1664. He mentions another ſtar thereabouts, which he alſo eſteemed a new one.

8. γ Canis Majoris. Maraldi could not ſee this ſtar in 1670; but in 1692 and 1693 it appeared of the fourth magnitude. Mr Pigot made frequent obſervations upon it from 1782 to 1786, but could perceive no variation.

9. α, β Geminorum. "If either of theſe ſtars (ſays our author) have changed in brightneſs, it is probable the β. In 1783, 1784, and 1785, the β was undoubtedly brighter than α."

10. ξ Leonis. According to Montanari, this ſtar was hardly viſible in 1693. In 1783, 1784, and 1785, it was of the fifth magnitude. By Tycho, Flamſtead, Mayer, Bradley, &c. it is marked of the fourth.

11. ψ Leonis. This ſtar is ſaid to have diſappeared before the year 1667, but according to Mr Pigot's obſervations, was conſtantly of the fifth or ſixth magnitude ſince 1783.

12. 25th Leonis. In 1783 our author firſt perceived that this ſtar was miſſing, and could not perceive it in 1784 and 1785, even with a tranſit inſtrument.

13. Bayer's *i* Leonis, or Tycho's 16 Leonis, was not viſible in 1709, nor could it be ſeen in 1785. It is a different ſtar from the *i* Leonis of the other catalogues, though Tycho's deſcription of its place is the ſame.

14. δ Urſæ Majoris. This ſtar is ſuſpected to change in brightneſs, on account of its being marked by Tycho, the prince of Heſſe, &c. of the ſecond magnitude, while Hevelius, Bradley and others have marked it of the third. In 1786, and for three years before it appeared as a bright ſtar of the fourth magnitude.

15. η Virginis. This is ſuppoſed to be variable, becauſe Flamſtead, on the 27th of January 1680, could not ſee it; but he obſerved it in 1677, and ſome years afterwards. Mr Pigot obſerved it frequently in 1784 and 1785, and found it a ſtar of the ſixth magnitude without any perceptible change.

16. Bayer's ſtar of the ſixth magnitude 1° ſouth of *g* Virginis. "This ſtar (ſays Mr Pigot) is not in any of the nine catalogues that I have. Maraldi looked for it in vain; and in May 1785 I could not ſee the leaſt appearance of it. It certainly was not of the eighth magnitude.

17. A ſtar in the northern thigh of Virgo, marked by Ricciolus of the ſixth magnitude, could not be ſeen by Maraldi in 1709: nor was it of the ninth magnitude, if at all viſible in 1785.

18. The 91 and 92 Virginis. In 1785, one of theſe ſtars, probably the 91, was miſſing; the remaining one is of the ſixth or ſeventh magnitude.

19. α Draconis. Mr Pigot coincides in opinion with Mr Herſchel, that this ſtar is variable. Bradley, Flamſtead, &c. mark it of the ſecond magnitude, but in 1786 it was only a bright fourth. It was frequently examined by Mr Pigot from the 4th of October 1782, but without any alteration being perceived.

20. Bayer's ſtar in the weſt ſcale of Libra. Maraldi could not ſee this ſtar, and it was likewiſe inviſible to Mr Pigot in 1784 and 1785.

21. N° 6 of Ptolemy and Ulug Beigh's unformed in Libra. This ſtar is not mentioned in any other catalogues than the above. Mr Pigot frequently obſerved a little ſtar of the ſeventh magnitude very near its place.

22. κ Libræ. This ſtar is thought to be variable; but Mr Pigot is not of that opinion, though "certainly (ſays he) it is rather ſingular, that Hevelius, whoſe attention was directed to that part of the heavens to find Tycho's 11th, did not find the κ; and the more ſo, as he has noticed two much ſmaller ſtars not far from it. During theſe three years I have found the κ conſtantly of the fifth magnitude."

23. Tycho's 11th Libræ. Mr Pigot is of opinion that no ſuch ſtar as this ever exiſted; and that it is no other than the κ with an error of 2 degrees of longitude.

24. 33 Serpentis. This ſtar was miſſing in 1784; nor could it be perceived with a night-glaſs in 1785.

25. A ſtar marked by Bayer near ε urſæ majoris. This ſtar could not be ſeen by Caſſini; nor was Mr Pigot able to diſcover it with a night-glaſs in 1782.

26. The ρ, or Ptolemy and Ulug Beigh's 14th Ophiuchi, or Flamſtead's 36th. Mr Pigot has no doubt that this is the ſtar which is ſaid to have diſappeared before the year 1695; and it is evident that it was not ſeen by Hevelius. In 1784 and 1785 Mr Pigot found it of the fourth or fifth magnitude: but he is far from being certain of its having undergone any change, eſpecially as it has a ſouthern declination of 26 degrees; for which reaſon great attention muſt be paid to the ſtate of the atmoſphere.

27. Ptolemy's 13th and 18th Ophiuchi, fourth magnitude. Mr Pigot is of opinion that theſe ſtars are miſplaced in the catalogues. The 18th of Ptolemy he thinks ought to be marked with a north latitude inſtead of a ſouth, which would make it agree nearly with Flamſtead's 58th; and he is alſo of opinion that the 13th of Ptolemy is the 40th of Flamſtead.

28. σ Sagittarii. Mr Herſchel, as well as Mr Pigot, is of opinion, that this ſtar has probably changed its magnitude, though the reaſon ſeems only to be the great diſagreement concerning it among the different catalogues of ſtars.

29. θ Serpentis. This ſtar, according to Mr Montanari, is of variable magnitude; but Mr Pigot never could perceive any alteration.

30. Tycho's 27th Capricorni was miſſing in Hevelius's time, and Mr Pigot could not find it with a tranſit inſtrument.

31. Tycho's 22d Andromedæ, and ο Andromedæ. Mr Caſſini informs us, that in his time the former had grown ſo ſmall that it could ſcarcely be ſeen; and Mr Pigot, that no ſtar was to be ſeen its place in 1784 and 1785: but he is of opinion that Caſſini may have miſtaken the ο Andromedæ for the 22d; for which reaſon he obſerved this ſtar three years, but without any alteration in its brightneſs.

32. Tycho's 19th Aquarii. Hevelius ſays that this ſtar was miſſing, and that Flamſtead could not ſee it with his naked eye in 1679. Mr Pigot could not ſee it in 1782; but is perſuaded that it is the ſame with Flamſtead's

Apparent Motion, &c.

Flamſtead's 56th marked *f* by Bayer, from which it is only a degree and an half diſtant. The 53d of Flamſtead, marked *f* in Ptolemy's catalogue, is a different ſtar.

33. La Caille's 483 Aquarii was firſt diſcovered to be miſſing in 1778, and was not viſible in 1783 and 1784.

Beſides theſe there are ſeveral others certainly variable, but which cannot be ſeen in this country. There are ſome alſo ſuſpected to be variable, but for which Mr Pigot thinks there is no reaſon. Mr Herſchel alſo gives ſtrong reaſons for not laying great ſtreſs on all the obſervations by which new ſtars have been ſaid to be diſcovered. Mr Pigot aſſures us from repeated experience, that even more than a ſingle obſervation, if not particulariſed and compared with neighbouring ſtars, is very little to be depended upon; different ſtreaks of the clouds, the ſtate of the weather, &c. having often cauſed him to err a whole magnitude in the brightneſs of the ſtar.

55 Wollaſton's method of diſcovering variations among the fixed ſtars.

As theſe changes to which the fixed ſtars are liable do not ſeem to be ſubject to any certain rule, Mr Wollaſton has given an eaſy method of obſerving whether they do take place in any part of the heavens or not, and that without much expence of inſtruments or waſte of time, which are great objections to aſtronomical obſervations in general. His firſt idea was, that the work ſhould be undertaken by aſtronomers in general; each taking a particular diſtrict of the heavens, and from time to time obſerving the right aſcenſion and declination of every ſtar in that ſpace allotted to him, framing an exact map of it, and communicating their obſervations to one common place of information. This method, however, being too laborious, he next propoſes the noting down at the time, or making a drawing of what one ſees while they are obſerving. A drawing of this kind once made, would remain, and could be conſulted on any future occaſion; and if done at firſt with care, a tranſient review would diſcover whether any ſenſible change had taken place ſince it was laſt examined, which could not ſo well be done by catalogues or verbal deſcription. For this purpoſe he recommends the following method: "To a night-glaſs, but of Dollond's conſtruction, which magnifies about ſix times, and takes in about as many degrees of a great circle, I have added croſs wires interſecting one another at an angle of 45 degrees. More wires may be croſſed in other directions; but I apprehend theſe will be ſufficient. This teleſcope I mount on a polar axis. One coarſely made, and without any diviſions on its circle of declination, will anſwer the purpoſe, as there is no great occaſion for accuracy in that reſpect; but as the heavenly bodies are more readily followed by an equatorial motion of the teleſcope, ſo their relative poſitions are much more eaſily diſcerned when they are looked at conſtantly as in the ſame direction. An horizontal motion, except in the meridian, would be apt to miſlead the judgment. It is ſcarcely neceſſary to add, that the wires muſt ſtand ſo as for one to deſcribe a parrallel of the equator nearly; another will then be a horary circle, and the whole area will be divided into eight equal ſectors.

"Thus prepared, the teleſcope is to be pointed to a known ſtar, which is to be brought into the centre or common interſection of all the wires. The relative poſitions of ſuch other ſtars as appear within the field are to be judged of by the eye; whether at $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ from the centre towards the circumference, or *vice verſa*; and ſo with regard to the neareſt wire reſpectively. Theſe, as one ſees them, are to be noted down with a black-lead pencil upon a large meſſage-card held in the hand, upon which a circle ſimilarly divided is ready drawn. One of three inches diameter ſeems moſt convenient. The motion of the heavenly bodies in ſuch a teleſcope is ſo ſlow, and the noting down of the ſtars ſo quickly done, that there is commonly full time for it without moving the teleſcope. When that is wanted, the principal ſtar is eaſily brought back again into the centre of the field at pleaſure, and the work reſumed. After a little practice, it is aſtoniſhing how near one can come to the truth in this way: and tho' neither the right aſcenſions nor the declinations are laid down by it, nor the diſtances between the ſtars meaſured; yet their apparent ſituations being preſerved in black and white, with the day and year, and hour, if thought neceſſary, written underneath, each card then becomes a regiſter of the then appearance of the heavens; which is eaſily re-examined at any time with little more than a tranſient view; and which will yet ſhow, on the firſt glance, if there ſhould have happened in it any alteration of conſequence."

Plate LXVI.

Fig. 35. ſhows part of the corona borealis delineated in this manner, and which was afterwards fully taken down by making the ſtars α, β, γ, δ, ϵ, ζ, ϑ, ι, κ, π, ρ, σ, and τ ſucceſſively central; and theſe were joined with ſome of the ſtars of Bootes, for the ſake of connecting the whole, and united into one map, as repreſented fig. 37.

In obſerving in this way, it is evident, that the places of ſuch ſtars as happen to be under or very near any of the wires are more to be depended upon than thoſe which are in the intermediate ſpaces, eſpecially if towards the edges of the fields; ſo alſo thoſe which are neareſt to the centre, becauſe better defined, and more within the reach of one wire or another. For this reaſon, different ſtars of the ſame ſet muſt ſucceſſively be made central, or brought towards one of the wires, where any ſuſpicion ariſes of a miſtake, in order to approach nearer to a certainty; but if the ſtand of the teleſcope be tolerably well adjuſted and fixed, this is ſoon done.

In ſuch a glaſs it is ſeldom that light ſufficient for diſcerning the wires is wanting. When an illuminator is required, a piece of card or white paſteboard projecting on one ſide beyond the tube, and which may be brought forward occaſionally, is better than any other. By cutting acroſs a ſmall ſegment of the object-glaſs, it throws a ſufficient light down the tube though the candle be at a great diſtance, and one may loſe ſight of the falſe glare by drawing back the head, and moving the eye a little to one ſide, when the ſmall ſtars will be ſeen as if no illuminator was there. See a delineation of the principal fixed ſtars, with the apparent path of the ſun among them, on plate LXIV. and LXV.

56 Galaxy, or milky-way.

A very remarkable appearance in the heavens is that called the *galaxy*, or *milky-way*. This is a broad circle, in ſome places double, but for the moſt part ſingle, ſurrounding the whole celeſtial concave. It is of a whitiſh colour, ſomewhat reſembling a faint aurora borealis; but Mr Brydone, in his journey to the top of mount Ætna, found that phenomenon to make a glorious appearance

Appearances of Celestial Bodies thro' Telescopes.

pearance, being, as he expresses it, like a pure flame that shot across the heavens.

The only appearance, besides those already mentioned, which are very observable by the unassisted eye, are those unexpected obscurations of the sun and moon, commonly called *eclipses*. These are too well known, and attract the attention too much, to need any particular description. We have, however, accounts very well authenticated, of obscurations of the sun continuing for a much longer time than a common eclipse possibly can do, and likewise of the darkness being much greater than it usually is on such occasions: and that these accounts are probably true, we shall afterwards have occasion to observe.

57 Eclipses.

Sect. II. *Of the Appearances of the Celestial Bodies as seen through Telescopes.*

1. The sun, tho' to human eyes so extremely bright and splendid, is yet frequently observed, even through a telescope of but very small powers, to have dark spots on his surface. These were entirely unknown before the invention of telescopes, though they are sometimes of sufficient magnitude to be discerned by the naked eye, only looking through a smoked glass to prevent the brightness of the luminary from destroying the sight. The spots are said to have been first discovered in the year 1611; and the honour of the discovery is disputed betwixt Galileo and Scheiner, a German Jesuit at Ingoldstadt. But whatever merit Scheiner might have in the priority of the discovery, it is certain that Galileo far exceeded him in accuracy, though the work of Scheiner has considerable merit, as containing observations selected from above 3000, made by himself. Since his time the subject has been carefully studied by all the astronomers in Europe; the result of whose observations, as given by Dr Long, is to the following purpose.

58 Solar spots when first discovered.

59 Dr Long's account of them.

There is great variety in the magnitudes of the solar spots; the difference is chiefly in superficial extent of length and breadth; their depth or thickness is very small: some have been so large, as by computation to be capable of covering the continents of Asia and Africa; nay, the whole surface of the earth, or even five times its surface. The diameter of a spot, when near the middle of the disk, is measured by comparing the time it takes in passing over a cross hair in a telescope, with the time wherein the whole disk of the sun passes over the same hair; it may also be measured by the micrometer; and by either of these methods we may judge how many times the diameter of the spot is contained in the diameter of the sun. Spots are subject to increase and diminution of magnitude, and seldom continue long in the same state. They are of various shapes; most of them having a deep black nucleus surrounded by a dusky cloud, whereof the inner parts near the black are a little brighter than the outskirts. They change their shapes, something in the manner that our clouds do; though not often so suddenly: thus, what is of a certain figure to-day, shall, to-morrow, or perhaps in a few hours, be of a different one; what is now but one spot, shall in a little time be broken into two or three; and sometimes two or three spots shall coalesce, and be united into one. Dr Long, many years since, while he was viewing the image of the sun through a telescope cast upon white paper, saw one roundish spot, by estimation not much less than the diameter of our earth, break into two, which receded from one another with prodigious velocity. This observation was singular at the time; for though several writers had taken notice of this after it was done, none of them had been making any observation at the time it was actually doing.

The number of spots on the sun is very uncertain; sometimes there are a great many, sometimes very few; and sometimes none at all. Scheiner made observations on the sun from 1611 to 1629; and says he never found his disk quite free of spots, excepting a few days in December 1624. At other times he frequently saw 20, 30, and in the year 1625 he was able to count 50 spots on the sun at a time. In an interval afterwards of 20 years, from 1650 to 1670, scarce any spots were to be seen, and since that time some years have furnished a great number of spots, and others none at all; but since the beginning of the last century, not a year passed wherein some were not seen; and at present, says Mr Cassini, in his *Elemens d'Astronomie* published in 1740, they are so frequent, that the sun is seldom without spots, and often shows a good number of them at a time.

From these phenomena, it is evident, that the spots are not endowed with any permanency, nor are they at all regular in their shape, magnitude, number, or in the time of their appearance or continuance. Hevelius observed one that arose and vanished in 16 or 17 hours; nor has any been observed to continue longer than 70 days, which was the duration of one in the year 1676: those spots that are formed gradually, are gradually dissolved; while those that arise suddenly, are for the most part suddenly dissolved. When a spot disappears, that part where it was generally becomes brighter than the rest of the sun, and continues so for several days; on the other hand, those bright parts (called *faculæ*, as the others are called *maculæ*) sometimes turn to spots. 60

The solar spots move from west to east.

The solar spots appear to have a motion which carries them across the sun's disk. Every spot, if it continues long enough without being dissolved, appears to enter the sun's disk on the east side, to go from thence with a velocity continually increasing till it has gone half its way; and then to move slower and slower, till it goes off at the west side, after which it disappears for about the same space of time that it spent in crossing the disk, and then enters upon the east side again, nearly in the same place, and crosses it in the same tract, and with the same unequal motion as before. This apparent inequality in the motion of the spots is purely optical, and is in such proportion as demonstrates them to be carried round equably or in a circle, the plane of which continued passes through or near the eye of a spectator upon the earth.

Besides the real changes of the spots already mentioned, there is another which is purely optical, and is owing to their being seen on a globe differently turned towards us. If we imagine the globe of the sun to have a number of circles drawn upon its surface, all passing through the poles, and cutting his equator at equal distances, these circles which we may call meridians, if they were visible, would appear to us at unequal distances, as in fig. 2. Now, suppose a spot were round, and so large as to reach from one meridian to another, it would appear round only at *g*, when it was in the middle of that half of the globe which is towards

Plate LX.

Appearances of Celestial Bodies thro' Telescopes.

wards our earth; for then we view the full extent of it in length and breadth: in every other place it turns away from us, and appears narrower, though of the same length, the farther it is from the middle; and on its coming on at *a*, and going off at *n*, it appears as small as a thread, the thin edge being then all that we see.

The motion of the spots is in the order of the signs (the same way that all motions in the solar system, those of the comets alone excepted, are performed); and therefore, as the earth revolves round the sun the same way with the solar spots, one of these will appear to remain longer on the disk than it would otherwise do if the earth remained at rest. Thus, in fig. 3. let A B C D be the orbit of the earth, *a b c d* the equator of the sun; let *a* be a spot seen in the middle of the disk by a spectator upon the earth at A. The spot being carried round through *b c d*, according to the order of the letters, will in about 25 days bring it again to *a*: but during that interval, the earth will be got to B, and the middle of the disk at *b*; so that about two days more will intervene before a spectator upon the earth at C will view it in the middle of the then apparent disk at *c*. There are, however, but few instances of such returning spots; so that Scheiner, out of his multitude of observations, found only three or four of this kind.

Plate LX.

As fig. 2. is an orthographic projection of meridians on the sun's disk, it may be thought that they would show the apparent diurnal motion of the spots; so that, for example, a spot which to-day at noon is in the meridian marked *a*, would to-morrow at noon be in that marked *b*, the next day in that marked *c*, and so on: but Scheiner says, that, casting the sun's picture on paper through a telescope, the distance between the place of a spot at noon any given day and the place at noon the day immediately preceding, or the day immediately following, will be greater when the spot is near the circumference of the disk than according to the orthographic projection it ought to be. This deviation of spots he thought owing to the refraction of the glasses in the telescope being greater near the circumference than in the middle; and he was confirmed in this opinion, by finding, that if spots were observed by letting the sun shine through a small hole without a glass, upon white paper held at a good distance from the hole in a dark room, their places would then be every day according to the orthographic projection. But he found this method of observing the solar spots attended with great difficulties. Another proof that this deviation of the solar spots is occasioned by the different refraction of the glasses of the telescope, is deduced from the following experiment. Our author pierced with a needle 12 small holes at equal distances in a thin plate of brass; and placing the plate before the glasses of a short telescope, let the sun shine through, receiving 12 bright spots upon a white paper placed in such a manner that the light might fall perpendicularly upon it. Here also he found the distances between the spots near the outside greater than between those in the middle; whereas, when he received them upon paper without any glasses, the situation of the bright spots exactly corresponded to that of the small holes in the plate.

The face of the sun, when clear of spots, seen by the naked eye through a smoked or coloured glass, or through a thin cloud, or the vapours near the horizon, appears all over equally luminous: but when viewed thro' the telescope, the glasses being smoked or coloured, besides the difference between the faculæ and the other parts, the middle of the disk appears brighter than the outskirts; because the light is darted more directly towards us from the middle than from any other part, and the faculæ appear more distinctly near the sides, as being on a darker ground than in the middle.

61 Account of their phenomena by different observers.

The phenomena of the solar spots, as delivered by Scheiner and Hevelius, may be summed up in the following particulars. 1. Every spot which hath a nucleus, or considerably dark part, hath also an umbra, or fainter shade, surrounding it. 2. The boundary betwixt the nucleus and umbra is always distinct and well defined. 3. The increase of a spot is gradual, the breadth of the nucleus and umbra dilating at the same time. 4. In like manner, the decrease of a spot is gradual, the breadth of the nucleus and umbra contracting at the same time. 5. The exterior boundary of the umbra never consists of sharp angles; but is always curvilinear, how irregular soever the outline of the nucleus may be. 6. The nucleus of a spot, whilst on the decrease, often changes its figure by the umbræ encroaching irregularly upon it, insomuch that in a small space of time new encroachments are discernible, whereby the boundary betwixt the nucleus and umbra is perpetually varying. 7. It often happens, by these encroachments, that the nucleus of a spot is divided into two or more nuclei. 8. The nuclei of the spots vanish sooner than the umbra. 9. Small umbræ are often seen without nuclei. 10. An umbra of any considerable size is seldom seen without a nucleus in the middle of it. 11. When a spot which consisted of a nucleus and umbra is about to disappear, if it is not succeeded by a *facula*, or spot brighter than the rest of the disk, the place where it was is soon after not distinguished from the rest.

In the Philosophical Transanctions, Vol. LXIV. Dr Wilson, professor of astronomy at Glasgow, hath given a dissertation on the nature of the solar spots, and mentions the following appearances. 1. When the spot is about to disappear on the western edge of the sun's limb, the eastern part of the umbra first contracts, then vanishes, the nucleus and western part of the umbra remaining; then the nucleus gradually contracts and vanishes, while the western part of the umbra remains. At last this disappears also; and if the spot remains long enough to become again visible, the eastern part of the umbra first becomes visible, then the nucleus; and when the spot approaches the middle of the disk, the nucleus appears environed by the umbra on all sides, as already mentioned. 2. When two spots lie very near to one another, the umbra is deficient on that side which lies next the other spot: and this will be the case, though a large spot should be contiguous to one much smaller; the umbra of the large spot will be totally wanting on that side next the small one. If there are little spots on each side of the large one, the umbra does not tototally vanish; but appears flattened, or pressed in towards the nucleus on each side. When the little spots disappear, the umbra of the large one extends itself as usual. This circumstance, he observes, may sometimes prevent the disappearance of the umbra in the manner above-

Appearances of Celestial Bodies thro' Telescopes.

abovementioned; ſo that the weſtern umbra may diſappear before the nucleus, if a ſmall ſpot happens to break out on that ſide.

In the ſame volume, p. 337. Mr Wollaſton obſerves, that the appearances mentioned by Dr Wilſon are not conſtant. He poſitively affirms, that the faculæ or bright ſpots on the ſun are often converted into dark ones. "I have many times (ſays he) obſerved, near the eaſtern limb, a bright facula juſt come on, which has the next day ſhown itſelf as a ſpot, though I do not recollect to have ſeen ſuch a facula near the weſtern one after a ſpot's diſappearance. Yet, I believe, both theſe circumſtances have been obſerved by others; and perhaps not only near the limbs. The circumſtance of the faculæ being converted into ſpots I think I may be ſure of. That there is generally (perhaps always) a mottled appearance over the face of the ſun, when carefully attended to, I think I may be as certain. It is moſt viſible towards the limbs, but I have undoubtedly ſeen it in the centre; yet I do not recollect to have obſerved this appearance, or indeed any ſpots towards his poles. Once I ſaw with a twelve-inch reflector, a ſpot burſt to pieces while I was looking at it. I could not expect ſuch an event, and therefore cannot be certain of the exact particulars; but the appearance, as it ſtruck me at the time, was like that of a piece of ice when daſhed on a frozen pond, which breaks to pieces and ſlides in various directions." He alſo acquaints us, that the nuclei of the ſpots are not always in the middle of the umbræ; and gives the figure of one ſeen November 13th 1773, which is a remarkable inſtance to the contrary. Mr Dunn, however, in his new Atlas of the Mundane Syſtem, gives ſome particulars very different from the above. "The face of the ſun (ſays he) has frequently many large black ſpots, of various forms and dimenſions, which move from eaſt to weſt, and round the ſun, according to ſome obſervations in 25 days, according to others in 26, and according to ſome in 27 days. The black or central part of each ſpot is in the middle of a great number of very ſmall ones, which permit the light to paſs between them. The ſmall ſpots are ſcarce ever in contact with the central ones: but what is moſt remarkable when the whole ſpot is near the limb of the ſun, the ſurrounding ſmall ones form nearly a ſtraight line, and the central part projects a little over it, like Saturn in his ring."

62 Mr Dunn's account.

The ſpots are by no means confined to one part of the ſun's diſk; though we have not heard of any being obſerved about his polar regions; and though their direction is from eaſt to weſt, yet the paths they deſcribe in their courſe over the diſk are exceedingly different; ſometimes being ſtraight lines, ſometimes curves, ſometimes deſcending from the northern to the ſouthern part of the diſk, ſometimes aſcending from the ſouthern to the northern, &c. This was obſerved by Mr Derham (Philoſ. Tranſ. Nº 330), who hath given figures of the apparent paths of many different ſpots, wherein the months in which they appeared, and their particular progreſs each day, are marked.

63 Mercury and Venus ſometimes appear as ſpots.

Beſides theſe ſpots, there are others which ſometimes appear very round and black, travelling over the diſk of the ſun in a few hours. They are totally unlike the others, and will be ſhown to proceed from an interpoſition of the planets Mercury and Venus between the earth and the ſun. Excepting the two kinds of ſpots abovementioned, however, no kind of object is diſcovered on the ſurface of the ſun, but he appears like an immenſe ocean of elementary fire or light.

63 Teleſcopic view of the moon.

2. With the moon the caſe is very different. Many darkiſh ſpots appear in her to the naked eye; and, through a teleſcope, their number is prodigiouſly increaſed: ſhe alſo appears very plainly to be more protuberant in the middle than at the edges, or to have the figure of a globe, and not a flat circle. When the moon is horned or gibbous, the one ſide appears very ragged and uneven, but the other always exactly defined and circular. The ſpots in the moon always keep their places exactly; never vaniſhing, or going from one ſide to the other, as thoſe of the ſun do. We ſometimes ſee more or leſs of the northern and ſouthern, and eaſtern and weſtern part of the diſk or face; but this is owing to what is called her libration, and will hereafter be explained.

The aſtronomers Florentius, Langrenus, John Hevelius of Dantzick, Grimaldus, Ricciolus, Caſſini, and M. de la Hire, have drawn the face of the moon as ſhe is ſeen through teleſcopes magnifying between 200 and 300 times. Particular care has been taken to note all the ſhining parts in her ſurface; and, for the better diſtinguiſhing them, each has been marked with a proper name. Langrenus and Ricciolus have divided the lunar regions among the philoſophers, aſtronomers, and other eminent men; but Hevelius and others, fearing leſt the philoſophers ſhould quarrel about the diviſion of their lands, have endeavoured to ſpoil them of their property, by giving the names belonging to different countries, iſlands, and ſeas on earth, to different parts of the moon's ſurface, without regard to ſituation or figure. The names adopted by Riccioli, however, are thoſe which are generally followed, as the names of *Hipparchus Tycho, Copernicus*, &c. are more pleaſing to aſtronomers than thoſe of Africa, the Mediterranean Sea, Sicily, and Mount Ætna. On Plate LXIII. is a tolerably exact repreſentation of the full moon in her mean libration, with the numbers to the principal ſpots according to Riccioli, Caſſini, Mayer, &c. The aſteriſk refers to one of the volcanoes diſcovered by Dr Herſchel, to be afterwards more particularly noticed. The names are as follow:

* Herſchel's Volcano.	20 Pitatus.
1 Grimaldus.	21 Tycho.
2 Galileus.	22 Eudoxus.
3 Ariſtarchus.	23 Ariſtoteles.
4 Keplerus.	24 Manilius.
5 Gaſſendus	25 Menelaus.
6 Shikardus.	26 Hermes.
7 Harpalus.	27 Poſſidonius.
8 Heraclides.	28 Dionyſius.
9 Lanſbergius.	29 Plinius.
10 Reinoldus.	30 { Calharina Cyrillus. / Theophilus. }
11 Copernicus	
12 Helicon.	31 Fracaſtorius.

We have already observed, that when the planet Mars approaches any of the fixed stars, they lose their light, and sometimes totally disappear before he seems to touch them: but it is not so with the moon; for though she very often comes in betwixt us and the stars, they preserve their lustre till immediately in seeming contact with her, when they suddenly disappear, and as suddenly re-appear on the opposite side. When Saturn, however, was hid by the moon in June 1762, Mr. Dunn, who watched his appearance at the emersion, observed a kind of faint shadow to follow him for a little from the edge of the moon's disk. This appearance is represented fig. 88.

Plate LXIX.

64 Mercury appears always equally luminous.

3. Mercury, when looked at through telescopes magnifying about 200 or 300 times, appears equally luminous throughout his whole surface, without the least dark spot. He appears indeed to have the same difference of phases with the moon, being sometimes horned, sometimes gibbous, and sometimes shining almost with a round face, though not entirely full, because his enlightened side is never turned directly towards us, unless when so near the sun as to be invisible; but at all times perfectly well defined without any ragged edge, and perfectly bright.

65 Spots, when first discovered on the disk of Venus.

4. Dr Long informs us, that the earliest account he had met with of any spots seen by means of the telescope on the disk of Venus was in a collection of letters printed at Paris in 1665, in one of which M. Auzout relates his having received advice from Poland that Mr Burratini had, by means of large telescopes, seen spots upon the planet Venus similar to those upon the moon.

66 Cassini's observations.

In 1667, Cassini, in a letter to Mr Pettit, mentions his having for a long time carefully observed Venus through an excellent telescope made by Campani, in order to know whether that planet revolved on its axis or not, as he had before found Jupiter and Mars to do. But though he then observed some spots upon her, he says, that even when the air was quiet and clear, they appeared faint, irregular, and not well defined: so that it was difficult to have such a distinct view of any of them as to be certain that it was the same spot which was seen again in any subsequent observation; and this difficulty was increased, in the first place, when Venus was in her inferior semicircle; because at that time she must be viewed through the thick vapours near the horizon; though otherwise it was most proper, on account of her being then nearest to us. In the second place, if we would observe her at some height above those vapours, it could only be for a short time; and, thirdly, when she is low in her inferior circle, and at that time nearest the earth, the enlightened part of her is too small to discover any motion in it. He was therefore of opinion, that he should succeed better in his observations when the planet was about its mean distance from us, showing about one-half of her enlightened hemisphere; at which time also he could observe her for a much longer time above the gross atmospherical vapours. His first appearance of success was October 14. 1666 at three-quarters past five in the evening; when he saw a bright spot (fig. 37.), but could not then view that spot long enough to draw any inference concerning the planet's motion. He had no farther success till the 20th of April, the following year; when, about a quarter of an hour before sunrise, he began again to perceive on the disk of Venus, now about half enlightened, a bright part near the section, distant from the southern horn a little more than a fourth-part of the diameter of the disk, and near the eastern edge. He took notice also of a darkish oblong spot nearer to the northern than the southern horn: at sunrise the bright part was advanced further from the southern horn than when he first observed it; but though he was pleased to find that he had now a convincing proof of the planet's motion, he was surprised that the spots moved from south to north in the lower part of the disk, and from north to south in the upper part; a kind of motion of which we have no example, except in the librations of the moon.

Plate LXVI.

67 Why the spots seem to move south to north, &c.

This, however, was occasioned by the situation of the planet's axis. Cassini expected to have found the rotation of Venus similar to that of Jupiter and Mars, both of which have their axes perpendicular to their respective orbits, and turn round according to the order of the signs; so that, in each of them, the motion of the inferior half of their respective globe, or that part next the sun, is from east to west; in the superior half from west to east; but in Venus, whose axis is inclined 75 degrees towards her orbit, the coincidence is so near, that one-half of her disk appears to move from south to north, the other from north to south.

68 Particular account of the appearances of the spots at different times.

On the 21st of April, at sunrise, the bright part was a good way off the section, and about a fourth-part of the diameter distant from the southern horn. When the sun was eight degrees six minutes high, it seemed to be got beyond the center, and was cut through by the section. At the time the sun was seven degrees high the section cut it in the middle, which showed its motion to have some inclination towards the centre.

May 9. a little before sunrise, the bright spot was seen near the centre, a little to the northward, with two obscure ones situated between the section and the circumference, at a distance from each other, equal to that of each of them from the nearest angular point or horn of the planet. The weather being at that time clear, he observed for an hour and half a quarter the motion of the bright spot, which seemed to be exactly from south to north, without any sensible declination to east or west. A variation was at the same time perceived in the darkish spot too great to be ascribed to any optical cause. The bright spot was also seen on the 10th and 13th days of May before sunrise between the northern horn and the centre, and the same irregular change of darkish spots was taken notice of; but as the planet removed to a greater distance from the earth, it became more difficult to observe these appearances. The above phenomena are represented as they occurred in figs. 37—43.

69 Cassini's conclusions concerning the revolution of Venus on her axis.

But though, from the appearances just now related, M. Cassini was of opinion that Venus revolved on her axis, he was by no means so positive in this matter as with regard to Mars and Jupiter. "The spots on these (says he) I could attentively observe for a whole night, when the planets were in opposition to the sun:

I

Appearances of Celeſtial Bodies thro' Teleſcopes.

I could ſee them return to the ſame ſituation, and conſider their motion during ſome hours, and judge whether they were the ſame ſpots or not, and what time they took in turning round: but it was not the ſame with the ſpots of Venus; for they can be obſerved only for ſo ſhort a time, that it is much more difficult to

70
Difficulties attending theſe obſervations.

ſhow with certainty when they return into the ſame ſituation. I can, however, ſuppoſing that the bright ſpot which I obſerved on Venus, and particularly this year, was the ſame, ſay that ſhe finiſhes her motion, whether of rotation or libration, in leſs than a day; ſo that, in 23 days nearly, the ſpot comes into the ſame ſituation on nearly the ſame hour of the day, though not without ſome irregularity. Now ſuppoſing the bright ſpot obſerved to be always the ſame) whether this motion is an entire turning round or only a libration, is what I dare not poſitively affirm."

In 1669 M. Caſſini again obſerved Venus through a teleſcope, but could not then perceive any ſpots upon her ſurface; the reaſon of which Du Hamel conjectures to have been the fluctuation of the vapours near the horizon, which prevented them from being viſible. However, we hear nothing more of any ſpots being ſeen on her diſk till the year 1726; when, on

71
Bianchini's obſervations.

the 9th of February, Bianchini, with ſome of Campani's teleſcopes of 90 and 100 Roman palms, began to obſerve the planet at the altitude of 40° above the horizon, and continued his obſervations till, by the motion of ſeveral ſpots, he determined the poſition of her axis to be inclined as above mentioned, that the north pole pointed at a circle of latitude drawn through the 20th degree of Aquarius, elevated 15 or 20° above the orbit of Venus. He delineated alſo the figures of ſeveral ſpots which he ſuppoſed to be ſeas, and complimented the king of Portugal and ſome other great men by calling them by their names. Though none of Bianchini's obſervations were continued long enough to know whether the ſpots, at the end of the period aſſigned for the rotation of the planet, would have been in a different ſituation from what they were at the beginning of it; yet, from obſervations of two and of four days, he concluded the motion of the ſpots to be at the rate of 15° per day; at which advance the planet muſt turn round either once in 24 days or in 23 hours; but without farther obſervation it could

72
Doubts concerning the time ſhe takes up in revolving round her axis.

not be determined which of the two was the period of revolution; for if an obſerver ſhould at a particular hour, ſuppoſe ſeven in the evening, mark exactly the place of a ſpot, and at the ſame hour next evening find the ſpot advanced 15°, he would not be able to determine whether the ſpot had advanced only 15°, or had gone once quite round with the addition of 15° more in part of another rotation. Mr Bianchini, however, ſuppoſes Venus to revolve in 24 days eight hours; the principal proof adduced for which is an obſervation of three ſpots, A B C, being ſituated as

Plate LXVI.

in fig. 44. when they were viewed by himſelf and ſeveral perſons of diſtinction for about an hour, during which they could not perceive any change of place. The planet being then hid behind Barbarine palace, they could not have another view of her till three hours after, when the ſpots ſtill appeared unmoved. "Now (ſays M. Bianchini) if her rotation were ſo ſwift as to go round in 23 hours, in this ſecond view, three hours after the former, the ſpots muſt have advanced near 50 degrees; ſo that the ſpot C would have been gone off at R, the ſpot B would have ſucceeded into the place of C, the ſpot A into the place of B, and there would have been no more but two ſpots, A and B, to have been ſeen."

73
Diſpute between Caſſini and Bianchini.

Caſſini, the ſon, in a memoir for 1732, denies the concluſion of Bianchini to be certain. He ſays, that, during the three hours interval, the ſpot C might be gone off the diſk, and the ſpot B got into the place thereof, where, being near the edge, it would appear leſs than in the middle. That A, ſucceeding into the place of B, would appear larger than it had done near the edge, and that another ſpot might come into the place of A; and there were other ſpots beſides theſe three on the globe of the planet, as appears by the figures of Bianchini himſelf, particularly one which would naturally come into the place of A. That if the rotation of Venus be ſuppoſed to be in 23 hours, it will agree with Bianchini's, obſervations, as well as with thoſe of his father; but that, on the other ſuppoſition, the latter muſt be entirely rejected as erroneous: and he concludes with telling us, that Venus had frequently been obſerved in the moſt favourable times by M. Maraldi and himſelf with excellent teleſcopes of 80 and 100 feet focus, without their being able to ſee any diſtinct ſpot upon her diſk. "Perhaps, (ſays Dr Long), thoſe ſeen by Bianchini had diſappeared, or the air in France was not clear enough; which laſt might be the reaſon why his father could never ſee thoſe ſpots in France which he had obſerved in Italy, even when he made uſe of the longeſt teleſcopes. Neither of theſe aſtronomers take notice of any indentings in the curve which divides the illuminated part from the dark in the diſk of Venus, though in ſome views of that planet by Fontana and Ricciolus, the curve is indented; and it has from thence been concluded, that the ſurface of the planet is mountainous like that of the moon. This had alſo been ſuppoſed by Burratini, already mentioned; and a late writer has obſerved, that 'When the air is in a good ſtate for obſervation, mountains like thoſe of the moon may be obſerved with a very powerful teleſcope.'

74
Caſſini diſcovers her ſatellite.

Caſſini, beſides the diſcovery of the ſpots on the diſk of Venus by which he was enabled to aſcertain her revolution on an axis, had alſo a view of her ſatellite or moon, of which he gives the following account.—"A. D. 1686, Aug. 28th, at 15 minutes after four in the morning, looking at Venus with a teleſcope of 34 feet, I ſaw, at the diſtance of one-third of her diameter, eaſtward, a luminous appearance, of a ſhape not well defined, that ſeemed to have the ſame phaſe with Venus, which was then gibbous on the weſtern ſide. The diameter of this phenomenon was nearly equal to a fourth part of the diameter of Venus. I obſerved it attentively for a quarter of an hour, and having left off looking at it for four or five minutes, I ſaw it no more; but day-light was then advanced. I had ſeen a like phenomenon which reſembled the phaſe of Venus, Jan. 25th, A.D. 1672, from 52 minutes after ſix in the morning to two minutes after ſeven, when the brightneſs of the twilight made it diſappear. Venus was then horned, and this phenomenon, the diameter whereof was nearly a fourth-part of the diameter of Venus, was of the ſame ſhape. It was diſtant from the ſouthern horn of Venus, a diameter of the planet, on

Appearances of Celestial Bodies thro' Telescopes.

on the western side. In these two observations, I was in doubt whether it was not a satellite of Venus of such a consistence as not to be very well fitted to reflect the light of the sun; and which, in magnitude bore nearly the same proportion to Venus as the moon does to the earth, being at the same distance from the sun and the earth as Venus was, the phases whereof it resembled. Notwithstanding all the pains I took in looking for it after these two observations, and at divers other times, in order to complete so considerable a discovery, I was never able to see it. I therefore suspend my judgment of this phenomenon. If it should return often, there will be these two epochas, which, compared with other observations, may be of use to find out the periodical time of its return, if it can be reduced to any rule."

75 Discovered also by Mr Short.

A similar observation was made by Mr Short on the 23d of October 1740, about sunrise. He used at this time a reflecting telescope of about 16.5 inches, which magnified between 50 and 60 times, with which he perceived a small star at about 10′ distance from Venus, as measured by the micrometer; and putting on a magnifying power of 240 times, he found the star put on the same appearance with the planet herself. Its diameter was somewhat less than a third of that of the primary, but its light was less vivid, though exceedingly sharp and well defined. The same appearance continued with a magnifying power of 140 times. A line, passing through the centre of Venus and it, made an angle of 18 or 20 degrees with the equator: he saw it several times that morning for about the space of an hour, after which he lost sight of it, and could never find it again.

From this time the satellite of Venus, though very frequently looked for by Astronomers, could never be perceived, which made it generally believed that Cassini and Mr Short had been mistaken; but as the transits of the planet over the sun in 1761 and 1769 seemed to promise a greater certainty of finding it, the satellite was very carefully looked for by almost every one who had an opportunity of seeing the transit, but generally without success. M. Baudouin at Paris had provided a telescope of 25 feet, in order to observe the passage of the planet over the sun, and to look for its satellite; but he did not succeed either at that time or in the months of April and May following. M. Montaigne, however, one of the members of the Society of Limoges, had better success. On the 3d of May 1761, he perceived, about half an hour after nine at night, at the distance of 20′ from Venus, a small crescent, with the horns pointing the same way as those of the planet; the diameter of the former being about one-fourth of that of the latter; and a line drawn from Venus to the satellite making an angle with the vertical of about 20° towards the south. But though he repeated this observation several times, some doubt remained whether it was not a small star. Next day he saw the same star at the same hour, distant from Venus about half a minute, or a minute more than before, and making with the vertical an angle of 10° below on the north side; so that the satellite seemed to have described an arc of about 30°, whereof Venus was the centre, and the radius 20′. The two following nights were hazy, so that Venus could only be seen; but on the 7th of May, at the same hour as before, he saw the satellite again above Venus, and on the north side, at the distance of 25 or 26′ upon a line which made an angle of about 45°, with the vertical towards the right hand. The light of the satellite was always very weak, but it had the same phasis with its primary, whether viewed together with it in the field of his telescope or by itself. The telescope was nine feet long, and magnified an object between 40 and 50 times, but had no micrometer; so that the distance abovementioned are only from estimation.

76 Seen by M. Montaigne at the transit in 1761.

Fig. 4. Represents the three observations of M. Montaigne. V is the planet Venus; ZN the vertical. EC, a parallel to the ecliptic, making then an angle with the vertical of 45°; the numbers 3, 4, 7, mark the situations of the satellite on the respective days. From the figure it appears that the points 3 and 7 would have been diametrically opposite, had the satellite gone 15° more round the point V at the last observation; so that in four days it went through 155°. Then, as 155° is to four days or 96 hours, so is 360 to a fourth number, which gives 9 days 7 hours for the whole length of the synodical revolution. Hence M. Baudouin concluded, that the distance of this satellite was about 60 of the semidiameters of Venus from its surface; that its orbit cut the ecliptic nearly at right angles; had its ascending node in 22° of Virgo; and was in its greatest northern digression on the 7th atnine at night; and he supposed, that at the transit of the primary the satellite would be seen accompanying it. By a subsequent observation, however, on the 11th of May, he corrected his calculation of the periodical time of the satellite, which he now enlarged to 12 days; in consequence of which he found that it would not pass over the disk of the sun along with its primary, but go at the distance of above 20′ from his southern limb; though if the time of its revolution should be 15 hours longer than 12 days, it might then pass over the sun after Venus was gone off. He imagined the reason why this satellite was so difficult to be observed, might be, that one part of its globe was crusted over with spots, or otherwise unfit to reflect the light of the sun. By comparing the periodical time of this satellite with that of our moon, he computed the quantity of matter in Venus to be nearly equal to that in our earth; in which case it must have considerable influence in changing the obliquity of the ecliptic, the latitudes and longitudes of stars, &c.

Plate LX.

77 Why this satellite is so difficult to be seen.

This is all the evidence which has yet been published concerning the existence of the satellite of Venus; as it does not appear that, during the transit of 1769, any of the observers had the good fortune to perceive it. In the Philosophical Transactions for 1761, Mr Hirst gives an account of his having observed an atmosphere round the planet Venus. The observations were made at Fort St George; and looking attentively at that part of the sun's disk where he expected the planet would enter, he plainly perceived a faint shade or penumbra; on which he called out to his two assistants, "'Tis a coming!" and two or three seconds after, the first external contact took place in the moment whereof all the three agreed; but he could not see the penumbra after the egress: and of the other two gentlemen, one had gone home, and the other lost the planet out of the field of his telescope. Mr Dunn at Chelsea saw a penumbra, or small diminution of light,

78 Observations concerning the atmosphere of Venus.

Appearances of Celestial Bodies thro' Telescopes.

light, that grew darker and darker for about five seconds before the internal contact preceding the egress; from whence he determines that Venus is surrounded with an atmosphere of about 50 geographical miles high. His observations, he tells us, were made with an excellent six-feet Newtonian reflector, with a magnifying power of 110, and of 220 times: he had a clear dark glass next his eye, and the sun's limb appeared well defined; but a very narrow waterish penumbra appeared round Venus. The darkest part of the planet's phasis was at the distance of about a sixth-part of her diameter from its edge; from which an imperfect light encreased to the centre, and illuminated round about.

In the northern parts of Europe this penumbra could not be seen. Mr Wargentin, who communicated several observations of the first external contact, says, that he could not mark the time exactly, because of the undulation of the limb of the sun; but thought it very remarkable that, at the egress, the limb of Venus that was gone off the sun showed itself with a faint light during almost the whole time of emersion. Mr. Bergman, who was then at the observatory at Upsal, begins his account at the time when three-fourths of the disk of the planet was entered upon that of the sun; and he says, that the part which was not come upon the sun was visible, though dark, and surrounded

Plate LXI. by a crescent of faint light, as in fig. 7.: but this appearance was much more remarkable at the egress; for as soon as any part of the planet was got off the sun, that part was visible with a like crescent, but brighter, fig. 8. As more of the planetary disk went off that of the sun, however, that part of the crescent which was farthest from the sun grew fainter, and vanished, until at last only the horns could be seen, as in fig. 9. The total ingress was not instantaneous: but, as two drops of water, when about to part, form a ligament between them; so there was a dark swelling stretched out between Venus and the sun, as in fig. 10.; and when this ligament broke, the planet appeared to have got about an eighth-part of her diameter from the nearest limb of the sun; fig. 11. he saw the like appearance at going off, but not so distinct, fig. 12. Mr Chappe likewise took notice, that the part of Venus which was not upon the sun was visible during part of the time of ingress and egress; that it was farther surrounded by a small luminous ring of a deep yellow near the place that appeared in the form of the crescent, which was much brighter at the going off than coming upon the sun; and that, during the whole time the disk of Venus was upon the sun, he saw nothing of it. The time of the total ingress was instantaneous like a flash of lightening; but at the egress the limb of the sun began to be obscured three seconds before the interior contact. Some of the French astronomers attributed this luminous ring round Venus to the inflection of the sun's rays, as they also do the light seen round the moon in solar eclipses; but Mr Chappe supposes it to have been owing to the sun enlightening more than one half of the planetary globe, though he owns this cause not to be altogether sufficient. Mr Fouchy, who observed the transit at La Muette in France, perceived, during the whole time, a kind of ring round Venus, brighter than the rest of the sun, which became fainter the farther it went from the planet, but appeared more vivid in proportion as the sun was clearer. Mr. Ferner, who observed at the same place, confirms the testimony of Mr Fouchy. "During the whole time (says he) of my observing with the telescope, and the blue and green glasses, I perceived a light round about Venus, which followed her like a luminous atmosphere more or less lively, according as the air was more or less clear. Its extent altered in the same manner; nor was it well terminated; throwing out, as it were, some feeble rays on all sides."

79 Dr Long's opinion on these observations.

"I am not clear (says Dr. Long) as to the meaning of the luminous circle here mentioned, whether, when the whole planet was upon the sun, they saw a ring of light round it, distinct from the light of the sun; or whether they mean only the light which surrounded that part of Venus that was not upon the sun." Mr Chappe takes this and other accounts of the observations made in France in this latter sense: and though he sometimes called the luminous part of the crescent that surrounded the part of the planet not upon the sun a ring, he explains himself, that he did so, because at the coming upon the sun he perceived it at one side of the planet, and on the opposite side on its going off: for which reason he supposed that it surrounded it on all sides. See fig. 13. 14.

80 Spots when first seen on Mars.

5. Much larger and more remarkable spots have been perceived on the disk of Mars than that of any other primary planet. They were first observed in 1666 by Cassini at Bologna, with a telescope of Campani about $16\frac{1}{2}$ feet long; and continuing to observe them for a month, he found they came into the same situation in 24 hours and 40 minutes. The planet was observed by some astronomers at Rome with longer telescopes made by Eustachio Divini; but they assigned to it a rotation in 13 hours only. This, however, was afterwards shown by Mr Cassini to have been a mistake, and to have arisen from their not distinguishing the opposite sides of the planet, which it seems have spots pretty much alike. He made further observations on the spots of this planet in 1670; from whence he drew an additional confirmation of the time the planet took to revolve. The spots were again observed in subsequent oppositions; particularly for several days in 1704 by Maraldi, who took notice that they were not always well defined, and that they not only changed their shape frequently in the space between two oppositions, but even in the space of a month. Some of them, however, continued of the same form long enough to ascertain the time of the planet's revolution. Among these there appeared this year an oblong spot, resembling one of the belts of Jupiter when broken. It did not reach quite round the body of the planet; but had, not far from the middle of it, a small protuberance towards the north, so well defined that he was thereby enabled to settle the period of its revolution at 24 hours 39 minutes; only one minute less than what Cassini had determined it to be. See fig. 45. Plate LXVII.

The near approach of Mars to the earth in 1719 gave a much better opportunity of viewing him than had been obtained before; as he was then within $2\frac{1}{2}$ deg. of his perihelion, and at the same time in opposition to the sun. His apparent magnitude and brightness were thus so much increased, that he was by the vulgar taken for a new star. His appearance at that

time,

Appearances of Celestial Bodies thro' Telescopes.

Plate LXVII.

time, as seen by Maraldi through a telescope of 34 feet long, is represented fig. 46. There was then a long belt that reached half way round, to the end of which another shorter belt was joined, forming an obtuse angle with the former, as in fig. 47. This angular point was observed on the 19th and 20th of August, at 11 hours 15 minutes, a little east of the middle of the disk; and 37 days after, on the 25th and 26th of September, returned to the same situation. This interval, divided by 36, the number of revolutions contained in it gives 24 hours 40 minutes for the period of one revolution; which was verified by another spot of a triangular shape, one angle whereof was towards the north pole, and the base towards the south, which on the 5th and 6th of August appeared as in fig. 48. and after 72 revolutions returned to the same situation on the 16th and 17th of October. The appearances of Mars, as delineated by Mr Hook, when viewed through a 36 feet telescope, are represented fig. 28. He appeared through this instrument as big as the full moon. Some of the belts of this planet are said to be parallel to his equator; but that seen by Maraldi was very much inclined to it.

Plate LXIV.

81 Bright spots about the poles of Mars.

Besides these dark spots, the former astronomers took notice, that a segment of his globe about the south pole exceeded the rest of his disk so much in brightness, that it appeared beyond them as if it were the segment of a larger globe. Maraldi informs us, that this bright spot had been taken notice of for 60 years, and was more permanent than the other spots on the planet. One part of it is brighter than the rest, and the least bright part is subject to great changes, and has sometimes disappeared.

82 Mr Herschel's account of these spots.

A similar brightness about the north pole of Mars was also sometimes observed; and these observations are now confirmed by Mr Herschel, who hath viewed the planet with much better instruments, and much higher magnifying powers than any other astronomer ever was in possession of. His observations were made with a view to determine the figure of the planet, the position of his axis, &c. A very particular account of them is given in the 74th volume of the Philosophical Transactions, but which our limits will not allow us to insert. Figs 49—72. show the particular appearances of Mars, as viewed on the days there marked. The magnifying powers he used were sometimes as high as 932; and with this the south polar spot was found to be in diameter 41‴. Fig. 73 shows the connection of the other figures marked 64, 65, 66, 67, 68, 69, 70, which complete the whole equatorial succession of spots on the disk of the planet. The centre of the circle marked 65 is placed on the circumference of the inner circle, by making its distance from the circle marked 67 answer to the interval of time between the two observations, properly calculated and reduced to sidereal measure. The same is done with regard to the circles marked 66, 67, &c.; and it will be found by placing any one of these connected circles in such a manner as to have its contents in a similar situation with the figures in the single representation, which bears the same number, that there is a sufficient resemblance between them; though some allowance must undoubtedly be made for the distortions occasioned by this kind of projection.

Plate LXVII.

With regard to the bright spots themselves, Mr Herschel informs us, that the poles of the planet are not exactly in the middle of them, though nearly so. "From the appearance and disappearance (says he) of the bright north polar spot in the year 1781, we collect that the circle of its motion was at some considerable distance from the pole. By calculation, its latitude must have been about 76 or 77° north; for I find that, to the inhabitants of Mars, the declination of the sun, June 25th, 12 hours 15 minutes of our time was about 9° 56′ south; and the spot must have been so far removed from the north pole as to fall a few degrees within the enlightened part of the disk to become visible to us. The south pole of Mars could not be many degrees from the centre of the large bright southern spot of the year 1781; though this spot was of such a magnitude as to cover all the polar regions farther than the 70th or 65th degree; and in that part which was on the meridian, July 3d, at 10 hours 54 minutes, perhaps a little farther.

83 Causes of the appearance and disappearance of these spots.

"From the appearances of the south polar spot in 1781, we may conclude that its centre was nearly polar. We find it continued visible all the time Mars revolved on his axis; and to present us generally with a pretty equal share of the luminous appearance, a spot which covered from 45 to 60° of a great circle on the globe of the planet, could not have any considerable polar distance. From the observations and calculations made concerning the poles of Mars, we may conclude, that his north pole must be directed towards some point of the heavens, between $9^s\ 24^\circ\ 35'$ and $0^s\ 7^\circ\ 15'$; because the change of the situation of the pole from left to right, which happened in the time the planet passed from one place to the other, is a plain indication of its having gone through the node of its axis. Next, we may also conclude, that the node must be considerably nearer the latter point of the ecliptic than the former; for, whatever be the inclination of the axis, it will be seen under equal angles at equal distances from the node. But by a trigonometrical process of solving a few triangles, we soon discover both the inclination of the axis and the place where it intersects the ecliptic at rectangles (which, for want of a better term, I have perhaps improperly called it *node*). Accordingly I find by the calculation, that the node is in 17° 47′ of Pisces, the north pole of Mars being directed towards that part of the heavens; and that the inclination of the axis to the ecliptic is 59° 40′. By further calculations we find that the pole of Mars, on the 17th of April 1777, was then actually 81° 27′ inclined to the ecliptic, and pointed towards the left as seen from the sun.

84 Of the exact position of the poles of Mars.

"The inclination and situation of the node of the axis of Mars, with respect to the ecliptic, being found, may be thus reduced to the orbit of the planet himself. Let E C (fig. 74.) be a part of the ecliptic, O M part of the orbit of Mars, P E O a line drawn from P, the celestial pole of Mars, through E, that point which has been determined to be the place of the node of the axis of Mars in the ecliptic, and continued to O, where it intersects his orbit. Now, if, according to M. de La Lande, we put the node of the orbit of Mars for 1783 in $1^s\ 17^\circ\ 58'$, we have from the place of the node of the axis, that is, $11^s\ 17^\circ\ 47'$, to the place of the node of the orbit, an arch E N of 60° 11′. In the triangle N E O, right angled

Appearances of Celeſtial Bodies thro' Teleſcopes.

at E, there is alſo given the angle E N O, according to the ſame author, 1° 51′, which is the inclination of the orbit of Mars to the ecliptic. Hence we find the angle E O N 89° 5′, and the ſide O N 60° 12′. Again, when Mars is in the node of its orbit N, we have by calculation the angle P N E = 63° 7′; to which adding the angle E N O = 1° 51′, we have P N O = 64° 58′: from which two angles, P O N and P N O, with the diſtance O N, we obtain the inclination of the axis of Mars, and place of its node with reſpect to its own orbit; the inclination being 61° 18′, and the place of the node of the axis 58° 31′ preceding the interſection of the ecliptic with the orbit of Mars, or in our 19° 28′ of Piſces."

85 Of the ſeaſons in Mars.

Our author next proceeds to ſhow how the ſeaſons in this planet may be calculated, &c. Which conjectures, though they belong properly to the next ſection, yet are ſo much connected with what has gone before, that we ſhall inſert here what he ſays upon the ſubject.

"Being thus acquainted with what the inhabitants of Mars will call the obliquity of their ecliptic, and the ſituation of their equinoctial and ſolſtitial points, we are furniſhed with the means of calculating the ſeaſons on that planet, and may account, in a manner which I think highly probable, for the remarkable appearance about its polar regions.

"But firſt, it may not be improper to give an inſtance how to reſolve any query concerning the Martial ſeaſons. Thus, let it be required to compute the declination of the ſun on Mars, June 25. 1781, at midnight of our time. If ♈, ♉, ♊, ♋, &c. (fig. 75.) repreſent the ecliptic of Mars, and ♈ ♋ ♎ ♑ the ecliptic of our planet, A *a*, *b* B, the mutual interſection of the Martial and terreſtrial ecliptics, then there is given the heliocentric longitude of Mars, ♈ *m* = 9ˢ 10° 30′: then taking away ſix ſigns, and ♎ *b* or ♈ *a* = 1ˢ 17° 58′, there remains *b m* = 1ˢ 22° 32′. From this arch, with the given inclination, 1° 51′ of the orbits to teach other, we have coſine of inclination to radius, as tangent of *b m* to tangent of B M = 1ˢ 22° 33′. And taking away B ♈ = 1ˢ 1° 29′, which is the complement to ♑ B (or ♋ A, already ſhown to be 1ˢ 28° 31′), there will remain ♈ M = 0ˢ 21° 4′, the place of Mars in its own orbit; that is, on the time above mentioned, the ſun's longitude on Mars will be 6ˢ 21° 4′; and the obliquity of the Martial ecliptic, 28° 42′, being alſo given, we find, by the uſual method, the ſun's declination, 9° 56′ ſouth.

86 Conſiderable reſemblance betwixt the earth and Mars.

"The analogy between Mars and the earth is perhaps by far the greateſt in the whole ſolar ſyſtem. Their diurnal motion is nearly the ſame; the obliquity of their reſpective ecliptics not very different; of all the ſuperior planets, the diſtance of Mars from the ſun is by far the neareſt alike to that of the earth: nor will the length of the Martial year appear very different from what we enjoy, when compared to the ſurpriſing duration of the years of Jupiter, Saturn, and the Georgium Sidus. If then we find that the globe we inhabit has its polar regions frozen and covered with mountains of ice and ſnow, that only partly melt when alternately expoſed to the ſun, I may well be permitted to ſurmiſe, that the ſame cauſes may probably have the ſame effect on the globe of Mars; that the bright polar ſpots are owing to the vivid reflection of light from frozen regions; and that the reduction of thoſe ſpots is to be aſcribed to their being expoſed to the ſun. In the year 1781, the ſouth polar ſpot was extremely large, which we might well expect as that pole had but lately been involved in a whole twelvemonth's darkneſs and abſence of the ſun; but in 1783, I found it conſiderably ſmaller than before, and it decreaſed continually from the 20th of May till about the middle of September, when it ſeemed to be at a ſtand. During this laſt period the ſouth pole had already been above eight months enjoying the benefit of ſummer, and ſtill continued to receive the ſun-beams, though, towards the latter end, in ſuch an oblique direction as to be but little benefited by them. On the other hand, in the year 1781, the north polar ſpot, which had then been its twelvemonth in the ſunſhine, and was but lately returning into darkneſs, appeared ſmall, though undoubtedly increaſing in ſize. Its not being viſible in the year 1783, is no objection to theſe phenomena; being owing to the poſition of the axis, by which it was removed out of ſight.

87 White ſpots about the poles of Mars ſuppoſed to be occaſioned by ſnow.

88 Of the ſpheroidal form of Mars.

"That a planetary globe, ſuch as Mars, turning on an axis, ſhould be of a ſpheroidical form, will eaſily find admittance, when two familiar inſtances in Jupiter and the earth, as well as the known laws of gravitation and the centrifugal force of rotatory bodies, lead the way to the reception of ſuch doctrines. So far from creating difficulties or doubts, it will rather appear ſingular, that the ſpheroidical form of this planet has not already been noticed by former aſtronomers; and yet, reflecting on the general appearances of Mars, we ſoon find, that opportunities of making obſervations on its real form cannot be very frequent: for when it is near enough to view it to an advantage, we ſee it generally gibbous; and its appoſitions are ſo ſcarce, and of ſo ſhort a duration, that in more than two years time we have not above three or four weeks for ſuch obſervations. Beſides, aſtronomers being generally accuſtomed to ſee this planet diſtorted, the ſpheroidical form might eaſily be overlooked.

89 Difference betwixt the equatorial and polar diameters of Mars.

"September 25. 1783. At 9h. 50′, the equatorial diameter of Mars meaſured 21″ 53‴; the polar diameter 21″ 15‴, *full meaſure*; that is certainly not too ſmall. This difference of the diameters was ſhown, on the 28th of the ſame month, to Mr Wilſon of Glaſgow, who ſaw it perfectly well, ſo as to be convinced that it was not owing to any defect or diſtortion occaſioned by the lens: and becauſe I wiſhed him to be ſatisfied of the reality of the appearance, I reminded him of ſeveral precautions; ſuch as cauſing the planet to paſs directly through the centre of the field of view, and judging of its figure when it was moſt diſtinct and beſt defined, &c. Next day the difference between the two diameters was ſhown to Dr Blagden and Mr Aubert. The former not only ſaw it immediately, but thought the flattening almoſt as much as that of Jupiter. Mr Aubert alſo ſaw it very plainly, ſo as to entertain no manner of doubt about the appearance.

"September 30th, 10h. 52′, the equatorial diameter was 22″ 9‴, with a magnifying power of 278. By a ſecond meaſure it was 22″ 31‴, full large; the polar diameter, very exact, was 21″ 26‴. On the 1ſt of October, at 10h. 50′, the equatorial diameter meaſured 103 by the micrometer, and the polar 98; the value of the diviſions in ſeconds and thirds not being well determined,

determined, on account of ſome changes lately made in the focal length of the object metals of the teleſcope. On the 13th, the equatorial diameter was exactly 22″ 35‴; the polar diameter 21″ 33‴." In a great number of ſucceeding obſervations, the ſame appearance occurred; but on account of the quick changes in the appearance of this planet, Mr Herſchel thought proper to ſettle the proportion betwixt the equatorial and polar diameters from thoſe which were made on the very day of the appoſition, and which were alſo to be preferred on account of their being repeated with a very high power, and in a fine clear air, with two different inſtruments of an excellent quality. From theſe he determined the proportions to be as 103 to 98, or 1355 to 1272.

90 Of the atmoſphere of Mars.

It has been commonly related by aſtronomers, that the atmoſphere of this planet is poſſeſſed of ſuch ſtrong refractive powers, as to render the ſmall fixed ſtars near which it paſſes inviſible. Dr Smith relates an obſervation of Caſſini, where a ſtar in the water of Aquarius, at the diſtance of ſix minutes from the diſk of Mars, became ſo faint before its occultation that it could not be ſeen by the naked eye, nor with a three-feet teleſcope. This would indicate an atmoſphere of a very extraordinary ſize and denſity; but the following obſervations of Mr Herſchel ſeem to ſhow that it is of much ſmaller dimenſions. "1783, Oct. 26th, There are two ſmall ſtars preceding Mars, of different ſizes; with 460 they appear both duſky red, and are pretty unequal; with 278 they appear conſiderably unequal. The diſtance from Mars of the neareſt, which is alſo the largeſt, with 227 meaſured 3′ 26″ 20‴. Some time after, the ſame evening, the diſtance was 3′ 8″ 55‴, Mars being retrograde. Both of them were ſeen very diſtinctly. They were viewed with a new 20 feet reflector, and appeared very bright. October 27th, the ſmall ſtar is not quite ſo bright in proportion to the large one as it was laſt night, being a good deal nearer to Mars, which is now on the ſide of the ſmall ſtar; but when the planet was drawn aſide, or out of view, it appeared as plainly as uſual. The diſtance of the ſmall ſtar was 2′ 5″ 25‴. The largeſt of the two ſtars (adds he), on which the above obſervations were made, cannot exceed the 12th, and the ſmalleſt the 13th or 14th magnitude; and I have no reaſon to ſuppoſe that they were any otherwiſe affected by the approach of Mars, than what the brightneſs of its ſuperior light may account for. From other phenomena it appears, however, that this planet is not without a conſiderable atmoſphere; for beſides the permanent ſpots on its ſurface, I have often noticed occaſional changes of partial bright belts, and alſo once a darkiſh one in a pretty high latitude; and theſe alterations we can hardly aſcribe to any other cauſe than the variable diſpoſition of clouds and vapours floating in the atmoſphere of the planet."

91 Belts of Jupiter, when firſt diſcovered.

6. Jupiter has the ſame general appearance with Mars, only that the belts on his ſurface are much larger and more permanent. Their general appearance, as deſcribed by Dr Long, is repreſented fig. 76—79.; by Mr Dunn, fig. 18.; by Mr Wollaſton fig. 21. 22, 22.; and by Mr Ferguſon, fig. 153. But they are not to be ſeen but by an excellent teleſcope. They are ſaid to have been firſt diſcovered by Fontana and two other Italians; but Caſſini was the firſt who gave a good account of them. Their number is very variable, as ſometimes only one, and at others no fewer than eight, may be perceived. They are generally parallel to one another, but not always ſo; and their breadth is likewiſe variable, one belt having been obſerved to grow narrow, while another in its neighbourhood has increaſed in breadth, as if the one had flowed into the other: and in this caſe Dr Long obſerves, that a part of an oblique belt lay between them, as if to form a communication for this purpoſe. The time of their continuance is very uncertain, ſometimes remaining unchanged for three months; at others, new belts have been formed in an hour or two.

92 Spots ſometimes appear in them.

In ſome of theſe belts large black ſpots have appeared, which moved ſwiftly over the diſk from eaſt to weſt, and returned in a ſhort time to the ſame place; from whence the rotation of this planet about its axis has been determined. On the 9th of May 1664, Dr Hook, with a good 12 feet teleſcope, obſerved a ſmall ſpot in the biggeſt of the three obſcure belts of Jupiter; and obſerving it from time to time, found that in two hours it had moved from eaſt to weſt about half the viſible diameter of the planet. In 1665, Caſſini obſerved a ſpot near the largeſt belt of Jupiter which is moſt frequently ſeen. It appeared round, and moved with the greateſt velocity when in the middle, but appeared narrower, and moved ſlower, the nearer it was to the circumference. "Theſe circumſtances (ſays Dr Long), ſhowed that the ſpot adhered to the body of Jupiter, and was carried round upon it. It continued thereon till the year following; long enough to determine the periodical time of Jupiter's rotation upon his axis to be nine hours 56 minutes."

93 Account of one theſe ſpots.

This principal, or ancient ſpot as it is called, is the largeſt, and of the longeſt continuance of any hitherto known, has appeared and vaniſhed no fewer than eight times between the years 1665 and 1708: from the year laſt mentioned it was inviſible till 1713. The longeſt time of its continuing to be viſible was three years; and the longeſt time of its diſappearing was from 1708 to 1713: it ſeems to have ſome connection with the principal ſouthern belt; for the ſpot has never been ſeen when that diſappeared, though that belt has often been viſible without the ſpot. Beſides this ancient ſpot, Caſſini, in the year 1699, ſaw one of leſs ſtability that did not continue, of the ſame ſhape or dimenſions, but broke into ſeveral ſmall ones, whereof the revolution was but nine hours 51 minutes; and two other ſpots that revolved in nine hours 52 minutes and a half. The figure of Jupiter is evidently an oblate ſpheroid, the longeſt diameter of his diſk being to the ſhorteſt as 13 to 12. His rotation is from weſt to eaſt, like that of the ſun, and the plane of his equator is very nearly coincident with that of his orbit; ſo that there can ſcarce be any difference of ſeaſons in that planet. His rotation has been obſerved to be ſomewhat quicker in his aphelion than his perihelion.

94 No difference of ſeaſons in Jupiter.

95 Is attended by four moons.

The moſt remarkable circumſtance attending this planet is his having four moons, which conſtantly revolve round him at different diſtances. See fig. 18. and 186. Theſe are all ſuppoſed to move in ellipſes; though the excentricities of all of them are too ſmall to be meaſured, excepting that of the fourth; and even this amounts to no more than 0.007 of its mean diſtance from the primary. The orbits of theſe planets were

thought

Appearances of Celestial Bodies thro' Telescopes.

thought by Galileo to be in the same plane with that of their primary: but M. Cassini has found that their orbits make a small angle with it; and as he did not find any difference in the place of their nodes, he concluded that they were all in the same place, and that their ascending nodes were in the middle of Aquarius. After observing them for more than 36 years, he found their greatest latitude, or deviation from the plane of Jupiter's orbit, to be 2° 55′. The first of these satellites revolves at the distance of 5.697 of Jupiter's semidiameters, or 1′ 51″ as measured by proper instruments; its periodical time is 1 d. 18 h. 27′ 34″. The next satellite revolves at the distance of 9.017 semidiameters, or 2′ 56″, in 3d. 13h. 13′ 42″; the third at the distance of 14.384 semidiameters, or 4′ 42″, in 7d. 3h. 42′ 36″; and the fourth at the distance of 25.266, or 8′ 16″, in 16d. 16h. 32′ 09″.

96 Distances and periodical times of Jupiter's moons.

Since the time of Cassini, it has been found that the nodes of Jupiter's satellites are not in the same place; and from the different points of view in which we have an opportunity of observing them from the earth, we see them sometimes apparently moving in straight lines, and at other times in elliptic curves. All of them, by reason of their immense distance, seem to keep near their primary, and their apparent motion is a kind of oscillation like that of a pendulum, going alternately from the geatest distance on one side to the greatest distance on the other, sometimes in a straight line, and sometimes in an elliptic curve. When a satellite is in its superior semicircle, or that half of its orbit which is more distant from the earth than Jupiter is, its motion appears to us direct, according to the order of the signs; but in its inferior semicircle, when it is nearer to us than Jupiter, its motion appears retrograde; and both these motions seem quicker the nearer the satellites are to the centre of the primary, slower the more distant they are, and at the greatest distance of all they appear for a short time to be stationary.

97 Occultations and eclipses of Jupiter's satellites.

From this account of the system of Jupiter and his satellites, it is evident, that occultations of them must frequently happen by their going behind their primary, or by coming in betwixt us and it. The former takes place when they proceed towards the middle of the upper semicircle; the latter, when they pass through the same part of their inferior semicircle. Occultations of the former kind happen to the first and second satellite; at every revolution, the third very rarely escapes an occultation, but the fourth more frequently by reason of its greater distance. It is seldom that a satellite can be discovered upon the disk of Jupiter, even by the best telescopes, excepting at its first entrance, when by reason of its being more directly illuminated by the rays of the sun than the planet itself, it appears like a lucid spot upon it. Sometimes, however, a satellite in passing over the disk, appears like a dark spot, and is easily to be distinguished. This is supposed to be owing to spots on the body of these secondary planets; and it is remarkable, that the same satellite has been known to pass over the disk at one time as a dark spot, and at another so luminous that it could not be distinguished from Jupiter himself, except at its coming on and going off. To account for this, we must say, that either the spots are subject to change; or if they be permanent, like those of our moon, that the satellites at different times turn different parts of their globes towards us. Possibly both these causes may contribute to produce the phenomena just mentioned. For these reasons also both the light and apparent magnitude of the satellites are variable: for the fewer spots there are upon that side which is turned towards us, the brighter it will appear; and as the bright side only can be seen, a satellite must appear larger the more of its bright side it turns towards the earth, and the less so the more it happens to be covered with spots. The fourth satellite, though generally the smallest, sometimes appears bigger than any of the rest: the third sometimes seems least, though usually the largest; nay, a satellite may be so covered with spots as to appear less than its shadow passing over the disk of the primary, though we are certain that the shadow must be smaller than the body which casts it. To a spectator placed on the surface of Jupiter, each of these satellites would put on the phases of the moon; but as the distance of any of them from Jupiter is but small when compared with the distance of that planet from the sun, the satellites are therefore illuminated by the sun very nearly in the same manner with the primary itself; hence they apper to us always round, having constantly the greatest part of their enlightened half turned towards the earth; and indeed they are so small, that were they to put on the phases of the moon, these phases could scarce be discerned through the best telescopes.

98 The satellites sometimes appear as dark spots

99 Why they vary in their light and apparent magnitude.

100 Their shadows sometimes visible on the disk of Jupiter.

When the satellites pass through their inferior semicircles, they may cast a shadow upon their primary, and thus cause an eclipse of the sun to his inhabitants if there are any; and in some situations this shadow may be observed going before or following the satellite. On the other hand, in passing through their superior semicircles, the satellites may be eclipsed in the same manner as our moon, by passing through the shadow of Jupiter: and this is actually the case with the first, second, and third of these bodies; but the fourth, by reason of the largeness of its orbit, passes sometimes above or below the shadow, as is the case with our moon. The beginnings and ending of these eclipses are easily seen by a telescope when the earth is in a proper situation with regard to Jupiter and the sun; but when this or any other planet is in conjunction with the sun, the superior brightness of that luminary renders both it and the satellites invisible. From the time of its first appearing after a conjunction until near the opposition, only the immersions of the satellites into his shadow, or the beginnings of the eclipses, are visible; at the opposition, only the occultations of the satellites, by going behind or coming before their primary, are observable; and from the opposition to the conjunction, only the emersions, or end of the eclipses, are to be seen. This is exactly true in the first satellite, of which we can never see an immersion with its immediately subsequent emersion: and it is but rarely that they can be both seen in the second; as in order to their being so, that satellite must be near one of its limits, at the same time that the planet is near his perihelion and quadrature with the sun. With regard to the third, when Jupiter is more than 46 degrees from conjunction with, or opposition to the sun, both its immersions and immediately subsequent emersions are visible; as they likewise are in the fourth, when the distance of Jupiter from conjunction or opposition is 24 degrees.

101 Three of Jupiter's moons eclipsed in every revolution.

102 At what time the eclipses, occultations, &c. of Jupiter's satelites are visible.

When

Appearances of Celestial Bodies thro' Telescopes.

When Jupiter is in quadrature with the sun, the earth is farthest out of the line that passes through the centres of the sun and Jupiter, and therefore the shadow of the planet is then most exposed to our view; but even then the body of the planet will hide from us one side of that part of the shadow which is nearest to it, through which the first satellite passes; which is the reason that, though we see the entrance of that satellite into the shadow, or its coming out from thence, as the earth is situated on the east or west side thereof, we cannot see them both; whereas the other satellites going through the shadow at a greater distance from Jupiter, their ingress and egress are both visible.

103 Telescopic appearance of Saturn.

7. Saturn, when viewed through a good telescope, makes a more remarkable appearance than any of the other planets. Galileo first discovered his uncommon shape, which he thought to be like two small globes, one on each side of a large one: and he published his discovery in a Latin sentence; the meaning of which was, that he had seen him appear with three bodies; though, in order to keep the discovery a secret, the letters were transposed. Having viewed him for two years, he was surprised to see him become quite round without these appendages, and then after some time to assume them as before. These adjoining globes were what are now called the *ansæ* of his ring, the true shape of which was first discovered by Huygens about 40 years after Galileo, first with a telescope of 12 feet, and then with one of 23 feet, which magnified objects 100 times. From the discoveries made by him and other astronomers, it appears that this planet is surrounded by a broad thin ring, the edge of which reflects little or none of the sun's light to us, but the planes of the ring reflect the light in the same manner that the planet itself does; and if we suppose the diameter of Saturn to be divided into three equal parts, the diameter of the ring is about seven of these parts. The ring is detached from the body of Saturn in such a manner, that the distance between the innermost part of the ring and the body is equal to its breadth. If we had a view of the planet and his ring, with our eyes, perpendicular to one of the planes of the latter, we should see them as in fig. 80.: but our eye is never so much elevated above either plane as to have the visual ray stand at right angles to it; nor indeed is it ever elevated more than about 30 degrees above it; so that the ring, being commonly viewed at an oblique angle, appears of an oval form, and through very good telescopes double, as represented fig. 18. and 153. Both the outward and inward rim is projected into an ellipsis, more or less oblong according to the different degrees of obliquity with which it is viewed. Sometimes our eye is in the plane of the ring, and then it becomes invisible; either because the outward edge is not fitted to reflect the sun's light, or more probably because it is too thin to be seen at such a distance. As the plane of this ring keeps always parallel to itself, that is, its situation in one part of the orbit is always parallel to that in any other part, it disappears twice in every revolution of the planet, that is, about once in 15 years; and he sometimes appears quite round for nine months together. At other times, the distance betwixt the body of the planet and the ring is very perceptible; insomuch that Mr Whiston tells us of Dr Clarke's father having seen a star through the opening, and supposed him to have been the only person who ever saw a sight so rare, as the opening, though certainly very large, appears very small to us. When Saturn appears round, if our eye be in the plane of the ring, it will appear as a dark line across the middle of the planet's disk; and if our eye be elevated above the plane of the ring, a shadowy belt will be visible, caused by the shadow of the ring as well as by the interposition of part of it betwixt the eye and the planet. The shadow of the ring is broadest when the sun is most elevated, but its obscure parts appear broadest when our eye is most elevated above the plane of it. When it appears double, the ring next the body of the planet appears brightest; when the ring appears of an elliptical form, the parts about the ends of the largest axis are called the *ansæ*, as has been already mentioned. These, a little before and after the disappearing of the ring, are of unequal magnitude: the largest ansa is longer visible before the planets round phase, and appears again sooner than the other. On the 1st of October 1714, the largest ansa was on the east side, and on the 12th on the west side of the disk of the planet, which makes it probable that the ring has a rotation round an axis: but whether or not this is the case with Saturn himself has not been discovered, on account of the deficiency of spots by which it might be determined. He has indeed two belts, discovered with very long telescopes, which appear parallel to that formed by the edge of the ring above mentioned; but these are rectilinear when the ring appears elliptic, as in fig. 81. and seem to be permanent. In 1683, however, Dom. Cassini and Fatio perceived a bright streak upon Saturn, which was not permanent like the dark belts, but was visible one day and disappeared the next, when another came into view near the edge of his disk. This induced Cassini to suppose, that Saturn might have a rotation round his axis; but the distance of this planet is so great, that we can scarce hope to determine his revolation so accurately as that of the others. It disappeared in May 1789; the earth being about to pass from its northern side, which is enlightened, to the southern, which is obscure.

104 His ring first discovered by Huygens.

105 Ring of Saturn probably has a revolution on its axis.

106 Belts discovered on Saturn.

The astronomer-royal (Dr Maskelyne) informs us of this disappearance in 1789, and reappearance in 1790, in the following manner: "On May 3d and August 26th 1789, the plane of Saturn's ring will pass through the earth; in October 11th it will pass through the sun; and January 29th 1790 it will again pass through the earth. Hence, and supposing with M. de la Lande that the ring is but just visible with the best telescopes in common use, when the sun is elevated 3′ above its plane, or 3 days before the plane passes through the sun, and when the earth is elevated 2¼′ above the plane, or one day from the earth's passing it, the phenomena of disappearance and reappearance may be expected to take place as follows.

"May 2d 1789, Saturn's ring will disappear; the earth being about to pass from its northern side, which is enlightened, to its southern side, which is obscure.

"August 27th, the earth having repassed to the northern or enlightened side, the ring will reappear.

"October 8th, the ring will disappear; its plane being near passing through the sun, when it will change its enlightened side from the northern to the southern one,

ASTRONOMY

Plate LXV

one, conſequently the dark ſide will be then turned to the earth.

"January 30th 1790, the earth having paſſed from the northern or dark ſide of the ring, to the ſouthern or enlightened one, the ring will become viſible, to continue ſo until the year 1803."

In the diagram, fig. 159 are delineated the phaſes of the ring from its full appearance in the year 1782 to its diſappearance in 1789, and its full reappearance 1796.

107 His five ſatellites.

Saturn is ſtill better attended than Jupiter (ſee fig. 18. and 186); having, beſides the ring abovementioned, no fewer than five moons continually circulating round him. The firſt, at the diſtance of 2.097 ſemidiameters of his ring, and 4.893 of the planet itſelf, performs its revolution in 1d. 21h. 18′ 27″; the ſecond, at 2.686 ſemidiameters of the ring, and 6.268 of Saturn, revolves in 2d. 17h. 41′ 22″: the third, at the diſtance of 8.754 ſemidiameters of Saturn, and 3.752 of the ring, in 4d, 12h. 25′ 12″; the fourth, called the *Huygenian ſatellite*, at 8.698 ſemidiameters of the ring, and 20.295 of Saturn, revolves in 15d. 21h. 41′ 12″; while the fifth, placed at the vaſt diſtance of 59.154 ſemidiameters of Saturn, or 25.348 of his ring, does not perform its revolution in leſs than 79d. 7h. 47′ 00″. The orbits of all theſe ſatellites, except the fifth, are nearly in the ſame plane, which makes an angle with the plane of Saturn's orbit of about 31°; and by reaſon of their being inclined at ſuch large angles, they cannot paſs either acroſs their primary or behind it with reſpect to the earth, except when very near their nodes; ſo that eclipſes of them happen much more ſeldom than of the ſatellites of Juper. There is, however, an account in the Philoſ. Tranſact. of an occultation of the fourth ſatellite behind the body of Saturn; and there is a curious account by Caſſini, in the Memoirs of the Royal Academy for 1692, of a fixed ſtar being covered by the fourth ſatellite, ſo that for 13 minutes they appeared both as one ſtar. By

108 Fifth ſatellite ſometimes diſappears, and why.

reaſon of their extreme ſmallneſs, theſe ſatellites cannot be ſeen unleſs the air is very clear; and Dom. Caſſini for ſeveral years obſerved the fifth ſatellite to grow leſs and leſs as it went through the eaſtern part of its orbit until it became quite inviſible, while in the weſtern part it gradually became more and more bright until it arrived at its greateſt ſplendor.—"This phenomenon (ſays Dr Long) cannot be better accounted for than by ſuppoſing one half of the ſurface of this ſatallite to be unfit to reflect the light of the ſun in ſufficient quantity to make it viſible, and that it turns round its axis nearly in the ſame time as it revolves round its primary; and that, by means of this rotation, and keeping always the ſame face toward Saturn, we upon the earth may during one half of its periodical time, be able to ſee ſucceſſively more and more of its bright ſide, and during the other half of its period have more and more of the ſpotted or dark ſide turned toward us. In the year 1705, this ſatellite unexpectedly became viſible in all parts of its orbit through the very ſame teleſcopes that were before often made uſe of to view it in the eaſtern part without ſucceſs: this ſhows the ſpots upon this ſatellite, like thoſe upon Jupiter and ſome other of the primary planets, are not permanent, but ſubject to change."

8. With regard to the Georgium Sidus, ſtill leſs is known than of Saturn. Its apparent magnitude is ſo ſmall, that it can ſeldom be ſeen with the naked eye; and even with the teleſcope it appears but of a few ſeconds diameter. It is attended by two ſatellites at the proportional diſtances marked in fig. 82. according to the obſervations of Mr. Herſchel; but he had not an opportunity of obſerving them long enough to determine their periodical times with exactneſs; though he ſuppoſes the innermoſt to perform its revolution in about eight days and three quarters, the other in thirteen days and a half.

109 Georgium Sidus attended by two ſatellites.

110 Of the comets.

9. The Comets, viewed through a teleſcope, have a very different appearance from any of the planets. The nucleus, or ſtar, ſeems much more dim. Sturmius tells us, that obſerving the comet of 1680 with a teleſcope, it appeared like a coal dimly glowing; or a rude maſs of matter illuminated with a duſky fumid light, leſs ſenſible at the extremes than in the middle; and not at all like a ſtar, which appears with a round diſk and a vivid light.

Hevelius obſerved of the comet in 1661, that its body was of a yellowiſh colour, bright and conſpicuous, but without any glittering light. In the middle was a denſe ruddy nucleus, almoſt equal to Jupiter, encompaſſed with a much fainter, thinner matter.—Feb. 5th. The nucleus was ſomewhat bigger and brighter, of a gold colour, but its light more duſky than the reſt of the ſtars; it appeared alſo divided into a number of parts.—Feb. 6th. The nuclei ſtill appeared, though leſs than before. One of them on the left ſide of the lower part of the diſk appeared to be much denſer and brighter than the reſt; its body round, and repreſenting a little lucid ſtar; the nuclei ſtill encompaſſed with another kind of matter.—Feb. 10th. The nuclei more obſcure and confuſed, but brighter at top than at bottom.—Feb. 13th. The head diminiſhed much both in brightneſs and in magnitude.—March 2d. Its roundneſs a little impaired, and the edges lacerated.—March 28th. Its matter much diſperſed; and no diſtinct nucleus at all appearing.

Wiegelius, who ſaw through a teleſcope the comet of 1664, the moon, and a little cloud illuminated by the ſun, at the ſame time; obſerved that the moon appeared of a continued luminous ſurface, but the comet very different, being perfectly like the little cloud enlightened by the ſun's beams.

111 Their atmoſpheres and phaſes.

The comets, too, are to appearance ſurrounded with atmoſpheres of a prodigious ſize, often ariſing ten times higher than the nucleus. They have often likewiſe different phaſes, like the moon.

112 Dr Long's account of them.

"The head of a comet (ſays Dr Long) to the eye, unaſſiſted by glaſſes, appears ſometimes like a cloudy ſtar; ſometimes ſhines with a dull light like that of the planet Saturn; ſome comets have been ſaid to equal, ſome to exceed, ſtars of the firſt magnitude; ſome to have ſurpaſſed Jupiter, and even Venus; and to have caſt a ſhadow as Venus ſometimes does.

"The head of a comet, ſeen through a good teleſcope, appears to conſiſt of a ſolid globe, and an atmoſphere that ſurrounds it. The ſolid part is frequently called the *nucleus*; which through a teleſcope is eaſily diſtinguiſhed from the atmoſphere or hairy appearance.

"A comet is generally attended with a blaze or tail, whereby it is diſtinguiſhed from a ſtar or planet;

as

Appearances of Celeſtial Bodies thro' Teleſcopes.

as it is alſo by its motion. Sometimes the tail only of a comet has been viſible at a place where the head has been all the while under the horizon; ſuch an appearance is called a *beam*.

113 Appearances of the comet of 1618.

"The nucleus of the comet of 1618 is ſaid, a few days after coming into view, to have broken into three or four parts of irregular figures. One obſerver compares them to ſo many burning coals; and ſays they changed their ſituation while he was looking at them, as when a perſon ſtirs a fire; and a few days after were broken into a great number of ſmaller pieces. Another account of the ſame is that on the 1ſt and 4th of December, the nucleus appeared to be a round, ſolid, and luminous body, of a duſky lead colour, larger than any ſtar of the firſt magnitude. On the 8th of the ſame month it was broken into three or four parts of irregular figures; and on the 20th was changed into a cluſter of ſmall ſtars.

114 Phenomena of their tails.

"As the tail of a comet is owing to the heat of the ſun, it grows larger as the comet approaches near to, and ſhortens as it recedes from, that luminary. If the tail of a comet were to continue of the ſame length, it would appear longer or ſhorter according to the different views of the ſpectator; for if his eye be in a line drawn through the middle of the tail lengthwiſe, or nearly ſo, the tail will not be diſtinguiſhed from the reſt of the atmoſphere, but the whole will appear round; if the eye be a little out of that line, the tail will appear ſhort as in fig. 83. and it is called a *bearded comet* when the tail hangs down towards the horizon, as in that figure. If the tail of a comet be viewed ſideways, the whole length of it is ſeen. It is obvoius to remark, that the nearer the eye is to the tail, the greater will be the apparent length thereof.

"The tails of comets often appear bent, as in fig. 84 and 85, owing to the reſiſtance of the æther; which, though extremely ſmall, may have a ſenſible effect on ſo thin a vapour as the tails conſiſts of. This bending is ſeen only when the earth is not in the plane of the orbit of the comet continued. When that plane paſſes thro' the eye of the ſpectator, the tail appears ſtraight, as in fig. 86, 87.

"Longomontanus mentions a comet, that, in 1618, Dec. 10th, had a tail above 100 degrees in length; which ſhows that it muſt then have been very near the earth. The tail of a comet will at the ſame time appear of different length in different places, according as the air in one place is clearer than in another. It need not be mentioned, that in the ſame place, the difference in the eyes of their ſpectators will be the cauſe of their diſagreeing in their eſtimate of the length of the tail of a comet.

115 Difference between the obſervations of Hevelius and Hooke.

"Hevelius is very particular in telling us, that he obſerved the comet of 1665 to caſt a ſhadow upon the tail; for in the middle thereof there appeared a dark line. It is ſomewhat ſurpriſing, that Hooke ſhould be poſitive in affirming, on the contrary, that the place where the ſhadow of that comet ſhould have been, if there had been any ſhadow, was brighter that any other part of the tail. He was of opinion that comets have ſome light of their own. His obſervations were made in a hurry; he owns they were ſhort and tranſitory: Hevelius's were made with ſo much care, that there is more reaſon to depend upon them. Dom. Caſſini obſerved, in the tail of the comet of 1680, a darkneſs in the middle; and the like was taken notice of by a curious obſerver in that of 1744.

Appearances of Celeſtial Bodies thro' Teleſcopes.

"There are three comets, viz. of 1680, 1744, and 1759, that deſerve to have a farther account given of them. The comet of 1680 was remarkable for its near approach to the ſun; ſo near, that in its perihelion it was not above a ſixth part of the diameter of that luminary from the ſurface thereof. Fig. 85, taken from Newton's Principia, repreſents ſo much of the trajectory of this comet as it paſſed through while it was viſible to the inhabitants of our earth, in going from and returning to its perihelion. It ſhows alſo the tail as it appeared on the days mentioned in the figure. The tail, like that of other comets, increaſed in length and brightneſs as it came nearer to the ſun; and grew ſhorter and fainter as it went farther from him and from the earth, till that and the comet were too far off to be any longer viſible.

116 Account of the comet of 1680.

117 Of that of 1744.

"The comet of 1744 was firſt ſeen at Lauſanne in Switzerland, Dec. 13th, 1743, N. S. From that time it increaſed in brightneſs and magnitude as it was coming nearer to the ſun. The diameter of it, when at the diſtance of the ſun from us, meaſured about one minute; which brings it out equal to three times the diameter of the earth. It came ſo near Mercury, that, if its attraction had been proportionable to its magnitude, it was thought probable it would have diſturbed the motion of that planet. Mr Betts of Oxford, however, from ſome obſervations made there, and at Lord Macclesfield's obſervatory at Sherburn, found, that when the comet was at its leaſt diſtance from Mercury, and almoſt twice as near the ſun as that planet was, it was ſtill diſtant from him a fifth part of the diſtance of the ſun from the earth; and could therefore have no effect upon the planet's motions. He judged the comet to be at leaſt equal in magnitude to the earth. He ſays, that in the evening of Jan. 23, this comet appeared exceedingly diſtinct and bright, and the diameter of its nucleus nearly equal to that of Jupiter. Its tail extended above 16 degrees from its body; and was in length, ſuppoſing the ſun's parallax 10″, no leſs than 23 millions of miles. Dr Bevis, in the month of May 1744, made four obſervations of Mercury, and found the places of that planet, calculated from correct tables, differed ſo little from the places obſerved, as to ſhow that the comet had no influence upon Mercury's motion.

"The nucleus, which had before been always round, on the 10th of February appeared oblong in the direction of the tail, and ſeemed divided into two parts by a black ſtroke in the middle. One of the parts had a ſort of beard brighter than the tail; this beard was ſurrounded by two unequal dark ſtrokes, that ſeparated the beard from the hair of the comet. The odd phenomena diſappeared the next day, and nothing was ſeen but irregular obſcure ſpaces like ſmoke in the middle of the tail; and the head reſumed its natural form. Feb. 15th, the tail was divided into two branches; the eaſtern part about ſeven or eight degrees long, the weſtern 24. On the 23d, the tail began to be bent; it ſhowed no tail till it was as near to the ſun as the orbit of Mars; the tail grew longer as it approached nearer the ſun; and at its greateſt length was computed to equal a third part of the diſtance of the earth from the ſun. Fig. 84. is a view of this comet, taken

by

Appearances of Celestial Bodies thro' Telescopes.

by an observer at Cambridge. I remember that in viewing it I thought the tail seemed to sparkle, or vibrate luminous particles. Hevelius mentions the like in other comets; and that their tails lengthen and shorten while we are viewing. This is probably owing to the motion of our air.

118 Of the comet of 1759.

"The comet of 1759 did not make any considerable appearance by reason of the unfavourable situation of the earth all the time, its tail might otherwise have been conspicuous; the comet being then too near the sun to be seen by us; but deserves our particular consideration, as it was the first that ever had its return foretold." See the following Section.

Hevelius gives pictures of comets of various shapes; as they are described by historians to have been like a sword, a buckle, a tun, &c. These are drawn by fancy only, from the description in words. He gives, however, also pictures of some comets, engraved by his own hand from the views he had of them through a very long and excellent telescope. In these we find changes in the nucleus and the atmosphere of the same comet. The nucleus of the comet of 1661, which in one observation appeared as one round body, as it is represented in fig. 87. in subsequent views seemed to consist of several smaller ones separated from one another, as in fig. 86. The atmosphere surrounding the nucleus, at different times, varied in the extent thereof; as did also the tail in length and breadth. The nuclei of other comets, as has already been observed, have sometimes phases like the moon. Those of 1744 and 1769 had both this kind of appearance. See fig. 34.

119 Number of fixed stars increased by telescope.

10. The fixed stars, when viewed through the best telescopes, appear not at all magnified, but rather diminished in bulk; by reason, as is thought by some, that the telescope takes off that twinkling appearance they make to the naked eye; but by others more probably, that the telescopic tube excludes a quantity of the rays of light, which are not only emitted from the particular stars themselves, but by many thousands more, which falling upon our eye-lids and the aërial particles about us, are reflected into our eyes so strongly as to excite vibrations, not only on those points of the retina where the images of the stars are formed, but also in other points at the same distance round about. This without the telescope makes us imagine the stars to be much bigger than when we see them only by a few rays coming directly from them, so as to enter our eyes without being intermixed with others. The number of stars appears increased prodigiously through the telescope; 70 stars have been counted in the constellation called *Pleiades*, and no fewer than 2000 in that of Orion. The late improvements of Mr Herschel, however, have shown the number of stars to be exceedingly beyond even what the discoveries of former astronomers would induce us to suppose. He has also shown, that many which to the eye, or through ordinary glasses, appear single, do in fact consist of two or more stars; and that the galaxy or milky-way owes its light entirely to multitudes of small stars placed so close that the naked eye, or even ordinary telescopes, cannot discover them.

120 Of the nebulæ.

He has shown also, that the nebulæ, or small whitish specks, discoverable by telescopes in various parts of the heavens, are owing to the same cause. Former astronomers could only reckon 103; but Dr Herschel has discovered upwards of 1250. He has also discovered a species of them, which he calls *planetary nebulæ*, on account of their brightness and shining with a well-defined disk, being also capable of being magnified more than the fixed stars.

Conclusions from the foregoing Appearances.

Sect. III. *Conclusions from the foregoing Appearances.*

The conjectures which have been formed concerning the nature of the celestial bodies are so numerous, that a recital of them would fill a volume; while at the same time many of them are so ridiculous, that absurdity itself would seem almost to have been exhausted on this subject.

121 Opinions of the ancients concerning the sun.

1. As a specimen of what were the opinions of the ancient philosophers concerning the nature of the sun, it may suffice to mention that Anaximander and Anaximenes held, that there was a circle of fire all along the heavens, which they called *the circle of the sun*; between the earth and this fiery circle was placed another circle of some opaque matter, in which there was a hole like the mouth of a German flute. Through this hole the light was transmitted, and appeared to the inhabitants of this earth as a round and distinct body of fire. The eclipses of the sun were occasioned by stopping this hole.

We must not, however, imagine, that the opinions of all the ancients were equally absurd with those of Anaximander and Anaximenes. Many of them had more just notions, though very imperfect and obscure. Anaxagoras held the sun to be a fiery globe of some solid substance, bigger than Peloponnesus; and many of the moderns have adopted this notion, only increasing the magnitude of the globe prodigiously. Sir Isaac Newton has proposed it as a query, Whether the sun and fixed stars are not great *Earths* made vehemently hot, whose parts are kept from fuming away by the vast weight and density of their superincumbent atmospheres, and whose heat is preserved by the prodigious action and reaction of their parts upon one another? But though Sir Isaac has proposed this as a query and taken the existence of a solar atmosphere for granted, there have yet been no proofs adduced in favour of that opinion besides those of analogy and probability. There is however, an appearance in the heavens termed the *semita luminosa*, or *zodiacal light*, which is now generally supposed to be owing to the sun's atmosphere. This was first discovered by Dom. Cassini in 1683. It is something like the milky-way, a faint twilight, or the tail of a comet, thin enough to let stars be seen through it, and seems to surround the sun in the form of a lens, the plane whereof is nearly coincident with that of the sun's equator. It is seen stretched along the zodiac, and accompanies the sun in his annual motion through the twelve signs. Each end terminates in an angle of about 21°: the extent of it in length from either of the angular points varies from 50 to 100°; it reaches beyond the orbit of Venus, but not so far as that of the earth. The breadth of it near the horizon is also various; from 12 almost to 30°: near the sun, where it may reasonably be supposed to be broadest, it cannot be seen. This light is weakest in the morning and strongest at night; disappearing in full

122 Of Sir Isaac Newton.

123 Of the existence of a solar atmosphere.

124 Semita luminosa, or zodiacal light.

Conclusions from the foregoing Appearances.

moonlight or in strong twilight, and therefore is not at all visible about midsummer in places so near either of the poles as to have their twilight all the night long, but may be seen in those places in the middle of winter both morning and evening, as it may in places under and near the equator all the year round. In north latitude it is most conspicuous after the evening twilight about the latter end of February, and before the morning twilight in the beginning of October; for at those times it stands most erect above the horizon, and is therefore clearest from the thick vapours of the twilight. Besides the difference of real extension of this light in length and breadth at different times, it is diminished by the nearness of any other light in the sky; not to mention that the extent of it will be differently determined by different spectators according to the goodness of their eyes.

125 Cassini's explanation of this phenomenon.

Cassini inquiring into the cause of this light, says first, that it might be owing to a great number of small planets surrounding the sun within the orbit of Venus; but soon rejects this for what he thinks a more probable solution, viz. that as by the rotation of the sun some gross parts are thrown up on his surface, whereof spots and nebulosities are formed; so the great rapidity wherewith the equatorial parts are moved, may throw out to a considerable distance a number of particles of a much finer texture, of sufficient density to reflect light: now, that this light was caused by an emanation from the sun, similar to that of the spots, he thought probable from the following observation: That after the year 1688, when this light began to grow weaker, no spots appeared upon the sun; whereas, in the preceding years, they were frequently seen there; and that the great inequality in the intervals between the times of the appearances of the solar spots has some analogy to the irregular returns of weakness and strength in this light, in like circumstances of the constitution of the air, and of the darkness of the sky. Cassini was of opinion that this light in the zodiac, as it is subject to great increase at one time and diminution at another, may sometimes become quite imperceptible; and thought this was the case in the years 1665, 1672, and 1681, when he saw nothing of it, though he surveyed with great attention those parts of the heaven where, according to his theory, it must have appeared if it had been as visible then as it was in others. He cites also passages out of several authors both ancient and modern, which make it probable that it had been seen both in former and latter ages, but without being sufficiently attended to, or its nature inquired into. It had been taken for the tail of a comet, part of the twilight, or a meteor of short continuance; and he was fully convinced of its having appeared formerly, from a passage in an English book of Mr Childrey's, printed in 1661. This passage is as follows:

126 Supposes some analogy between the solar spots and zodiacal light.

"There is something more that we would recommend to the observation of the mathematicians; namely, that in the month of February, and a little before and after it (as I have observed for several years), about six o'clock in the evening, when the twilight has entirely left the horizon, a path of light tending from the twilight towards the Pleiades, and touching them as it were, presented itself very plainly to my view. This path is to be seen when the weather is clear, but best of all when the moon does not shine." The same appearance is taken notice of in Gregory's Astronomy; and there expressly attributed to the sun's atmosphere.

With regard to the solar spots, Dr Long informs us, that "they do not change their places upon the sun, but adhere to his surface, or float in his atmosphere, very near his body; and if there be 20 spots or faculæ upon him at a time, they all keep in the same situation with respect to one another; and, as long as they last are carried round together in the same manner: by the motion of the spots therefore we learn what we should not otherwise have known, that *the sun is a globe, and has a rotation* about his axis." Notwithstanding this he tells us afterwards, "The spots, generally speaking, may be said to adhere to the sun, or to be so near him as to be carried round upon him uniformly; nevertheless, sometimes, though rarely, a spot has been seen to move with a velocity a little different from the rest; spots that were in different parallels have appeared to be carried along, not keeping always the same distance, but approaching nearer to each other; and when two spots moved in the same parallel, the hindmost has been observed to overtake and pass by the other. The revolution of spots near the equator of the sun is shorter than of those that are more distant from it."

127 Dr Long's opinion of the solar spots.

128 Of the sun's revolution on his axis.

The apparent change of shape in the spots, as they approach the circumference of the disk, according to our author, is likewise a proof of the sun's rotation round his axis, and that they either adhere to the surface of the luminary, or are carried round his atmosphere very near his surface.

"The rotation of the sun (says Dr Long) being known, we may consider his axis and poles, and their situation, as also his equator, or a circle imagined to be drawn upon that luminous globe equally distant from his poles; we may also imagine lesser circles drawn thereon, parallel to his equator.

"The rotation of the sun is according to the order of the signs; that is, any point on the surface of that vast globe turns round so as to look successively at Aries, Taurus, Gemini, &c. which is also the way that all the primary planets are carried round him, though each of them in a plane a little different from that of the rest. We must likewise observe, that the plane of the sun's equator produced does not coincide with the heliocentric orbit of any of the planets, but cuts every one of them at a small angle; it is nearest to coincidence with the orbit of Venus.

129 Visible part of the sun's globe less than the invisible.

"The sun being a globe at a great distance from us, we always see nearly one-half of that globe at a time; but the visible half is continually changing, by the rotation of the sun, and the revolution of the earth in her orbit. To speak accurately, we do not see quite half the sun's globe at a time, we want so much of it as the sun's apparent diameter amounts to; which, at his mean distance, is about 32 minutes; so much is the diameter of the invisible part of the sun greater than that of the visible part: for this reason a spot may be about two hours longer invisible than visible.

"The time between the entrance of a spot upon the disk and its exit therefrom, gives us nearly half the apparent period of the sun's rotation, which is usually in about 13 days; a spot that, after passing the disk and disappearing, returns again, gives the whole time,

Concluſions from the foregoing Appearances.

time, but not with preciſion; becauſe the ſpot may perhaps not keep all the while exactly in the ſame place, but have ſome floating motion of its own upon the ſurface of the ſun. Dom. Caſſini, taking notice that ſeveral ſpots had often appeared in the ſame parallel, thought that ſome particular places of the ſun might be more diſpoſed than others to ſupply the matter of theſe ſpots; and if ſo, that they would not move far from the place of their origin, juſt as the ſmoke of mount Ætna, if it could be ſeen from the ſun, would appear always to return to the ſame place of the diſk of the earth once every 24 hours, very nearly; ſometimes a little ſooner, ſometimes a little later, according as the ſmoke was driven by the wind from the place of its eruption. In conſequence of this ſuppoſition, he compared ſeveral large intervals between the appearances of ſpots carried in the ſame parallel, which he judged to be returns of the ſame ſpots ariſing out of the ſame place on the ſurface of the ſun, and found that 27 days 22 hours and 20 ſeconds was a common meaſure of thoſe intervals very nearly; this, therefore, he thought the moſt proper period to be taken for an apparent revolution of the ſolar ſpots, and conſequently of the ſun himſelf as ſeen from the earth. Theſe obſervations were made in April and May, nearly in the ſame time of the year, and therefore are not much affected by the inequality of the earth's motion. The ſame period is confirmed by Dom. Caſſini.

130 How to find the true time of a revolution of the ſpots. Fig. 3.

The time of the apparent revolution of a ſpot being known, the true time of its going round upon the ſun may be thus found: In fig. 3. the arc AC, which in the month of May, the earth goes through in her orbit in 27 days 12 hours and 20 minutes, is 26° 22′; the arc *a c* being equal to AC: the apparent revolution of a ſpot is the whole circle *a b c d*, or 360°, with the addition of the arc *a c* of 26° 22′, which makes 386° 22′: then ſay, as 386.22 is to 27 d. 12 h. 20′; ſo is 360° to 25 d. 15 h. 16′; the true time of the rotation of the ſun, as it would be ſeen from a fixed ſtar.

The angle of interſection of the ſun's equator with the ecliptic is but ſmall, according to Scheiner being never more than 8°, nor leſs than 6°; for which reaſon he ſettled it at 7°, though Caſſini makes it 7½.

131 Sun's nodes and limits.

This plane continued cuts the ecliptic in two oppoſite points, which are called the *ſun's nodes*, being 8° of ♊ and 8° of ♐; and two points in the ecliptic, 90° from the nodes, may be called the *limits*. Theſe are 8° of ♓ and 8° of ♍. When the earth is in either of theſe nodes, the equator of the ſun, if viſible, would appear as a ſtraight line; and, by reaſon of the vaſt diſtance of the ſun from us, all his parallels would likewiſe appear as ſtraight lines; but in every other ſituation of the earth, the equator and parallels of the ſun would, if viſible, appear as ellipſes growing wider the farther the earth is from the nodes, and wideſt of all when the earth is in one of her limits.

"In the preſent age (ſays Dr Long), on the 18th, of May, the earth is in the 8° of ♐, one of the nodes of the ſun, and conſequently the ſun's equator and parallels, if viſible, would appear as ſtraight lines, fig. 92. From that time the ſun's equator, and every parallel, begin to appear as half of an ellipſis convex, or ſwelling towards the ſouth, and growing wider every day to the 20th of Auguſt, where it is at the wideſt, as in fig. 93, the earth being then in the 8° of ♓, one of the limits. Immediately after, the apparent curvature of the ſun's equator and parallels continually decreaſes to the 19th of November, when they again appear as ſtraight lines, the earth being then in the other node. From that time the equator of the ſun and parallels become elliptical, convex towards the north; their curvature continually increaſing to the 15th of February, when the earth is arrived at the other limit; and their curvature then decreaſes continually to the 18th of May, when they again appear as ſtraight lines. Every ſpot is carried round the ſun in his equator, or in a parallel; therefore the apparent motion of the ſpots upon the ſun is rectilinear every year in May and November, at all other times elliptical." See fig. 16, 17. where the paths of ſome ſolar ſpots are delineated by Mr Dunn, in a manner ſeemingly inconſiſtent with what is juſt now delivered from Dr Long. From a farther conſideration of the nature of the paths deſcribed by the ſolar ſpots, the Doctor concludes that their appearance may be retarded about four hours by the unequal motion of the earth in its orbit.

132 Of the nature and formation of the ſolar ſpots.

The nature and formation of the ſolar ſpots have been the ſubject of much ſpeculation and conjecture. Some have thought that the ſun is an opaque body, mountainous and uneven, as our earth is, covered all over with a fiery and luminous fluid; that this fluid is ſubject to ebbing and flowing, after the manner of our tides, ſo as ſometimes to leave uncovered the tops of rocks or hills, which appear like black ſpots; and that the nebuloſities about them are cauſed by a kind of froth. Others have imagined, that the fluid which ſends us ſo much light and heat, contains a nucleus or ſolid globe, wherein are ſeveral volcanoes, that, like Ætna or Veſuvius, from time to time caſt up quantities of bituminous matter to the ſurface of the ſun, and form thoſe ſpots which are ſeen thereon; and that as this matter is gradually conſumed by the luminous fluid, the ſpots diſappear for a time, but are ſeen to riſe again in the ſame places when thoſe volcanoes caſt up new matter. A third opinion is, that the ſun conſiſts of a fiery luminous fluid, wherein are immerſed ſeveral opaque bodies of irregular ſhapes; and that theſe bodies, by the rapid motion of the ſun, are ſometimes buoyed or raiſed up to the ſurface, where they form the appearance of ſpots, which ſeem to change their ſhapes according as different ſides of them are preſented to the view. A fourth opinion is, that the ſun conſiſts of a fluid in continual agitation; that, by the rapid motion of this fluid, ſome parts more groſs than the reſt are carried up to the ſurface of the luminary, like the ſcum of melted metal riſing up to the top in a furnace: that theſe ſcums, as they are differently agitated by the motion of the fluid, form themſelves into thoſe ſpots we ſee on the ſolar diſk; and, beſides the optical changes already mentioned, grow larger, are diminiſhed in their apparent magnitude, recede a little from, or approach nearer to, each other, and are at laſt entirely diſſipated by the continual rapid motion of the fluid, or are otherwiſe conſumed or abſorbed.

133 Spots of the ſun ſuppoſed by Dr Wilſon to be hollows.

In the 64th volume of the Philoſophical Tranſactions, Dr Wilſon advances a new opinion concerning the ſolar ſpots, viz. that they are hollows in the ſurface of the luminary. "All the foregoing appearances (ſays he), when taken together, and when duly conſidered, ſeem to prove in the moſt convincing manner, that

Conclusions from the foregoing Appearances.

that the nucleus of this spot (December 1762) was considerably beneath the level of the sun's spherical surface.

"The next thing which I took into consideration was, to think of some means whereby I could form an estimate of its depth. At the time of the observation I had, on December 12th, remarked that the breadth of the side of the umbra next the limb was about 14″; but, for determining the point in question, it was also requisite to know the inclination of the shelving side of the umbra to the sun's spherical surface. And here it occurred, that, in the case of a large spot, this would in some measure be deduced from observation. For, at the time when the side of the umbra is just hid, or begins first to come in view, it is evident, that a line joining the eye and its observed edge, or uppermost limit, coincides with the plane of its declivity. By measuring therefore the distance of the edge from the limb, when this change takes place, and by representing it by a projection, the inclination or declivity may in some

134 His method of measuring their depth.

measure be ascertained. For in fig. 27, let ILDK be a portion of the sun's limb, and A B C D a section of the spot, S L the sun's semidiameter, L G the observed distance from the limb, when the side of the umbra changes; then will the plane of the umbra CD coincide with the line E D G drawn perpendicular to S L at the point G. Let F H be a tangent to the limb at the point D, and join S D.

"Since G L, the versed sine of the angle L S D, is given by observation, that angle is given, which by the figure is equal to F D E or G D H; which angle is therefore given, and is the angle of inclination of the plane of the umbra to the sun's spherical surface. In the small triangle therefore CMD, which may be considered as rectangular, the angle M D C is given, and the side D C equal to A B is given nearly by observation; therefore the side M C is given, which may be regarded as the depth of the nucleus without any material error.

"I had not an opportunity, in the course of the foregoing observations, to measure the distance G L, not having seen the spot at the time when either of the sides of the umbra changed. It is, however, certain, that when the spot came upon the disk for the second time, this change happened some time in the night between the 11th and 12th of December, and I judge that the distance of the plane of the umbra, when in a line with the eye, must have been about 1′ 55″ from the sun's eastern limb; from which we may safely conclude, that the nucleus of the spot was, at that time, not less than a semidiameter of the earth below the level of the sun's spherical surface, and made the bottom of an amazing cavity, from the surface downwards, whose other dimensions were of much greater extent."

135 His conjectures concerning the nature of the sun.

Having thus demonstrated that the solar spots are vast cavities in the sun, the Doctor next proceeds to offer some queries and conjectures concerning the nature of the sun himself, and to answer some objections to his hypothesis. He begins with asking, Whether it is not reasonable to think, that the vast body of the sun is made up of two kinds of matter very different in their qualities; that by far the greatest part is solid and dark; and that this dark globe is encompassed with a thin covering of that resplendent substance, from which the sun would seem to derive the whole of his vivifying heat and energy?—This, if granted, will afford a satisfactory solution of the appearance of spots; because, if any part of this resplendent surface shall be by any means displaced, the dark globe must necessarily appear; the bottom of the cavity corresponding to the nucleus, and the shelving sides to the umbra. The shining substance, he thinks, may be displaced by the action of some elastic vapour generated within the substance of the dark globe. This vapour, swelling into such a volume as to reach up to the surface of the luminous matter, would thereby throw it aside in all directions: and as we cannot expect any regularity in the production of such a vapour, the irregular appearance and disappearance of the spots is by that means accounted for; as the reflux of the luminous matter must always occasion the dark nucleus gradually to decrease, till at last it becomes indistinguishable from the rest of the surface.

Here an objection occurs, viz. That, on this supposition, the nucleus of a spot whilst on the decrease should always appear nearly circular, by the gradual descent of the luminous matter from all sides to cover it. But to this the Doctor replies, that in all probability the surface of the dark globe is very uneven and mountainous, which prevents the regular reflux of the shining matter. This, he thinks, is rendered very probable by the enormous mountains and cavities which are observed in the moon; and why, says he, may there not be the same on the surface of the sun? He thinks his hypothesis also confirmed by the dividing of the nucleus into several parts, which might arise from the luminous matter flowing in different channels in the bottom of the hollow.—The appearance of the umbra after the nucleus is gone, he thinks, may be owing to a cavity remaining in the luminous matter, tho' the dark globe is entirely covered.

As to a motion of the spots, distinct from what they are supposed to receive from the rotation of the sun round his axis, he says he never could observe any, except what might be attributed to the enlargement or diminution of them when in the neighbourhood of one another. "But (says he) what would farther contribute towards forming a judgment of this kind is, the apparent alteration of the relative place, which must arise from the motion across the disk on a spherical surface; a circumstance which I am uncertain if it has been sufficiently attended to."

The above mentioned hypothesis, the Doctor thinks, is further confirmed by the disappearance of the umbræ on the sides of the spots contiguous to one another; as the action of the elastic vapour must necessarily drive the luminous matter away from each, and thus as it were accumulate it between them, so that no umbra can be perceived. As to the luminous matter itself, he conjectures, that it cannot be any very ponderous fluid, but that it rather resembles a dense fog which broods on the surface of the sun's dark body. His general conclusion we shall give in his own words.

"According to the view of things given in the foregoing queries, there would seem to be something very extraordinary in the dark and unignited state of the great internal globe of the sun. Does not this seem to indicate that the luminous matter that encompasses it derives not its splendor from any intensity of heat? For, if this were the case, would not the parts underneath,

Conclusions from the foregoing Appearances.

neath, which would be perpetually in contact with that glowing matter, be heated to such a degree as to become luminous and bright? At the same time it must be confessed, that although the internal globe was in reality much ignited, yet when any part of it forming the nucleus of a spot is exposed to our view, and is seen in competition with a substance of such amazing splendor, it is no wonder that an inferior degree of light should, in these cases, be unperceivable.

136 Experiment proposed in order to confirm his hypothesis.

"In order to obtain some knowledge of this point, I think an experiment might be tried, if we had an opportunity of a very large spot, by making a contrivance in the eye-piece of a telescope, whereby an observer could look at the nuclues alone with the naked eye, without being in danger of light coming from any other part of the sun. In this case, if the observer found no greater splendor than what might be expected from a planet very near the sun, and illumined by as much of his surface as corresponds to the spot's umbra, we might reasonably conclude, that the solar matter, at the depth of the nucleus, is in reality not ignited. But from the nature of the thing, doth there seem any necessity for thinking that there prevails such a raging and fervent heat as many have imagined? It is proper here to attend to the distinction between this shining matter of the sun and the rays of light which proceed from it. It may perhaps be thought, that the reaction of the rays upon the matter, at their emission, may be productive of a violent degree of heat. But whoever would urge this argument in favour of the sun being intensely heated, as arising from the nature of the thing, ought to consider that all polished bodies are less and less disposed to be heated by the action of the rays of light, in proportion as their surfaces are more polished, and as their powers of reflection are brought to a greater degree of perfection. And is there not a strong analogy betwixt the reaction of light upon matter in cases where it is reflected and in cases where it is emitted?"

To this account of the solar spots, some objections have been made, particularly by Mr Wollaston, in the Philosophical Transactions, and M. de la Lande in the Memoirs of the Academy of Sciences; and to these Dr Wilson replied in the Philosophical Transactions for 1783, to the following purpose.

137 The Doctor's reply to objections.

"First of all (says he) it has been urged, as an objection of great weight, that the absence of the umbra on one side, where spots are near the limb, is not always constant; and of this I was sufficiently aware, having stated three cases from my own observation, when I did not perceive this change to take place. The reverend Francis Wollaston is the only person who, in the Philosophical Transactions, has bestowed any remarks on my publication; and though he acknowledges that the umbra generally changes in the manner I have determined, yet he expresses a difficulty as to my conclusion, on account of this circumstance not obtaining universally. Under similar expressions, M. de la Lande produces from his own observations, which appear to have been long continued, only three cases of the same kind, and four more from the ancient observations of M. Cassini and De la Hire. In regard to these last, I am not sure if such obsolete ones ought to be referred to in a question of the present kind. These excellent observers, entertaining no thought that any thing of moment depended upon a nice attention to the form of the spots, might easily overlook less obvious circumstances, especially when they were found near the limb. We may add further, that even when they were so situated, they retain the umbra at both ends; and that whole side of it which lies farthest from the centre of the disk and these parts in the aggregate, they might sometimes mistake for the umbra as not deficient in any particular place. But, even admitting the anomaly we at present consider to be much more frequent than can be contended for, still such cases can only be brought as so many exceptions to the general law or uniformity of appearance, from which the condition of by far the greatest number of spots is most undeniably deduced. The utmost therefore that can be alleged is, that some few spots differ from all the rest, or from the multitude; and are not, like them, excavations in the sun. But notwithstanding these few instances where the umbra is not found to change, when we consider how perfectly all spots resemble one another in their most striking features, there naturally rises some presumption for all under that description we have given, partaking of one common nature; and for this only difference in the phenomena depending upon something, which does not necessarily imply a complete generical distinction. It comes therefore to be inquired, how far spots, which when near the middle of the disk appear equal and similar in all things, may yet differ from one another as excavations, or as possessing the third dimension of depth? and how far the peculiar circumstances by which they may disagree, can contribute to make some resist this change of the umbra when near the limb much more than others?

"In order to this, suppose two spots which occupy a space upon the sun corresponding to the equal arches GD, fig. 94. and let GM, DM, be drawn so as to coincide with the plane of the excavation in such a case. The breadth of the nucleus being commonly equal to that of the surrounding umbra, if the base MD of the triangle GDM conceived rectilineal, be divided in L, so as ML : LD : : MD : DG; and if through L be drawn LS parallel to DG, then will DGSL be the section of two spots having this condition; and which, as to sense, would, when far away from the limb, be equal in all apparent measures; tho' very unequal in the third dimension HE, or depth of the nucleus SL, and also in the inclination DGM of their sides parallel to the spherical surface of the sun. Now it is manifest from the construction of the figure, that the distances AB, AK, from the limb A, when the sides GS of the umbra disappear, must depend very much on the latter of these two circumstances; and when, according as the angle of inclination, DGM is smaller, the respective spot will go nearer to the limb than the other before the side of the umbra GS vanishes. But these very exceptions to the general phenomena which we are at present examining are of this kind; and may perhaps, from what has been now shown, proceed wholly from the shallowness and the very gradual shelving of some few spots which break out in certain tracts of the sun's body, over which the luminous matter lies very thinly mantled.

"In order to avoid circumlocution, we may call that side of the umbra which lies nearest the limb the *nearest umbra*, and the side opposite the *farthest umbra*; and

Conclusions from the foregoing Appearances.

and to enter more particularly into the consideration now before us, let us suppose a spot of 40″ over all, with its nucleus and umbra equally broad; then will the depth of the nucleus, and the apparent breadth of the nearest umbra, when the plane of the farthest comes to coincide with the visual ray, be expressed as in the following examples, where the apparent semidiameter of the sun is supposed to be 16′, and his parallax 8.5″.

	Farthest umbra supposed to vanish when distant from the limb.	Depth of nucleus in English miles and seconds.		Apparent breadth of nearest umbra.
I.	1′ 0″	4.54″	2118	8.58
II.	0 30	3.09	1442	6.02
III.	0 15	2.09	975	4.13
IV.	0 8	1.44	672	2.87

"Now because in every aspect of a spot the real breadth of either the farthest or nearest umbra must be to the projected or apparent breadth as radius to the sine of the angle which this respective plane makes with the visual ray, it follows, that at any time before the spot comes so near the limb as is expressed in the above examples, the apparent breadth of the nearest and furthest umbra cannot differ so much as by the quantity there set down for the apparent breadth of the nearest when the other is supposed to vanish. Regarding, therefore, the farthest and nearest umbra of the spot in Case IV. as two neighbouring visible objects which turn narrower by degrees as the spot goes towards the limb, we should undoubtedly judge that they contract as to sense alike; since, so long as the farthest could be perceived, the other cannot appear to exceed it by a quantity that we could distinguish; and by the time the former coincides with the visual ray, the extreme nearness to the limb would prevent our forming any certain judgment of either.

"From this last example, therefore, it appears manifest, that a spot answering to the description and conditions therein mentioned, or one a little more shallow, would approach the limb, and finally go off the disk, without that peculiar change of the umbra on one side which is so obvious on common occasions, notwithstanding it were an excavation whose nucleus or bottom is so many miles below the level of the surface. In the four cases above stated, the distance of the remotest part of the nucleus from the sun's limb, when the visual ray coming from it is just interrupted by the lip of the excavation, or, in other words, the distance of the nucleus from the limb when it was totally hid, was also computed. These distances are as follows:

Case I.	-	16.93″	Case III.	-	4.70″
II.	-	8.90	IV.	-	2.70

And it is remarkable, from the two last, how very near the limb a shallow spot of not more than 40″ in diameter may come before the nucleus wholly disappears."

After describing the method in which these computations were made, the doctor proceeds thus: "Perhaps it may be urged, that very shallow spots ought always to be known from the rest, and discover themselves, by a surrounding umbra, very narrow, compared to the extent of the nucleus; but we know far too little of the qualities of the luminous matter, and of the proximate causes of the spots, to say any thing at all upon a point of this kind. The breadth of the umbra is, as assumed in the computations, about equal to that of the nucleus, though sometimes it varies more or less; but how far these relative dimensions indicate depth or shallowness must be expounded only by observation, and not by any vague and imperfect notions of the nature and constitution of the sun.

"The mention of a pit, or hollow or excavation several thousands of miles deep, reaching to that extent down through a luminous matter to darker regions, is ready to strike the imagination in a manner unfavourable to a just conception of the nature of the solar spots as now described. Upon first thoughts it may look strange how the sides and bottom of such vast abysses can remain so very long in sight, whilst, by the sun's rotation, they are made to present themselves more and more obliquely to our view. But when it is considered how extremely inconsiderable their greatest depth is compared to the diameter of the sun, and how very wide and shelving they are, all difficulties of this sort will be entirely removed." Unless, however, we duly attend to these proportions, our notions upon the subject must be very erroneous; and it seems the more necessary to offer this caution, as this very thing is inaccurately represented in fig. 9. belonging to the Memoir under view, and in a way that may lead to mistakes. Instead of exhibiting a spot as depressed below the surface of the sun one hundredth part of his semidiameter, the section of it is there determined by two lines drawn from the circumference, and meeting in a point at the prodigious distance of one-fifth of the semidiameter below. Any reader, therefore, who pleases, by turning to fig. 95. may see how very small a portion of the sun's body is made up of the luminous matter when supposed every where 3967 English miles deep. A is a section of a spot 50″ diameter, situated in the deepest part of this resplendent substance.

"What has now been insisted on at so much length concerning the shallowness and more gradual shelving of some few spots, will also apply to another objection which Mr de la Lande views in a strong light.

138 How a spot may appear to make an indentation on the sun's limb.

"Here we find quoted the great spot in 1719, seen by M. Cassini; and, for the second time, that of June 1703, seen by M. de la Hire; both which, on their arrival at the limb, are said to have made an indentation or dark notch in the disk; and this phenomenon is mentioned as absolutely incompatible with spots being below the surface.

"It is most true, that if we look for any thing like this when the plane which coincides with the external boundary of the spots passes through the eye, the way that M. de la Lande considers the matter, it must be very large indeed before the disk could be perceived deficient by any dark segment. But may not a spot, even no larger than M. Cassini's, considered as an excavation, make, in a manner very different from this, something like a notch; for, by the way, this phenomenon is not in the *Mem. Acad.* nor any where else that I know of, described with any sort of precision.—M. Cassini's great spot, by which we understood the nucleus, was of 30″; and supposing the umbra equally broad, its diameter over all must have been 1′ 30″. It would therefore occupy an extent upon the sun's surface of 5° 22′ fully. Now, suppose a circular space of that size upon the sun distinguished from the surrounding

Conclusions from the foregoing Appearances.

ing lustre by such a failure of light as is peculiar to some spots, and suppose that it just touches the limb, it would still subtend an angle of more than 4″. This being the case, might not a dusky shade, more or less remarkable according to the darkness of the umbra, commencing at the limb, and reaching inwards upon the disk, or in other words, a notch be perceived? Had M. Cassini's spot been a very shallow excavation, it appears by Case IV. that when viewed in this aspect, some small part of the nucleus might have yet been visible; and might have contributed, along with the shade of the farthest umbra, and the still broader and deeper shade of the two ends of the umbra, to mark out the indentation.

"Should it be said, that these notches are always distinct and jet-black impressions on the disk, of an obvious breadth, and originating entirely from the opaque nucleus conceived as something prominent above the general surface, this can be shewn inconsistent with some circumstances we find accidentally mentioned in the case of M. de la Hire's spot; for of this great one it was said, that when only 8″ distant from the limb, the nucleus was seen as a very narrow line. This was on June 3d 1703, at six o'clock in the morning. Now, forasmuch as at that time its alleged elevation must have been to its apparent subtense very nearly as radius to cosine of that arch of the sun's circumference whose versed sine was the 8′ of distance from the limb, it is impossible that its breadth could have increased sensibly in its further progress towards the limb; and how any obvious black notch could be produced by the elevation contended for in this case is not conceivable.

"I do not imagine, therefore, that the phenomena of notches in the disk, so inconsiderable and dubious as these seem to be, are by any means a proof of projecting nuclei, or that they are not reconcileable to spots being depressions on the sun. A large shallow excavation, with the sloping sides or umbra darker than the common, may, as has been shown, be more or less perceptible at the limb; and what perhaps is a further confirmation of this, and seems to evince that such a concurrence of circumstances is necessary, is, that sometimes even large spots make no indentation. M. Cassini, in *Mem. Acad.* Tom X. p. 581. describes the great spot of 1676, which he saw at its entrance with a telescope of 35 feet, as an obscure line, parallel to the limb: but no where mentions that it made a notch in it.

"Though we now and then see the surrounding umbra darker than at other times; yet when spots are deep, and the umbræ but little dusky, it is indeed impossible that we should see any thing of them, even though large, very near the limb: for here even the nucleus, which lies buried, cannot in the least contribute to the effect, as it may do a little before its state of evanescence, when spots are very shallow. Accordingly, cases of this kind are perfectly agreeable to experience.

"In reasoning concerning the nature of the spots, and particularly about their third dimension, the only arguments which are admissible, and which carry with them a perfect conviction, are those grounded upon the principles of optical projection. If, for example, the far greater number of them be excavations some thousands of miles deep, certain changes of the umbra would be observable when near the limb, as has been shown at so much length. Were they very shallow, or quite superficial, both sides of the umbra would as to sense contract alike in their progress toward the limb; for if, in case 4th above stated, the spot had been supposed superficial, the apparent breadth of the side of the umbra next the centre of the disk would have made them only 1.62′, and that of the side opposite 1.27′. Now, the whole of either of these quantities, and much more their difference, would be quite insensible. Again, if the nucleus extended much above the common level, whilst the surrounding umbra was superficial, we should behold the manifest indications of this by such an opaque body when seen very obliquely being projected across the farthest side of the umbra, and by hiding the whole or part of it before the time it would otherwise disappear. According to this or that condition of the spot, such things must infallibly obtain by the known laws of vision; and hence arguments resting upon such principles may be denominated optical ones. On the other hand, when spots are contemplated near the middle of the disk, a great variety of changes are observed in them, which depend not upon position, but upon certain physical causes producing real alterations in their form and dimensions. It is plain, that arguments derived from the consideration of such changes, and which, on that account, may be called *physical arguments*, can assist us but little in investigating their third dimensions; and, from the nature of the thing, must be liable to great uncertainty. The author of the *Memoire*, in p. 511, &c. takes new ground, and proceeds with a number of objections depending upon that sort of reasoning which we have last defined. I must take notice, that a certain distinction has been here overlooked, which in my paper I have endeavoured to point out. Presuming upon our great ignorance of many things which doubtless affect deeply the constitution of that wonderful body the sun, I offered in part II. an account of the productions, changes, and decay of the spots, considered as excavations, in the most loose and problematical manner; stating every thing on this head in the form of queries.—— Hence I would remark, that whatever inconsistencies are imagined in the account I have delivered Part II. though such may be justly chargeable on certain principles there assumed, yet they ought not to be stated as presumptions against the spots being really excavations or depressions in the luminous matter of the sun. This opinion must rest entirely upon the evidence held forth in the first part of the paper, whatever be the fate of the account laid down in the second. It does not enter there as an *hypothesis*, but as a matter of fact previously established by *optical arguments;* and from optical arguments alone can there arise even any just presumptions against it.

139

Remarks on M. de la Lande's theory of the solar spots.

"It remains now only to make a few strictures upon M. de la Lande's theory of the solar spots, humbly submitting them to the consideration of the reader. The import of it is, 'that the spots as phenomena arise from dark bodies like rocks, which by an alternate flux and reflux of the liquid igneous matter of the sun, sometimes raise their heads above the general surface. That part of the opaque rock, which at any time thus stands above, gives the appearance of the nucleus, whilst those parts,

Conclusions from the foregoing Appearances.

parts, which in each lie only a little under the igneous matter, appear to us as the surrounding umbra.'

"In the first place it may be remarked, that the whole proceeds upon mere supposition. This indeed the author himself very readily acknowledges. Though therefore it could not be disputed by arguments derived from observation, yet conjecture of any kind, if equally plausible, might fitly be employed to set aside its credit. Without entering into any tedious discussion, however, we shall confine ourselves to such particulars as appertain to the more obvious characters of the spots, and which also seem to be irreconcileable with the theory; and first of all with regard to the distinguishing features of the umbra.

"M. Cassini, Mem. Acad. tom. x. p. 582. Pl. VII. and M. de la Hire, Mem. Acad. 1703. p. 16. and I may add all other observers, and all good representations of the spots, bear testimony to the exterior boundary of the umbra being always well defined, and to the umbra itself being less and less shady the nearer it comes to the nucleus. Now it may be asked, how this could possibly be, according to M. de la Lande's theory? If the umbra be occasioned by our seeing parts of the opaque rock which lie a little under the surface of the igneous matter, should it not always be darkest next the nucleus? and, from the nucleus outward, should it not wax more and more bright, and at last lose itself in the general lustre of the sun's surface, and not terminate all at once in the darkest shade, as in fact it does? These few incongruities, which meet as it were in the very threshold of the theory, are so very palpable, that of themselves they raise unsurmountable doubts. For, generally speaking, the umbra immediately contiguous to the nucleus, instead of being very dark, as it ought to be, from our seeing the immersed parts of the opaque rock through a thin stratum of the igneous matter, is on the contrary very nearly of the same splendor as the external surface.

"Concerning the nucleus, or that part of the opaque rock, which stands above the surface of the sun, M. de la Lande produces no optical arguments in support of this third dimension or height. Neither does he say any thing particular as to the degree of elevation above the surface. But from what has been already hinted in the course of this paper, it appears that if this were any thing sensible, it ought to be discovered by phenomena very opposite to those which we have found to be so general.

"Again, a flux and reflux of the igneous matter, so considerable as sometimes to produce a great number of spots all over the middle zone, might affect the apparent diameter of the sun, making that which passes through his equator less than the polar one, by the retreat of the igneous matter towards those regions where no spots ever appear. But as a difference of this kind, of nearly one thousandth part of the whole would be perceivable, as we learn from M. de la Lande's own observations, compared with those of Mr. Short in *Histoire Acad.* 1760, p. 123. it would seem, that the theory had this difficulty also to combat. Further, when among spots very near one another some are observed to be increasing whilst others are diminishing, how is it possible this can be the effect of such a supposed flux and reflux? This last inconsistency is mentioned by the author himself, who endeavours to avoid it by making a new demand upon the general fund of hypothesis, deriving from thence such qualities of the igneous matter as the case seems to require; and such must be the method of proceeding in all systems merely theoretical. But it is unnecessary to pursue at more length illusive speculations of this kind, especially as we lie under a conviction founded on fact, of the theory being utterly erroneous. It hardly differs in any respect from that proposed by M. de la Hire, and a little amended by the writer of the *Histoire de l'Academie* for 1707, p. 111. Views very much of the same kind were even entertained by some so long ago as the days of Scheiner, as we find mentioned by that indefatigable author in his *Rosa Ursina*, p. 746."

140 Great inequalities on the surface of the moon.

2. Concerning the moon, it is allowed on all hands, that there are prodigious inequalities on her surface. This is proved by looking at her through a telescope, at any other time than when she is full; for then there is no regular line bounding light and darkness; but the confines of these parts appear as it were toothed and cut with innumerable notches and breaks; and even in the dark part, near the borders of the lucid surface, there are seen some small spaces enlightened by the sun's beams. Upon the fourth day after new moon, there may be perceived some shining points like rocks or small islands within the dark body of the moon; but not far from the confines of light and darkness there are observed other little spaces which join to the enlightened surface, but run out into the dark side, which by degrees change their figure, till at last they come wholly within the illuminated face, and have no dark parts round them at all. Afterwards many more shining spaces are observed to arise by degrees, and to appear within the dark side of the moon, which before they drew near to the confines of light and darkness were invisible, being without any light, and totally immersed in the shadow. The contrary is observed in the decreasing phases, where the lucid spaces which joined the illuminated surface by degrees recede from it, and after they are quite separated from the confines of light and darkness, remain for some time visible, till at last they also disappear. Now it is impossible that this should be the case, unless these shining points were higher than the rest of the surface, so that the light of the sun may reach them.

141 Method of measuring the lunar mountains. Fig. 20.

Not content with perceiving the bare existence of these lunar mountains, astronomers have endeavoured to measure their hight in the following manner. Let EGD be the hemisphere of the moon illuminated by the sun, ECD the diameter of the circle bounding light and darkness, and A the top of a hill within the dark part when it first begins to be illuminated. Observe with a telescope the proportion of the right line AE, or the distance of the point A from the lucid surface to the diameter of the moon ED; and because in this case the ray of light ES touches the globe of the moon, AEC will be a right angle by 16 prop. of Euclid's third book; and therefore in the triangle AEC having the two sides AE and EC, we can find out the third side AC; from which subducting BC or EC, there will remain AB the height of the mountain. Ricciolus affirms, that upon the fourth day after new moon he has observed the top of the hill called *St Catharine's* to be illuminated, and that it was distant from the confines of the lucid surface about a sixteenth part

of

Conclusions from the foregoing Appearances.

of the moon's diameter. Therefore, if CE=8, AE will be 1, and $AC^2=CE^2+AE^2$ by prop. 47. of Euclid's first book. Now the square of CE being 64, and the square of AE being 1, the square of AC will be 65, whose square root is 8,062, which expresses the length of AC. From which deducting BC=8, there will remain AB=0,062. So that CB or CE is therefore to AB as 8 is to 0,062, that is, as 8000 is to 62. If the diameter of the moon therefore was known, the height of this mountain would also be known. This demonstration is taken from Dr Keil, who supposes the semidiameter of the moon to be 1182 miles; according to which, the mountain must be somewhat more than nine miles of perpendicular height: but astronomer's having now determined the moon's semidiameter to be only 1090 miles, the height of the mountain will be nearly $8\frac{1}{4}$ miles.

142 Height of the lunar mountains over-rated.

In the former edition of this work, we could not help making some remarks on the improbability that the mountains of the moon, a planet so much inferior in size to the earth, should exceed in such vast proportion to the highest of our mountains, which are computed at little more than one-third of the height just mentioned.

143 Mr Herschel's observations on them.

Our remark is now confirmed by the observations of Mr Herschel. After explaining the method used by Galileo, Hevelius, &c. for measuring the lunar mountains, he tells us, that the former takes the distance of the top of a lunar mountain from the line that divides the illuminated part of the disk from that which is in the shade to be equal to one-twentieth of the moon's diameter; but Hevelius makes it only one-twenty-sixth. When we calculate the height of such a mountain, therefore, it will be found, according to Galileo, almost $5\frac{1}{4}$ miles; and according to Hevelius $3\frac{1}{2}$ miles, admitting the moon's diameter to be 2180 miles. Mr Ferguson, however, says, (Astronomy explained, § 252.), that some of her mountains, by comparing their height with her diameter, are found to be three times higher than the highest hills on earth; and Keil, in his Astronomical Lectures, has calculated the height of St. Catharine's hill, according to the observations of Ricciolus, and finds it nine miles. Having premised these accounts, Mr Herschel explains his method of taking the height of a lunar mountain from observations made when the moon was not in her quadrature as the method laid down by Hevelius answers only to that particular case: for in all others the projection must appear shorter than it really is. "Let SLM, says he, or *s l m*, (fig. 96.) be a line drawn from the sun to the mountain, touching the moon at L or *l*, and the mountain at M or *m*. Then, to an observer at E or *e*, the lines LM, *l m*, will not appear of the same length, though the mountains should be of an equal height; for LM will be projected into *o n*, and *l m* into ON. But these are the quantities that are taken by a micrometer when we observe a mountain to project from the line of illumination. From the observed quantity *o n*, when the moon is not in her quadrature, to find LM, we have the following analogy. The triangles *o* OL, *r* ML, are similar; therefore $Lo : LO :: Lr : LM$, or $\frac{LO \times on}{Lo} = LM$: but LO is the radius of the moon, and L*r* or *o n* is the observed distance of the mountain's projection; and L*o* is the sine of the angle ROL=*o*LS; which we may take to be the distance of the sun from the moon without any material error, and which therefore we may find at any given time from an ephemeris.

Conclusions from the foregoing Appearances.

"The telescope used in these observations was a Newtonian reflector of six feet eight inches focal length, to which a micrometer was adopted, consisting of two parallel hairs, one of which was moveable by means of a fine screw. The value of the parts shown by the index was determined by a trigonometrical observation of a known object at a known distance, and was verified by several trials. The power was always 222, excepting where another is expressly mentioned; and this was also determined by experiment which frequently differs from theory on account of some small errors in the data, hardly to be avoided. The moon having sufficient light, an aperture of no more than four inches was made use of; and, says Mr Herschel, "I believe, that, for distinctness of vision, this instrument is perhaps equal to any that ever was made."

With this instrument he observed a prominence, which he calls *a rock*, situated near the *Lacus Niger* of Hevelius, and found that it projected 41.56″. To reduce this into miles, put R for the semidiameter of the moon in seconds, as given by the nautical almanack at the time of observation, and Q for the observed quantity, also in seconds and centesimals; then it will be in general, $R : 1090 :: Q : \frac{1090Q}{R} = on$ in miles. Thus it is found, that 41.56″ is 46.79 miles. The distance of the sun from the moon at that time was, by the nautical almanack, about 93° $57\frac{1}{4}$′; the sine of which to the radius 1 is .9985, &c. and $\frac{on}{Lo}$ in this case is LM=46.85 miles. Then, by Hevelius's method, the perpendicular height of the rock is found to be about one mile. At the same time, a great many rocks, situated about the middle of the disk, projected from 25.92″ to 26.56″; which gives *o n* about 29.3 miles: so that these rocks are all less than half a mile high.

These observations were made on the 13th of November 1779. On the 13th of January 1780, examining the mountains of the moon, he found that there was not one of them fairly placed on level ground, which is very necessary for an exact measurement of the projection: for if there should be a declivity on the moon before the mountains, or a tract of hills placed so as to cast a shadow upon that part before them which would otherwise be illuminated, the projection would appear too large; and on the contrary, should there be a rising ground before them, it would appear too little.

Proceeding in this cautious manner, Mr Herschel measured the height of many of the lunar prominences, and draws at last the following conclusions.—"From these observations I believe it is evident, that the height of the lunar mountains in general is greatly over-rated; and that, when we have excepted a few, the generality do not exceed half a mile in their perpendicular elevation. It is not so easy to find any certain mountain exactly in the same situation it has been measured in before; therefore some little difference must be expected in these measures. Hitherto I have not had an opportunity of particularly observing the three mountains mentioned by Hevelius; nor that which

Conclusions from the foregoing Appearances.

which Ricciolus found to project a sixteenth part of the moon's diameter. If Keill had calculated the height of this last mentioned hill according to the theorem I have given, he would have found (supposing his observation to have been made, as he says, on the fourth day after new moon) that its perpendicular height could not well be less than between 11 and 12 miles. I shall not fail to take the first opportunity of observing these four, and every other mountain of any eminence; and if other persons, who are furnished with good telescopes and micrometers, would take the quantity of the projection of the lunar mountains, I make no doubt but that we should be nearly as well acquainted with their heights, as we are with the elevation of our own. One caution I would beg leave to mention to those who may use the excellent $3\frac{1}{2}$ feet refractors of Mr Dollond. The admirable quantity of light, which on most occasions is so desirable, will probably give the measure of the projection somewhat larger than the true, if not guarded against by proper limitations placed before the object-glass. I have taken no notice of any allowance to be made for the refraction a ray of light must suffer in passing through the atmosphere of the moon, when it illuminates the top of the mountain, whereby its apparent height will be lessened, as we are too little acquainted with that atmosphere to take it into consideration. It is also to be observed, that this would equally affect the conclusions of Hevelius, and therefore the difference in our inferences would still remain the same."

144 Caution to be observed in using Dollond's telescopes.

In the continuation of his observations Mr Herschel informs us that he had measured the height of one of the mountains which had been measured by Hevelius. "Antitaurus (says he), the mountain measured by Hevelius, was badly situated; because Mount Moschus, and its neighbouring hills cast a deep shadow which may be mistaken for the natural convexity of the moon. A good, full, but just measure, 25.105″; in miles, 29.27: therefore LM 31.7 miles, and the perpendicular height not quite half a mile. As great exactness was desired in this observation, it was repeated with very nearly the same result. Several other mountains were measured by the same method, and all his observations concurred in making the height of the lunar mountains much less than what former astronomers had done. Mount Lipulus was found to be near two-thirds of a mile; one of the Appenine mountains between Lacus Trasimenus and Pontus Euxinus measured a mile and a quarter; Mons Armenia, near Taurus, two-thirds of a mile; Mons Leucoptera three quarters of a mile. Mons Sacer projected 45.625″; 'but (says he) I am almost certain that there are two very considerable cavities or places where the ground descends below the level of the convexity, just before these mountains; so that these measures must of course be a good deal too large; but supposing them to be just, it follows, that *o n* is 50.193 miles, LM=64 miles, and the perpendicular height above $1\frac{3}{4}$ miles.'

145 Volcanoes discovered in the moon.

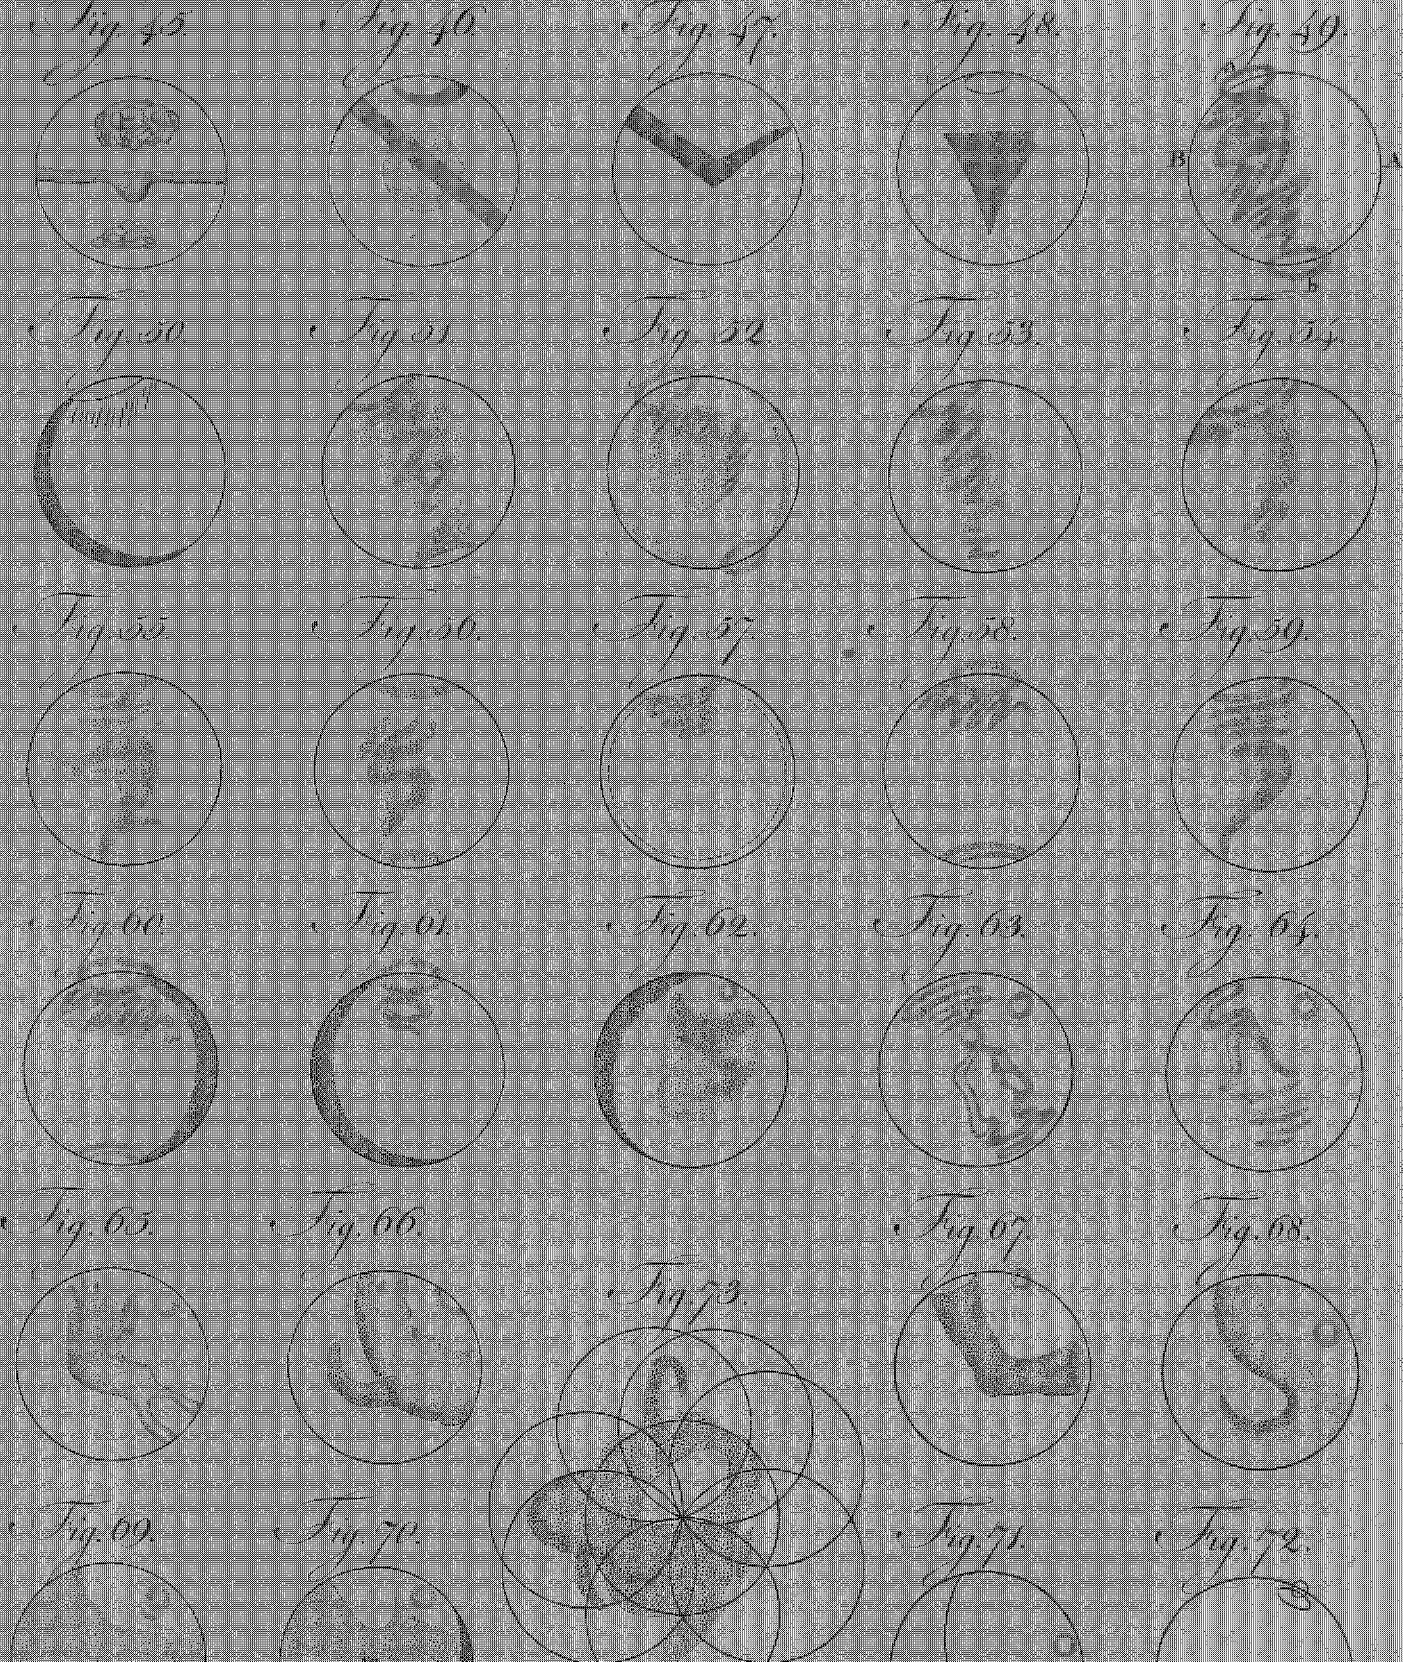
As the moon has on its surface mountains and valleys in common with the earth, some modern astronomers have discovered a still greater similarity, viz. that some of these are really volcanoes, emitting fire as those on earth do. An appearance of this kind was discovered some years ago by Don Ulloa in an eclipse of the sun. It was a bright small spot like a star near the margin of the moon, and which he at that time supposed to have been a hole with the sun's light shining through it. Succeeding observations, however, have induced astronomers to attribute appearances of this kind to the eruption of volcanic fire; and Mr Herschel has particularly observed several eruptions of the lunar volcanoes, the last of which he gives an account of in the Phil. Transf. for 1787. "April 19. 10h. 36, sidereal time. I perceive (says he) three volcanoes in different places of the dark part of the new moon. Two of them are either already nearly extinct, or otherwise in a state of going to break out; which perhaps may be decided next lunation. The third shows an actual eruption of fire or luminous matter. I measured the distance of the crater from the northern limb of the moon, and found it 3′ 57.3″: its light is much brighter than the nucleus of the comet which M. Mechain discovered at Paris the 10th of this month.

"April 20. 10 h. 2′ sidereal time. The volcano burns with greater violence than last night. Its diameter cannot be less than 3″, by comparing it with that of the Georgian planet: as Jupiter was near at hand, I turned the telescope to his third satellite, and estimated the diameter of the burning part of the volcano to be equal to at least twice that of the satellite; whence we may compute that the shining or burning matter must be above three miles in diameter. It is of an irregular round figure, and very sharply defined on the edges. The other two volcanoes are much farther towards the centre of the moon, and resemble large, pretty faint nebulæ, that are gradually much brighter in the middle; but no well-defined luminous spot can be discerned in them. These three spots are plainly to be distinguished from the rest of the marks upon the moon; for the reflection of the sun's rays from the earth is, in its present situation, sufficiently bright, with a ten-feet reflector, to show the moon's spots, even the darkest of them; nor did I perceive any similar phenomena last lunation, though I then viewed the same places with the same instrument.

"The appearance of what I have called the *actual fire*, or eruption of a volcano, exactly resembled a small piece of burning charcoal when it is covered by a very thin coat of white ashes, which frequently adhere to it when it has been some time ignited; and it had a degree of brightness about as strong as that with which such a coal would be seen to glow in faint daylight. All the adjacent part of the volcanic mountain seemed to be faintly illuminated by the eruption, and were gradually more obscure as they lay at a greater distance from the crater. This eruption resembled much that which I saw on the 4th of May in the year 1783, but differed considerably in magnitude and brightness; for the volcano of the year 1783, though much brighter than that which is now burning, was not near so large in the dimensions of its eruption: the former seen in the telescope resembled a star of the fourth magnitude as it appears to the naked eye; this, on the contrary, shows a visible disk of luminous matter very different from the sparkling brightness of star-light."

146 Conjectures concerning her surface.

Concerning the nature of the moon's substance there have been many conjectures formed. Some have imagined,



Thackara & Vallance Sculpt

Conclusions from the foregoing Appearances.

gined, that, besides the light reflected from the sun, the moon hath also some obsure light of her own, by which she would be visible without being illuminated by the sun-beams. In proof of this it is urged, that during the time of even total eclipses the moon is still visible, appearing of a dull red colour, as if obscured by a great deal of smoke. In reply to this it hath been advanced, that this is not always the case; the moon sometimes disappearing totally in the time of an eclipse, so as not to be discernable by the best glasses, while little stars of the fifth and sixth magnitudes were distinctly seen as usual. This phenomenon was observed by Kepler twice, in the years 1580 and 1583; and by Hevelius in 1620. Ricciolus and other Jesuits at Bologna, and many people throughout Holland, observed the same on April 14, 1642; yet at Venice and Vienna she was all the time conspicuous. In the year 1703, Dec. 23, there was another total obscuration. At Arles, she appeared of a yellowish brown; at Avignon, ruddy and transparent, as if the sun had shone through her: at Marseilles, one part was reddish and the other very dusky; and at length, though in a clear sky, she totally disappeared. The general reason for her appearance at all during the time of eclipses shall be given afterwards: but as for these particular phenomena, they have not yet, as far as we know, been satisfactorily accounted for.

Different conjectures have also been formed concerning the spots on the moon's surface. Some philosophers have been so taken with the beauty of the brightest places observed in her disk, that they have imagined them to be rocks of diamonds; and others have compared them to pearls and precious stones. Dr Keill and the greatest part of astronomers now are of opinion, that those are only the tops of mountains which by reason of their elevation are more capable of reflecting the sun's light than others which are lower. The duskish spots, he says, cannot be seas, nor any thing of a liquid substance; because, when examined by the telescope, they appear to consist of an infinity of caverns and empty pits, whose shadows fall within them, which can never be the case with seas, or any liquid substance: but, even within these spots, brighter places are also to be observed; which, according to his hypothesis, ought to be the points of rocks standing up within the cavities. Dr Long, however, is of opinion that several of the dark spots on the moon are really water. May not the lunar seas and lakes (says he) have islands in them, wherein there may be pits and caverns? And if some of these dark parts be brighter than others, may not that be owing to the seas and lakes being of different depths, and to their having rocks in some places and flats in others?

It has also been urged, that if all the dark spots observed on the moon's surface were really the shadows of mountains, or of the sides of deep pits, they could not possibly be so permanent as they are found to be; but would vary according to the position of the moon with regard to the sun, as we find shadows on earth are varied according as the earth is turned towards or from the sun. Accordingly it is pretended, that variable spots are actually discovered on the moon's disk, and that the direction of these is always opposite to the sun. Hence they are found among those parts which are soonest illuminated in the increasing moon, and in the decreasing moon lose their light sooner than the intermediate ones; running round, and appearing sometimes longer, and sometimes shorter. The permanent dark spots, therefore, it is said, must be some matter which is not fitted for reflecting the rays of the sun so much as the bright parts do; and this property, we know by experience, belongs to water rather than land: whence these philosophers conclude, that the moon, as well as our earth, is made up of land and seas.

147 Whether the moon has any atmosphere.

It has been a matter of dispute whether the moon has any atmosphere or not. The following arguments have been urged by those who take the negative side. 1. The moon constantly appears with the same brightness when there are no clouds in our atmosphere; which could not be the case if she were surrounded with an atmosphere like ours, so variable in its density, and so frequently obscured by clouds and vapours. 2. In an appulse of the moon to a star, when she comes so near it that part of her atmosphere is interposed between our eye and the star, refraction would cause the latter seem to change its place, so that the moon would appear to touch it later than by her own motion she would do. 3. Some philosophers are of opinion, that because there are no seas or lakes in the moon, there is therefore no atmosphere, as there is no water to be raised up in vapours.

All these arguments, however, have been answered by other astronomers in the following manner. 1. It is denied that the moon appears always with the same brightness, even when our atmosphere appears equally clear. Hevelius relates, that he has several times found in skies perfectly clear, when even stars of the sixth and seventh magnitude were visible, that at the same altitude of the moon and the same elongation from the earth, and with one and the same telescope, the moon and its maculæ do not appear equally lucid, clear, and conspicuous at all times; but are much brighter and more distinct at some times than at others. From the circumstances of this observation, say they, it is evident that the reason of this phenomenon is neither in our air, in the tube, in the moon, nor in the spectator's eye; but must be looked for in something existing about the moon. An additional argument is drawn from the different appearances of the moon already mentioned in total eclipses, which are supposed to be owing to the different constitutions of the lunar atmosphere.

148 Why the light is not refracted by the moon's atmosphere.

To the second argument Dr Long replies, that Sir Isaac Newton has shown (*Princip.* prop. 37. cor. 5.), that the weight of any body upon the moon is but a third part of what the weight of the same would be upon the earth: now the expansion of the air is reciprocally as the weight that compresses it: the air, therefore, surrounding the moon, being pressed together by a weight, or being attracted towards the centre of the moon by a force equal only to one-third of that which attracts our air towards the centre of the earth, it thence follows, that the lunar atmosphere is only one-third as dense as that of the earth, which is too little to produce any sensible refraction of the star's light. Other astronomers have contended that such refraction was sometimes very apparent. Mr. Cassini says that he frequently observed Saturn, Jupiter, and the fixed stars, to have their circular figure changed into an elliptical one, when they approached either to the moon's dark or illuminated limb, though they own,

Conclusions from the foregoing Appearances.

own, that, in other occultations, no such change could be observed. With regard to the fixed stars, indeed, it has been urged, that, granting the moon to have an atmosphere of the same nature and quantity as ours, no such effect as a gradual diminution of light ought to take place; at least, that we could by no means be capable of perceiving it. Our atmosphere is found to be so rare at the height of 44 miles as to be incapable of refracting the rays of light. This height is the 180th part of the earth's diameter; but since clouds are never observed higher than four miles, we must conclude that the vaporous or obscure part is only one 1980th. The mean apparent diameter of the moon is 31′ 29″, or 1889 seconds: therefore the obscure parts of her atmosphere, when viewed from the earth, must subtend an angle of less than one second; which space is passed over by the moon in less than two seconds of time. It can therefore hardly be expected that observation should generally determine whether the supposed obscuration takes place or not.

The third argument is necessarily inconclusive, because we know not whether there is any water in the moon or not; nor, though this could be demonstrated, would it follow that the lunar atmosphere answers no other purpose than the raising of water into vapour. There is, however, a strong argument in favour of the existence of a lunar atmosphere, taken from the appearance of a luminous ring round the moon in the time of solar eclipses. In the eclipse of May 1, 1706, Captain Stanyan, from Bern in Switzerland, writes, that "the sun was totally darkened there for the space of four minutes and a half: that a fixed star and planet appeared very bright: that his getting out of the eclipse was preceded by a blood-red streak of light from his left limb, which continued not longer than six or seven seconds of time; then part of the sun's disk appeared, all on a sudden, brighter than Venus was ever seen in the night; and in that very instant gave light and shadow to things as strong as moon-light uses to do." The publisher of this account observes, that the red streak of light preceding the emersion of the sun's body, is a proof that the moon has an atmosphere; and its short continuance of five or six seconds shows that its height is not more than the five or six hundredth part of her diameter.

149 Luminous ring observed about the moon in total eclipses.

Fatio, who observed the same eclipse at Geneva, tells us, that "there was seen, during the whole time of the total immersion, a whiteness which seemed to break out from behind the moon, and to encompass her on all sides equally: this whiteness was not well defined on its outward side, and the breadth of it was not a twelfth part of the diameter of the moon. The planet appeared very black, and her disk very well defined with the whiteness which encompassed it about, and was of the same colour as that of a white crown or halo of about four or five degrees in diameter, which accompanied it, and had the moon for its centre. A little after the sun had begun to appear again, the whiteness, and the crown which had encompassed the moon did entirely vanish." "I must add (says Dr Long), that this description is a little perplexed, either through the fault of the author or of the translator; for I suppose Fatio wrote in French; however, it plainly appears by it that the moon's atmosphere was visible, surrounded by a light of larger extent, which I think must be that luminous appearance (the zodiacal light) mentioned from Cassini." Flamstead, who published this account, takes notice, that, according to these observations, the altitude of the moon's atmosphere cannot be well supposed less than 130 geographical miles; and that probably this atmosphere was never discovered before this eclipse, by reason of the smallness of the refraction, and the want of proper observations.

An account of the same eclipse as it appeared at Zurich, is given by Dr Scheuchzer, in the following words: "We had an eclipse of the sun, which was both total and annular: total, because the whole sun was covered by the moon; annular, not what is properly so called, but by refraction; for there appeared round the moon a bright shining, which was owing to the rays of the sun refracted through the atmosphere of the moon.

Dom. Cassini, from a number of accounts sent him from different parts, says, that in all those places where it was total, during the time of total darkness, there was seen round the moon a crown or broad circle of pale light, the breadth whereof was about a 12th part of the moon's diameter: that at Montpelier, where the observers were particularly attentive to see if they could distinguish the zodiacal light already mentioned, they took notice of a paler light of a larger extent, which surrounded the crown of light before mentioned, and spread itself on each side of it, to the distance of four degrees. He then mentions Kepler's opinion, that the crown of light which appears round the moon during the total darkness in an eclipse of the sun, is caused by some celestial matter surrounding the moon, of sufficient density to receive the rays of the sun and send them to us; and that the moon may have an atmosphere similar to that of our earth, which may refract the sun's light. 150

Dr Halley's account of a solar eclipse in 1715.

A total eclipse of the sun was observed on the 22d of April O. S. in the year 1715, by Dr Halley at London, and by M. Louville of the Academy of Sciences at Paris. Dr Halley relates, that "when the last part of the sun remained on his east side, it grew very faint, and was easily supportable to the naked eye even through the telescope, for above a minute of time before the total darkness; whereas, on the contrary, the eye could not endure the splendor of the emerging beams through the telescope even from the first moment. To this two causes perhaps concurred: the one, that the pupil of the eye did necessarily dilate itself during the darkness, which before had been much contracted by looking on the sun: the other, that the eastern parts of the moon, having been heated with a day near as long as 30 of ours, must of necessity have that part of its atmosphere replete with vapours raised by the so long continued action of the sun; and, by consequence, it was more dense near the moon's surface, and more capable of obstructing the sun's beams; whereas at the same time the western edge of the moon had suffered as long a night, during which there might fall in dews all the vapours that were raised in the preceding long day; and for that reason, that part of its atmosphere might be seen much more pure and transparent.

"About two minutes before the total immersion, the remaining part of the sun was reduced to a very fine horn, whose extremities seemed to loose their acuteness,

Concluſions from the foregoing Appearances.

neſs, and to become round like ſtars; and for the ſpace of about a quarter of a minute a ſmall piece of the ſouthern horn of the eclipſe ſeemed to be cut off from the reſt by a good interval, and appeared like an oblong ſtar rounded at both ends: which appearance would proceed from no other cauſe but the inequalities of the moon's ſurface: there being ſome elevated parts thereof near the moon's ſouthern pole, by whoſe interpoſition part of that exceedingly fine filament of light was intercepted. A few ſeconds before the ſun was totally hid there diſcovered itſelf round the moon a luminous ring about a digit, or perhaps a tenth part of the moon's diameter in breadth. It was of a pale whiteneſs, or rather of a pearl colour, ſeeming to me a little tinged with the colour of the iris and to be concentric with the moon; whence I concluded it the moon's atmoſphere. But the great height of it, far exceeding that of our earth's atmoſphere, and the obſervations of ſome who found the breadth of the ring to increaſe on the weſt ſide of the moon as the emerſion approached, together with the contrary ſentiments of thoſe whoſe judgments I ſhall always revere, make me leſs confident, eſpecially in a matter to which I gave not all the attention requiſite.

"Whatever it was, this ring appeared much brighter and whiter near the body of the moon than at a diſtance from it; and its outward circumference, which was ill defined, ſeemed terminated only by the extreme rarity of the matter of which it was compoſed, and in all reſpects reſembled the appearance of an enlightened atmoſphere ſeen from far: but whether it belonged to the ſun or moon, I ſhall not pretend to determine.

151 Flaſhes of light appear to dart from behind the moon.

During the whole time of the total eclipſe, I kept my teleſcope conſtantly fixed on the moon, in order to obſerve what might occur in this uncommon appearance; and I ſaw perpetual flaſhes or coruſcations of light, which ſeemed for a moment to dart out from behind the moon, now here, now there, on all ſides, but more eſpecially on the weſtern ſide, a little before the emerſion; and about two or three ſeconds before it, on the ſame weſtern ſide, where the ſun was juſt coming out, a long and very narrow ſtreak of duſky but ſtrong red light ſeemed to colour the dark edge of the moon, though nothing like it had been ſeen immediately after the immerſion. But this inſtantly vaniſhed after the appearance of the ſun, as did alſo the aforeſaid luminous ring."

152 Mr Louville's obſervations.

Mr Louville relates, that a luminous ring of a ſilver colour appeared round the moon as ſoon as the ſun was entirely covered by her diſk, and diſappeared the moment he recovered his light; that this ring was brighteſt near the moon, and grew gradually fainter towards its outer circumference, where it was, however, defined; that it was not equally bright all over, but had ſeveral breaks in it: but he makes no doubt of its being occaſioned by the moon's atmoſphere, and thinks that the breaks in it were occaſioned by the mountains of the moon: he ſays alſo, that this ring had the moon, and not the ſun, for its centre, during the whole time of its appearance. Another proof brought by him of the moon having an atmoſphere is, that, towards the end of the total darkneſs, there was ſeen on that ſide of the moon on which the ſun was going to appear, a piece of a circle of a lively red, which might be owing to the red rays that are leaſt refrangible being tranſmitted through the moon's atmoſphere in the greateſt quantity: and that he might be aſſured this redneſs did not proceed from the glaſſes of his teleſcope, he took care to bring the red part into the middle of his glaſſes.

153 Lightning ſuppoſed to be frequent in the moon.

He lays great ſtreſs on the ſtreaks of light which he ſaw dart inſtantaneouſly from different places of the moon during the time of total darkneſs, but chiefly near the eaſtern edge of the diſk: theſe he takes to be lightning, ſuch as a ſpectator would ſee flaſhing from the dark hemiſphere of the earth, if he were placed upon the moon and ſaw the earth come between himſelf and the ſun. "Now (ſays Dr Long) it is highly probable, that if a man had, at any time, a view of that half of the earth where it is night, he would ſee lightning in ſome part of it or other." Louville farther obſerves, that the moſt mountainous countries are moſt liable to tempeſts; and that mountains being more frequent in the moon, and *higher, than on earth**, thunder and lightning muſt be more frequent there than with us; and that the eaſtern ſide of the moon would be moſt ſubject to thunder and lightning, thoſe parts having been heated by the ſun for half the month immediately preceding. It muſt here be obſerved, that Halley, in mentioning theſe flaſhes, ſays they ſeemed to come from behind the moon; and Louville, though he ſays they came ſometimes from one part and ſometimes from another, owns, that he himſelf only ſaw them near the eaſtern part of the diſk; and that, not knowing at that time what it was that he ſaw, he did not take notice whether the ſame appearance was to be ſeen on the other parts of the moon or not. He tells us, however, of an Engliſh aſtronomer, who preſented the Royal Society with a draught of what he ſaw in the moon at the time of this eclipſe; from which Louville ſeems to conclude that lightnings had been obſerved by that aſtronomer near the centre of the moon's diſk. "Now (ſays Dr Long) thunder and lightning would be a demonſtration of the moon having an atmoſphere ſimilar to ours, wherein vapours and exhalations may be ſupported, and furniſh materials for clouds, ſtorms, and tempeſts. But the ſtrongeſt proof brought by Louville of the moon having an atmoſphere is this, that as ſoon as the eclipſe began, thoſe parts of the ſun which were going to be hid by the moon grew ſenſibly paliſh as the former came near them, ſuffering beforehand a kind of imperfect eclipſe or diminution of light; this could be owing to nothing elſe but the atmoſphere of the moon, the eaſtern part whereof going before her reached the ſun before the moon did.

154 Great height of the lunar atmoſphere accounted for.

As to the great height of the lunar atmoſphere, which from the breadth of the luminous ring being about a whole digit would upon a calculation come out 180 miles, above three times as high as the atmoſphere of the earth, Louville thinks that no objection; ſince, if the moon were ſurrounded with an atmoſphere of the ſame nature with that which encompaſſes the earth, the gravitation thereof towards the moon would be but one-third of that of our atmoſphere towards the earth; and conſequently its expanſion would make the height of it three times as great from the moon as is the height of our atmoſphere from the earth."

The ſame luminous ring has been obſerved in other total eclipſes, and even in ſuch as are annular, though without the luminous ſtreaks or flaſhes of lightning above-

* See n° 142 *et ſeq.*

Conclusions from the foregoing Appearances.

bovementioned; it is even taken notice of by Plutarch: however, some members of the academy at Paris have endeavoured to account for both these phenomena without having recourse to a lunar atmosphere; and for this purpose they made the following experiments.

155 These phenomena otherwise accounted for.

The image of the sun coming through a small hole into a darkened room, was received upon a circle of wood or metal of a diameter a good deal larger than that of the sun's image; then the shadow of this opaque circle was cast upon white paper, and there appeared round it, on the paper, a luminous circle such as that which surrounds the moon. The like experiment being made with a globe of wood, and with another of stone not polished, the shadows of both these cast upon paper were surrounded with a palish light, most vivid near the shadows, and gradually more diluted at a distance from them. They observe also, that the ring round the moon was seen in the eclipse of 1706 by Wurzelbaur, who cast her shadow upon white paper. The same appearance was observed on holding an opaque globe in the sun, so as to cover his whole body from the eye; for, looking at it through a smoked glass, in order to prevent the eye from being hurt by the glare of light it would otherwise be exposed to, the globe appeared surrounded with a light resembling that round the moon in a total eclipse of the sun.

Thus they solve the phenemenon of the ring seen round the moon by the inflection, or *diffraction* as they call it, of the solar rays passing near an opaque substance. As for the small streaks of light abovementioned, and which are supposed to be lightning, they explain these by an hypothesis concerning the cavities of the moon themselves; which they consider as concave mirrors reflecting the light of the sun nearly to the same point; and as these are continually changing their situation with great velocity by the moon's motion from the sun, the light which any one of them sends to our eye is seen but for a moment. This, however, will not account for the flashes, if any such there are, seen near the centre of the disk, though it does, in no very satisfactory manner, account for those at the edges.

156 Occultations of the fixed stars by the moon.

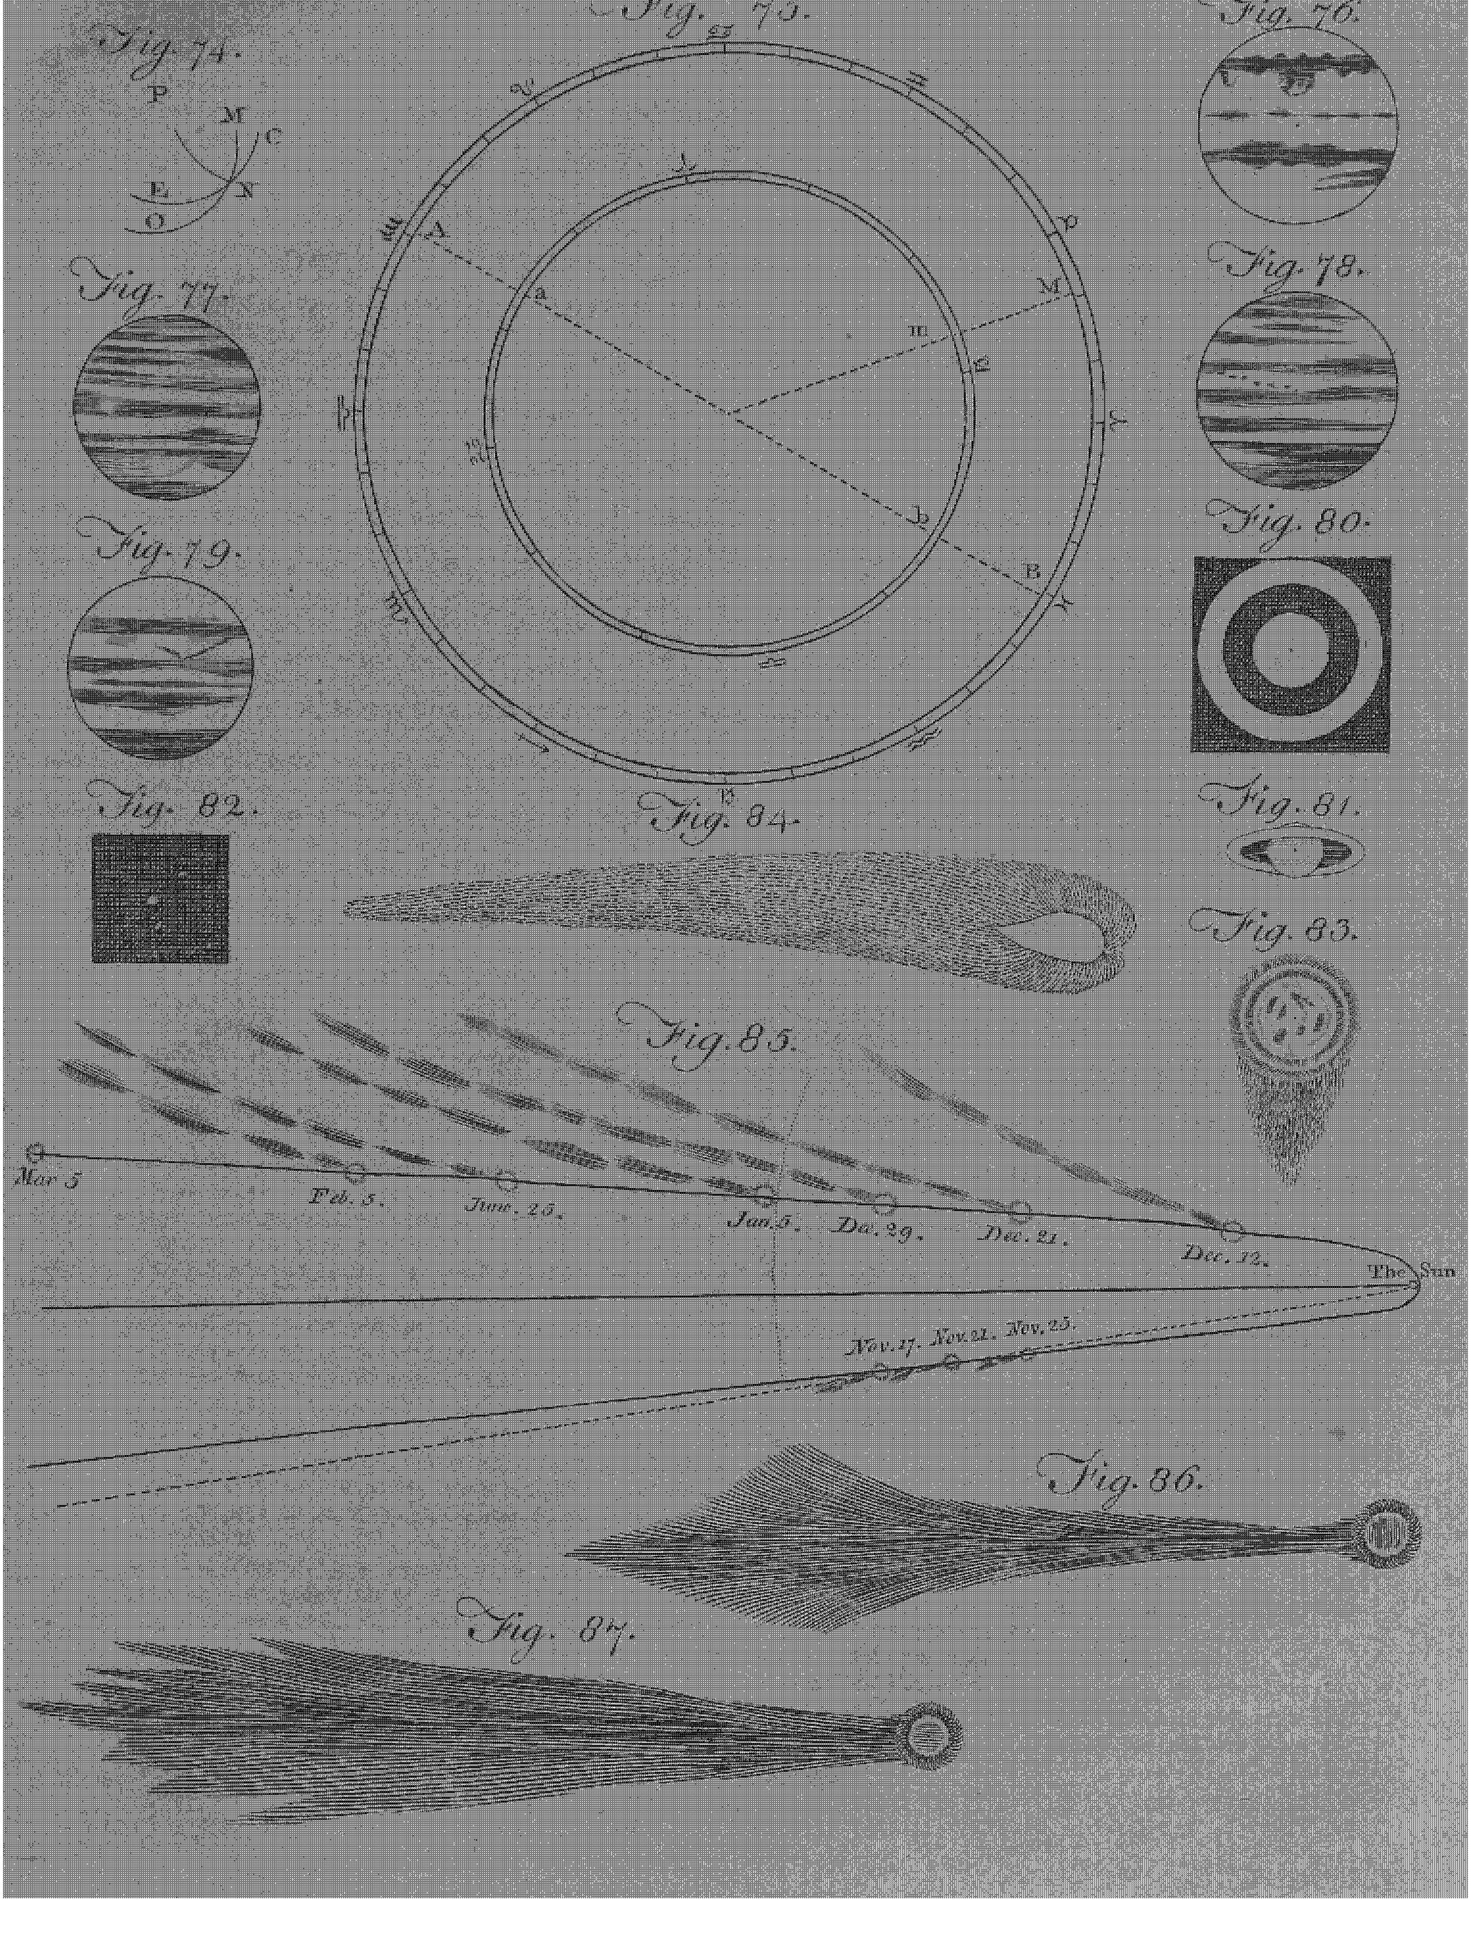
It has already been observed, that the occultations of the fixed stars and planets by the moon in general happen without any kind of refraction of their light by the lunar atmosphere. The contrary, however, has sometimes been observed, and the stars have been seen manifestly to change their shape and colour on going behind the moon's disk. An instance of this happened on the 28th of June N. S. in the year 1715, when an occultation of Venus by the moon happened in the day-time. Some astronomers in France observing this with a telescope, saw Venus change colour for about a minute before she was hid by the moon; and the same change of colour was observed immediately after her emersion from behind the disk. At both times the edge of the disk of Venus that was nearest the moon appeared reddish, and that which was most distant of a bluish, colour. These appearances, however, which might have been taken for proofs of a lunar atmosphere, were supposed to be owing to the observers having directed the axes of their telescopes towards the moon. This would necessarily cause any planet or star near the edge of the moon's disk to be seen through those parts of the glasses which are near their circumference, and consequently to appear coloured. This was evidently the case from other observations of an occultation of Jupiter by the moon the same year, when no such appearance of refraction could be perceived while he was kept in the middle of the telescope. Maraldi also informs us, that he had observed before this two other occultations of Venus and one of Jupiter; and was always attentive to see whether those planets changed their figure or colour either upon the approach of the moon to cover them, or at their first coming again into sight; but never could perceive any such thing. Nor could he, in a great number of occultations of the fixed stars, perceive the smallest apparent change in any of them, excepting once that a fixed star seemed to increase its distance a little from the moon as it was going to be covered by her; but this, he suspected, might be owing to his telescope being directed so as to have the star seen too far from the middle of its aperture. He concludes, therefore, that the moon has no atmosphere: and he remarks, that at Montpelier, perhaps because the air is clearer there than at London, the luminous ring round the moon appeared much larger than at London; that it was very white near the moon, and gradually decreasing in brightness formed round her a circular area of about eight degrees in diameter. If, says he, this light was caused by the atmosphere of the moon, of what a prodigious extent must that atmosphere be?

157 Of a plurality of worlds.

Before we enter upon any further speculations concerning the celestial bodies, we shall here take some notice of the doctrine of a plurality of worlds; to which we are naturally led by the question, Whether the moon is inhabited or not? This is an hypothesis of very ancient date, and which in modern times has been revived in such a manner as now to be almost adopted as an undoubted truth. Plutarch, Diogenes, Laertius, and Stobæus, informs us, that this doctrine was embraced by several of the ancient Greek philosophers; from which authors Gregory has given us extracts in the Preface to his Astronomy. "Among the moderns (says Dr Long), Huygens has written a treatise, which he calls *Cosmotheoros*, or *A view of the world*, worth perusing. One thing, however, I must find fault with; that, in peopling the planets with reasonable creatures, he insists upon their being in all points exactly similar to the human race, as to the shape of their bodies and the endowments of their minds: this is too confined a thought; for we cannot but acknowledge that infinite power and wisdom is able to form rational beings of various kinds, not only in shape and figure different from the human, but endowed also with faculties and senses very different; such as in our present state we can have no idea of." With regard to the probability of the doctrine itself, the Doctor expresses himself in the following manner. "That the earth and all the creatures thereon were created to be subservient to the use of man, we may believe upon the authority of the sacred writer, Psalm viii. but that the stars and planets were formed only to bespangle the canopy of heaven with their glimmering, which does not furnish us with the twentieth part of the light the moon gives, I think is not at all probable: this is contrary to the observation made by the best philosophers, that nature is magnificent in all her designs, but frugal in the execution of them. It is commonly said, that nature

ASTRONOMY.

Plate LXVIII



Conclusions from the foregoing Appearances.

nature does nothing in vain: now by *Nature*, in a sound sense, must be understood the present order and disposition of things according to the will of the supreme Being."

158 Objections to the possibility of this doctrine.

Objections have been made to the possibility of this hypothesis from the different degrees of heat and light which the planets receive from the sun, according to their various distances from him. On Venus, for instance, the heat must be more than double what it is with us, and on Mercury upwards of ten times as great; so that were our earth brought as near the sun as Mercury, every drop of liquid would be evaporated into steam, and every combustible solid set on fire; while, on the other hand, were we removed to the distance of the superior planets, such as the Georgium Sidus, Saturn, or even Jupiter, there is the highest probability that our liquids would all be congealed into ice, at the same time that the climate would be utterly insupportable by such creatures as we are. Objections of the same kind are drawn from the small quantity of light which falls upon the more distant planets, which

160 Inconclusive.

it is thought would be insufficient for the purposes of living and rational creatures. Such arguments as these, however, are by no means conclusive; for as Dr Long justly observes, "we are sure, that if the all-wise supreme Being hath placed animals on the planets, he has fitted the inhabitants to the places, and the places to the inhabitants." We shall therefore only add the following quotation from Mr Nicholson † concerning final causes, which sums up all that can be said with propriety in favour of the doctrine in question.—"The purposes or motives (says he) which determine the actions of intelligent beings, and produce their effects in a manner similar to the operation of the laws of nature, or the properties of matter in cases where thought is not supposed to concerned, are called *final causes*. In the works of nature we behold enough of exquisite contrivance, and can see far enough into many final causes, to convince us that the arrangement of the universe has been made, and probably still is occasionally adjusted, by a Being whose intelligence and power are immensely beyond what we possess. To judge properly of his intentions, or, in other words, to be equal to the task of exploring final causes, requires no less than a perfect knowledge and recollection of every purpose to which the objects around us may be applied, together with a clear conception of the ideas of fitness and order that form the prototypes in the mind of that Great Being who directs their motions. These considerations show the absurdity of attempting to explain the final causes of every event we see; but they by no means require that we should neglect them in cases where we have reason to believe that we understand the phenomena, and have sufficient experience to be assured that we discern the principal, or at least one of the principal, purposes to which things may have been destined. Thus it is scarcely to be imagined that we can err in concluding, that the eyes, ears, legs, wings, and other parts of animals were made for the purposes of seeing, hearing, walking, flying, and so forth. Neither can we avoid inferring, that the Power who constructed living creatures with mouths, teeth, and organs to digest and assimilate food for their nutriment, did likewise form other organized bodies, which we call *vegetables*, for the express purpose of affording that food. It is needless to multiply instances. We cannot avoid seeing them every moment; and their effect is so striking, that we are insensibly forced from analogy to allow the existence of a final cause in all cases, whether we are able to discover it or not.

† *Introd. to Nat. Phil.* page 141. Philad. Edition.

161 Of the various climates of the planets.

"On this ground, an inquiry into the final causes of the planetary bodies offers itself to our consideration. The earth is shown to be a planet in circumstances very similar to the other five: we know its final cause—to support a number of inhabitants: And by analogy we may conclude that the others are also habitable worlds; though, from their different proportions of heat, it is credible that beings of our make and temperature could not live upon them. However, even that can scarcely be affirmed of all the planets; for the warmest climate on the planet Mars is not colder than many parts of Norway or Lapland are in the spring or autumn. Jupiter, Saturn, and the Georgium Sidus, it must be granted, are colder than any of the inhabited parts of our globe. The greatest heat on the planet Venus exceeds the heat on the island of St Thomas on the coast of Guinea, or Sumatra in the East Indies, about as much as the heat in those places exceeds that of the Orkney islands, or the city of Stockholm in Sweden: therefore, at 60° north latitude on that planet, if its axis were perpendicular to the plane of its orbit, the heat would not exceed the greatest heat on the earth; and of course vegetation like ours might be there carried on, and animals of the species on earth might subsist. If Mercury's axis be supposed to have a like position, a circle of about 20° diameter round each pole would enjoy the same temperature as the warmer regions of the earth, though in its hottest climate water would continually boil, and most inflammable substances would be parched up, destroyed, or converted into vapour. But it is not at all necessary that the planets should be peopled with animals like those on the earth; the Creator has doubtless adapted the inhabitants of each to their situation.

162 Comparison of the light of the superior planets with our day.

"From the observations that have been just made, a better idea may be formed of the proportions of heat on the planets than can be conveyed by numbers. It will not, however, be remote from our purpose to compare the light of the superior planets with that of our day; from whence it will appear, that they are by no means in a state of darkness notwithstanding their great distance from the sun. This might be instanced by several different methods; as by the sun's light admitted into a dark chamber, and received on paper with different degrees of obliquity; by a greater or less number of candles brought into a room for the purpose of illuminating it with various degrees of light; or by various optical methods that need not here be described. It will be sufficient for the illustration of the subject to compare their different proportions of light with that of a moonshine night at the time of full.

"When the moon is visible in the day-time, its light is so nearly equal to that of the lighter thin clouds, that it is with difficulty distinguished among them. Its light continues the same during the night; but the absence of the sun suffering the pupil of the eye to dilate itself, it become more conspicuous. It therefore follows, that if every part of the sky were equally

Concluſions from the foregoing Appearances.

equally luminous with the moon's diſk, the light would be the ſame as if in the day-time it were covered with the thin clouds abovementioned. This day-light is conſequently in proportion to that of the moon as the whole ſurface of the ſky or viſible hemiſphere is to the ſurface of the moon; that is to ſay, nearly as 90,000 to 1. The light of the Georgium Sidus being to that of the earth as 0.276 to 100, will be equal to the effect of 248 full moons. Jupiter's day will equal the light of 3,330 moons; and that of Mars will require 38,700, a number ſo great that they would almoſt touch one another. It is even probable, that the comets in the moſt diſtant parts of their orbits enjoy a degree of light much exceeding moonſhine."

Of all the celeſtial bodies, comets have given riſe to the greateſt number of ſpeculations and conjectures. Their ſtrange appearance has in all ages been a matter of terror to the vulgar, who uniformly have looked upon them to be evil omens and forerunners of war, peſtilence, &c. Others, leſs ſuperſtitious, ſuppoſed them to be meteors raiſed in the higher regions of the air. But we find that ſome part of the modern doctrine concerning them had been received into the ancient Italic and Pythagorean ſchools: for they held them to be ſo far of the nature of planets, that they had their periodical times of appearing; that they were out of ſight for a long time, while they were carried aloft at an immenſe diſtance from the earth, but become viſible when they deſcended into the lower regions of the air, when they were nearer to us.

163
Suppoſed by the ancients to be planets.

Theſe opinions were probably brought from Egypt, from whence the Greeks borrowed great part of their learning. However, it ſeems not to have been generally received; for Ariſtotle, who mentions it, aſſerted that the heavens were unchangeable, and not liable to generation or corruption. Comets, therefore, which he believed to be generated when they firſt made their appearance, and deſtroyed when they vaniſhed from our ſight, he maintained could not be heavenly bodies, but rather meteors or exhalations raiſed into the upper regions of the atmoſphere, where they blazed out for a while, and diſappeared when the matter of which they were formed was conſumed. Seneca, who lived in the firſt century, mentions Appollonius of Myndus, a very careful obſerver of natural cauſes, to have been of the ſame ſentiments with the moſt ancient Greek philoſophers with regard to comets. He himſelf had ſeen two; one in the reign of Claudius, the other in that of Nero; beſides another which he ſaw while a boy, before the death of Auguſtus. He plainly intimates, that he thought them above the moon; and argues ſtrongly againſt thoſe who ſuppoſed them to be meteors, or held other abſurd opinions concerning them; declaring his belief that they were not fires ſuddenly kindled, but the eternal productions of nature. He points out alſo the only way to come at a certainty on this ſubject, viz. by collecting a number of obſervations concerning their appearance, in order to diſcover whether they return periodically or not. "For this purpoſe (ſays he) one age is not ſufficient; but the time will come when the nature of comets and their magnitudes will be demonſtrated, and the routs they take, ſo different from the planets, explained. Poſterity will then wonder that the preceding ages ſhould be ignorant of matters ſo plain and eaſy to be known."

164
Ariſtotle's opinion concerning them.

For a long time this prediction of Seneca ſeemed very unlikely to be fulfilled. The great authority which Ariſtotle maintained for many ages, determined them to be nothing but meteors caſually lighted up in the air; though they were manifeſtly at a great height, not only above the clouds, but ſubject to the diurnal revolution of the earth. In the dark and ſuperſtitious ages, they were held to be the forerunners of every kind of calamity, and were ſuppoſed to have different degrees of malignity according to the ſhape they aſſumed; from whence alſo they were differently denominated. Thus, ſome were ſaid to be bearded, ſome hairy; ſome to repreſent a beam, ſword, or ſpear; others a target, &c.; whereas modern aſtronomers acknowledge only one ſpecies of comets, and account for their different appearances from their different ſituations from the ſun and earth.

165
Only one ſpecies of them exiſts.

166
Kepler and Bodin's opinion of them.

It was not till ſome time after people began to throw off the fetters of ſuperſtition and ignorance which had ſo long held them, that any rational hypotheſis was formed concerning comets. Kepler, in other reſpects a very great genius, indulged the moſt extravagant conjectures, not only concerning comets, but the whole ſyſtem of nature in general. The planets he imagined to be huge animals who ſwam round the ſun by means of certain fins acting upon the ethereal fluid, as thoſe of fiſhes do on the water: and agreeable to this notion, he imagined the comets to be monſtrous and uncommon animals generated in the celeſtial ſpaces; and he explained how the air engendered them by an animal faculty. A yet more ridiculous opinion, if poſſible, was that of John Bodin, a learned man of France in the 16th century. He maintained that comets "are ſpirits, which having lived on the earth innumerable ages, and being at laſt arrived on the confines of death, celebrate their laſt triumph, or are recalled to the firmament like ſhining ſtars! This is followed by famine, plague, &c. becauſe the cities and people deſtroy the governors and chiefs who appeaſe the wrath of God." This opinion he ſays he borrowed from the philoſopher Democritus, who imagined them to be the ſouls of famous heroes: but that being irreconcileable with Bodin's Chriſtian ſentiments, he was obliged to ſuppoſe them to be a kind of genii, or ſpirits ſubject to death, like thoſe ſo much mentioned in the Mahometan fables. Others, again, have denied even the exiſtence of comets, and maintained that they were only falſe appearances occaſioned by the refraction or reflection of light.

167
Bernouilli's opinion.

The firſt rational conjecture we meet with is that of James Bernouilli, an Italian aſtronomer, who imagined them to be the ſatellites of ſome very diſtant planet, which was inviſible to us on account of its diſtance, as were alſo the ſatellites unleſs when in a certain part of their courſe.

168
True doctrine concerning them revived by Tycho Brache.

Tycho Brache was the firſt who reſtored the comets to their true rank in the creation. Before his time, ſeveral comets had been obſerved with tolerable exactneſs by Regiomontanus, Appian, Fabricius, and others; yet they all thought them below the moon. But Tycho, being provided with much better inſtruments ſet himſelf with great diligence to obſerve the famous

Conclusions from the foregoing Appearances.

famous comet of 1577: and from many careful observations, deduced that it had no sensible diurnal parallax; and therefore was not only far above the regions of our atmosphere, but much higher than the moon. But though few have come so near the earth as to have any diurnal parallax, all of them have what may be called an annual parallax; that is, the revolution of the earth in her orbit causes their apparent motion to be very different from what it would be if viewed from the sun; and this shows them to be much nearer than the fixed stars, which have no such parallax. Kepler, the disciple of Tycho, notwithstanding his ridiculous conjecture already mentioned, was very attentive to the motions of the comets, and found that they did not move in straight lines, as had been supposed. He showed that their paths were concave towards the sun, and supposed them to move in parabolic trajectories.

169 Their motion exactly determined by Sir Isaac Newton.

Their true motion, however, was only discovered from the observations made by Sir Isaac Newton on the great comet of 1680. This descended almost perpendicularly towards the sun with a prodigious velocity; ascending again with the same velocity retarded, as it had been before accelerated. It was seen in the morning by a great number of astronomers in different parts of Europe, from the 4th to the 25th of November, in its way towards the sun; and in the evening from the 12th of December to the 9th of March following. The many exact observations made on this comet, enabled Sir Isaac Newton to determine that they are a kind of planets which move in very eccentric ellipsis; and this opinion is now looked upon to be certainly established. It was opposed, however, by M. de la Hire, and some other French philosophers; and it is evident that the whole dispute now turned on mere practical observation. If the return of any comet could be predicted, and its periodical time calculated like that of a planet, then the doctrine might be concluded certainly true, but not otherwise.

170 Dr Halley predicts a comet's return.

Dr Halley therefore set himself to collect all the observations he could on comets; and afterwards calculated the orbits of twenty-four of them, on a supposition of their being paraboles; but afterwards found that they agreed better with the supposition of their motion being performed in very eccentric elliptical orbits. On this he calculated a table of their elements; from which it was manifest that they were not comprehended in the zodiac, some of them making an angle of upwards of 80° with the ecliptic.

171 Periodical times of different comets determined.

By computations founded on these elements, the Doctor concluded that the comet of 1682, was the same which had appeared in 1607 and 1531; that it had a period of 75 or 76 years; and he ventured to foretel that it would return about the year 1758. The comet which appeared in 1661 was supposed to be the same with that of 1532, and to have a period of 129 years; and from the equality of periods, and similitude of appearances, it was concluded that the great comet of 1680 was the same which had appeared in 1106 in the time of Henry I. and the consulate of Lampadius and Orestes about the year 531, and in the year 44 B. C. before Julius Cæsar was murdered; and thence concluded that its period was 575 years. Mr Dunthorne, however, has endeavoured to show from a MS. in Pembroke-hall library, that the comet of 1106 could not be the same with that of 1680; but M. de la Lande thinks the four appearances related by Dr Halley stronger proofs than a single observation, which might be very faulty.

Since the time of Dr Halley other astronomers have calculated the elements of 25 other comets: all of which, excepting one of three which appeared in 1759, and which differs but little from that of 1531, 1607, and 1682, and is therefore accounted the same; differ very much from each other; so that we cannot help concluding them all to be different, and that the number of these bodies is very great.

172 Why comets may sometimes be invisible even in their perihelion.

"It is not, however, unlikely (says Dr Long), from the immense interval between the orbit of Saturn and the nearest fixed stars, that many of them have not descended into the planetary regions since they have been looked upon as celestial bodies, and observed accordingly; besides, it may often happen, that a body may finish its whole period without being observed by us, on account of the unfavourable situation of the earth in her orbit when the comet is in its perihelion. Thus, if the comet be either behind or before the sun, or nearly so, it must be above our horizon in the day-time, and consequently invisible, except the sun should at that time be in a total eclipse; for then the comet might be seen near the sun, as well as the stars and planets are: and this case is said to have happened; for Seneca relates from Possidonius, that a comet was seen when the sun was eclipsed, which had before been invisible by being near that luminary."

173 Why more are seen in the hemisphere towards the sun than in the opposite.

A greater number of comets are seen in the hemisphere towards the sun than in the opposite; the reason of which will easily appear from fig. 97. wherein S represents the sun, E the earth, ABCD the sphere of the fixed stars: and because comets either do not reflect the light enough to be visible, or emit tails conspicuous enough to attract our notice, till they come within the planetary regions, commonly a good way within the sphere of Jupiter, let KLMN be a sphere concentric to the sun, at such a distance from him, that no comet can be seen by us till it come within that distance; through E draw the plane BD perpendicular to SE, which will divide the sphere KLMN into two hemispheres, one of which BCD, is towards the sun, the other, DAB, opposite. Now it is manifest, that the spherical portion LMN, which is in the hemisphere BCD towards the sun, is larger than the portion NKL in the hemisphere opposite to him; and consequently a greater number of comets will appear in the hemisphere BCD than in that marked DAB.

174 Great differences in the eccentricities of the orbits of comets.

Though the orbits of all comets are very eccentric ellipses, there are vast differences among them; but excepting Mercury, there are no great differences among the planets either as to the eccentricity of their orbits, or the inclination of their planes; the planes of some comets are almost perpendicular to others, and some of their ellipses are much wider than others. The narrowest ellipsis of any comet hitherto observed was that of 1680. There is also a much greater inequality in the motion of the comets than of the planets; the velocity of the former being incomparably greater in their perihelion than in their aphelion; but the planets are but very little accelerated.

175 Opinions concerning their substance.

Astronomers are now generally agreed, that comets are opaque bodies, enlightened by the sun. Hevelius, in a large work, wherein he gives the opinion of various

Conclusions from the foregoing Appearances.

ous authors on the subject, mentions some who were of the same sentiments with himself, that comets were so far transparent as to let the light of the sun pass through them, which formed their tails. Sir Isaac Newton was of opinion, that they are quite opaque; and in confirmation of this, he observes, that if a comet be seen in two parts of its orbit, at equal distances from the earth, but at unequal distances from the sun, it always shines brightest in that nearest the sun. They are of very different magnitudes, which may be conjectured from their apparent diameter and brightness. Thus the head of a comet, when of the same brightness and apparent diameter with Saturn, may be supposed to be nearly about the same magnitude with that planet; though this must be attended with some uncertainty, as we know not whether the heads of comets reflect the sun's light in the same manner the planets do. Their distance may be known from their parallax, in the manner related in a subsequent section.

176 Distances, diameters, &c. of some comets computed.

In this manner he found the distance of the comet of 1577 to be about 210 semidiameters of the earth, or about 840,000 miles distant from us, its apparent diameter being seven minutes; whence he concluded, that the true diameter of the comet was to that of the earth as 3 to 14. "But (says Dr Long) it was the atmosphere of the comet which was then measured." Hevelius, from the parallax and apparent diameter of the head of the comet in 1652, computed its diameter to be to that of the earth as 52 to 100. By the same method he found the diameter of the head of the comet of 1664 to be at one time 12 semidiameters of the earth, and at another not much more than 5. "That the head of a comet must appear less the farther it is from the earth (says Dr Long) is obvious; but besides this apparent change, there is also a real one in the dimensions of the head of the same comet; for, when near the sun, the atmosphere is diminished by the heat raising more of it into the tail; whereas, at a greater distance, the tail is diminished and the head enlarged." Hevelius computed the diameter of the nucleus of the comets of 1661 and 1665 to be only about a tenth part of that of the earth; and Cysatus makes the true diameter of the comet of 1618 to be about the same size. Some comets, however, from their apparent magnitude and distance, have been supposed much larger than the moon, or even equal in magnitude to some of the primary planets; and some

177 Eclipses occasioned by comets.

have imagined, that by an interposition of these bodies betwixt the earth and sun, we might account for those darknesses which cannot be derived from any interposition of the moon. Such are those mentioned by Herodotus, l. 7. c. 37. and l. 9. c. 70. likewise the eclipse mentioned by Dion, which happened a little before the death of Augustus; and it is observable that Seneca saw a comet that year. Some have even attempted to account in this manner for the darkness which happened at our Saviour's crucifixion; and indeed it is certain, that were a comet in its perigee to come between the earth and sun, and to be moving the same way with the earth, it must cause a darkness much more intense, as well as of more considerable duration, than what could take place in any lunar eclipse.

178 Conjectures concerning their tails.

Various conjectures have been formed respecting the tails of comets; though it is acknowledged by all, that they depend on the sun somehow or other; and for this plain reason, that they are always turned from him; but in what manner this is accomplished, we cannot easily determine. Apian, Tycho-Brache, and others, thought the tail was formed by the sun's rays transmitted through the nucleus of the comet, which they fancied transparent, and was there refracted as in a lens of glass, so as to form a beam of light behind the comet: but this cannot be the case, as well because the figure of a comet's tail does not answer to such a refraction, as that such refracted light would not be seen by a spectator placed sideways to it, unless it fell upon some substance sufficiently dense to cause a reflexion. 179

179 Opinion of Des Cartes.

Des Cartes and his followers were of opinion, that the tail of a comet was owing to the refraction of its head: but if this were the case, the planets and principal fixed stars must have tails also; for the rays from them pass through the same medium as the light from the comets. Sir Isaac Newton was of opinion, that the tail of a comet is a very thin vapour which the head sends out by reason of its heat: that it ascends from the sun just as smoke does from the earth: that as the ascent of smoke is caused by the rarefaction of the air wherein it is entangled, causing such air to ascend and carry the smoke up with it; so the sun's rays acting upon the coma or atmosphere of the comet, do by rarefaction and refraction heat the same; that this heated atmosphere heats, and by heating rarefies, the ether that is involved therein; and that the specific gravity with which such ether tends to the sun, is so diminished by its rarefaction, that will now ascend from him by its relative lightness, and carry with it the reflecting particles whereof the tail is composed. Tho' the immensely large tails of some comets seem to require a great quantity of matter to produce them, this is no objection to the foregoing solution: for every day's experience shows what a great quantity of smoke is produced from a very little wood or coal; and Newton has demonstrated, that a cubic inch of air equally rarefied with that at the distance of a semidiameter from the earth's surface, would fill all the planetary regions to the orbit of Saturn and beyond. Mairan entertained a very different opinion. He supposed the tails of the comets to be formed out of the luminous matter whereof the sun's atmosphere consists. This he supposes to extend as far as the orbit of the earth, and to furnish matter for the aurora borealis. M. de la Lande is for joining the two last opinions together. Part of the matter which forms the tails of comets he supposes to arise from their own atmosphere rarefied by heat and pushed forward by the force of the light streaming from the sun; and also that a comet passing through the sun's atmosphere is drenched therein, and carries away some of it. Mr Rowning objects to Newton's account, that it can hardly be supposed the thin vapour of the tail should go before the more solid body of the comet, when the motion thereof is sometimes so extremely swift, as that of some of the comets is said to be after the rate, as Sir Isaac Newton calculated the motion of the comet of 1680 to be, of no less than 880,000 miles an hour. He therefore supposes the atmosphere of the comet to extend every way round it as far as the tail reaches; and that the part of it which makes the tail is distinguished from the rest, so as to fall thick upon that part of the atmosphere which goes before the comet in its progress along its elliptic orbit.

Conclusions from the foregoing Appearances.

The greatest objection to this is the immense magnitude of the atmospheres; as it must now be supposed to account for the vast lengths of the tails of some comets, which have been said to measure above 80 millions of miles.

The many discoveries which, since the time of Newton, Halley, and other celebrated mathematicians, have been made in electricity, having brought in a new element unknown to former ages, and which shows a vast power through every part of the creation with which we are acquainted, it became natural to imagine that it must extend also into those higher regions which are altogether inaccessible to man. The similarity of the tails of comets to the aurora borealis, which is commonly looked upon to be an electrical phenomenon, therefore suggested an opinion at present far from being generally disbelieved, that the tails of comets are streams of electric matter. An hypothesis of this kind was published by Dr Hamilton of Dublin in a small treatise, entitled, *Conjectures on the Nature of the Aurora Borealis, and on the Tails of Comets.* His hypothesis is, that the comets are of use to bring back the electric fluid to the planets, which is continually discharged from the higher regions of their atmospheres. Having given at length the abovementioned opinion of Sir Isaac, "We find (says he) in this account, that Sir Isaac ascribes the ascent of comets tails to their being rarer and lighter, and moving round the sun more swiftly, than the solar atmosphere, with which he supposes them to be surrounded whilst in the neighbourhood of the sun; he says also, that whatever position (in respect to each other) the head and tail of a comet then receive, they will keep the same afterwards most freely; and in another place he observes, 'That the celestial spaces must be entirely void of any power of resisting, since not only the solid bodies of the planets and comets, but even the exceeding thin vapours of which comets tails are formed, move thro' those spaces with immense velocity, and yet with the greatest freedom.' I cannot help thinking that this account is liable to many difficulties and objections, and that it seems not very consistent with itself or with the phenomena.

180
Dr Hamilton of Dublin's opinion.

"I do not know that we have any proof of the existence of a solar atmosphere of any considerable extent, nor are we any where taught how to guess at the limits of it. It is evident that the existence of such an atmosphere cannot be proved merely by the ascent of comets tails from the sun, as that phenomenon may possibly arise from some other cause. However, let us suppose for the present, that the ascent of comets tails is owing to an atmosphere surrounding the sun, and see how the effects arising from thence will agree with the phenomena. When a comet comes into the solar atmosphere, and is then descending almost directly to the sun, if the vapours which compose the tail are raised up from it by the superior density and weight of that atmosphere, they must rise into those parts that the comet has left, and therefore at that time they may appear in a direction opposite to the sun. But as soon as the comet comes near the sun, and moves in a direction nearly at right angles with the direction of its tail, the vapours which then arise, partaking of the great velocity of the comet, and being specifically lighter than the medium in which they move, and being vastly expanded through it, must necessarily suffer a resistance immensely greater than what the small and dense body of the comet meets with, and consequently cannot possibly keep up with it, but must be left behind, or, as it were, driven backwards by the resistance of that medium into a line directed towards the parts which the comet has left, and therefore can no longer appear in a direction opposite to the sun. And, in like manner, when a comet passes its perihelion, and begins to ascend from the sun, it certainly ought to appear ever after with its tail behind it, or in a direction pointed towards the sun; for if the tail of the comet be specifically lighter than the medium in which it moves with so great velocity, it must be just as impossible it should move foremost, as it is that a torch moved swiftly thro' the air should project its flame and smoke before it. Since therefore we find that the tail of a comet, even when it is ascending from the sun, moves foremost, and appears in a direction nearly opposite to the sun, I think we must conclude that the comet and its tail do not move in a medium heavier and denser than the matter of which the tail consists, and consequently that the constant ascent of the tail from the sun must be owing to some other cause. For that the solar atmosphere should have density and weight sufficient to raise up the vapours of a comet from the sun, and yet not be able to give any sensible resistence to these vapours in their rapid progress through it, are two things inconsistent with each other: And therefore, since the tail of a comet is found to move as freely as the body does, we ought rather to conclude, that the celestial spaces are void of all resisting matter, than that they are filled with a solar atmosphere, be it ever so rare.

"But there is, I think, a further consideration, which will show that the received opinion, as to the ascent of comets tails, is not agreeable to the phenomena, and may at the same time lead us to some knowledge of the matter of which these tails consist; which I suspect is of a very different nature from what it has been hitherto supposed to be. Sir Isaac says, the vapours, of which the tail of a comet consists, grow hot by reflecting the rays of the sun, and thereby warm and rarefy the medium which surrounds them; which must therefore ascend from the sun, and carry with it the reflecting particles of which the tail is formed; for he always speaks of the tail as shining by reflected light. But one would rather imagine, from the phenomena, that the matter which forms a comet's tail has not the least sensible power of reflecting the rays of light. For it appears from Sir Isaac's observation, which I have quoted already, that the light of the smallest stars, coming to us through the immense thickness of a comet's tail, does not suffer the least diminution. And yet, if the tail can reflect the light of the sun so copiously as it must do if its great splendor be owing to such reflection, it must undoubtedly have the same effect on the light of the stars; that is, it must reflect back the light which comes from the stars behind it, and by so doing must intercept them from our sight, considering its vast thickness, and how exceedingly slender a ray is that comes from a small star; or if it did not intercept their whole light, it must at least increase their twinkling. But we do not find that it has even this small effect: for those stars that appear through the tail are not observed to twinkle more than others

Conclusions from the foregoing Appearances.

others in their neighbourhood. Since therefore this fact is supported by observations, what can be a plainer proof that the matter of a comet's tail has no power of reflecting the rays of light? and consequently that it must be a self-shining substance. But the same thing will further appear, from considering that bodies reflect and refract light by one and the same power; and therefore if comets tails want the power of refracting the rays of light, they must also want the power of reflecting them. Now, that they want this refracting power appears from hence: If that great column of transparent matter which forms a comet's tail, and moves either in a vacuum or in some medium of a different density from its own, had any power of refracting a ray of light coming through it from a star to us, that ray must be turned far out of its way in passing over the great distance between the comet and the earth; and therefore we should very sensibly perceive the smallest refraction that the light of the stars might suffer in passing through a comet's tail. The consequence of such a refraction must be very remarkable: the stars that lie near the tail would, in some cases, appear double; for they would appear in their proper places by their direct rays, and we should see their images behind the tail, by means of their rays which it might refract to our eyes; and those stars that were really behind the tail would disappear in some situations, their rays being turned aside from us by refraction. In short, it is easy to imagine what strange alterations would be made in the apparent places of the fixed stars by the tails of comets, if they had a power of refracting their light, which could not fail to be taken notice of if any such ever happened. But since astronomers have not mentioned any such apparent changes of place among the stars, I take it for granted that the stars seen through all parts of a comet's tail appear in their proper places, and with their usual colours; and consequently I infer, that the rays of light suffer no refraction in passing through a comet's tail. And thence I conclude (as before), that the matter of a comet's tail has not the power of refracting or reflecting the rays of light, and must therefore be a lucid or self-shining substance."

181 Sir Isaac's account defended.

But whatever probability the Doctor's conjecture concerning the materials whereof the tails are formed may have in it, his criticism on Sir Isaac Newton's account of them seems not to be just: for that great philosopher supposes the comets to have an atmosphere peculiar to themselves; and consequently, in their nearest approaches to the sun, both comet and atmosphere are immersed in the atmosphere of that luminary. In this case, the atmosphere of the comet being prodigiously heated on the side next to the sun, and consequently the equilibrium in it broken, the denser parts will continually pour in from the regions farthest from the sun; for the same reason, the more rarefied part which is before will continually fly off opposite to the sun, being displaced by that which comes from behind; for tho' we must suppose the comet and its atmosphere to be heated on all sides to an extreme degree, yet still that part which is farthest from the sun will be less hot, and consequently more dense, than what is nearest to his body. The consequence of this is, that there must be a constant stream of dense atmosphere descending towards the sun, and another stream of rarefied vapours and atmosphere ascending on the contrary side; just as, in a common fire, there is a constant stream of dense air descending, which pushes up another of rarefied air, flame, and smoke. The resistance of the solar atmosphere may indeed be very well supposed to occasion the curvature observable in the tails of comets, and their being better defined in the fore part than behind; and this appearance we think Dr Hamilton's hypothesis is incapable of solving. We grant, that there is the utmost probability that the tails of comets are streams of electric matter; but they who advance a theory of any kind ought to solve every phenomenon, otherwise their theory is insufficient. It was incumbent on Dr Hamilton, therefore, to have explained how this stream of electric matter comes to be bent into a curve; and also why it is better defined and brighter on the outer side of the arch than on the inner. This, indeed, he attempts in the following manner: "But that this curvature was not owing to any resisting matter appears from hence, that the tail must be bent into a curve though it met with no resistance; for it could not be a right line, unless all its particles were projected in parallel directions, and with the same velocity, and unless the comet moved uniformly in a right line. But the comet moves in a curve, and each part of the tail is projected in a direction opposite to the sun, and at the same time partakes of the motion of the comet; so that the different parts of the tail must move on in lines which diverge from each other; and a line drawn from the head of a comet to the extremity of the tail, will be parallel to a line drawn from the sun to the place where the comet was when that part of the tail began to ascend, as Sir Isaac observes; and so all the chords or lines drawn from the head of the comet to the intermediate parts of the tail, will be respectively parallel to lines drawn from the sun to the places where the comet was when these parts of the tail began to ascend. And therefore, since these chords of the tail will be of different lengths, and parallel to different lines, they must make different angles, with a great circle passing through the sun and comet, and consequently a line passing through their extremities will be a curve.

182 Dr Hamilton's hypothesis insufficient.

"It is observed, that the convex side of the tail which is turned from the sun is better defined, and shines a little brighter, than the concave side. Sir Isaac accounts for this, by saying, that the vapour on the convex side is fresher (that is, has ascended later) than that on the concave side; and yet I cannot see how the particles on the convex side can be thought to have ascended later than those on the concave side which may be nearer to the head of the comet. I think it rather looks as if the tail, in its rapid motion, met with some slight resistance just sufficient to cause a small condensation in that side of it which moves foremost, and which would occasion it to appear a little brighter and better defined than the other side; which slight resistance may arise from that subtile ether which is supposed to be dispersed through the celestial regions, or from this very electric matter dispersed in the same manner, if it be different from the ether."

On the last part of this observation we must remark, that though a slight resistance in the etherial medium would have served Sir Isaac Newton's turn, it will by no means serve Dr Hamilton's; for though a stream of

water

Conclusions from the foregoing Appearances.

water or air may be easily destroyed or broken by resistance, yet a stream of electric matter seems to set every obstacle at defiance. If a sharp needle is placed on the conductor of an electric machine, and the machine set in motion, we will perceive a small stream of electric matter issuing from the point; but though we blow against this stream of fire with the utmost violence, it is impossible either to move it, or to brighten it on the side against which we blow. If the celestial spaces then are full of a subtile ether capable of thus affecting a stream of electric matter, we may be sure that it also will resist very violently: and we are then as much difficulted to account for the projectile motion continuing amidst such violent resistance; for if the ether resists the tail of the comet, it is impossible to prove that it doth not resist the head also.

183 Electric matter not always passive.

This objection may appear to some to be but weakly founded, as we perceive the electric fluid to be endowed with such extreme subtility, and to yield to the impression of solid bodies with such facility, that we easily imagine it to be of a very passive nature in all cases. But it is certain, that this fluid only shows itself passive where it passes from one body into another, which it seems very much inclined to do of itself. It will be also found, on proper examination of all the phenomena, that the only way we can manage the electric fluid at all is by allowing it to direct its own motions. In all cases where we ourselves attempt to assume the government of it, it shows itself the most untractable and stubborn being in nature. But these things come more properly under the article Electricity, where they are fully considered. Here it is sufficient to observe, that a stream of electric matter resists air, and from the phenomena of electric repulsion we are sure that one stream of electric matter resists another; from which we may be also certain, that if a stream of electric matter moves in an aerial fluid, such fluid will resist it: and we can only judge of the degree of resistance it meets with in the heavens from what we observe on earth. Here we see the most violent blast of air has no effect upon a stream of electric fluid; in the celestial regions, either air or some other fluid has an effect upon it according to Dr Hamilton. The resistance of that fluid, therefore, must be greater than that of the most violent blast of air we can imagine.

As to the Doctor's method of accounting for the curvature of the comet's tail, it might do very well on Sir Isaac Newton's principles, but cannot do so on his. There is no comparison between the celerity with which rarefied vapour ascends in our atmosphere, and that whereby the electric fluid is discharged. The velocity of the latter seems to equal that of light; of consequence, supposing the velocity of the comet to be equal to that of the earth in its annual course, and its tail equal in length to the distance of the sun from the earth, the curvature of the tail could only be to a straight line as the velocity of the comet in its orbit is to the velocity of light, which, according to the calculations of Dr Bradley, is as 10,201 to 1. The apparent curvature of such a comet's tail, therefore, would at this rate

184 Prodigious velocity of a comet observed by Mr Brydone.

only be $\frac{1}{10201}$ part of its visible length, and thus would always be imperceptible to us. The velocity of comets is indeed sometimes inconceivably great. Mr Brydone observed one at Palermo, in July 1770, which in 24 hours described an arch in the heavens upwards of 50 degrees in length; according to which he supposes, that if it was as far distant as the sun, it must have moved at the rate of upwards of 60 millions of miles in a day. But this comet was attended with no tail, so that we cannot be certain whether the curvature of the tails of these bodies corresponds with their velocity or not.

The near approach of some comets to the sun subjects them to intense and inconceivable degrees of heat. Newton calculated that the heat of the comet of 1680 must have been near 2000 times as great as that of red hot iron. The calculation is founded upon this principle, that the heat of the sun falling upon any body at different distances is reciprocally as the squares of those distances; but it may be observed, that the effect of the heat of the sun upon all bodies near our earth depends very much on the constitution of those bodies, and of the air that surrounds them. "The comet in question (says Dr Long) certainly acquired a prodigious heat; but I cannot think it came up to what the calculation makes it: the effect of the strongest burning-glass that has ever been made use of was the vitrification of most bodies placed in its focus. What would be the effect of a still greater heat we can only conjecture; it would perhaps so disunite the parts as to make them fly off every way in atoms. This comet, according to Halley, in passing thro' its southern node, came within the length of the sun's semidiameter of the orbit of the earth. Had the earth then been in the part of her orbit nearest to that node, their mutual gravitation must have caused a change in the plane of the orbit of the earth, and in the length of our year: he adds, that if so large a body with so rapid a motion as that of this comet were to strike against the earth, a thing by no means impossible, the shock might reduce this beautiful frame to its original chaos."

185 Vehement heat of the comet of 1680.

We must not conclude this account without observing, that Whiston, who, from Flamstead's measure of its apparent diameter, concluded the nucleus of the comet to be about ten times as big as the moon, or equal to a fourth part of the earth, attributes the universal deluge in the time of Noah to the near approach thereof. His opinion was, that the earth passing thro' the atmosphere of the comet, attracted therefrom great part of the water of the flood; that the nearness of the comet raised a great tide in the subterraneous waters, so that the outer crust of the earth was changed from a spherical to an oval figure; that this could not be done without making fissures and cracks in it, thro' which the waters forced themselves by the hollow of the earth being changed into a less capacious form; that along with the water thus squeezed up on the surface of the earth, much slime or mud would rise; which, together with the grosser part of the comet's atmosphere, would after the subsiding of the water, partly into the fissures and partly into the lower parts of the earth to form the sea, cover all over, to a considerable depth, the antediluvian earth. Thus he accounts for trees and bones of animals being found at very great depths in the earth. He also held that, before the fall, the earth revolved round the sun in the plane of the ecliptic, keeping always the same points of its surface towards the same fixed stars. By this means, as every meridian would come to the sun but once in every revolution, a day and a year were then the same: but that

Conclusions from the foregoing Appearances.

that a comet striking obliquely upon some part of the earth gave it the diurnal rotation; that the antediluvian year consisted of 360 days; but that the additional matter deposited upon the earth from the atmosphere of the comet at the flood so retarded the revolution thereof round the sun, that it is not now performed in less than 365 days and about a quarter. The same comet he thought would probably, coming near the earth when heated in an immense degree in its perihelion, be the instrumental cause of that great catastrophe, the general conflagration, foretold in the sacred writings and from ancient tradition.

186 Conjectures of Hevelius, &c. concerning the nature of comets.

These conjectures lead us to speak somewhat more particularly concerning the nature of the comets, and the purposes they may possibly answer in the creation. Hevelius, in order to account for the various appearances of the nucleus already related, supposed that they were composed of several masses compacted together with a transparent fluid interspersed, but the apparent changes in the nucleus may be only on the surface: comets may be subject to spots as the planets are; and the vastly different degrees of heat they go through may occasion great and sudden changes, not only in their surfaces, but even in their internal frame and texture. Newton places all these apparent changes to the atmosphere that environs them; which must be very dense near the surface, and have clouds floating therein. It was his opinion, that the changes mentioned may all be in the clouds, not in the nucleus. This last indeed he looked upon to be a body of extreme solidity, in order to sustain such an intense heat as the comets are sometimes destined to undergo; and that, notwithstanding their running out into the immense regions of space, where they were exposed to the most intense degrees of cold, they would hardly be cooled again on their return to the sun. Indeed, according to his calculation, the comet of 1680 must be for ever in a state of violent ignition. He hath computed that a globe of red-hot iron of the same dimensions with the earth, would scarce be cool in 50,000 years. If then the comet be supposed to cool 100 times faster than red-hot-iron, as its heat was 2000 times greater, it must require upwards of a million of years to cool it. In the short period of 575 years, therefore, its heat will be in a manner scarce diminished; and, of consequence, in its next and every succeeding revolution, it must acquire an increase of heat: so that, since the creation, having received a proportional addition in every succeeding revolution, it must now be in a state of ignition very little inferior to that of the sun itself. Sir Isaac Newton hath farther concluded, that this comet must be considerably retarded in every succeeding revolution by the atmosphere of the sun within which it enters; and thus must continually come nearer and nearer his body, till at last it falls into it. This, he thinks, may be one use of the comets, to furnish fuel for the sun, which otherwise would be in danger of wasting from the continual emission of its light.

He adds, that for the conservation of the water and moisture of the planets, comets seem absolutely requisite; from whose condensed vapours and exhalation all the moisture which is spent in vegetation and putrefaction, and turned into dry earth, &c. may be resupplied and recruited; for all vegetables grow and increase wholly from fluids; and again, as to their greatest part, turn by putrefaction into earth; an earthy slime being perpetually precipitated to the bottom of putrefying liquors. Hence the quantity of dry earth must continually increase, and the moisture of the globe decrease, and be quite evaporated, if it have not a continual supply from some part or other of the universe. "And I suspect (adds our great author), that the spirit, which makes the finest, subtilest, and best part of our air, and which is absolutely requisite for the life and being of all things, comes principally from the comets."

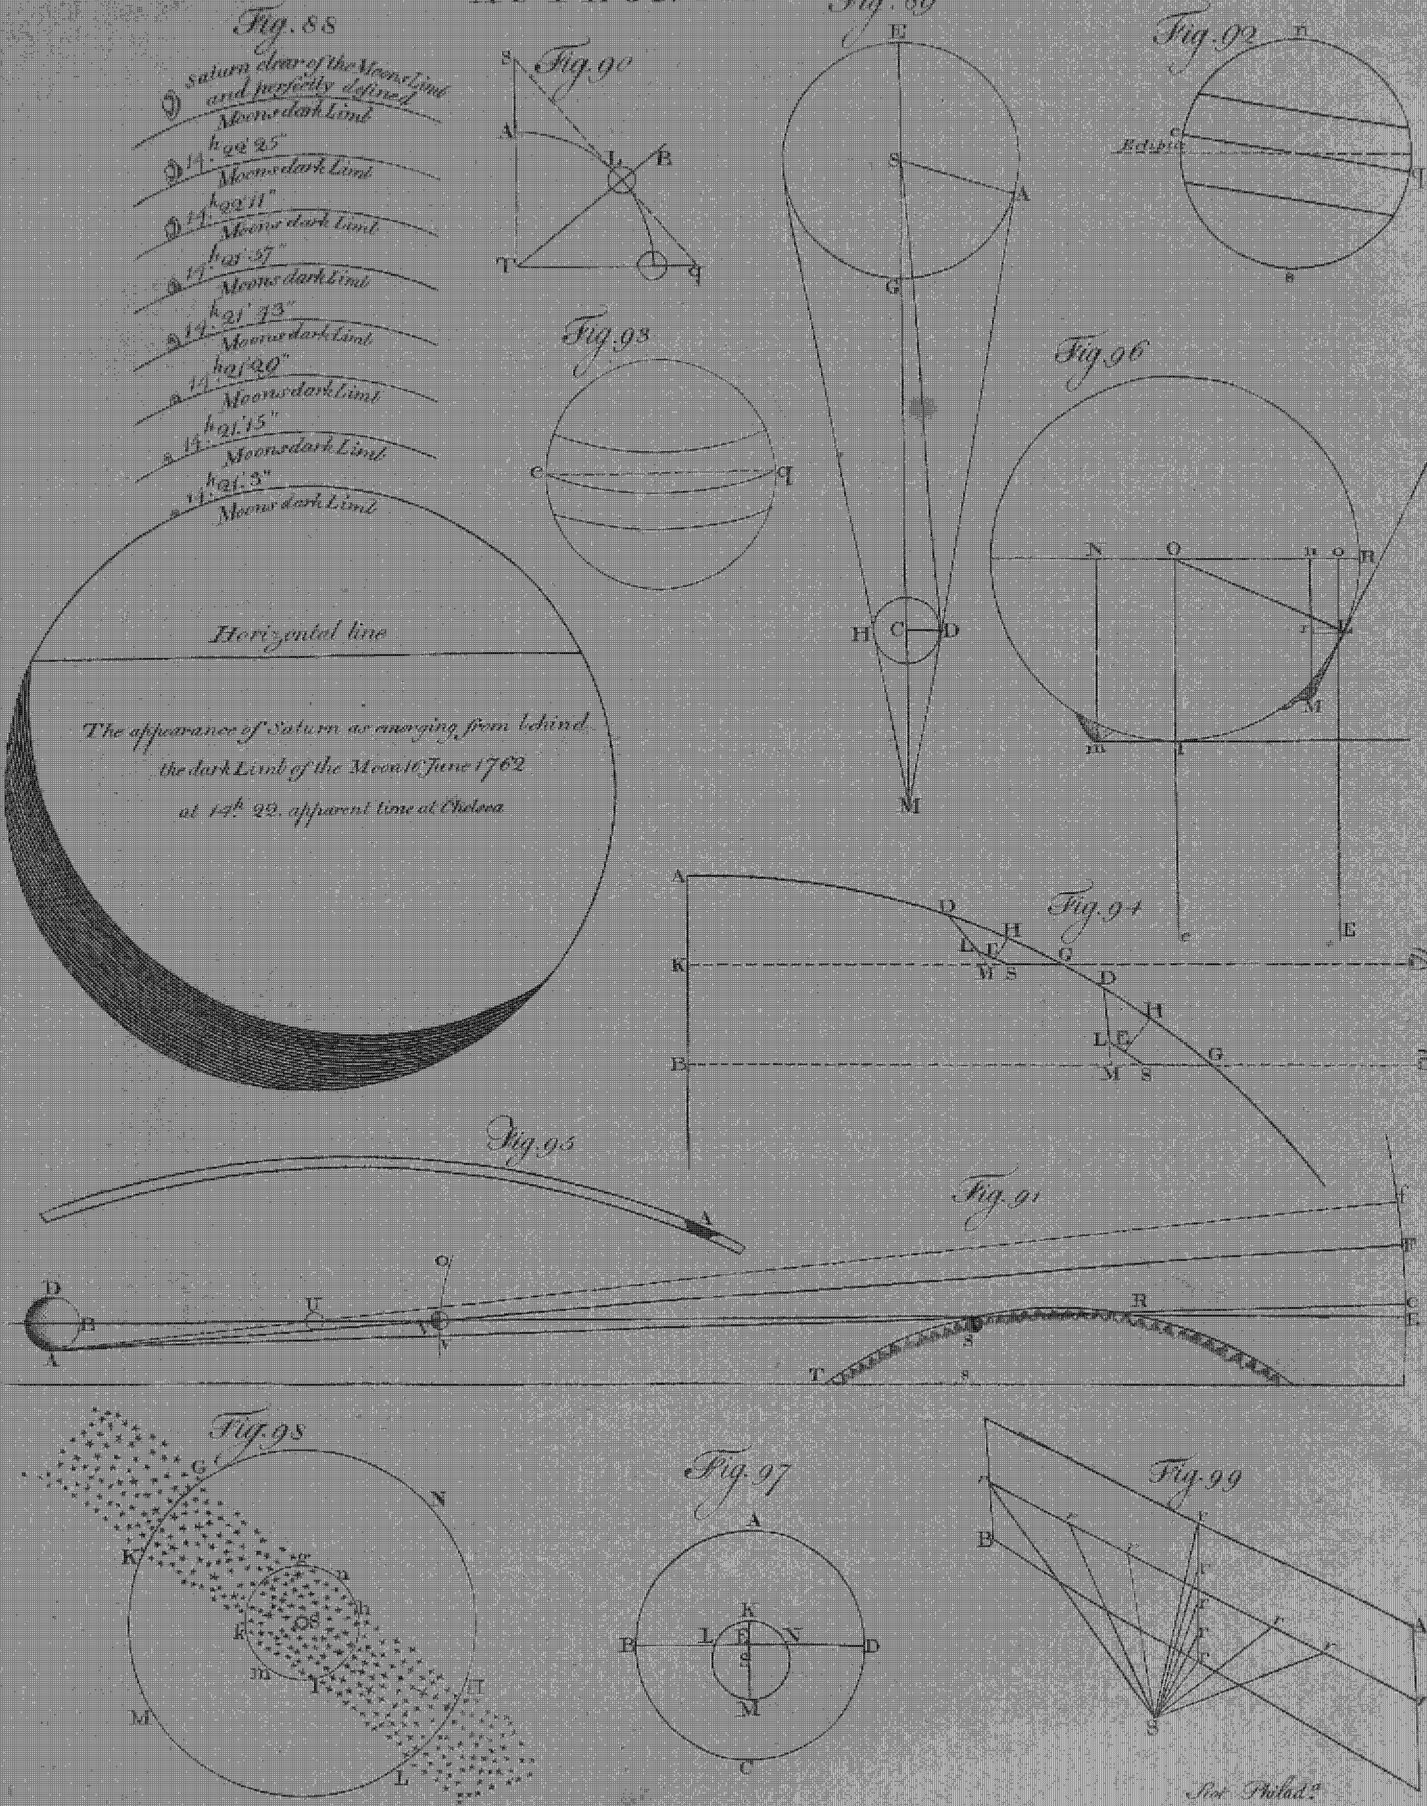
187 Mr Brydone's conjectures concerning comets without tails.

Mr Brydone observes, that the comets without tails seem to be of a very different species from those which have tails: To the latter, he says, they appear to bear a much less resemblance than they do even to planets. He tells us, that comets with tails have seldom been visible but on their recess from the sun: that they are kindled up, and receive their alarming appearance, in their near approach to this glorious luminary; but that those without tails are seldom or never seen but on their way to the sun; and he does not recollect any whose return has been tolerably well ascertained. "I remember indeed (says he), a few years ago, a small one, that was said to have been discovered by a telescope after it had passed the sun, but never more became visible to the naked eye. This assertion is easily made, and nobody can contradict it; but it does not at all appear probable that it should have been so much less luminous after it had passed the sun than before it approached him: and I will own to you, when I have heard that the return of these comets had escaped the eyes of the most acute astronomers, I have been tempted to think that they did not return at all, but were absorbed in the body of the sun, which their violent motion towards him seemed to indicate." He then attempts to account for the continual emission of the sun's light without waste, by supposing that there are numberless bodies throughout the universe that are attracted into the body of the sun, which serve to supply the waste of light, and which for some time remain obscure and occasion spots on his surface, till at last they are perfectly dissolved and become bright like the rest. This hypothesis may account for the dark spots becoming as bright, or even brighter, than the rest of the disk, but will by no means account for the brighter spots becoming dark. Of this comet too, Mr Brydone remarks, that it was evidently surrounded by an atmosphere which refracted the light of the fixed stars, and seemed to cause them change their places as the comet came near them.

188 Mr Cole's hypothesis.

A very strange opinion we find set forth in a book entitled "Observations and Conjectures on the Nature and Properties of Light, and on the Theory of Comets, by William Cole." This gentleman supposes that the comets belong to no particular system; but were originally projected in such directions as would successively expose them to the attraction of different centres, and thus they would describe various curves of the parabolic and the hyperbolic kind. This treatise is written in answer to some objections thrown out in Mr Brydone's Tour, against the motions of the comets by means of the two forces of gravitation and projection, which

ASTRONOMY Plate LXIX



Conclusions from the foregoing Appearances.

which were thought sufficient for that purpose by Sir Isaac Newton; of which we shall treat as fully as our limits will allow in the next section.

189
Of the periodical times, &c. of the comets.

The analogy between the periodical times of the planets and their distances from the sun discovered by Kepler, takes place also in the comets. In consequence of this, the mean distance of a comet from the sun may be found by comparing its period with the time of the earth's revolution round the sun. Thus the period of the comet that appeared in 1531, 1607, 1682, and 1759, being about 76 years, its mean distance from the sun may be found by this proportion: As 1, the square of one year, the earth's periodical time, is to 5776 the square of 76, the comet's periodical time; so is 1,000,000, the cube of 100 the earth's mean distance from the sun, to 5,776,000,000, the cube of the comet's mean distance. The cube root of this last number is 1794, the mean distance itself in such parts as the mean distance of the earth from the sun contains 100. If the perihelion distance of this comet, 58, be taken from 3588 double the mean distance, we shall have the aphelion distance, 3530, of such parts as the distance of the earth contains 100; which is a little more than 35 times the distance of the earth from the sun. By a like method, the aphelion distance of the comet of 1680 comes out 138 times the mean distance of the earth from the sun, supposing its period to be 575 years; so that this comet in its aphelion, goes more than 14 times the distance from the sun that Saturn does. Euler computes the orbit of this comet from three of Flamstead's observations taken near together, compared with a fourth taken at some distance from the other three; and from thence concludes the period to be a little more than 170 years. "It seems something surprising (says Dr Long), that, from the same observations which were used by Newton and Halley, he should bring out a period so very different from what those great men have determined: but it is the less to be wondered at, if we consider how small a portion of the comet's orbit lay between the most distant places used in this computation, or indeed that could be had for that purpose; so small, that the form of the ellipsis cannot be found with precision by this method, except the comet's places were more exactly verified than is possible to be done: and that he does not pretend to confirm his determination of the period by pointing out and comparing together any former appearances of this comet; a method which Newton recommended as the only one whereby the periodical times and transverse diameters of the orbits of the comets can be determined with accuracy."

The period of the comet in 1744 is much longer than even that of 1680. Mr Betts, in attempting to compute the transverse axis of its orbit, found it come out so near infinite, that, though the orbit showed itself in this manner to be a very long one, he found it impossible to calculate it without some observations made after its perihelion. Halley, after he had finished his table of comets, found such a similitude in the elements of those of 1531, 1607, and 1682, that he was induced to believe them to be returns of the same comet in an elliptic orbit: but as there was such a difference in their periodical times and inclinations of their orbits as seemed to make against this opinion; and as the observations of the first of them in 1531 by Apian, and the second in 1607 by Kepler were not exact enough to determine so nice a point when he first published his synopsis in 1705; he only mentioned this as a thing probable, and recommended it to posterity to watch for an appearance of the same in 1758. Afterwards, looking over the catalogue of ancient comets, and finding three others at equal intervals with those now mentioned, he grew more positive in his opinion; and knowing a method of calculating with ease a motion in an elliptic orbit, how eccentric soever it might be, instead of the parabolic orbit which he had given for the comet of 1682, he set about adapting the plan of that orbit to an ellipsis of a given space and magnitude, having the sun in one of its foci, so as to tally with the observations of that comet made by Flamstead with great accuracy, by the help of a very large sextant. He likewise corrected the places of the comet of 1531 from Apian, and those of the comet 1607 from Kepler and Longomontanus, by rectifying the places of the stars they had made use of, and found those places agree as well with the motion in such an ellipsis as could be expected from the manner of observing of these astronomers and the imperfections of their instruments. The greatest objection to this theory was some difference in the inclination of the orbits, and that there was above a year's difference between the two periods. The comet of 1531 was in its perihelion August 24.; that of 1607, October 16.; and that of 1682, September 4.: so that the first of these periods was more than 76, the latter not quite 75 years. To obviate this, he reminds his readers of an observation made by him of the periodical revolution of Saturn having at one time been about 13 days longer than at another time; occasioned, as he supposed, by the near approach of Saturn and Jupiter, and the mutual attraction and gravitation of the two planets: and observes, that in the summer of the year 1681, the comet in its descent was for some time so near Jupiter, that its gravitation towards that planet was one-fiftieth part of its gravitation towards the sun. This, he concluded, would cause a change in the inclination of its orbit, and also in the velocity of its motion: for by continuing longer near the planet Jupiter on the side most remote from the sun, its velocity, would be more increased by the joint forces of both those bodies, than it would be diminished by them acting contrary-wise, when on the side next to the sun where its motion was swiftest. The projectile motion being thus increased, its orbit would be enlarged, and its period lenghtened; so that he thought it probable it would not return till after a longer period than 76 years, about the end of the year 1758 or beginning of 1759.

190
Dr Halley calculates the return of comets.

191
Why the periodical return of comets may happen at unequal intervals.

As Halley expressed his opinon modestly, though clearly enough, that this comet would appear again about the end of 1758, or the beginning of the following year, M. de la Lande pretends he must have been at a loss to know whether the period he foretold would have been of 75 or of 76 years; that he did not give a decisive prediction, as if it had been the result of calculation; and that, by considering the affair in so loose a manner as Halley did, there was a good deal of room for objecting to his reasoning. After these reflections, he is very large in his commendation of the performance of Mr Clairault; who, he says, not

only

Conclusions from the foregoing Appearances.

only calculated strictly the effect of the attraction of Jupiter in 1681 and 1683, when the comet was again near Jupiter, but did not neglect the attraction of that planet when the comet was most distant; that he considered the uninterrupted attractions of Jupiter and Saturn upon the sun and upon the comet, but chiefly the attraction of Jupiter upon the sun, whereby that luminary was a little displaced, and gave different elements to the orbit of the comet. By this method he found the comet would be in its perihelion about the middle of April: but that, on account of some small quantities necessarily neglected in the method of approximation made use of by him, Mr. Clairault desired to be indulged one month; and that the comet came just 30 days before the time he had fixed for its appearance.

That comets may have their motion disturbed by the planets, especially by the two largest, Jupiter and Saturn, appears by an instance just now mentioned. They may also affect one another by their mutual gravitation when out of the planetary regions; but of this we can take no account, nor can we estimate the resistance of the ether through which they pass; and yet both these causes may have some influence on the inclination of their orbits and the length of their periods.

192 Fixed stars supposed to be suns.

THUS much concerning the bodies of which our solar system is composed. But the conjectures of astronomers have reached even beyond its boundaries: they have supposed every one of the innumerable multitude of fixed stars to be a sun attended by planets and comets, each of which is an habitable world like our own; so that the universe may in some measure be represented by fig. 161. where several adjacent systems are marked. The strongest argument for this hypothesis is, that they cannot be magnified by a telescope on account of their extreme distance; whence we must conclude that they shine by their own light, and are therefore as many suns; each of which we may suppose to be equal, if not superior, in lustre and magnitude to our own. They are not supposed to be at equal distances from us, but to be more remote in proportion to their apparent smallness. This supposition is necessary to prevent any interference of their planets; and thus there may be as great a distance between a star of the first magnitude and one of the second apparently close to it, as between the earth and the fixed stars first mentioned.

193 Opposed, from the variable nature of the stars.

Those who take the contrary side of the question affirm, that the disappearance of some of the fixed stars is a demonstration that they cannot be suns, as it would be to the highest degree absurd to think that God would create a sun which might disappear of a sudden, and leave its planets and their inhabitants in endless night. Yet this opinion we find adopted by Dr Keill, who tells us, "It is no ways improbable that these stars lost their brightness by a prodigious number of spots which entirely covered and overwhelmed them. In what dismal condition must their planets remain, who have nothing but the dim and twinkling light of the fixed stars to enlighten them?" Others, however, have made suppositions more agreeable to our notions of the benevolent character of the Deity. Sir Isaac Newton thinks that the sudden blaze of some stars may have been occasioned by the falling of a comet into them, by which means they would be enabled to emit a prodigious light for a little time, after which they would gradually return to their former state. Others have thought that the variable ones, which disappear for a time, were planets, which were only visible during some part of their course. But this their apparent immobility, notwithstanding their decrease of lustre, will not allow us to think. Some have imagined, that one side of them might be naturally much darker than the other, and when by the revolution of the star upon its axis the dark side was turned towards us, the star became invisible, and, for the same reason, after some interval, resumed its former lustre.

194 Conjectures concerning new stars, &c.

195 Opinion of M. Maupertuis.

M. Maupertuis, in his dissertation on the figures of the celestial bodies (p. 61—63.), is of opinion, that some stars, by their prodigious quick rotations on their axes, may not only assume the figures of oblate spheroids, but that, by the great centrifugal force arising from such rotations, they may become of the figures of mill-stones; or be reduced to flat circular planes, so thin as to be quite invisible when their edges are turned towards us; as Saturn's ring is in such positions. But when very eccentric planets or comets go round any flat star, in orbits much inclined to its equator, the attraction of the planets or comets in their perihelions must alter the inclination of the axis of that star; on which account it will appear more or less large and luminous, as its broad side is more or less turned towards us. And thus he imagines we may account for the apparent changes of magnitude and lustre in those stars, and likewise for their appearing and disappearing.

196 Mr Dunn's hypothesis.

Lastly, Mr Dunn (Phil. Transf. Vol. LII.) in a dissertation concerning the apparent increase of magnitude in the heavenly bodies when they approach the horizon, conjectures that the interposition of some gross atmosphere may solve the phenomena both of nebulous and new stars. "The phenomena of nebulous and new stars (says he) have engaged the attention of curious astronomers; but none that I know of have given any reason for the appearance of nebulous stars. Possibly what has been before advanced may also be applicable for investigating reasons for those strange appearances in the remote parts of the universe. From many instances which might be produced concerning the nature and properties of lights and illuminations on the earth's surface, concerning the nature and properties of the earth's atmosphere, and concerning the atmospheres and illuminations of comets, we may safely conclude, that the atmospheres of comets and of our earth are more gross in their nature than the etherial medium which is generally diffused through the solar system. Possibly a more aqueous vapour in the one than the other makes the difference. Now, as the atmospheres of comets and of planets in our solar system are more gross than the ether which is generally diffused through our solar system, why may not the etherial medium diffused throughout those other solar systems (whose centres are their respective fixed stars) be more gross than the etherial medium diffused throughout our solar system? This indeed is an hypothesis, but such an one as agrees exactly with nature. For these nebulous stars appear so much like comets, both to the naked eye and through telescopes, that the one cannot always, by any difference of their extraneous light, be known from the other. Such orbs of gross ether reflecting

Conclusions from the foregoing Appearances.

flecting light more copiously, or like the atmospheres of comets, may help us to judge of the magnitudes of the orbs illuminated by those remote suns, when all other means seem to fail. The appearance of new stars, and disappearance of others, possibly may be occasioned by the interposition of such an etherial medium, within their respective orbs, as either admits light to pass freely, or wholly absorbs it at certain times, whilst light is constantly pursuing its journey through the vast regions of space."

In the Philosophical Transactions for 1783, however, Mr Michell, in proposing a method to determine the distance, magnitude, &c. of the fixed stars by the diminution of the velocity of their light, should any such thing be discovered, makes such suppositions as seem totally inconsistent with what has been just now advanced. "The very great number of stars (says he) that have been discovered to be double, treble, &c. particularly by Mr Herschel, if we apply the doctrine of chances, as I have heretofore done in my Inquiry into the probable parallax, &c. of the fixed stars, published in the Philosophical Transactions for the year 1767, cannot leave a doubt with any one who is properly acquainted with the force of those arguments, that by far the greatest part, if not all of them, are systems of stars so near each other, as probably to be liable to be affected sensibly by their mutual gravitation; and it is therefore not unlikely, that the periods of the revolutions of some of these about their principals (the smaller ones being, upon this hypothesis, to be considered as satellites to the others) may some time or other be discovered." Having then shown in what manner the magnitude of a fixed star, if its density were known, would affect the velocity of its light, he concludes at last, that "if the semidiameter of a sphere of the same density with the sun were to exceed his in the proportion of 500 to 1, a body falling from an infinite height towards it (or moving in a parabolic curve at its surface) would have acquired a greater velocity than that of light; and consequently, supposing light to be attracted by the same force in proportion to its *vis inertiæ* with other bodies, all light emitted from such a body would be made to return towards it by its own proper gravity. But if the semidiameter of a sphere, of the same density with the sun, was of any other size less than 497 times that of the sun, though the velocity of light emitted by such a body would never be wholly destroyed, yet it would always suffer some diminution, more or less according to the magnitude of the sphere. The same effects would likewise take place if the semidiameters were different from those already mentioned, provided the density was greater or less in the duplicate ratio of those semidiameters inversely."

197 Mr Michell's conjectures concerning the nature of the fixed stars.

198 In what cases light may be supposed to return to the body that emits it.

After proceeding in his calculations, in order to find the diameter and distance of any star, he proceeds thus: "According to Mr Bouguer, the brightness of the sun exceeds that of a wax candle in no less a proportion than that of 8000 to 1. If therefore the brightness of any of the fixed stars should not exceed that of our common candles, which, as being something less luminous than wax, we will suppose in round numbers to be only one ten thousandth part as bright as the sun, such a star would not be visible at more than one hundredth part of the distance at which it would be seen if it were as bright as the sun. Now, because the sun would still, I apprehend, appear as bright and luminous as the star Sirius, if removed to 400,000 times his present distance, such a body, if no brighter than our common candles, would only appear equally luminous with that star at 4000 times the distance of the sun; and we might then be able, with the best telescopes, to distinguish some sensible apparent diameter of it: but the apparent diameters of the stars of lesser magnitudes would still be too small to be distinguishable even with our best telescopes, unless they were yet a good deal less luminous; which may possibly, however, be the case with some of them: for though we have indeed very slight grounds to go upon with regard to the specific brightness of the fixed stars, compared with that of the sun at present, and can therefore form only very uncertain and random conjectures concerning it; yet from the infinite variety which we find in the works of the creation, it is not unreasonable to suspect, that very possibly some of the fixed stars may have so little natural brightness in proportion to their magnitude, as to admit of their diameters having some sensible apparent size when they shall come to be more carefully examined, and with larger and better telescopes than have been hitherto in common use.

199 Comparative brightness of the sun and fixed stars.

Conclusions from the foregoing Appearances.

"With regard to the sun, we know that his whole surface is extremely luminous, a very small and temporary interruption sometimes, from a few spots, excepted. This universal and excessive brightness of the whole surface is probably owing to an atmosphere, which being luminous throughout, and in some measure also transparent, the light proceeding from a considerable depth of it all arrives at the eye, in the same manner as the light of a great number of candles would do if they were placed one behind another, and their flames were sufficiently transparent to permit the light of the more distant ones to pass through those that were nearer without interruption.

200 Luminous appearance of the sun supposed to proceed from an atmosphere

"How far the same constitution may take place in the fixed stars we do not know: probably, however, it may still do so in many; but there are some appearances, with regard to a few of them, which seem to make it probable that it does not do so universally. Now, if I am right in supposing the light of the sun to proceed from a luminous atmosphere which must necessarily diffuse itself equally over the whole surface, and I think there can be very little doubt that this is really the case, this constitution cannot well take place in those stars which are in some degree periodically more and less luminous, such as that in Collo Ceti, &c. It is also not very improbable, that there is some difference from that of the sun in the constitution of those stars which have sometimes appeared and disappeared, of which that in the constellation of Cassiopeia is a notable instance. And if these conjectures are well founded, which have been formed by some philosophers, concerning stars of this kind, that they are not wholly luminous, or at least not constantly so, but that all, or by far the greatest part of their surfaces, is subject to considerable changes, sometimes becoming luminous, at others extinguished; it is amongst stars of this sort that we are most likely to meet with instances of a sensible apparent diameter, their light being much more likely not to be so great in proportion as that of the sun, which if removed to 400,000 times his present distance, would still appear,

201 Of the variable stars.

I ap-

Conclusions from the foregoing Appearances.

I apprehend, as bright as Sirius, as I have observed above; whereas it is hardly to be expected, with any telescope whatsoever, that we should ever be able to distinguish a well-defined disk of any body of the same size with the sun at much more than 10,000 times his present distance.

"Hence the greatest distance at which it would be possible to distinguish any sensible apparent diameter of a body as dense as the sun, cannot well greatly exceed five hundred times ten thousand; that is five million times the distance of the sun; for if the diameter of such a body was not less than 500 times that of the sun, its light, as has been shown above, could never arrive at us."

202 Mr Herschel's opinion concerning the construction of the universe.

Mr Herschel improving on Mr Michell's idea of the fixed stars being collected into groups, and assisted by his own observations with the extraordinary telescopic powers already mentioned, has suggested a theory concerning the construction of the universe entirely new and singular. It had been the opinion of former astronomers, that our sun, besides occupying the centre of the system which properly belongs to him, occupied also the centre of the universe; but Mr Herschel is of a very different opinion. "Hitherto (says he) the sidereal heavens have, not inadequately for the purpose designed, been represented by the concave surface of a sphere, in the centre of which the eye of the observer might be supposed to be placed." It is true, the various magnitudes of the fixed stars even then plainly suggested to us, and would have better suited the idea of an expanded firmament of three dimensions; but the observations upon which I am now going to enter, still farther illustrate and enforce the necessity of considering the heavens in this point of view. In future therefore we shall look upon those regions into which we may now penetrate by means of such large telescopes *, as a naturalist regards a rich extent of ground or chain of mountains, containing strata variously inclined and directed, as well as consisting of very different materials. A surface of a globe or map therefore will but ill delineate the interior parts of the heavens."

203 His observations on the Via Lactea.

With the powerful telescope mentioned in the note, Mr Herschel first began to survey the Via Lactea, and found that it completely resolved the whitish appearance into stars, which the telescopes he formerly used had not light enough to do. The portion he first observed was that about the hand and club of Orion; and found therein an astonishing multitude of stars, whose number he endeavoured to estimate by counting many fields †, and computing from a mean of these how many might be contained in a given portion of the milky way. In the most vacant place to be met with in that neighbourhood he found 63 stars; other six fields contained 110, 60, 70, 90, 70, and 74 stars; a mean of all which gave 79 for the number of stars to each field: and thus he found, that by allowing 15 minutes for the diameter of his field of view, a belt of 15 degrees long and two broad, which he had often seen pass before his telescope in an hour's time, could not contain less than 50,000 stars, large enough to be distinctly numbered; besides which, he suspected twice as many more, which could be seen only now and then by faint glimpses for want of sufficient light.

204 On the nebulæ.

The success he had in the milky-way soon induced him to turn his telescope to the nebulous parts of the heavens, of which an accurate list had been published in the *Connoissance des Temps* for 1783 and 1784. Most of these yielded to a Newtonian reflector of 20 feet focal distance and 12 inches aperture; which plainly discovered them to be composed of stars, or at least to contain stars, and to show every other indication of consisting of them entirely.

205 They are arranged into strata.

"The nebulæ (says he) are arranged into strata, and run on to a great length; and some of them I have been able to pursue, and to guess pretty well at their form and direction. It is probable enough that they may surround the whole starry sphere of the heavens, not unlike the milky-way, which undoubtedly is nothing but a stratum of fixed stars: and as this latter immense starry bed is not of equal breadth or lustre in every part, nor runs on in one straight direction, but is curved, and even divided into two streams along a very considerable portion of it; we may likewise expect the greatest variety in the strata of the clusters of stars and nebulæ. One of these nebulous beds is so rich, that in passing through a section of it in the time of only 36 minutes, I have detected no less than 31 nebulæ, all distinctly visible upon a fine blue sky.

206 Variety of shapes assumed by them.

Their situation and shape, as well as condition, seem to denote the greatest variety imaginable. In another stratum, or perhaps a different branch of the former, I have often seen double and treble nebulæ variously arranged; large ones with small, seemingly attendants; narrow, but much extended lucid nebulæ or bright dashes; some of the shape of a fan, resembling an electric brush issuing from a lucid point; others of the cometic shape, with a seeming nucleus in the centre, or like cloudy stars surrounded with a nebulous atmosphere: a different sort again contain a nebulosity of the milky kind, like that wonderful inexplicable phenomenon about θ Orionis; while others shine with a fainter mottled kind of light, which denotes their being resolvable into stars.

207 Why the milky-way appears to surround the heavens

"It is very probable that the great stratum called the *milky-way*, is that in which the sun is placed, though perhaps not in the very centre of its thickness. We gather this from the appearance of the galaxy, which seems to encompass the whole heavens, as it certainly must do if the sun is within the same. For suppose a number of stars arranged between two parallel planes, indefinitely extended every way, but at a given considerable distance from one another, and calling this a sidereal stratum, an eye placed somewhere within it will see all the stars in the direction of the planes of the stratum projected into a great circle, which will appear lucid on account of the accumulation of the stars, while the rest of the heavens at the sides will only seem to be scattered over with constellations, more or less

* Mr Herschel's observations, on which this theory is founded, were made with a Newtonian reflector of 20 feet focal length, and an aperture of 18 inches.

† By this word we are to understand the apparent space in the heavens he could see at once through his telescope.

Conclusions from the foregoing Appearances.

less crowded according to the distance of the planes or number of stars contained in the thickness or sides of the stratum.

"Thus in fig. 102. an eye at S within the stratum *ab*, will see the stars in the direction of its length *ab*, or height *ed*, with all those in the intermediate situation, projected into the lucid circle ABCD; while those in the sides *me*, *nw*, will be seen scattered over the remaining part of the heavens at MVNW.

208 Celestial appearances solved on Mr Herschel's hypothesis.

"If the eye were placed somewhere without the stratum, at no very great distance, the appearance of the stars within it would assume the form of one of the lesser circles of the sphere, which would be more or less contracted to the distance of the eye: and if this distance were exceedingly increased, the whole stratum might at last be drawn together into a lucid spot of any shape, according to the position, length, and height of the stratum.

"Let us now suppose, that a branch or smaller stratum should run out from the former in a certain direction, and let it also be contained between two parallel planes extended indefinitely onwards, but so that the eye may be placed in the great stratum somewhere before the separation, and not far from the place where the strata are still united; then will this second stratum not be projected into a bright circle like the former, but will be seen as a lucid branch proceeding from the first, and returning to it again at a certain distance less than a semicircle. Thus, in the same figure, the stars in the small stratum *p g* will be projected into a bright arch at PRRP, which, after its separation from the circle CBD, unites with it again at P.

"What has been instanced in parallel planes may easily be applied to strata irregularly bounded, and running in various directions; for their projection will of consequence vary according to the quantities of the variations in the strata and the distance of the eye from the same. And thus any kind of curvatures, as well as various degrees of brightness, may be produced in the projections.

209 Of the sun's place in the universe.

"From appearances, then, as I observed before, we may infer, that the sun is most likely placed in one of the great strata of the fixed stars, and very probably not far from the place where some smaller stratum branches out from it. Such a supposition will satisfactorily, and with great simplicity, account for all the phenomena of the milky way; which according to this hypothesis, is no other than the appearance of the projection of the stars contained in this stratum and its secondary branch. As a farther inducement to look on the galaxy in this point of view, let it be considered, that we can no longer doubt of its whitish appearance arising from the mixed lustre of the numberless stars that compose it. Now, should we suppose it to be an irregular ring of stars, in the centre nearly of which we must then suppose the sun to be placed, it will appear not a little extraordinary, that the sun, being a fixed star like those which compose this imagined ring, should just be in the centre of such a multitude of celestial bodies, without any apparent reason for this singular distinction; whereas, on our supposition, every star in this stratum, not very near the termination of its length or height, will be so placed as also to have its own galaxy, with only such variations in the form and lustre of it as may arise from the particular situation of each star.

"Various methods may be taken to come to a knowledge of the sun's place in the sidereal stratum, one of which I have already begun to put in practice. I call it *gauging the heavens*, or the *star-gauge*. It consists in repeatedly taking the number of stars in ten fields of view of my reflector very near each other; and by adding their sums, and cutting off one decimal on the right, a mean of the contents of the heavens in all the parts which are thus gauged are obtained. Thus it appears, that the number of stars increases very much as we approach the milky way; for in the parallel from 92 to 24 degrees north polar distance, and right ascension 15h. 10′, the star-gauge runs up from 9.4 stars in the field to 18.6 in about an hour and an half; whereas in the parallel from 78 to 80 degrees north polar distance, and R. A. 11, 12, 13, and 14 hours, it very seldom rises above 4. We are, however, to remember, that, with different instruments, the account of the gauges will be very different, especially on our supposition of the sun in a stratum of stars. For let *ab*, fig. 98. be the stratum, and suppose the small circle *g h l k* to represent the space into which, by the light and power of a given telescope, we are enabled to penetrate, and let GHLK be the extent of another portion which we are enabled to visit by means of a larger aperture and power; it is evident, that the gauges with the latter instrument will differ very much in their account of stars contained at MN and at KG or LH, when with the former they will hardly be affected with the change from *m n* to *kg* or *lk*.

210 Herschel's method of gauging the heavens.

211 How to find the place of the sun in the sidereal stratum.

"The situation of the sun in the sidereal stratum will be found by considering in what manner the star-gauge agrees with the length of a ray revolving in several directions about an assumed point, and cut off by the bounds of the stratum. Thus, in fig. 99. let S be the place of an observer; Srrr, *Srrr*, lines in the plane rSr, *rSr*, drawn from S within the stratum to one of the boundaries here represented by the plane AB. Then, since neither the situation of S nor the form of the limiting surface AB is known, we are to assume a point, and apply to it lines proportional to the several gauges that have been obtained, and at such angles from each other as they may point out; then will the termination of these lines delineate the boundary of the stratum, and consequently manifest the situation of the sun within the same.

112 Observations on nebulæ.

"In my late observations on nebulæ, I soon found, that I generally detected them in certain directions rather than in others: that the spaces preceding them were generally quite deprived of their stars, so as often to afford many fields without a single star in it: that the nebulæ generally appeared some time after among stars of a certain considerable size, and but seldom among very small stars: that when I came to one nebula, I generally found several more in the neighbourhood: that afterwards a considerable time passed before I came to another parcel. These events being often repeated in different altitudes of my instrument, and some of them at considerable distances from each other, it occurred to me that the intermediate spaces between the sweeps might also contain nebulæ; and finding this to hold good more than once, I ventured to give notice

Conclusions from the foregoing Appearances.

notice to my assistant at the clock, that 'I found myself on nebulous ground.' But how far these circumstances of vacant places preceding and following the nebulous strata, and their being as it were contained in a bed of stars sparingly scattered between them, may hold good in more distant portions of the heavens, and which I have not yet been able to visit in any regular manner, I ought by no means to hazard a conjecture.

213 Direction of some of the principal strata of stars.

I may venture, however, to add a few particulars about the direction of some of the capital strata, or their branches. The well-known nebula of Cancer, visible to the naked eye, is probably one belonging to a certain stratum, in which I suppose it to be so placed as to lie nearest to us. This stratum I shall call that of Cancer. It runs from ε Cancri towards the south, over the 67th nebula of the *Connoissance des Temps*, which is a very beautiful and pretty much compressed cluster of stars, easily to be seen by any good telescope; and in which I have observed above 200 stars at once in the field of view of my great reflector with a power of 157. This cluster appearing so plainly with any good common telescope, and being so near to the one which may be seen with the naked eye, denotes it to be probably the next in distance to that within the quartile formed by γ, δ, η, θ. From the 67th nebula, the stratum of Cancer proceeds towards the head of Hydra; but I have not yet had time to trace it farther than the equator.

"Another stratum, which perhaps approaches nearer to the solar system than any of the rest, and whose situation is nearly at rectangles with the great sidereal stratum in which the sun is placed, is that of Coma Berenices, as I shall call it. I suppose the Coma itself to be one of the clusters in it, and that on account of its nearness it appears to be so scattered. It has many capital nebulæ very near it; and in all probability this stratum runs out a very considerable way. It may perhaps even make the circuit of the heavens, though very likely not in one of the great circles of the sphere; for unless it should chance to intersect the great sidereal stratum of the milky way before mentioned in the very place in which the sun is stationed, such an appearance would hardly be produced. However, if the stratum of Coma Berenices should extend so far as I apprehend it may, the direction of it towards the north lies probably, with some windings, through the Great Bear onwards to Cassiopeia, thence through the Girdle of Andromeda and the Northern Fish, proceeding towards Cetus; while towards the south it passes through the Virgin, probably on to the tail of Hydra and Centaurus."

* Philos. Trans. vol. 75.

214 Of the interior construction of the heavens.

By a continued series of observations, Mr Herschel became confirmed in his notions; and in a succeeding paper has given a sketch of his opinions concerning the interior construction of the heavens.—"That the milky way (says he) is a most extensive stratum of stars of various sizes, admits no longer of the least doubt; and that our sun is one of the heavenly bodies belonging to it, is as evident. I have now viewed and gauged this shining zone in almost every direction, and find it composed of shining stars, whose number, by the account of those gauges, constantly increases and decreases in proportion to its apparent brightness to the naked eye. But in order to develope the ideas of the universe that have been suggested by my late observations, it will be best to take the subject from a point of view at a considerable distance both of space and time.

215 Consequences of the laws of attraction acting among the stars.

"Let us then suppose numberless stars of various sizes scattered over an indefinite portion of space, in such a manner as to be almost equally distributed thro' the whole. The laws of attraction which no doubt extend to the remotest regions of the fixed stars, will operate in such a manner as most probably to produce the following remarkable effects.

216 Nebulæ how formed.

"I. It will frequently happen, that a star, being considerably larger than its neighbouring ones, will attract them more than they will be attracted by others that are immediately around them; by which means they will be in time, as it were, condensed about a centre; or, in other words, form themselves into a cluster of stars of almost a globular figure, more or less regularly so according to the size and original distance of the surrounding stars. The perturbations of these mutual attractions must undoubtedly be very intricate, as we may easily comprehend by considering what Sir Isaac Newton has said, *Princip.* lib. i. prob. 38, *et seq.*: but in order to apply this great author's reasoning of bodies moving in ellipsis to such as are here for a while supposed to have no other motion than what their mutual gravity has imparted to them, we must suppose the conjugate axes of these ellipses indefinitely diminished, whereby the ellipses will become straight lines.

"II. The next case, which will happen almost as frequently as the former, is where a few stars, though not superior in size to the rest, may chance to be rather nearer each other than the surrounding ones; for here also will be formed a prevailing attraction in the combined centre of gravity of them all, which will occasion the neighbouring stars to draw together; not, indeed, so as to form a regular globular figure, but, however, in such a manner as to be condensed towards the common centre of gravity of the whole irregular cluster. And this construction admits of the utmost variety of shapes, according to the number and situation of the stars which first gave rise to the condensation of the rest.

"III. From the composition and repeated conjunction of both the foregoing forms, a third may be derived, when many large stars, or combined small ones, are situated in long extended regular or crooked rows, hooks, or branches; for they will also draw the surrounding ones so as to produce figures of condensed stars coarsely similar to the former, which gave rise to these condensations.

"IV. We may likewise admit of still more extensive combinations; when at the same time that a cluster of stars is forming in one part of space, there may be another collecting in a different, but perhaps not far distant quarter, which may occasion a mutual approach towards their common centre of gravity.

217 Vacancies how they are occasioned in the heavens.

"V. In the last place, as a natural consequence of the former cases, there will be great cavities or vacancies formed by the retreat of the stars towards the various centres which attract them; so that, upon the whole, there is evidently a field of the greatest variety for the mutual and combined attractions of the heavenly bodies to exert themselves in.

"From this theoretical view of the heavens, which

has

Concluſions from the foregoing Appearances.

has been taken from a point not leſs diſtant in time than in ſpace, we will now retreat to our own retired ſtation, in one of the planets attending a ſtar in its great combination with numberleſs others: and in order to inveſtigate what will be the appearances from this contracted ſituation, let us begin with the naked

218
How the ſtars muſt appear to us according to this hypotheſis.

eye. The ſtars of the firſt magnitude, being in all probability the neareſt, will furniſh us with a ſtep to begin our ſcale. Setting off, therefore, with the diſtance of Sirius or Arcturus, for inſtance, as unity, we will at preſent ſuppoſe, that thoſe of the ſecond magnitude are at double, thoſe of the third at treble, the diſtance, &c. Taking it for granted, then, that a ſtar of the ſeventh magnitude (the ſmalleſt ſuppoſed viſible with the naked eye) is about ſeven times as far as one of the firſt, it follows, that an obſerver who is incloſed in a globular cluſter of ſtars, and not far from the centre, will never be able with the naked eye to ſee to the end of it; for ſince, according to the above eſtimations, he can only extend his view to about ſeven times the diſtance of Sirius, it cannot be expected that his eyes ſhould reach the borders of a cluſter which has perhaps not leſs than 50 ſtars in depth every where around him. The whole univerſe to him, therefore, will be compriſed in a ſet of conſtellations richly ornamented with ſcattered ſtars of all ſizes. Or if the united brightneſs of a neighbouring cluſter of ſtars ſhould, in a remarkable clear night, reach his ſight, it will put on the appearance of a ſmall, faint, whitiſh, nebulous cloud, not to be perceived without the greateſt attention. Let us ſuppoſe him placed in a much extended ſtratum, or branching cluſter of millions of ſtars, ſuch as may fall under the third form of nebulæ already conſidered. Here alſo the heavens will not only be richly ſcattered over with brilliant conſtellations, but a ſhining zone or milky way will be perceived to ſurround the whole ſphere of the heavens, owing to the combined light of thoſe ſtars which are too ſmall, that is, too remote to be ſeen. Our obſerver's ſight will be ſo confined, that he will imagine this ſingle collection of ſtars, though he does not even perceive the thouſandth part of them, to be the whole contents of the heavens. Allowing him now the uſe of a common teleſcope, he begins to ſuſpect that all the milkineſs of the bright path which ſurrounds the ſphere may be owing to ſtars. He perceives a few cluſters of them in various parts of the heavens, and finds alſo that there are a kind of nebulous patches: but ſtill his views are not extended to reach ſo far as to the end of the ſtratum in which he is ſituated; ſo that he looks upon theſe patches as belonging to that ſyſtem which to him ſeems to comprehend every celeſtial object. He now increaſes his power of viſion; and, applying himſelf to a cloſe obſervation, finds that the milky way is indeed no other than a collection of very ſmall ſtars. He perceives, that thoſe objects which had been called *nebulæ*, are evidently nothing but cluſters of ſtars. Their number increaſes upon him; and when he reſolves one nebula into ſtars, he diſcovers ten new ones which he cannot reſolve. He then forms the idea of immenſe ſtrata of fixed ſtars, of cluſters of ſtars and of nebulæ; till, going on with ſuch intereſting obſervations, he now perceives, that all theſe appearances muſt naturally ariſe from the confined ſituation in which we are placed. *Confined* it may juſtly be called, though in no leſs a ſpace than what appeared before to be the whole region of the fixed ſtars, but which now has aſſumed the ſhape of a crookedly branching nebula; not indeed one of the leaſt, but perhaps very far from being the moſt conſiderable, of thoſe numberleſs cluſters that enter into the conſtruction of the heavens."

Concluſions from the foregoing Appearances.

219
Arguments in favour of the foregoing theory from obſervations on nebulæ.

Our author now proceeds to ſhow that this theoretical view of the heavens is perfectly conſiſtent with facts, and ſeems to be confirmed by a ſeries of obſervations. Many hundreds of nebulæ of the firſt and ſecond forms are to be ſeen in the heavens; and their places, he ſays, will hereafter be pointed out; many of the third form deſcribed, and inſtances of the fourth related; a few of the cavities mentioned in the fifth particulariſed, though many more have been already obſerved: ſo that, "upon the whole (ſays he), I believe it will be found, that the forgoing theoretical view, with all its conſequential appearances, as ſeen by an eye incloſed in one of the nebulæ, is no other than a drawing from nature, wherein the features of the original have been cloſely copied: and I hope the reſemblance will not be called a bad one, when it ſhall be conſidered how very limited muſt be the pencil of an inhabitant of ſo ſmall and retired a portion of an indefinite ſyſtem in attempting the picture of ſo unbounded an extent."

220
Method of meaſuring the dimenſions of the heavens.

Mr Herſchel next preſent us with a long table of ſtar-gauges, or accounts of the number of ſtars at once in the field of his teleſcope, which go as high as 588; after which he propoſes the following

PROBLEM.

"The ſtars being ſuppoſed nearly equally ſcattered, and their number, in a field of view of a known angular diameter, being given, to determine the length of the viſual ray.

"Here, the arrangement of the ſtars not being fixed upon, we muſt endeavour to find which way they may be placed ſo as to fill a given ſpace moſt equally. Suppoſe a rectangular cone cut into fruſtula by many equidiſtant planes perpendicular to the axis; then, if one ſtar be placed at the vertex and another in the axis at the firſt interſection, ſix ſtars may be ſet around it ſo as to be equally diſtant from one another and from the central ſtar. Theſe poſitions being carried on in the ſame manner, we ſhall have every ſtar within the cone ſurrounded by eight others at an equal diſtance from that ſtar taken at a centre. Fig. 100 contains four ſections of ſuch a cone diſtinguiſhed by alternate ſhades; which will be ſufficient to explain what ſort of arrangements I would point out.

"The ſeries of the number of ſtars contained in the ſeveral ſections will be 1, 7, 19, 37, 61, 91, &c. which, continued to n terms, the ſum of it, by the differential method, will be $na+n.\frac{n-1}{2}d'+n.\frac{n-1}{2}.\frac{n-2}{3}d''$, &c. where a is the firſt term, d', d'', d''', &c. the firſt, ſecond, and third differences. Then, ſince $a=1$, $d'=6$, $d''=6$, $d'''=0$, the ſum of the ſeries will be n^3. Let S be the given number of ſtars; 1 the diameter of the baſe of the field of view; and B the diameter of the great rectangular cone; and by trigonometry we ſhall

have

Conclusions from the foregoing Appearances.

have $B = \frac{\text{Radius}}{\text{Tang. } \frac{1}{2} \text{ field}}$. Now, since the field of view of a telescope is a cone, we shall have its solidity to that of the great cone of the stars formed by the above construction, as the square of the diameter of the base of the field of view to the square of the diameter of the great cone, the height of both being the same; and the stars in each cone being in the ratio of the solidity, as being equally scattered, we have $n = \sqrt[3]{B^2 S}$; and the length of the visual ray $= n - 1$, which was to be determined." Another solution of this problem, on the supposition of another arrangement of stars, is given; but Mr Herschel prefers the former.

221 Proofs of our sidereal system being a nebula.

From the data now laid down, Mr Herschel next endeavours to prove that the earth is 'the planet of a star belonging to a compound nebula of the third form.' "I shall now (says he) proceed to show, that the stupendous sidereal system we inhabit, this extensive stratum, and its secondary branch, consisting of many millions of stars, is in all probability *a detached nebula*. In order to go upon grounds that seem to me to be capable of great certainty, they being no less than an actual survey of the boundaries of our sidereal system, which I have plainly perceived as far as I have yet gone round it, every where terminated, and in most places very narrowly too, it will be proper to show the length of my sounding line, if I may so call it, that it may appear whether it was sufficiently long for the purpose.

222 Length of the line by which Mr Herschel measures the heavens.

"In the most crowded parts of the milky-way, I have had fields of view that contained no fewer than 588 stars, and these were continued for many minutes; so that in one quarter of an hour's time there passed no less than 116,000 stars through the field of view of my telescope. Now, if we compute the length of the visual ray, by putting $S = 588$, and the diameter of the field of view 15 minutes, we shall find $n = \sqrt[3]{B^2 S} = 498$; so that it appears the length of what I have called my Sounding Line, or $n - 1$, was not probably less than 497 times the distance of Sirius from the sun.

"It may seem inaccurate that we should found an argument on the stars being equally scattered, when, in all probability, there may not be any two of them in the heavens whose mutual distance shall be equal to that of any other two given stars: but it should be considered, that when we take all the stars collectively, there will be a mean distance which may be assumed as the general one; and an argument founded on such a supposition will have in its favour the greatest probability of not being far short of truth. And here I must observe, that the difference between a crowded place and a cluster (none of the latter being put into the gauge table), may easily be perceived by the arrangement as well as the size and mutual distance of the stars: for in a cluster they are generally not only resembling each other pretty nearly in size, but a certain uniformity of distance also takes place: they are more and more accumulated towards the centre, and put on all the appearances which we should naturally expect from a number of them collected into a group at a certain distance from us. On the other hand, the rich parts of the milky-way, as well as those in the distant broad parts of the stratum, consist of a mixture of stars of all possible sizes, that are seemingly placed without any particular apparent order. Perhaps we might recollect, that a greater condensation towards the centre of our system than towards the borders of it should be taken into consideration; but with a nebula of the third form, containing such various and extensive combinations as I have found to take place in ours, this circumstance, which in one of the first form would be of considerable moment, may, I think, be safely neglected.

223 Cluster of stars defined.

"If some other high gauge be selected from the table, such as 472 or 344, the length of the visual ray will be found 461 and 415. And although in consequence of what has been said, a certain degree of doubt may be left about the arrangement and scattering of the stars, yet when it is recollected, that in those parts of the milky-way, where these high gauges were taken, the stars were neither so small nor so crowded as they must have been, on a supposition of a much farther continuance of them, when certainly a milky or nebulous appearance must have come on, I need not fear to have over-rated the extent of my visual ray; and indeed every thing that can be said to shorten it will only contract the limits of our nebulæ, as it has in most places been of sufficient length to go far beyond the bounds of it. Thus in the sides of our stratum, opposite to our situation in it, where the gauges often run below 5, our nebulæ cannot extend to 100 times the distance of Sirius; and the same telescope which could show 588 stars in a field of view of 15 minutes, must certainly have presented me also with the stars in these situations, had they been there. If we should answer this by observing, that they might be at too great a distance to be perceived, it will be allowing that there must at least be a vacancy amounting to the length of a visual ray, not short of 400 times the distance of Sirius: and this is amply sufficient to make our nebulæ a detached one. It is true, that it would not be consistent confidently to affirm that we were on an island, unless we had found ourselves every where bounded by the ocean; and therefore I shall go no farther than the gauges will authorise: but considering the little depth of the stratum in all those places which have been actually gauged, to which must be added all the intermediate parts that have been viewed and found to be much like the rest, there is but little room to expect a connection between our nebula and any of the neighbouring ones. A telescope, with a much larger aperture than my present one, grasping together a greater quantity of light, and thereby enabling us to see farther into space, will be the surest means of completing and establishing the arguments that have been used: for if our nebula is not absolutely a detached one, I am firmly persuaded that an instrument may be made large enough to discover the places where the stars continue onwards. A very bright milky nebulosity must there undoubtedly come on, since the stars in a field of view will increase in the ratio of n^3 greater than that of the cube of the visual ray. Thus, if 588 stars in a given field of view are to be seen by a ray of 497 times the distance of Sirius, when this is lengthened to 1000, which is but little more than double the former, the number of stars in the same field of view will

224 Extent of our nebula.

Conclusions from the foregoing Appearances.

will be no less than 4774: for when the visual ray r is given, the number of stars S will be $=\frac{n^3}{B^3}$; where $n=r+1$; and a telescope with a threefold power of extending into space, or with a ray of 1500, which I think may easily be constructed, will give us 16,096 stars. Nor would these be so close, but that a good power applied to such an instrument might easily distinguish them; for they need not, if arranged in regular squares, approach nearer to each other than 6″.27: but the milky nebulosity I have mentioned, would be produced by the numberless stars beyond them, which, in one respect, the visual ray might also be said to reach. To make this appear, we must return to the naked eye; which, as we have before estimated, can only see the stars of the seventh magnitude so as to distinguish them: but it is nevertheless very evident, that the united lustre of millions of stars, such as I suppose the nebula in Andromeda to be, will reach our sight in the shape of a very small faint nebulosity; since the nebula of which I speak may easily be seen in a fine evening. In the same manner, my present telescope, as I have argued, has not only a visual ray that will reach the stars at 497 times the distance of Sirius, so as to distinguish them, and probably much farther, but also a power of showing the united lustre of the accumulated stars that compose a milky nebulosity at a distance far exceeding the former limits; so that from these considerations it appears again highly probable, that my present telescope not showing such a nebulosity in the milky-way, goes already far beyond its extent: and consequently much more would an instrument, such as I have mentioned, remove all doubt on the subject, both by showing the stars in the continuation of the stratum, and by exposing a very strong milky nebulosity beyond them, that could no longer be mistaken for the dark ground of the heavens.

225 Analogical arguments in favour of his doctrine.

"To these arguments, which rest on the firm basis of a series of observation, we may add the following considerations drawn from analogy. Among the great number of nebulæ which I have now already seen, amounting to more than 900, there are many which in all probability are equally extensive with that which we inhabit; and yet they are all separated from each other by very considerable intervals. Some, indeed, there are that seem to be double and treble; and though with most of these it may be that they are at a very great distance from each other, yet we allow that some such conjunctions really are to be found; nor is this what we mean to exclude. But then these compound, or double nebulæ, which are those of the third and fourth forms, still make a detached link in the great chain. It is also to be supposed, that there may be some thinly scattered solitary stars between the large interstices of nebulæ; which being situated so as to be nearly equally attracted by the several clusters when they were forming, remain unassociated: and though we cannot expect to see those stars on account of their vast distance, yet we may well presume that their number cannot be very considerable in comparison to those that are already drawn into systems: which conjecture is also abundantly confirmed in situations where the nebulæ are near enough to have their stars visible; for they are all insulated, and generally to be seen upon a very clear and pure ground, without any star near them that might be thought to belong to them. And though I have often seen them in beds of stars, yet from the size of these latter we may be certain, that they were much nearer to us than those nebulæ, and belonged undoubtedly to our own system.

Having thus determined that the visible system of nature, by us called the *universe*, consisting of all the celestial bodies and many more than can be seen by the naked eye, is only a group of stars or suns with their planets, constituting one of those patches called a *nebula*, and perhaps not one ten thousandth part of what is really the universe, Mr Herschel goes on to delineate the figure of this vast nebula, which he is of opinion may now be done; and for this purpose he gives a table, calculating the distance of the stars which form its extreme boundaries, or the length of the visual ray in different parts, by the number of stars contained in the field of his telescope at different times, according to the principles already laid down. He does not, however, as yet attempt the whole nebula, but of a particular section, represented fig. 160. "I have taken one (says he) which passes through the poles of our system, and is at rectangles to the conjunction of the branches, which I have called its *length*. The name of *poles* seemed to me not improperly applied to those points which are 90 degrees distant from a circle passing along the milky way; and the north pole is here supposed to be situated in right ascension 186°, and polar distance (that is from the pole commonly so called) 58°. The section is one which makes and angle of 35 degrees with our equator, crossing it in 124½ and 304½ degrees. A celestial globe, adjusted to the latitude of 55° north, and having σ Ceti near the meridian, will have the plane of this section pointed out by the horizon. The visual rays are to be projected on the plane of the horizon of the latitude just mentioned, which may be done accurately enough by a globe adjusted in the manner directed. The stars in the border, which are marked larger than the rest, are those pointed out by the gauges. The intermediate parts are filled up by smaller stars, arranged in straight lines between the gauged ones. From this figure, which I hope is not a very inaccurate one, we may see that our nebula, as we observed before, is of the third form; that is, a very extensive, branching, compound congeries of many millions of stars, which most probably owes its origin to many remarkably large, as well as pretty closely scattered small stars, that may have drawn together the rest. Now to have some idea of the wonderful extent of this system, I must observe, that this section of it is drawn upon a scale where the distance of Sirius is no more than the 80th part of an inch; so that probably all the stars, which in the finest nights we are able to distinguish with the naked eye, may be comprehended within a sphere drawn round the large star near the middle, representing our situation in the nebula of less than half a quarter of an inch radius."

226 How the figure of our nebula may be delineated.

Mr Herschel now proceeds to offer some further thoughts on the origin of the nebulous strata of the heavens; in doing which he gives some hints concerning the antiquity of them. "If it were possible (says he) to distinguish between the parts of an indefinitely extended whole, the nebula we inhabit might be said

to

Concluſions from the foregoing Appearances.

to be one that has fewer marks of antiquity than any of the reſt. To explain this idea perhaps more clearly, we ſhould recollect, that the condenſation of cluſters of ſtars has been aſcribed to a gradual approach; and whoever reflects on the number of ages that muſt have paſſed before ſome of the cluſters that are to be found in my intended catalogue of them could be ſo far condenſed as we find them at preſent, will not wonder if I aſcribe a certain air of youth and vigour to many very regularly ſcattered regions of our ſidereal ſtratum.

127 Of the decay and recompoſition of nebulæ.

There are, moreover, many places in it in which, if we may judge from appearances, there is the greateſt reaſon to believe that the ſtars are drawing towards ſecondary centres, and will in time ſeparate into cluſters, ſo as to occaſion many ſubdiviſions. Hence we may ſurmiſe, that when a nebulous ſtratum conſiſts chiefly of nebulæ of the firſt and ſecond forms, it probably owes its origin to what may be called the decay of a great compound nebula of the third form; and that the ſubdiviſions which happened to it in length of time, occaſioned all the ſmall nebulæ which ſprung from it to lie in a certain range, according as they were detached from the primary one. In like manner, our ſyſtem, after numbers of ages, may very poſſibly become divided ſo as to give riſe to a ſtratum of two or three hundred nebulæ; for it would not be difficult to point out ſo many beginning or gathering cluſters in it. This throws a conſiderable light upon that remarkable collection of many hundreds of nebulæ which are to be ſeen in what I have called the *nebulous ſtratum* in Coma Berenices. It appears from the extended and branching figure of our nebula, that there is room for the decompoſed ſmall nebulæ of a large reduced former great one to approach nearer to us in the ſides than in any other parts. Nay, poſſibly there might originally be another very large joining branch, which in time became ſeparated by the condenſation of the ſtars: and this may be the reaſon of the little remaining breadth of our ſyſtem in that very place; for the nebulæ of the ſtratum of the Coma are brighteſt and moſt crowded juſt oppoſite to our ſituation, or in the pole of our ſyſtem. As ſoon as this idea was ſuggeſted, I tried alſo the oppoſite pole; where accordingly I have met with a great number of nebulæ, though under a much more ſcattered form.

"Some parts of our ſyſtem indeed ſeem already to have ſuſtained greater ravages of time than others: for inſtance, in the body of the Scorpion is an opening or hole, which is probably owing to this cauſe. It is at leaſt four degrees broad; but its height I have not yet aſcertained. It is remarkable, that the 80 *Nebuleuſe ſans Etoiles* of the *Connoiſſance des Temps*, which is one of the richeſt and moſt compreſſed cluſters of ſmall ſtars I remember to have ſeen, is ſituated juſt on the weſt border of it, and would almoſt authoriſe a ſuſpicion that the ſtars of which it is compoſed were collected from that place, and had left the vacancy. What adds not a little to this ſurmiſe is, that the ſame phenomenon is once more repeated with the fourth cluſter of the *Connoiſſance des Temps*; which is alſo on the weſtern border of another vacancy, and has moreover a ſmall miniature cluſter, or eaſily reſolvable nebula, of about $2\frac{1}{2}$ minutes in diameter north, following it at no very great diſtance.

"There is a remarkable purity or clearneſs in the heavens when we look out of our ſtratum at the ſides; that is, towards Leo, Virgo, and Coma Berenices on one hand, and towards Cetus on the other; whereas the ground of the heavens becomes troubled as we approach towards the length or height of it. Theſe troubled appearances are eaſily to be explained by aſcribing them to ſome of the diſtant ſtraggling ſtars that yield hardly light enough to be diſtinguiſhed. And I have indeed often experienced this to be the cauſe, by examining theſe troubled ſpots for a long while together, when at laſt I generally perceived the ſtars which occaſioned them. But when we look towards the poles of our ſyſtem, where the viſual ray does not graze along the ſide, the ſtraggling ſtars will of courſe be very few in number: and therefore the ground of the heavens will aſſume that purity which I have always obſerved to take place in thoſe regions."

228 Univerſe compoſed of nebulæ.

Thus, then, according Mr Herſchel, the univerſe conſiſts of *nebulæ*, or innumerable collections of innumerable ſtars, each individual of which is a ſun not only equal, but much ſuperior to ours: at leaſt if the words of Mr Nicholſon have any weight; for he tells us, that "each individual ſun is deſtined to give light to *hundreds* of worlds that revolve about it, but which can no more be ſeen by us, on account of their great diſtance, than the ſolar planets can be ſeen from the fixed ſtars." "Yet (continues he), as in this unexplored, and perhaps unexplorable, abyſs of ſpace, it is no neceſſary condition that the planets ſhould be of the ſame magnitudes as thoſe belonging to our ſyſtem, it is not impoſſible but that planetary bodies may be diſcovered among the double and treble ſtars."

Nat. Phil. 165, 166. *Philad. Edit.*

Though in the above extracts from Mr Herſchel's papers, the words *condenſation*, *cluſters*, &c. of ſtars frequently occur, we are by no means from thence to imagine that any of the celeſtial bodies in our nebulæ are nearer to one another than we are to Sirius, whoſe diſtance is ſuppoſed not to be leſs than 400,000 times that of the ſun from us, or 38 millions of millions of miles. The whole extent of the nebula being in ſome places near 500 times as great, muſt be ſuch, that the light of a ſtar placed at its extreme boundary, ſuppoſing it to fly with the velocity of 12 millions of miles every minute, muſt have taken near 3000 years to reach us. Mr Herſchel, however, is by no means of opinion, that our nebula is the moſt conſiderable in the univerſe. "As we are uſed (ſays he to call the appearance of the heavens, where it is ſurrounded with a bright zone, the *milky-way*, it may not be amiſs to point out ſome other very remarkable nebulæ, which cannot well be leſs, but are probably much larger, than our own ſyſtem; and being alſo extended, the inhabitants of the planets that attend the ſtars which compoſe them, muſt likewiſe perceive the ſame phenomena: for which reaſon they may alſo be called *milky ways*, by way of diſtinction.

229 Of the ſize and diſtance of nebulæ.

"My opinion of their ſize is grounded on the following obſervations: There are many round nebulæ of the firſt form, of about five or ſix minutes in diameter, the ſtars of which I can ſee very diſtinctly; and on comparing them with the viſual ray calculated from ſome of my long guages, I ſuppoſe by the appearance of the ſmall ſtars in thoſe guages, that the centres of theſe round nebulæ may be 600 times the diſtance of Sirius

Conclusions from the foregoing Appearances.

Sirius from us."—He then goes on to tell us, that the stars in such nebulæ are probably twice as much condensed as those of our system; otherwise the centre of it would not be less than 6000 times the distance of Sirius from us; and that it is probably much underrated by supposing it only 600 times the distance of that star.

"Some of these round nebulæ (says Mr Herschel), have others near them, perfectly similar in form, colour, and the distribution of stars, but of only half the diameter: and the stars in them seem to be doubly crowded, and only at about half the distance from each other. They are indeed so small, as not to be visible without the utmost attention. I suppose these miniature nebulæ to be at double the distance of the first. An instance equally remarkable and instructive is a case where, in the neighbourhood of two such nebulæ as have been mentioned, I met with a third similar, resolvable, but much smaller and fainter nebula. The stars of it are no longer to be perceived; but a resemblance of colour with the former two, and its diminished size and light, may well permit us to place it at full twice the distance of the second, or about four or five times the distance of the first. And yet the nebulosity is not of the milky kind; nor is it so much as difficultly resolvable or colourless. Now in a few of the extended nebulæ, the light changes gradually, so as from the resolvable to approach to the milky kind; which appears to me an indication, that the milky light of nebulæ is owing to their much greater distance. A nebula, therefore, whose light is perfectly milky, cannot well be supposed to be at less than six or eight thousand times the distance of Sirius; and though the numbers here assumed are not to be taken otherwise than as very coarse estimates, yet an extended nebula, which in an oblique situation, where it is possibly foreshortened by one-half, two-thirds, or three-fourths of its length, subtends a degree or more in diameter, cannot be otherwise than of a wonderful magnitude, and may well out-vie our milky-way in grandeur."

Mr Herschel next proceeds to give an account of several remarkable nebulæ, and then concludes thus.

230 Vast length of time requisite to form the nebulæ.

"Now, what great length of time must be required to produce these effects (the formation of nebulæ) may easily be conceived, when, in all probablility, our whole system, of about 800 stars in diameter, if it were seen at such a distance that one end of it might assume the resolvable nebulosity, would not, at the other end, present us with the irresolvable, much less with the colourless and milky, sort of nebulosities." Great indeed must be the length of time requisite for such distant bodies to form combinations by the laws of attraction, since, according to the distances he has assumed, the light of some of his nebulæ must be thirty-six or forty-eight thousand years in arriving from them to us. It would be worth while then to inquire, whether *attraction* is a virtue propagated in time or not; or whether it moves quicker or slower than light?

231 Why the stars do not fall upon one another

In the course of Mr Herschel's observations and inquiries concerning the structure of the heavens, an objection occurred, that if the different systems were formed by the mutual attractions of the stars, the whole would be in danger of destruction by the falling of them one upon another. A sufficient answer to this, he thinks, is, that if we can really prove the system of the universe to be what he has said, there is no doubt but that the great Author of it has amply provided for the preservation of the whole, though it should not appear to us in what manner this is effected. Several circumstances, however, he is of opinion, manifestly tend to a general preservation; as, in the first place, the indefinite extent of the sidereal heavens; which must produce a balance that will effectually secure all the great parts of the whole from approaching to each other. "There remains then (says he) only to see how the particular stars belonging to separate clusters are prevented from rushing on to their centres of attraction." This he supposes may be done by projectile forces; "the admission of which will prove such a barrier against the seeming destructive power of attraction, as to secure from it all the stars belonging to a cluster, if not for ever, at least for millions of ages. Besides, we ought perhaps to look upon such clusters, and the destruction of a star now and then in some thousands of ages, as the very means by which the whole is preserved and renewed. These clusters may be the *laboratories* of the universe, wherein the most salutary remedies for the decay of the whole are prepared."

232 Of the planetary nebulæ.

In speaking of the planetary nebulæ, by which name he distinguishes those spots that are all over equally luminous, he says, "if we should suppose them to be single stars with large diameters, we shall find it difficult to account for their not being brighter, unless we should admit that the intrinsic light of some stars may be very much inferior to that of the generality; which, however, can hardly be imagined to extend to such a degree. We might suppose them to be comets about their aphelion, if the brightness, as well as magnitude of their diameters, did not oppose this idea: so that, after all, we can hardly find any hypothesis so probable as that of their being nebulæ; but then they must consist of stars that are compressed and accumulated in the highest degree. If it were not perhaps too hazardous to pursue a former surmise of a renewal in what I figuratively called the *Laboratories of the Universe*, the stars forming these extraordinary nebulæ, by some decay or waste of nature being no longer fit for their former purposes, and having their projectile forces, if any such they had, retarded in each others atmosphere, may rush at last together; and, either in succession, or by one general tremendous shock, unite into a new body. Perhaps the extraordinary and sudden blaze of a new star in Cassiopeia's chair, in 1572, might possibly be of such a nature. If a little attention to these bodies should prove that, having no annual parallax, they belong most probably to the class of nebulæ, they may then be expected to keep their station better than any one of the stars belonging to our system, on account of their being probably at a very great distance."

233 Motion of the fixed stars and solar system.

Having thus at length got through the conjectures and theories concerning the nature and situations of the heavenly bodies, we must now proceed to consider those projectile forces which are supposed necessary to the preservation of the system of Nature, and to prevent the stars from falling upon one another more frequently than they do. It was first suspected by Dr Halley, that many of the stars which we call *fixed*, are really in motion, though that motion is either so slow

in

Conclusions from the foregoing Appearances.

in itself, or their distance is so great, that it can scarce be perceptible in half a century. It is, however, now confirmed by astronomical observations, that Arcturus, Sirius, Aldebaran, Procyon, Castor, Rigel, Altair, and many others, are actually in motion: which consideration, with the length of time necessary to show any change of place in bodies at such extreme distance, with the lateness of any observations on this head, "would lead us (says Mr Herschel) to suppose that there is not one fixed star in the heavens: but "many other reasons (adds he) will render this so obvious, that there can hardly remain a doubt of the general motion of all the starry systems, and consequently of the solar one among the rest.

234 Attraction prevents the stars from remaining at absolute rest.

"I might begin with principles drawn from the theory of attraction, which evidently oppose every idea of absolute rest in any one of the stars, when once it is known that some of them are in motion, for the change that must arise by such motion, in the value of a power which acts inversely as the squares of the distances, must be felt in all the neighbouring stars; and if these be influenced by the motion of the former, they will again affect those that are next to them, and so on, till all are in motion. Now, as we know several stars in divers parts of the heavens do actually change their place, it will follow, that the motion of our solar system is not a mere hypothesis. And what will give additional weight to this consideration is, that we have the greatest reason to suppose most of those very stars which have been observed to move, to be such as are nearest to us; and therefore their influence on our situation would alone prove a powerful argument in favor of the proper motion of the sun had it been originally at rest."

After enumerating a great many changes, which, from his own observation, have happened among the fixed stars, and of which we have already given an account, "Does it not seem natural (says he), that these observations should cause a strong suspicion that most probably every star in the heaven is more or less in motion? And though we have no reason to think that the disappearance of some stars, or new appearance of others, nor indeed that the frequent changes in the magnitude of so many of them, are owing to their change of distance from us by proper motions, which could not occasion these phenomena without being inconceivably quick; yet we may well suppose, that motion is some way or other concerned in producing these effects. A slow motion, for instance, in an orbit round some large opaque body, where the star which is lost or diminished in magnitude might undergo occasional occultations, would account for some of those changes; while others might perhaps be owing to the periodical return of some large spots on that side of the surface which is alternately turned towards us by the rotatory motion of the star. The idea, also, of a body much flattened by a quick rotation, and having a motion similar to the moon's orbit by a change of the place of its nodes, whereby more of the luminous surface would one time be exposed to us than another, tends to the same end: for we cannot help thinking with M. de la Lande (Mem. 1776), that the same force which gave such rotations, would probably also produce motions of a different kind by a translation of the centre. Now, if the proper motion of the stars in general be once admitted, who can refuse to allow that our sun, with all its planets and comets, that is, the solar system, is no less liable to such a general agitation as we find to obtain among the rest of the celestial bodies?

235 Conjectures concerning the appearance of new stars

236 How to discover the proper motion of the sun.

"Admitting this for granted, the greatest difficulty will be, how to discern the proper motion of the sun among so many other and variously compounded motions of the stars. This is an arduous task indeed; but I shall point out a method of detecting the direction and quantity of the supposed proper motion of the sun by a few geometrical deductions; and at the same time show, by an application of them to some known facts, that we have already some reason to guess which way the solar system is probably tending its course.

"Suppose the sun to be at S. fig. 101, the fixed stars to be dispersed in all possible directions and distances around, at *s, s, s, s*, &c. Now, setting aside the proper motion of the stars, let us first consider what will be the consequence of a proper motion in the sun, and let it move in a direction from A towards B." Suppose it now arrived at C: here, by a mere inspection of the figure, it will be evident, that the stars *s, s, s*, which were before seen at *a a a*, will now, by the motion of the sun from S to C, appear to have gone in a contrary direction, and be seen at *b b b*; that is to say, every star will appear more or less to have receded from the point B, in the order of the letters *ab, ab, ab*. The converse of this proposition is equally true; for if the stars should all appear to have had a retrograde motion with respect to the point B, it is plain, on a supposition of their being at rest, the sun must have a direct motion towards the point B, to occasion all these appearances. From a due consideration of what has been said, we may draw the following inferences:

"1. The greatest, or total systematical parallax of the fixed stars (fig. 103), will fall upon those that are in the line D E, at rectangles to the direction A B of the sun's motion.

"2. The partial systematical parallax of every other star *s, s, s*, not in the line D E, will be to the total parallax as the sine of the angle BS*a*, being the star's distance from that point towards which the sun moves, to radius.

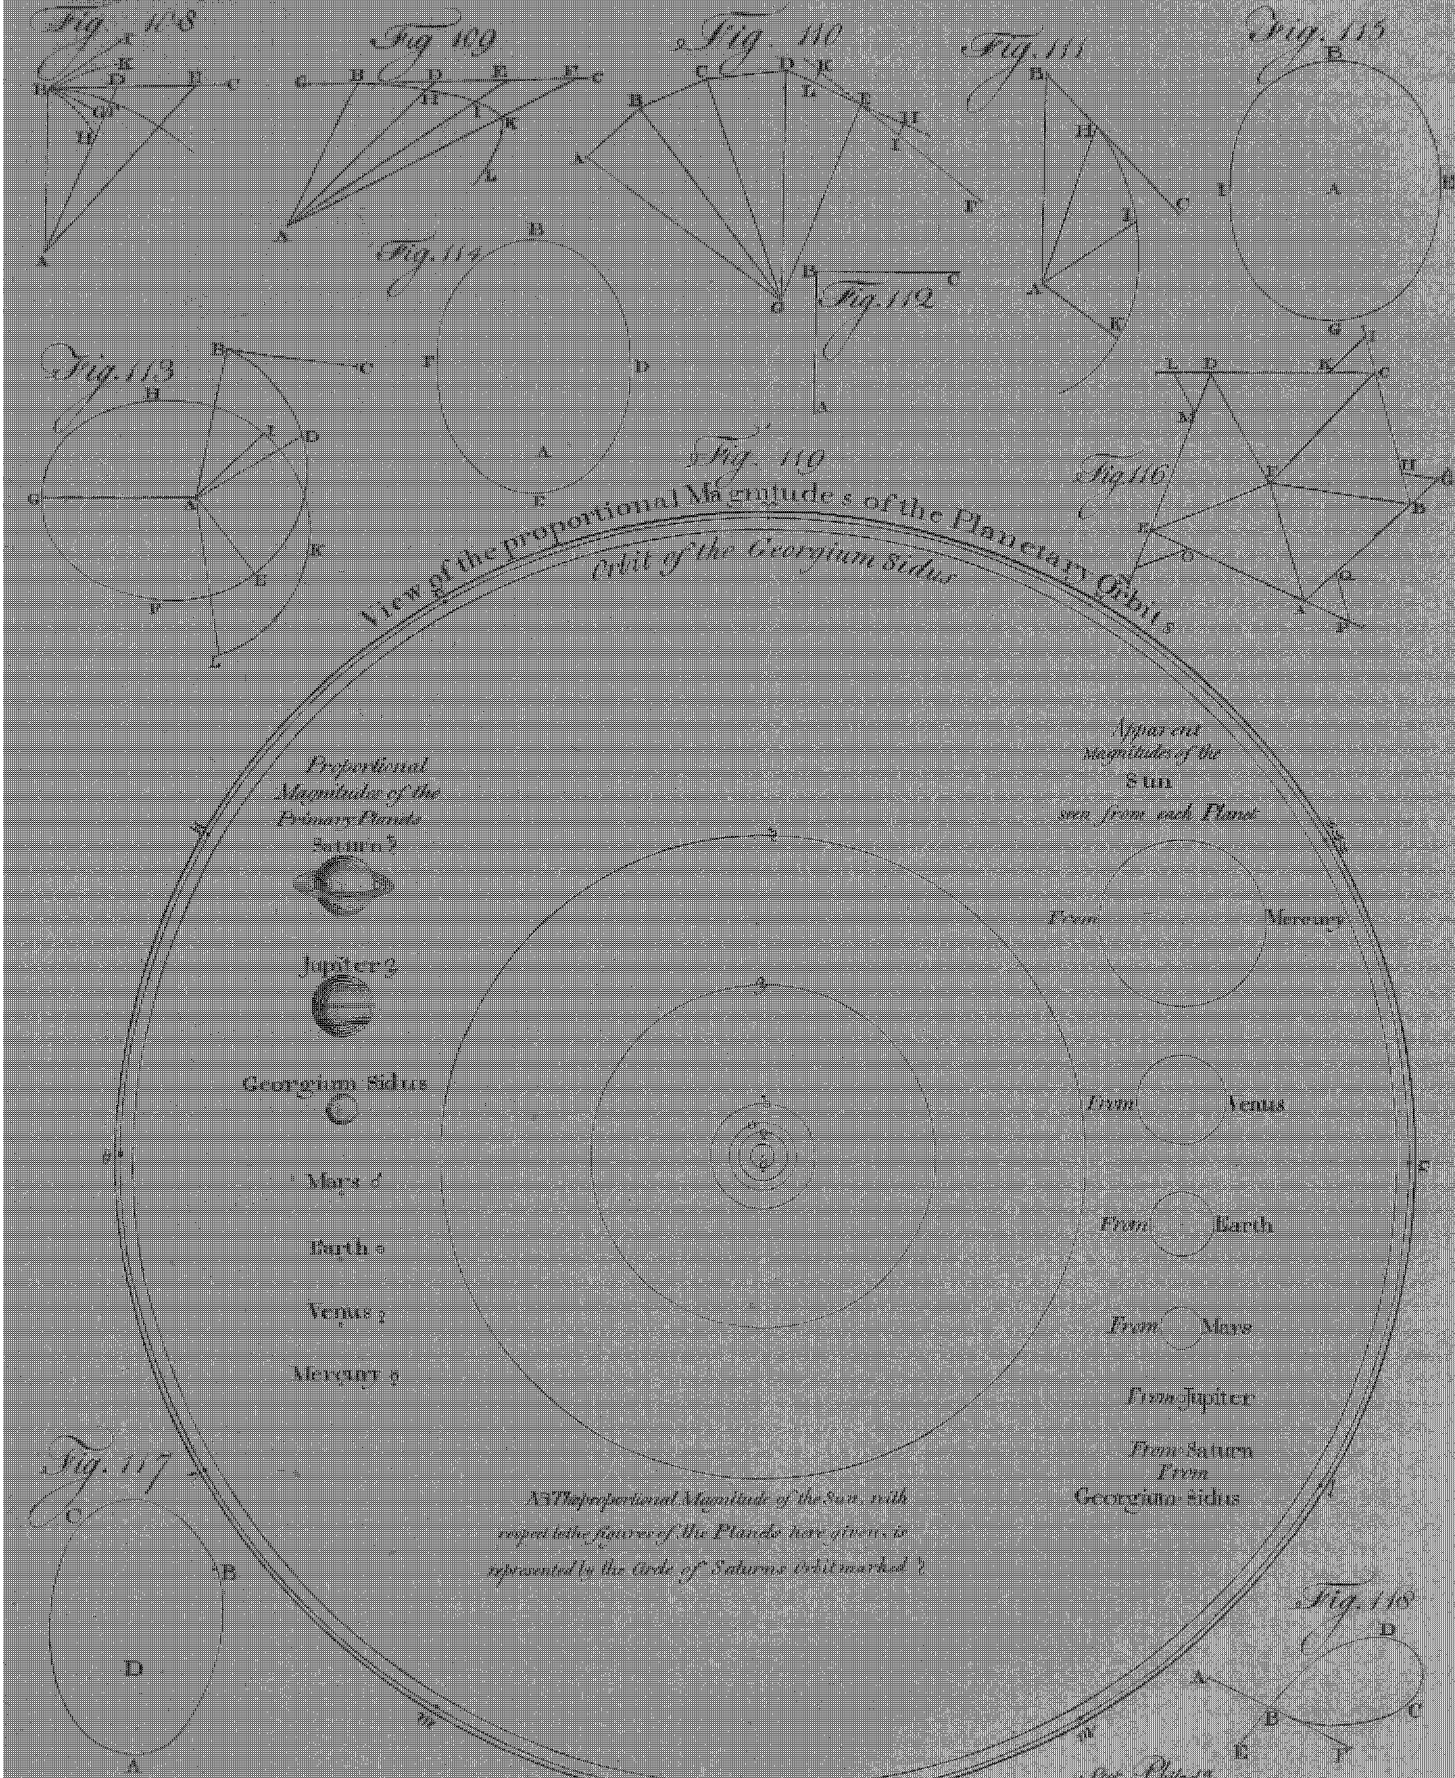
"3. The parallax of stars at different distances will be inversely as these distances; that is, one half at double the distance, one third at three times, and so on; for the subtense SC remaining the same, and the parallactic angle being very small, we may admit the angle S*s*C to be inversely as the side S*s*, which is the star's distance.

"4. Every star at rest, to a system in motion, will appear to move in a direction contrary to that which the system has. Hence it follows, that if the solar system be carried towards any star situated in the ecliptic, every star, whose angular distance in *antecedentia* (reckoned upon the ecliptic from the star towards which the system moves) is less than 180 degrees, will decrease in longitude; and that, on the contrary, every star, whose distance from the same star (reckoned upon the ecliptic, but *in consequentia*) is less than 180 degrees, will increase in longitude in both cases, without alteration of latitude.

The immense regions of the fixed stars may be considered as an infinitely expanded globe, having the so-

ASTRONOMY

Plate LXXI



Concluſions from the foregoing Appearances.

ſolar ſyſtem for its centre. The moſt proper method therefore of finding out the direction of the motion of the ſun is, to divide our obſervations on the ſyſtematical parallax of the fixed ſtars into three principal zones. Theſe, for the convenience of fixed inſtruments, may be aſſumed ſo as to let them paſs around the equator and the ſolſtitial colures, every one being at rectangles to the other two, according to the three dimenſions of ſolids." Our author, then, having informed us that obſervations on double ſtars are moſt proper for aſcertaining this point, gives an account of three zones he has marked out for this purpoſe; the equatorial zone, containing 150 double ſtars; that of the equinoctial colure, extending 10 degrees of a great circle on each ſide, as far as it is viſible on our hemiſphere, which will contain about 70 double ſtars; and that of the ſolſtitial colure, including 120, beſides a zone of the ecliptic containing a great many double ſtars which may undergo occultations by the moon. It is of the ſame extent, and includes about 120 double ſtars.

To apply this theory, it is neceſſary, in the firſt place to obſerve, that the rules of philoſophiſing direct us to refer all phenomena to as few and ſimple principles as are ſufficient to explain them. Aſtronomers, therefore, having already obſerved what they call a proper motion in ſeveral of the fixed ſtars, and which may be ſuppoſed common to them all, ought to reſolve it, as far as poſſible, into a ſingle and real motion of the ſolar ſyſtem, as far as that will anſwer the known facts, and only to attribute to the proper motion of each particular ſtar the deviations from the general law which the ſtars ſeem to follow.

237 Proper motions of ſome of the ſtars.

Dr Maſkelyne informs us, that the proper motions in right aſcenſion of Sirius, Caſtor, Procyon, Pollux, Regulus, Arcturus, and α Aquilæ, are as follow.—0″.63;— 0″.28; 0″.80—0″.93;— 0″.41;— 1″.40, and + 0″.57. Two of them, Sirius and Arcturus, have alſo a change of declination; viz. 1′.20 and 2″.01; both ſouthward. Let now fig. 104. repreſent an equatorial zone with the abovementioned ſtars referred to it, according to their reſpective right aſcenſions, having the ſolar ſyſtem in its centre. Aſſume the direction AB from a point ſomewhere not far from the 77th degree of right aſcenſion to its oppoſite 257th degree, and ſuppoſe the ſun to move in that direction from S towards B, then will that one motion anſwer that of all the ſtars together; for if the ſuppoſition be true, Arcturus, Regulus, Pollux, Procyon, Caſtor, and Sirius, ſhould appear to decreaſe in right aſcenſion, while α Aquilæ, on the contrary, ſhould appear to increaſe. Moreover, ſuppoſe the ſun to aſcend at the ſame time, in the ſame direction, towards ſome point in the northern hemiſphere, for inſtance towards the conſtellation Hercules; then will alſo the obſerved change of declination of Sirius and Arcturus be reſolved into the ſingle motion of the ſyſtem. Many difficulties indeed yet remain; ſuch as the correſpondence of the exact quantity of motion obſerved in each ſtar, with what will be aſſigned to it by this hypotheſis. But it is to be remembered, that the very different and ſtill unknown diſtances of the fixed ſtars muſt, for a good while yet, leave us in the dark as to the ſtrict application of the theory; and that any deviation from it may eaſily be accounted for from the ſtill unknown *real* proper motion of the ſtars; for if the ſolar ſyſtem have in reality the motion now aſcribed to it, then what aſtronomers have already obſerved concerning the change of place of the ſtars, and have called their proper motion, will become only an *apparent* motion; and future obſervations muſt ſtill point out, by the deviations from the general law, which the ſtars will follow in thoſe apparent motions, what may be their real proper motions, as well as relative diſtances. "But (ſays Mr Herſchel) leſt I ſhould be cenſured for admitting ſo new and capital a motion upon too ſlight a foundation, I muſt obſerve that the concurrence of thoſe ſeven principal ſtars cannot but give ſome value to an hypotheſis that will ſimplify the celeſtial motions in general. We know that the ſun, at the diſtance of a fixed ſtar, would appear like one of them; and from analogy we conclude the fixed ſtars to be ſuns. Now, ſince the apparent motions of thoſe ſeven ſtars may be accounted for, either by ſuppoſing them to move in the manner they appear to do, or elſe by ſuppoſing the ſun alone to have a motion in a direction ſome how not far from that which I have aſſigned to it, I think we are no more authoriſed to ſuppoſe the ſun at reſt than we ſhould be to deny the diurnal motion of the earth; excepting in this reſpect, that the proofs of the latter are very numerous, whereas the former reſt only on a few, though capital teſtimonies."

238 Change of right aſcenſion and declination of twelve ſtars.

The following table, taken from De la Lande, of the change of right aſcenſion and declination of twelve ſtars, is brought as an additional proof of this doctrine.

Names of Stars.	Change of R. A.			Change of Declin.		
Arcturus	—	1′	11″	—	1′	55″
Sirius	—		37	—		52
β Cygni	—		3	+		49
Procyon	—		33	—		47
ε Cygni	+		20	+		34
γ Arietis	—		14	—		29
γ Gemini	—		8	—		24
Aldebaran	+		3	—		18
β Gemini	—		48	—		16
γ Piſcium	+		53	+		7
α Aquilæ	+		32	—		4
α Gemini	—		24	—		1

Fig. 105. repreſents them projected on the plane of the equator. They are all in the northern hemiſphere except Sirius, which muſt be ſuppoſed to be viewed in the concave part of the oppoſite half of the globe, while the reſt are drawn on the convex ſurface. Regulus being added to that number, and Caſtor being double, we have 14 ſtars; and every ſtar's motion, except Regulus, being aſſigned in declination as well as right aſcenſion, we have no fewer than 27 given motions to account for. Now, by aſſuming a point ſomewhere near λ Herculis, and ſuppoſing the ſun to have a proper motion towards that part of the heavens, we ſhall account for 22 of theſe motions. For β Cygni, α Aquilæ, ε Cygni, γ Piſcium, γ Arietis, and Aldebaran, ought, upon the ſuppoſed motion of the ſun, to have an apparent progreſſion according to the hour-circle XVIII, XIX, XX, &c. or to increaſe in right aſcenſion; while Arcturus, Regulus, the two ſtars of α Geminorum, Pollux, Procyon, Sirius, and γ Geminorum, ſhould apparently go back in the order XVI, XV, XIV, &c. of the hour-circle, ſo as to decreaſe in right aſcenſion. But according to De la Lande's table, excepting β Cygni and γ Arietis, all theſe mo-

239 Motions of the ſtars accounted for.

tions

Conclusions from the foregoing Appearances.

tions really take place. With regard to the change of declination, every star in the table should go towards the south; and here we find but three exceptions, in β and ε Cygni and γ Piscium. So that, upon the whole, we have but five deviations out of 27 known motions, which this hypothesis will not account for; and these exceptions must be resolved into the real proper motion of the stars.

240 Of the velocity of the stars.

Some circumstances in the quantity of these motions also deserve our notice. In the first place, Arcturus and Sirius being the largest of the stars, and therefore probably the nearest, ought to have the greatest apparent motion, both in right ascension and declination; which is agreeable to observation, as appears from the table. 2. With regard to the right ascension only, Arcturus being better situated to show its motion, ought to have it much greater; as we find it actually has. Aldebaran, both badly situated and considerably smaller, ought, according to the same rule, to show but little motion, &c.; all of which is conformable to the table. A very striking agreement with the hypothesis may be also observed in Castor and Pollux, both of which are pretty well situated; and accordingly we find that Pollux, for the size of the star, shows as much motion in right ascension as we could expect; though it is remarkable that Castor, though equally well placed, shows no more than half the motion by the table. This is seemingly contrary to the hypothesis: but it must be remembered, that Castor is a double star, and the two of which it consists are nearly equal to each other in lustre; so that, as we can allow only half the light to each, there is a strong presumption of their being at twice the distance of Pollux, which agrees very well with observation. It might also be observed, that we should be involved in great difficulty by supposing the motion of Castor really to be in the star: for how extraordinary must be the concurrence, that two stars, viz. those that make up this apparently single one, should both have a proper motion so exactly alike, that in all our observations hitherto, we have not found them disagree a single second either in right ascension or in declination for 50 years together?

241 Arguments from the observations of Mr Mayer in favour of Herschel's hypothesis

In a postscript to this paper on the motion of the solar system, Mr Herschel brings several additional confirmations of his hypothesis from the works of Mr Mayer. These contain a catalogue of the places of 80 stars observed by Mr Mayer in 1756, and whose places he compared with those of the same stars given by Roemer in 1706. From the goodness of the instrument with which Mr Roemer made his observations, Mr Mayer gives it as his opinion, that where the disagreement in the place of a star is but small, it may be attributed to the imperfection of the instrument; but that when it amounts to 10″ or 15″, it is a very probable indication of motion in such a star; and he adds, that when the disagreement is so much as in some stars which he names (among which is *Fomahand*, where the difference is 21″ in 50 years), he has not the least doubt of a proper motion. The following tables are extracted from Mr Mayer's work; one contains the stars

242 Tables of moving stars.

whose motion agrees with Mr Herschel's hypothesis; the other those that disagree with it, and whose phenomena must therefore be either ascribed to a proper motion of the stars themselves, or to some other more hidden cause.

Conclusions from the foregoing Appearances.

"From the first table, (says Mr Herschel), we gather that the principal stars, Lucida, Lyræ, Capella, α Orionis, Rigel, Fomahand, α Serpentarii, α Aquarii, α Arietis, α Persei, α Andromedæ, α Tauri, α Ceti, and 20 more of the most distinguished of the second and third rank of the stars, agree with our proposed solar motion, when, on the contrary, the second table contains but a few stars, and not a single one of the first magnitude among them to oppose it. It is also remarkable, that many stars of the first table agree both in right ascension and declination with the supposition of a solar motion; whereas there is not one among those of the second table which opposes it in both directions. This seems to indicate, that the solar motion, in some

of

Conclusions from the foregoing Appearances.

of them at least, has counteracted and thereby destroyed, the effect of their own proper motion in one direction, so as to render it insensible; otherwise it would appear improbable, that eight stars out of twelve, contained in the latter table should only have a motion at rectangles, or in opposition to any one given direction. The same may also be said of 19 stars of the former table, that only agree with the solar motion one way, and are as to sense at rest in the other direction; but these singularities will not be near so remarkable when we have the motion of the sun to compound with their own proper motions.

The motions of α Lyræ and ι Ursæ Majoris towards the north, are placed in the first table: to understand the reason of which, it will be necessary to point out the general law by which the apparent declinations of
243 the stars at present under consideration are governed. Let an arch of 90° be applied to a sphere representing the fixed stars, so as always to pass through the apex of the solar motion: then, while one end of it is drawn along the equator, the other will describe on the spherical surface a curve which will pass through the pole of the equator, and return into itself at the apex. This

243 To delineate the apparent motions of the stars.

244 curve, not taken notice of by other authors, Mr Herschel calls a *spherical conchoid*, from the manner in which it is generated. The law then is, that all the stars in the northern hemisphere, situated within the nodated part of the conchoid, will seem to go to the north by the motion of the solar system towards its apex, the rest will appear to go southwards. A similar curve is to be delineated in the southern hemisphere. Mr Herschel then shows a method of finding whether any star, whose place in the heavens is known, will fall without or within the conchoid; after which he accounts for the want of sensible motion in α Lyræ and α Orionis in right ascension, and of Rigel both in right ascension and declination, in the following manner: "These stars are so bright, that we may reasonably suppose them to be among those that are nearest to us; and if they had any considerable motion, it would most likely have been discovered, since the variations of Sirius, Arcturus, Procyon, Castor, and Pollux, &c. have not escaped our notice. Now, from the same principle of the motion of the solar system, by which we have accounted for the apparent *motion* of the latter stars, we may account for the apparent *rest* of the former. Those two bright stars, α Lyræ and α Orionis, are placed so near the direction of the assigned solar motion, that from the application of the second theorem (n° 236), their motion ought to be insensible in right ascension, and not very considerable in declination; all which is confirmed by observations. With respect to Rigel and α Serpentarii, admitting them both as stars large enough to have shown a proper motion, were their situation otherwise than it is, we find that they also should be apparently at rest in right ascension; and Rigel, having southern declination, and being a less considerable star than α Orionis, which shows but 11″ motion towards the south in 50 years, its apparent motion in declination may on that account be also too small to become visible." Our author concludes with a remarkable passage from Mayer, to the following purpose, viz. "if it be possible that the sun has any proper motion of his own, the stars in that part of the heavens towards which he moves, must appear to open and recede from each other, while on the other hand, those on the opposite side will seem to contract their distances, and come nearer each other." "Now (says Mr Herschel), if we recollect what has been said of the motion of the stars, we find that those towards which I suppose the solar system to move, do really recede from each other: for instance, Arcturus from α Lyræ, α Aquilæ and α Aquarii from α Serpentarii and ε Ursæ Majoris; and, on the contrary, those in the opposite part of the heavens do really come nearer each other, as Sirius to Aldebaran, Procyon to α Arietis, Castor, Pollux, Regulus, &c. to α Ceti, α Persei, α Andromedæ, &c. It must be added however, that we cannot expect immediately to perceive any effects of this motion, excepting in such stars as are nearest to us. But as we have at present no other method of judging of the relative distance of the fixed stars than from their apparent brightness, those that are most likely on that account to be affected by a parallax arising from the motion of the solar system, are the very stars which have been pointed out from Mayer's own table."

244 Spherical conchoid described.

245 Velocity of the solar system.

With regard to the quantity of motion in the solar system, or the velocity with which the sun and planets change their places in absolute space, Mr Herschel proposes only a few distant hints. "From the annual parallax of the fixed stars (says he), which from my own observations I find much less than it has hitherto been thought to be, we may certainly admit that the diameter of the earth's orbit, at the distance of Sirius or Arcturus, would not nearly subtend an angle of one second; but the apparent motion of Arcturus, if owing to a translation of the solar system, amounts to no less 2″.7 a-year, as will appear if we compound the two motions of 1′ 11″ in right ascension, and 1′ 55″ in declination into one single motion, and reduce it into an annual quantity. Hence we may, in a general way estimate, that the solar motion can certainly not be less than that which the earth has in her annual orbit."

Sect. IV. *Of the different Systems by which the Celestial Phenomena have been accounted for.*

In treating of the various systems which have been invented in different ages, we do not mean to give an account of the various absurdities that have been broached by individuals on this subject; but shall confine ourselves to those systems which have been of considerable note, and been generally followed for a number of years. Concerning the opinions of the very first astronomers about the system of nature, we are necessarily as ignorant as we are of those astronomers themselves. Whatever opinions are handed down to us, must be of a vastly later date than the introduction of astronomy among mankind. If we may hazard a conjecture, however, we are inclined to think that the first opinions on this subject were much more just than those that were held afterwards for many ages. 246
We are told that Pythagoras maintained the motion of the earth, which is now universally believed, but at that time appears to have been the opinion of only a few detached individuals of Greece. As the Greeks borrowed many things from the Egyptians, and Pythagoras had travelled into Egypt and Phenice, it is probable he might receive an account of this hypothesis from thence; but whether he did so or not, we have

246 Pythagorean system

Of the different systems by which the Celestial Phenomena have been accounted for.

now no means of knowing, neither is it of any importance whether he did or not. Certain it is, however, that this opinion did not prevail in his days, nor for many ages after. In the 2d century after Christ, the very name of the Pythagorean hypothesis was suppressed by a system erected by the famous geographer and astronomer Claudius Ptolemæus. This system, which commonly goes by the name of the *Ptolemaic*, he seems not to have originally invented, but adopted as the prevailing one of that age; and perhaps made it somewhat more consistent than it was before. He supposed the earth at rest in the centre of the universe. Round the earth, and the nearest to it of all the heavenly bodies, the moon performed its monthly revolutions. Next to the moon was placed the planet Mercury; then Venus; and above that the Sun, Mars, Jupiter, and Saturn, in their proper orbits; then the sphere of the fixed stars; above these, two spheres of what he called *chrystalline* heavens; above these was the primum mobile, which, by turning round once in 24 hours, by some unaccountable means or other, carried all the rest along with it. This primum mobile was encompassed by the empyrean heaven, which was of a cubic form, and the seat of angels and blessed spirits. Besides the motions of all the heavens round the earth once in 24 hours, each planet was supposed to have a particular motion of its own; the moon, for instance, once in a month, performed an additional revolution, the sun in a year, &c. See Fig. 150.

247 Suppressed by the Ptolemaic.

248 Ptolemy's system insufficient.

It is easy to see, that, on this supposition, the confused motions of the planets already described could never be accounted for. Had they circulated uniformly round the earth, their apparent motion ought always to have been equal and uniform, without appearing either stationary or retrograde in any part of their courses. In consequence of this objection Ptolemy was obliged to invent a great number of circles, interfering with each other, which he called *epicycles* and *eccentrics*. These proved a ready and effectual salvo for all the defects of his system; as whenever a planet was deviating from the course it ought on his plan to have followed, it was then only moving in an epicycle or an eccentric, and would in due time fall into its proper path. As to the natural causes by which the planets were directed to move in these epicycles and eccentrics, it is no wonder that he found himself much at a loss, and was obliged to have recourse to divine power for an explanation, or, in other words, to own that his system was unintelligible.

249 Pythagorean system revived by Copernicus

This system continued to be in vogue till the beginning of the 16th century, when Nicolaus Copernicus, a native of Thorn (a city of regal Prussia), and a man of great abilities, began to try whether a more satisfactory manner of accounting for the apparent motions of the heavenly bodies could not be obtained than was afforded by the Ptolemaic hypothesis. He had recourse to every author upon the subject, to see whether any had been more consistent in explaining the irregular motions of the stars than the mathematical schools: but he received no satisfaction, till he found first from Cicero, that Nicetas the Syracusan had maintained the motion of the earth; and next from Plutarch, that others of the ancients had been of the same opinion. From the small hints he could obtain from the ancients, Copernicus then deduced a most complete system, capable of solving every phenomenon in a satisfactory manner. From him this system hath ever afterwards been called the *Copernican*, and represented fig. 152. Here the sun is supposed to be in the centre; next him revolves the planet Mercury, then Venus; next, the Earth, with the Moon; beyond these, Mars, Jupiter, and Saturn; and far beyond the orbit of Saturn, he supposed the fixed stars to be placed, which formed the boundaries of the visible creation.

250 Tychonic system.

Though this hypothesis afforded the only natural and satisfactory solution of the phenomena which so much perplexed Ptolemy's system, it met with great opposition at first; which is not to be wondered at, considering the age in which he lived. Even the famous astronomer Tycho Brache could never assent to the earth's motion, which was the foundation of Copernicus's scheme. He therefore invented another system, whereby he avoided the ascribing of motion to the earth, and at the same time got clear of the difficulties with which Ptolemy was embarrassed. In this system, the earth was supposed the centre of the orbits of the sun and moon; but the sun was supposed to be the centre of the orbits of the five planets; so that the sun with all the planets were by Tycho Brache supposed to turn round the earth in order to save the motion of the earth round its axis once in 24 hours. This system was never much followed, the superiority of the Copernican scheme being evident at first sight. Fig. 151.

251 Inquiries concerning the causes of the planetary motions.

The system of Copernicus coming soon into universal credit, philosophers began to inquire into the causes of the planetary motions; and here, without entering upon what has been advanced by detached individuals, we shall content ourselves with giving an account of the three famous systems, the Cartesian, the Newtonian, and what is sometimes called the *Mechanical* system.

252 Cartesian system.

Des Cartes, the founder of that system which since his time has been called the *Cartesian*, flourished about the beginning of the 17th century. His system seems to have been borrowed from the philosophers Democritus and Epicurus; who held, that every thing was formed by a particular motion of very minute bodies called *atoms*, which could not be divided into smaller parts. But though the philosophy of Des Cartes resembled that of the Corpuscularians, in accounting for all the phenomena of nature, merely from matter and motion; he differed from them in supposing the original parts of matter capable of being broken. To this property his *Materia Subtilis* owes its origin. To each of his atoms, or rather small masses of matter, Des Cartes attributed a motion on its axis, and likewise maintained that there was a general motion of the whole matter of the universe round like a vortex or whirlpool. From this complicated motion, those particles which were of an angular form, would have their angles broke off, and the fragments which were broke off being smaller than the particles from which they were abraded, behoved to form a matter of a more subtile kind than that made of large particles; and as there was no end of the abrasion, different kinds of mattter of all degrees of fineness would be produced. The finest sorts, he thought, would naturally separate themselves from the rest, and be accumulated in particular places. The finest of all would therefore be collected in the sun which was the centre of the universe, whose vortex was the whole etherial matter in the creation.

Of the different systems by which the Celestial Phenomena have been accounted for.

ation. As all the planets were immersed in this vortex, they behoved to be carried round by it, in different times, proportioned to their distances; those which were nearest the sun circulating the most quickly; and those farthest off more slowly; as those parts of a vortex which are farthest removed from the centre are observed to circulate more slowly than those which are nearest. Besides this general vortex of the sun, each of the planets had a particular vortex of their own by which their secondary planets were carried round, and any other body that happened to come within reach of it would likewise be carried away.

It is easy to see, from this short account of Des Cartes's system, that the whole of it was mere *petitio principii*: for had he been required to prove the existence of his materia subtilis, he must undoubtedly have failed in the attempt; and hence, though his hypothesis was for some time followed for want of a better, yet it gave way to that of Newton almost as soon as it was proposed.

253 Sir Isaac Newton's system, (fig. 119.)

THE general view of the solar system given by this celebrated philosopher is not different from what has been laid down in the foregoing sections. The sun is placed in or near the centre; about whom the six planets, to which a seventh, the *Georgium Sidus*, is now added, continually move with different degrees of velocity, and at different distances. The first and nearest to the sun is Mercury, next Venus, then the Earth and Moon: beyond these is Mars; after him, Jupiter; then Saturn; and last of all, at least as far as discoveries have hitherto reached, the *Georgium Sidus*. Four of these primary planets, as they are called, are attended by moons or satellites, as well as the earth. These are, Venus* Jupiter, Saturn, and the Georgium Sidus: of whom the first has only one; the second, four; the third, five; and the fourth two, though probably there may be more yet undiscovered by reason of their smallness or distance.

* See n° 74.

254 Orbits of the planets elliptical, &c.

Though these planets uniformly and at all times respect the sun as the centre of their motion, yet they do not always preserve the same distance from him; neither do they all move in the same plane, though every one of them revolves in an orbit whose plane if extended would pass through the sun's centre. The line in which the planes of any of the planetary orbits crosses the orbit of the earth is called the *line* of its nodes, and the points of intersection are the *nodes* themselves. Each of them moves in an orbit somewhat elliptical; and thus sometimes approaches nearer, and at others recedes farther from, the sun than before. This deviation from a circle is called the *eccentricity* of the orbit; the point where it is farthest distant from the sun is called its *aphelion*; and where nearest, the *perihelion*. The eccentricities of the different planets, however, are very different. In Saturn the proportion of the greatest distance to the least is something less than 9 to 8, but much nearer to this than 10 to 9; in Jupiter, it is something greater than that of 11 to 10; in Mars, it exceeds the proportion of 6 to 5; in the earth, it is only in the proportion of about 30 to 29; in Venus still less, being only as 70 to 69; but in Mercury it is much greater than in any of the rest, being little less than that of 3 to 2. The aphelia of all the planets are not situated on the same side of the sun, but in the positions shown fig. 106. though

255 Eccentricities, aphelia, &c. of the different planets.

these positions are also variable, as shall be afterwards more fully explained. The eccentricity of the Georgium Sidus is not yet determined, though it is supposed to be less than that of the rest. All of them revolve from west to east; and the most remote is the longest of finishing its course round the sun.

Of Centripetal Powers.

256 They describe equal spaces in equal times round the sun.

Each of the planets moves in its orbit round the sun in such a manner, that the line drawn from the sun to the planet, by accompanying the planet in its motion, will describe about the sun equal spaces in equal times. There is also a certain relation between the greater axes of these ellipses and the times in which the planets perform their revolutions through them, which may be expressed in the following manner: Let the period of one planet be expressed by the letter A, the greater axis of its orbit by D; let the period of another planet be denoted by B, and the greater axis of this planet's orbit by E. Then if C be taken to bear the same proportion to B as B bears to A; likewise if F be taken to bear the same proportion to E as E bears to D, and G taken to bear the same proportion likewise to F as E bears to D; then A shall bear the the same proportion to C as D bears to G.

§ 1. *Of Centripetal Powers in general.*

257 Sir Isaac's doctrine of centripetal powers.

BEFORE we attempt to give any particular explanation of the causes producing the planetary motions, it will be necessary to premise something of Sir Isaac Newton's doctrine of centripetal forces, as upon that depends his doctrine of gravitation, and of the whole celestial system. The first effect of these powers is, to cause any body projected in a straight line deviate from it, and describe an incurvated one, which shall always be bent towards the centre to which the body is supposed to have a tendency. It is not, however, necessary that the moving body should approach the centre; it may even recede farther from it notwithstanding its being drawn by it; but this property uniformly belongs to it, that the line in which it moves will be continually concave towards the centre to which the power is directed.

Let A (fig. 107.) be the centre of the force. Let a body in B be moving in the direction of the straight line BC, in which line it would continue to move if undisturbed; but being attracted by the centripetal force towards A, the body must necessarily depart from this line BC; and being drawn into the curve line BD, must pass between the lines AB and BC. It is evident, therefore, that the body in B being gradually turned off from the straight line BC, it will at first be convex towards that line and concave towards A. And that the curve will always continue to have this concavity towards A, may thus appear: In the line BC, near to B, take any point, as E, from which the line EFG may be so drawn as to touch the curve line BD in some point, as F. Now, when the body is come to E, if the centripetal power were immediately to be suspended, the body would no longer continue to move in a curve line, but, being left to itself, would forthwith reassume a straight course, and that straight course would be in the line FG; for that line is in the direction of the body's motion of the point F. But the centripetal force continuing its energy, the body will be gradually drawn from this line FG so as to keep in the

Of Centripetal Powers.

the line FD, and make that line, near the point F, to be concave towards the point A; and in this manner the body may be followed in its course throughout the line BD, and every part of that line be shown to be concave towards the point A.

Again, the point A (fig. 108.) being the centre of a centripetal force, let a body at B set out in the direction of the straight line BC perpendicular to the line AB. It will be easily conceived, that there is no other point in the line BC so near to A as the point B; that AB is the shortest of all the lines which can be drawn from A to any part of the line BC; all others, as AD or AE, being longer than AB. Hence it follows, that the body setting out from it, if it moved in the line BC, it would recede more and more from the point A. Now, as the operation of a centripetal force is to draw a body towards the centre of that force, if such a force act upon a resting body, it must necessarily put that body so into motion as to cause it move towards the centre of the force: if the body were of itself moving towards that centre, it would accelerate that motion, and cause it to move faster down; but if the body were in such a motion that it would of itself recede from the centre, it is not necessary that the action of a centripetal power should make it immediately approach the centre from which it would otherwise have receded; the centripetal force is not without effect if it cause the body to recede more slowly from that centre than otherwise it would have done. Thus, the smallest centripetal power, if it act on the body, will force it out of the line BC, and cause it to pass in a bent line between BC and the point A, as has been already explained. When the body, for instance, has advanced to the line AD, the effect of the centripetal force discovers itself by having removed the body out of the line BC, and brought it to cross the line AD somewhere between A and D, suppose at F. Now, AD being longer than AB, AF may also be longer than AB. The centripetal power may indeed be so strong, that AF shall be shorter than AB; or it may be so evenly balanced with the progressive motion of the body that AF and AB shall be just equal; in which case the body would describe a circle about the centre A; this centre of the force being also the centre of the circle.

If now the body, instead of setting out in the line BC perpendicular to AB, had set out in another line BG more inclined towards the line AB, moving in the curve line BH; then, as the body, if it were to continue its motion in the line BG, would for some time approach the centre A, the centripetal force would cause it to make greater advances toward that centre: But if the body were to set out in the line BI, reclined the other way from the perpendicular BC, and were to be drawn by the centripetal force into the curve line BK; the body, notwithstanding any centripetal force, would for some time recede from the centre; since some part at least of the curve line BK lies between the line BI and the perpendicular BC.

Let us next suppose a centripetal power directed toward the point A (Fig. 109.), to act on a body in B, which is moving in the direction of the straight line BC, the line BC reclining off from AB. If from A the straight lines AD, AE, AF, are drawn to the line CB, prolonged beyond B to G, it appears that AD is inclined to the line GC more obliquely than AB, AE more obliquely than AD, and AF than AE; or, to speak more correctly, the angle under ADG is less than that under ABG, that under AEG is less than ADG, and AFG less than AEG. Now suppose the body to move in the curve line BHIK, it is likewise evident that the line BHIK being concave towards A and convex towards BC, it is more and more turned off from that line: so that in the point H, the line AK will be more obliquely inclined to the curve line BHIK than the same line AHD is inclined to BC at the point D; at the point I the inclination of the line AI to the curve line will be more different from the inclination of the same line AIE to the line BC at the point IE; and in the points K and F the difference of inclination will be still greater; and in both, the inclination at the curve will be less oblique than at the straight line BC. But the straight line AB is less obliquely inclined to BG than AD is inclined towards DG: therefore, although the line AH be less obliquely inclined towards the curve HB than the same line AHD is inclined towards DG, yet it is possible, that the inclination at H may be more oblique than the inclination at B. The inclination at H may indeed be less oblique than the other, or they may be both the same. This depends upon the degree of strength wherewith the centripetal force exerts itself during the passage of the body from B to H; and in like manner the inclinations at I and K depend entirely on the degree of strength wherewith the centripetal force acts on the body in its passage from H to K: if the centripetal force be weak enough, the lines AH and AI drawn from the centre A to the body at H and at I, shall be more obliquely inclined to the curve than the line AB is inclined towards BG. The centripetal force may be of such a strength as to render all these inclinations equal; or if stronger, the inclinations at I and K will be less oblique than at B; and Sir Isaac Newton has particularly shown, that if the centripetal power decreases after a certain manner without the increase of distance, a body may describe such a curve line, that all the lines drawn from the centre to the body shall be equally inclined to that curve line.

258 Revolution of a body round a centre explained.

We must farther remark, that if the centripetal power, while the body increases its distance from the centre, retain sufficient strength to make the lines drawn from the centre to the body to become at length less oblique to the curve; then, if this diminution of the obliquity continue, till at last the line drawn from the centre to the body shall cease to be obliquely inclined to the curve, and become perpendicular thereto; from this instant the body shall no longer recede from the centre, but in its following motion shall again descend, and describe a curve in all respects like that which it has described already, provided the centripetal power, every where at the same distance from the body, acts with the same strength. This return of the body may be proved by the following proposition: That if the body in any place, suppose at I, were to be stopped, and thrown directly backward with the velocity wherewith it was moving forward in that point I, then the body, by the action of the centripetal force upon it, would move back again over the path IHB, in which it had before advanced

vanced forward, and would arrive again at the point B in the same space of time as was taken up in its passage from B to I; the velocity of the body at its return from the point B being the same as that wherewith it first set out from that point.

The truth of this proposition may be illustrated in the following manner. Suppose, in fig. 110, that a body were carried after the following manner through the bent figure ABCDEF, composed of the straight lines AB, BC, CD, DE, EF, let the body then first be supposed to receive an impulse to some point within the concavity of the figure, as G. Now, as this body, when once moving in the straight line AB, will continue to move on in this line as long as it shall be left to itself; but being disturbed at the point B by the impulse given it, it will be turned out of this line AB into some other straight line, wherein it will afterwards continue to move as long as it shall be left to itself: therefore, let this impulse have strength sufficient to turn the body into the line BC; then let the body move on undisturbed from B to C: but at C let it receive another impulse pointed also towards G, and of sufficient strength to turn the body into the line CD; at D let a third impulse turn it into the line DE; and at E let another turn it into EF. Now, if the body, while moving on in the line EF, be stopped and turned back again with the same velocity with which it was moving forward, then by the repetition of the former impulse at E, the body will be turned in the line ED, and move in it from E to D with the same velocity as that wherewith it was moving forward in this line; then by a repetition of the impulse at D, when the body shall have returned to that point, it will be turned into the line DC; and by the repetition of the former impulses at C and at B, the body will be brought back again into the line BA, with the velocity wherewith it first moved in that line.

To illustrate this still further, let DE and FE be continued beyond E. In DE thus continued, take at pleasure the length EH, and let HI be so drawn as to be equidistant from the line GE; then, from the second law of motion, it follows, that after the impulse on the body on E, it will move through the space EI in the same time it would have employed in moving from E to H with the velocity it had in the line DE. In FE prolonged, take EK equal to EI, and draw KL equidistant from GE. Then because the body is thrown back in the line FE with the same velocity with which it went forward in that line, if, when the body was returned to E, it were permitted to go straight on, it would pass through EK in the same time as it took up in passing through EI, when it went forward in the line EF. But if, at the body's return to the point E, such an impulse directed toward the point D were to be given it as was sufficient to turn it into the line DE, it is plain that this impulse must be equal to that which originally turned the body out of the line DE into EF; and that the velocity with which the body will return into the line ED is the same as that wherewith it moved before through this line from D to E. Because EK is equal to EI, and KL and HI being each equidistant from GE, are by consequence equidistant from each other; it follows, that the two triangular figures IEH and KEL are altogether like and equal to each other. EK therefore being equal to EI, and EL equal to KH, and KL equal to HL, it is plain, that the body, after its return to E, being turned out of the line FE into ED by an impulse acting upon it in E after the manner abovementioned, it will receive such a velocity by this impulse as will carry it through EL in the same time it would have taken to go through EK, if it had passed through it undisturbed. It has already been observed, that the time in which the body would pass over EK, with the velocity wherewith it returns, is equal to the time it took up in going forward from E to I; that is, to the time in which it would have gone through EH with the velocity wherewith it moved from D to E: therefore the time in which the body will pass from E to L, after its return into the line ED, is the same as would have been taken up by the body in passing through the line EH with the velocity wherewith it first moved in the line DE. Since, therefore EL and EH are equal, the body returns into the line DE with the velocity which it had before in that line.—Again, we may affirm, that the second impulse in E is equal to the first; for as the impulse in E, whereby the body was turned out of the line DE into the line EF, is of such strength, that if the body had been at rest when this impulse had acted upon it, it would have communicated as much motion to it as would have been sufficient to carry it through a length equal to HI, in the time wherein the body would have passed from E to H, or in the time wherein it passed from E to I. In the same manner on the return of the body, the impulse in E, whereby it is turned out of the line FE into ED, is of such strength, that if it had acted on the body at rest, it would have caused it move through a length equal to KL in the same time as the body would employ in passing through EK with the velocity wherewith it returns in the line FE: therefore the second impulse, had it acted on the body at rest, would have caused it to move through a length equal to KL in the same space of time as would have been taken up by the body in passing through a length equal to HI were the first impuse to act on the body while at rest. That is, the effects of the first and second impuse on the body when at rest would be the same: for KL and HI are equal; consequently the second impuse is equal to the first. Thus, if the body be returned through FE with the velocity wherewith it moved forward, it has been shown how, by the repetition of the impulse which acted on it in E, the body will return again into the line DE with the velocity which it had before in that line. By the same method of reasoning it may be proved, that when the body is returned back to D, the impulse which before acted on that point will throw the body into the line DC with the velocity which it first had in that line; and the other impulses being successively repeated, the body will at length be brought back again into the line BA with the velocity wherewith it set out in that line.—Thus these impulses, by acting over again in an inverted order all their operations on the body, bring it back again through the path in which it had proceeded forward; and this obtains equally whatever be the number of straight lines whereof this curve figure is composed. Now, by a method of reasoning of which Sir Isaac Newton made much use, and which he introduced into geometry.

Of Centripetal Powers.

metry, thereby greatly enriching that science, we might make a transition from this figure, composed of a number straight lines, to a figure of one continued curvature, and from a number of separate impulses repeated at distinct intervals to a continued centripetal force, and show, that because what has been here advanced holds universally true whatever be the number of straight lines whereof the curve figure ACF is composed, and however frequently the impulses at the angles of this figure are repeated; therefore the same will still remain true although this figure should be converted into one of a continued curvature; and these distinct impulses should be changed into a continual centripetal force.

This being allowed, suppose the body in K to have the line AK no longer obliquely inclined to its motion. In this case, if the body be turned back in the manner we have been considering, it must be directed back perpendicularly to AK; but if it had proceeded forward, it would likewise have moved in a direction perpendicular to AK: consequently, whether it move from this point K backward or forward, it must describe the same kind of course. Therefore, since by being turned back it will go over again the line KIHB, if it be permitted to go forward, the line KL, which it shall describe, will be altogether similar to the line KHB.

In like manner we may determine the nature of the motion, if the line wherein the body sets out be inclined, as in fig. 111. down toward the line BA drawn between the body and the centre. If the centripetal power so much increases in strength as the body approaches, that it can bend the path in which the body moves to that degree as to cause all the lines, AH, AI, AK, to remain no less oblique to the motion of the body than AB is oblique to BC, the body shall continually more and more approach the centre: But if the centripetal power increases in so much less a degree as to permit the line drawn from the centre to the body, as it accompanies the body in its motion, at length to become more and more erect to the curve wherein the body moves, and in the end, suppose at K, to become perpendicular to it; from that time the body shall rise again. This is evident from what has been said above; because, for the very same reason, here also the body will proceed from the point K to describe a line altogether similar to that in which it has moved from B to K. Thus it happens as in the pendulum, which, all the time it approaches a perpendicular position towards the horizon, descends more and more; but as soon as it is come into that situation, it immediately rises again by the same degrees as it descended before: so here the body more and more approaches the centre all the time it is moving from B to K; but thenceforward it rises from the centre again by the same degrees as it approached before.

If, as in fig. 112. the line BC be perpendicular to AB; then as has already been observed, the centripetal power may be so balanced with the progressive motion of the body, that it may keep moving round the centre A constantly at the same distance, as the body does when whirled about any point to which it is tied by a string. If the centripetal power be too weak to produce this effect, the motion of the body will presently become oblique to the line drawn from itself to the centre; but if it be stronger, the body must constantly keep moving in a curve to which a line drawn from it to the body is perpendicular.

If the centripetal power change with the change of distance, in such a manner that the body, after its motion has become oblique to the line drawn from itself to the centre, shall again become perpendicular thereto; then the body shall, in its subsequent motion, return again to the distance of AB, and from that distance take a course similar to the former: and thus, if the body move in a space void of all resistance, which has been all along supposed, it will continue in a perpetual motion about the centre, descending and ascending from it alternately. If the body, setting out from B (fig. 113.) in the line BC perpendicular to AB, describe the line BDE, which in D shall be oblique to the line AD; but in E shall again become erect to AE, drawn from the body in E to the centre A; then from this point E the body shall describe the line EFG entirely similar to BDE, and at G shall be at the same distance as it was at B; and the line AG shall be erect to the body's motion. Therefore the body shall proceed to describe from G the line GHI altogether similar to the line GFE, and at I it will have the same distance from the centre as it had at E; and also have the line AI erect to its motion: so that its subsequent motion must be in the line IKL similar to IKG, and the distance AL equal to AG. Thus the body will go on in a perpetual round without ceasing, alternately enlarging and contracting its distance from the centre.

If it so happen that the point E fall upon the line BA, continued beyond A; then the point G will fall upon B, I on E, and L also on B; so that the body will in this case describe a simple curve line round the centre A, like the line BDEF in fig. 114. in which it will revolve from B to E, and from E to B, without end. If AE in fig. 113. should happen to be perpendicular to AB, in this case also a simple line will be described; for the point G will fall on the line BA prolonged beyond A; the point I on the line AE prolonged beyond A, and the point L on B; so that the body will describe a line like the curve line BEGI in fig. 115. in which the opposite points B and G are equally distant from A; and the opposite points E and L are also equally distant from the same point A. In other cases the body will have a course of a more complicated nature.

Thus it must be apparent how a body, while it is constantly attracted towards a centre, may notwithstanding by its progressive motion keep itself from falling down to the centre, describing about it an endless circuit, sometimes approaching and sometimes receding from it. Hitherto, however, we have supposed, that the centripetal power is every where of equal strength at the same distance from the centre: and this is indeed the case with that power which keeps the planets in their orbits; but a body may be kept on in a perpetual circuit round the centre, although the centripetal power be kept moving in any curve line whatever, that shall have its concavity turned every where towards the centre of the force. To illustrate this, we shall in the first place propose the case of a body moving the incurvated figure ABCDE (fig. 116.), which is composed of the straight lines AB, BC, CD, DE,

and

Of Centripetal Powers.

and EA; the motion being carried on in the following manner. Let the body first move in the line AB with any uniform velocity. When it is arrived at the point B, let it receive an impulse directed towards any point F taken within the figure; and let the impulse be of such a strength as to turn the body out of the line AB into the line BC: The body after this impulse, while left to itself, will continue moving in the line BC. At C let the body receive another impulse directed towards the same point F, of such a strength as to turn it from the line BC into CD. At D, let the body, by another impulse, directed likewise to the point F, be turned out of the line CD into DE. At E let another impulse, directed likewise toward the point F, turn the body from the line DE into AE: and thus the body will, by means of these impulses, be carried thro' the whole figure ABCDE.

Again, when the body is come to the point A, if it there receive another impulse directed like the rest to the point F, and of such a degree of strength as to turn it into the line AB, wherein it first moved; the body will then return into this line with the same velocity it had originally. To understand this, let AB be prolonged beyond B at pleasure, suppose to G; and from G let GH be drawn; which, if produced, should always continue equidistant from BF, i. e. let GH be drawn parallel to BF, in the time, then, in which the body would have moved from B to G, had it not received a new impulse in B; by the means of that impulse it will have acquired a velocity which will carry it from B to H. After the same manner, if CI be taken equal to BH, and IK be drawn parallel to CF, the body will have moved from C to K, with the velocity which it has in the line CD, in the same time it would have employed in moving from C to I with the velocity it had in the line BC. Therefore, since CI and BH are equal, the body will move through CK in the same time as it would have taken up in moving from B to G with the velocity wherewith it moved through the line AB. Again, DL being taken equal to CK, and LM drawn parallel to DF, the body will, for the same reason as before, move through DM with the velocity which it has in the line DE, in the same time it would employ in moving through BG with its original velocity. Lastly, if EN be taken equal to DM, and NO be drawn parallel to EF; likewise, if AP be taken equal to EO, and PQ be drawn parallel to AF; then the body, with the velocity wherewith it returns into the line AB, will pass thro' AQ in the time it would have employed in passing through BG with its original velocity. Now as all this follows directly from what has been delivered concerning oblique impulses impressed upon bodies in motion; so we must here observe farther, that it can be proved by geometry, that AQ will always be equal to BG; which being granted, it follows, that the body has returned into the line AB with the same velocity which it had when it first moved in that line; for the velocity with which it returns into the line AB, will carry it over the line AQ in the same time as would have been taken up in its passing over an equal line BG with the original velocity.

The conclusion naturally deduced from the above reasoning is, that by means of a centripetal and projectile force, a body may be carried round any fixed point in a curve figure which shall be concave towards it, as that marked ABC, fig. 117. and when it is returned to that point from whence it set out, it shall recover again the velocity with which it departed from that point. It is not indeed always necessary that it should return again into its first course, for the curve line may have some such figure as ABCDBE in fig. 118. In this curve line, if the body set out from B in the direction BF, and moved through the line BCD till it returned to B; here the body would not enter again into the line BCD, because the two parts BD and BC of the curve line make an angle at the point B: so that the centripetal power, which at the point B would turn the body from the line BF into the curve, will not be able to turn it into the line BC from the direction in which it returns to the point B. A forcible impulse must be given the body in the point B to produce that effect. If, at the point B, whence the body sets out, the curve line return into itself, as in fig. 117. then the body, upon its arrival again at B, may return into its former course, and thus make an endless circuit about the centre.

259 A body may be moved in any curvilinear direction by means of centripetal force.

260 Calculation of the force requisite to carry a body in any curve line.

The force requisite to carry a body in any curve line proposed, is to be deduced from the curvature which the figure has in any part of it. Sir Isaac Newton has laid down the following proposition as a foundation for discovering this, viz. that if a line be drawn from some fixed point to the body, and remaining by one extreme united to that point, it be carried round along with the body; then if the power whereby the body is kept in its course be always pointed to this fixed point as a centre, this line will move over equal spaces in equal portions of time. Suppose a body were moving through the curve line ABCD (fig. 120), and passed over the arches AB, BC, CD in equal portions of time; then if a point, as E, can be found, from whence the line EA being drawn to the body in accompanying it in its motion, it shall make the spaces EAB, EBC, and ECD, over which it passes, equal where the times are equal; then is the body kept in this line by a power always pointed to E as a centre. To prove this, suppose a body set out from the point A, fig. 121. to move in the straight line AB; and after it had moved for some time in that line, it were to receive an impulse directed to some point, as C. Let it receive that impulse at D, and thereby be turned into the line DE; and let the body, after this impulse, take the same time in passing from D to E that is employed in passing from A to D. Then the straight lines CA, CD, and CE being drawn, the triangular spaces CAD and CDE are proved to be equal in the following manner. Let EF be drawn parallel to CD. Then, it follows, from the second law of motion, that since the body was moving in the line AB when it received the impulse in the direction DC, it will have moved after the impulse through the line DE in the same time as it would have moved through DF, provided it had received no disturbance in D. But the time of the body's moving from D to E is supposed to be equal to the time of its moving through AD; therefore the time which the body would have employed in moving through DF, had it not been disturbed in D, is equal to the time wherein it moved through AD; consequently DF is equal in length to AD; for if the body had gone on to move through the line AB without inter-

Of Centripetal Powers.

interruption, it would have moved through all the parts of it with the same velocity, and have passed over equal parts of that line in equal portions of time. Now CF being drawn, since AD and DF are equal, the triangular space CDF is equal to the triangular space CAD. Farther, the line EF being parallel to CD, it follows from the 37th proposition of Euclid's first book, that the triangle CED is equal to the triangle CFD: therefore the triangle CED is equal to the triangle CAD.

In like manner, if the body receive at E another impulse directed toward the point C, and be turned by that impulse into the line EG; if it move afterwards from E to G in the same space of time as was taken up by its motion from D to E, or from A to D; then CG being drawn, the triangle CEG is equal to CDE. A third impulse at G, directed as the two former to C, whereby the body shall be turned into the line GH, will have also the like effect with the rest. If the body move over GH in the same time as it took up in moving over EG, the triangle CGH will be equal to the triangle CEG. Lastly, if the body at H be turned by a fresh impulse directed toward C into the line HI, and at I by another impulse directed also to C be turned into the line IK; and if the body move over each of the lines HI and IK in the same time as it employed in moving over each of the preceding lines AD, DE, EG, and GH: then each of the triangles CHI and CIK will be equal to each of the preceding. Likewise, as the time in which the body moves over ADE is equal to the time of its moving over EGH, and to the time of its moving over HIK; the space CADE will be equal to the space CEGH and to the space CHIK. In the same manner, as the time in which the body moved over ADEG is equal to the time of its moving over GHIK, so the space CADEG will be equal to the space CGHIK. From this principle Sir Isaac Newton demonstrates the above-mentioned proposition, by making the transition from this incurvated figure composed of straight lines, to a figure of continued curvation; and by showing, that since equal spaces are described in equal times, in this present figure composed of straight lines, the same relation between the spaces described and the times of their description will also have place in a figure of one continued curvature. He also deduces from this proposition the reverse of it; and proves, that whenever equal spaces are continually described, the body is acted upon by a centripetal force directed to the centre at which the spaces terminate.

Having thus endeavoured to illustrate the fundamental principle of the Newtonian philosophy, at least as far as it regards the motion of the planets and heavenly bodies, we shall now proceed to the more particular application of it. The first thing undertaken by Sir Isaac in order to explain those motions, is to demonstrate, that in the celestial spaces there is no sensible matter. That the heavenly bodies suffer no sensible resistance from any matter of this kind, is evident from the agreement betwixt astronomical observations in all ages with regard to the time in which the planets have been found to perform their revolutions. Des Cartes, however, was of opinion, that the planets might be kept in their courses by means of a fluid matter,

261
No sensible matter in the celestial spaces.

which continually circulating round, should carry the planets along with it; and there is one appearance which seems to favour this opinion, viz. that the sun turns round his axis the same way the planets move; the earth also turns round its axis the same way as the moon turns round the earth, and the planet Jupiter turns round his axis the same way that his satellites revolve round him. It might therefore be supposed, that if the whole planetary region were filled with a fluid matter, the sun, by turning round on his own axis, might communicate motion first to that part of the fluid which was contiguous, and by degrees propagate the like motion to the parts more remote. After the same manner the earth might communicate motion to this fluid to a degree sufficient to carry round the moon; and Jupiter might communicate the like to the distance of its satellites. This system has been particularly examined by Sir Isaac Newton; who finds, that the velocities with which the parts of this fluid should move in different distances from the centre of motion will not agree with the motions observed in the different planets; for instance, that the time of one entire circulation of the fluid wherein Jupiter should swim, would bear a greater proportion to the time of one entire circulation of the fluid where the earth is, than the period of Jupiter bears to that of the earth. He proves also, that the planet cannot circulate in such a fluid, so as to keep long in the same course, unless the planet and the contiguous fluid are of the same density, and the planet be carried along with the same velocity as the fluid. There is also another remark made on this motion by Sir Isaac, viz. that some vivifying force will be continually necessary at the centre of the motion. The sun, in particular, by communicating motion to the ambient fluid, will lose from itself as much motion as it communicates to the fluid, unless some acting principle reside in the sun to renew its motion continually. If the fluid were infinite, this gradual loss of motion would continue till the whole should stop; and if the fluid were limited, this loss of motion would continue till there would remain no swifter a revolution in the sun than in the outermost part of the fluid, so that the whole would turn together about the axis of the sun like one solid globe. We must likewise observe, that as the planets do not move in perfect circles round the sun, there is a greater distance between their orbits in some places than others. For instance, the distance between the orbit of Mars and Venus is near half as great again in some part of their course as in others. Now here the fluid in which the earth should swim, must move with a less rapid motion where there is this greater interval between the contiguous orbits; but, on the contrary, where the space is straitest, the earth moves more slowly than where it is widest.

Again, if our globe of earth swam in a fluid of equal density with the earth itself, that is, in a fluid more dense than water, all bodies put in motion here upon the earth's surface must suffer a great resistance by it; whereas Sir Isaac Newton has made it evident, by experiments, that bodies, falling perpendicularly through the air, suffer only about one hundred and sixtieth part of the resistance from it that they meet with in water.

These

Motions of the Primary Planets.

These expetiments are applied by Sir Isaac yet farther to the general question concerning the absolute plenitude of space. He objects against the filling of all space with a subtile fluid, after the manner of Des Cartes, That all bodies must be immeasurably resisted by it. And lest it should be thought that this objection might be evaded by ascribing to this fluid such very minute and smooth parts as might remove all adhesion or friction between them, whereby all resistance would be lost, Sir Isaac proves, that fluids must resist from the inactivity of their particles, and that water and the air resist almost entirely on this account; so that in this subtile fluid, however smooth and lubricated the particles might be, yet if the whole were as dense as water, it would resist very near as much as water does: And whereas such a fluid, whose parts are absolutely close together without any intervening spaces, must be a great deal more dense than water, it must also resist more in proportion to its density, unless we suppose the matter of which this fluid is composed not to be endowed with the same degree of inactivity with other matter: But if you deprive any substance of the property so universally belonging to all other matter, without impropriety of speech it can scarce be called by this name. Sir Isaac also made an experiment to try in particular, whether the internal parts of bodies suffered any resistance; and the result did indeed appear to favour some small degree of resistance, but so very little as to leave it doubtful whether the effect did not arise from some other latent cause.

262 Objections to a pleuum.

§ 2. *Of the Motions of the Primary Planets.*

163 Planetry motions particularly explained.

Since the planets thus move in a space void of all resistance, they would, if once set in motion, continue to move on for ever on a straight line. We have, however, already observed, that the primary planets move about the sun in such a manner that a line extended from the sun to the planet would describe equal spaces in equal times; and this single property in the planetary motions proves, that they are continually acted upon by a power directed towards the sun as the centre. It has also been observed, that if the strength of the centripetal power were suitably accommodated every where to the motion of any body round a centre, the body might be carried in any bent line whatever, whose concavity should be every where turned towards the centre of that force; and likewise that the strength of the centripetal force in each place was to he collected from the nature of the line wherein the body moved. Now since each of the planets moves in an ellipsis, having the sun in one of its foci, Sir Isaac Newton demonstrates, that the strength of this power is reciprocally in the duplicate proportion of the distance from the sun. This proportion may be explained in the following manner: Suppose several distances to bear to each other the proportions of the numbers 1, 2, 3, 4, 5; that is, let the second distance be double the first, the third three times, the fourth four times, and the fifth five times as great as the first; multiply each of these numbers by itself, and 1 multiplied by 1 produces still 1, 2 multiplied by 2 produces 4, 3 by 3 produces 9, 4 by 4 produces 16, and 5 by 5 produces 25; this being done, the fractions $\frac{1}{4}$, $\frac{1}{9}$, $\frac{1}{16}$, and $\frac{1}{25}$, will respectively express the proportion which the centripetal power in each of the following distances bears to the power at the first distance: for in the second distance, which is double the first, the centripetal power will be one-fourth part only of the power at the first distance; at the third distance, the power will only be one-ninth part of the first power; at the fourth distance, the power will be only one-sixteenth; and at the fifth distance only one twenty-fifth, of the first power. Thus is found the proportion in which the centripetal power decreases, as the distance from the sun increases within the compass of one planet's motion. How it comes to pass that the planet can be carried about the sun by this centripetal power in a continual round, sometimes rising from the sun, then descending again as low, appears from what has been already said concerning centripetal forces.

264 Reciprocal duplicate proportion explained.

265 Centripetal power proved to extend throughout the system.

In order to know whether this centripetal power extends in the same proportion throughout the system, and consequently whether all the planets are influenced by it, Sir Isaac inquires what relation there ought to be between the periods of the different planets, provided they were acted upon by the same power, decreasing throughout in the proportion abovementioned; and he finds, that the period of each, in this case, would have that very proportion to the greater axis of its orbit which has been already related: which puts it beyond a doubt, that the different planets are pressed towards the sun in the same proportion to the distances as one planet is in its several distances; whence it is justly concluded, that there is such a power acting towards the sun in the foresaid proportion at all distances from it. This power, when refered to the earth, Sir Isaac calls *gravity*; when to the sun, *attraction*; and to the planets, *centripetal* force. By these means, however, he designs only to signify a power endowed with the properties abovementioned; but by no means would have it understood as if these names referred any way to the cause of it.

266 Centripetal power defined.

View of Sir Isaac Newton's Philosophy, p. 175.

267 Minute variations in the planetary motions accounted for.

" But now (says Mr Pemberton) in these demonstrations, some very minute inequalities in the motion of the planets are neglected; which is done with a great deal of judgment: for whatever be their cause, the effects are very inconsiderable, they being so exceedingly small, that some astronomers have thought fit wholly to pass them by. However, the excellency of this philosophy, when in the hands of so great a geometer as our author (Sir Isaac Newton), is such, that it is able to trace the least variations of things up to their causes. The only inequalities which have been observed common to all the planets are, the motion of the aphelion and the nodes. The transverse axis of each orbit does not remain always fixed, but moves about the sun with a very slow progressive motion; nor do the planets keep constantly in the same planes, but changes them and the lines by which these planes intersect each other by insensible degrees. The first of these inequalities, which is the motion of the aphelion, may be accounted for, by supposing the gravitation of the planets towards the sun to differ a little farther from the forementioned reciprocal duplicate proportion of the distances: but the second, which is the motion of the nodes, cannot be accounted for by any power directed towards the sun; for no such power can give it any lateral impulse to divert it from the plane of its motion into any new plane, but of necessity must be derived from some other centre. Where

268 Motion of the aphelion accounted for.

that

Motions of the Primary Planets.

that power is lodged, remains to be discovered. Now it is proved, as shall be afterwards explained, that the three primary planets, Saturn, Jupiter, and the Earth, which have satellites revolving about them, are endowed with a power of causing bodies, in particular those satellites, to gravitate towards them with a force which is reciprocally in the duplicate proportion of their distances; and the planets are, in all respects in which they come under our consideration, so similar and alike, that there is no reason to question but that they have all the same property, though it be sufficient for the present purpose to have it proved of Jupiter and Saturn only; for these planets contain much greater quantities of matter than the rest, and proportionally exceed the others in power. But the influence of these two planets being allowed, it is evident how the planets come to shift their places continually: for each of the planets moving in a different plane, the action of Jupiter and Saturn upon the rest will be oblique to the planes of their motion, and therefore will gradually draw them into new ones. The same action of these two planets upon the rest will likewise cause a progressive motion; and therefore will gradually draw them into new ones. The same action of these two planets upon the rest will likewise cause a progressive motion of the aphelion; so that there will be no necessity for having recourse to the other cause for this motion, which was before hinted at, viz, the gravitation of the planets towards the sun differing from the exact duplicate proportion of their distances. And in the last place, the action of Jupiter and Saturn upon each other will produce in their motions the same inequalities as their joint action produces upon the rest. All this is effected in the same manner as the sun produces the same kind of inequalities and many others in the motion of the moon and other secondary planets; and therefore will be best apprehended by what is said afterwards. Those other irregularities in the motion of the secondary planets have place likewise here, but are too minute to be observable, because they are produced and rectified alternately, for the most part in the time of a single revolution; whereas the motion of the aphelion and nodes which increase continually, become sensible after a long series of years.

269 Jupiter and Saturn influence eachother's motions.

Yet some of these other inequalities are discernible in Jupiter and Saturn; in Saturn chiefly: for when Jupiter, who moves faster than Saturn, approaches to a conjunction with him, his action upon the latter will a little retard the motion of that planet; and by the reciprocal action of Saturn, he will himself be accelerated. After conjunction, Jupiter will again accelerate Saturn, and be likewise retarded in the same degree as before the first was retarded and the latter accelerated. Whatever inequalities besides are produced in the motion of Saturn by the action of Jupiter upon that planet, will be sufficiently rectified by placing the focus of Saturn's ellipsis, which should otherwise be in the sun, in the common centre of gravity of the sun and Jupiter. And all the inequalities of Jupiter's motions, caused by the action of Saturn upon him, are much less considerable than the irregularities of Saturn's motion. This one principle therefore of the planets having a power as well as the sun to cause bodies gravitate towards them, which is proved by the motion of the secondary planets to obtain in fact, explains all the irregularities relating to the planetary motions ever observed by astronomers (A).

270 Method of correcting the planetary motions.

"Sir Isaac Newton after this proceeds to make an improvement in astronomy, by applying this theory to the farther correction of their motions. For as we have here observed the planets to possess a principle of gravitation as well as the sun; so it will be explained at large hereafter, that the third law of motion, which makes action and reaction equal, is to be applied in this case, and that the sun does not only attract each planet, but is also itself attracted by them; the force wherewith the planet is acted on bearing to the force wherewith the sun itself is acted upon at the same time, the proportion which the quantity of matter in the sun bears to the quantity of matter in the planet.

271 Sun moves round the common centre of gravity of him and the planets.

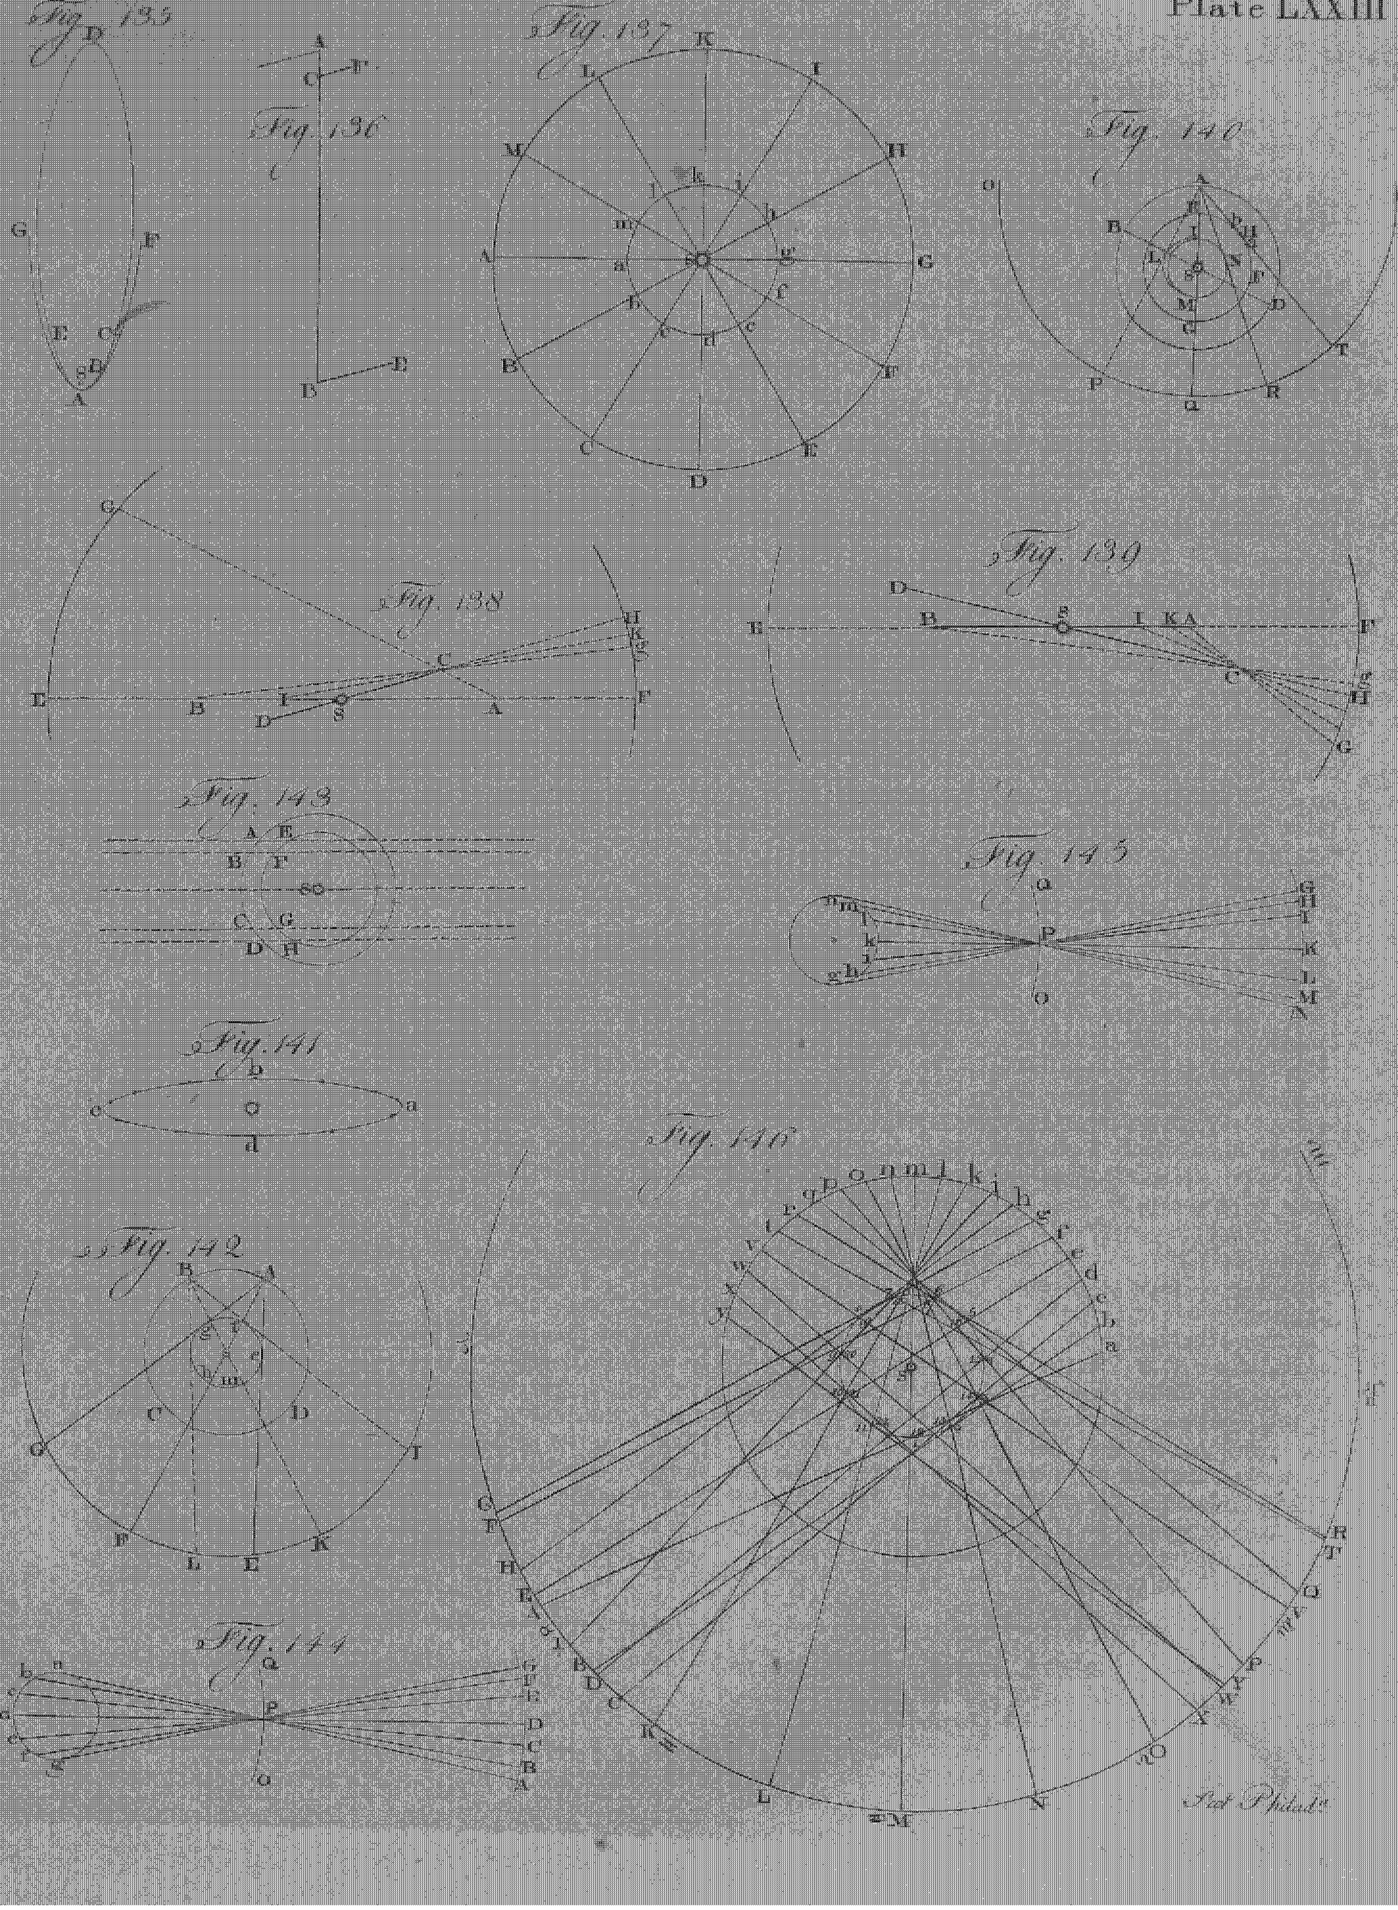
From the action of the sun and planet being thus mutual, Sir Isaac Newton proves that the sun and planet will describe about their common centre of gravity similar ellipses; and then, that the transverse axis of the ellipses, which would be described about the sun at rest in the same time, the same proportion as the quantity of solid matter in the sun and planet together bears to the first of two mean proportionals between this quantity and the quantity of matter in the sun only.

"It will be asked, perhaps, how this correction can be admitted, when the cause of the motions of the planets was before found, by supposing them to be the centre of the power which acted upon them? for, according to the present correction, this power appears rather to be directed to the common centre of gravity. But whereas the sun was at first concluded to be the centre to which the power acting on the planets was directed, because the spaces described in equal times round the sun were found to be equal; so Sir Isaac Newton proves, that if the sun and planet move round their common centre of gravity, yet, to an eye placed in the planet, the spaces which will appear to be described about the sun will have the same relation to the times of their description as the real spaces would if the sun were at rest. I further asserted, that, supposing the planets to move round the sun at rest, and to be attracted by a power which should every where act with degrees of strength reciprocally in the duplicate proportions of their distances; then the periods of the planets must observe the same relations to their distances as astronomers have found them to do. But here it must not be supposed, that the observations of astronomers absolutely agree without any the least difference: and the present correction will not cause a deviation

(A) Professor J. Robison, however, informs us in his paper on the *Georgium Sidus* (Edinburgh Philosophical Transactions, Vol. I.), That *all* the irregularities in the planetary motions *cannot* be accounted for from the laws of gravitation; for which reason he was obliged to suppose the existence of planets beyond the orbit of Saturn, even before the discovery of the *Georgium Sidus*. M. de la Lande also has observed some unaccountable inequalities in the motion of Saturn for more than 30 years past.

ASTRONOMY

Plate LXXIII



Motions of the Secondary Planets.

deviation from any one astronomer's observations so much as they differ from one another; for in Jupiter, where this correction is greatest, it hardly amounts to the 3000th part of the whole axis.

272 Argument against the eternity of the world.

"Upon this head, I think it not improper to mention a reflection made by our excellent author upon these small inequalities in the planets motions, which contains in it a very strong philosophical argument against the eternity of the world. It is this, that these inequalities must continually increase by slow degrees, till they render at length the present frame of nature unfit for the purposes it now serves. And a more convincing proof cannot be desired against the present constitution's having existed from eternity than this, that a certain period of years will bring it to an end. I am aware, that this thought of our author has been represented even as impious, and as no less than casting a reflection upon the wisdom of the Author of nature for framing a perishable work. But I think so bold an assertion ought to have been made with singular caution: for if this remark upon the increasing irregularies in the heavenly motions be true in fact, as it really is, the imputation must return upon the assertor, that this does not detract from the divine wisdom. Certainly we cannot pretend to know all the omniscient Creator's purposes in making this world, and therefor cannot pretend to determine how long he designed it should last; and it is sufficient if it endure the time designed by the Author. The body of every animal shows the unlimited wisdom of the Author no less, nay, in many respects more, than the larger frame of nature; and yet we see they are all designed to last but a small space of time.

§ 3. *The Motions of the Secondary Planets explained from the Principles laid down in* § 1.

The excellency of the Newtonian philosophy is discoverable even more in its solution of the motions of the secondary than in those of the primary planets; for thus not only all the irregularities formerly discovered by astronomers in these motions are solved in a satisfactory manner, but several others are discovered of such a complicated nature that they could never be distinguished into proper heads. These, however, are now not only found out from their causes, which this philosophy has brought to light; but the dependence of them upon their causes is also shown in such a perfect manner, that the degree of them may be exactly computed. Thus Sir Isaac Newton found means to compute the moon's motion so exactly, that he framed a theory from which the place of that planet may at all times be computed very nearly, or altogether, as exactly as the places of the primary planets themselves; which is much beyond what the greatest astronomers could ever effect.

273 Secondaries attracted by their primaries.

The first thing demonstrated of these secondary planets is, that they are drawn towards their respective primaries in the same manner as the latter are attracted by the sun. That each secondary planet is kept in its orbit by a power directed towards its primary, &c. is proved from the phenomenon of the satellites of Jupiter and Saturn; because they move in circles, as far as we can observe, about their respective primaries with an equable course, the primary being the centre of each orbit: and by comparing the times in which the different satellites of the same primary perform their periods, they are found to observe the same relation to the distances from their primary as the primary planets observe in respect of their mean distances from the sun. The same thing holds good also with regard to the earth and moon: for she is found to move round the earth in an ellipsis after the same manner as the primary planets do about the sun, excepting only some small irregularities in her motions, the cause of which will be particularly explained in what follows; whereby it will appear that they are no objections against the earth's acting on the moon in the same manner as the sun acts on the primary planets; that is, as Jupiter and Saturn act upon their satellites.

274 Power of Jupiter and Saturn discovered by their satellites.

By the number of satellites which move round Jupiter and Saturn, the power of each of these planets may be measured to a very considerable distance; for the distance of the outermost satellite in each of these planets exceeds several times the distance of the innermost. The force of the earth upon the moon, however, at different distances, is more confirmed by the following consideration than any analogical reasoning.

275 Gravity retains the moon in her orbit.

It will appear, that if the power of the earth by which it retains the moon in her orbit be supposed to act at all distances between the earth and moon, according to the rule already mentioned, this power will be sufficient to produce upon bodies near the surface of the earth all the effects ascribed to the principle of gravity. This is discovered by the following method. Let A (in fig. 122.) represent the earth, B the moon, BCD the moon's orbit; which differs little from a circle of which A is the centre. If the moon in B were left to itself to move with the velocity it has in the point B, it would leave the orbit, and proceed straight forward in the line BE which touches the orbit in B. Suppose the moon would upon this condition move from

276 Her motion particularly explained.

B to E in the space of one minute of time. By the action of the earth upon the moon, whereby it is retained in its orbit, the moon will really be found at the end of this minute in the point F, from whence a stright line drawn to A shall make the space BFA in the circle equal to the triangular space BEA; so that the moon in the time wherein it would have moved from B to E, if left to itself, has been impelled towards the earth from E to F. And when the time of the moon's passing from B to F is small, as here it is only one minute, the distance between E and F scarce differs from the space through which the moon would descend in the same time if it were to fall directly down from B toward A without any other motion. AB, the distance of the moon from the earth, is about 60 of the semidiameters of the latter; and the moon completes her revolution round the earth in about 27 days 7 hours and 43 minutes; therefore the space EF will here be found by computation to be about $16\frac{1}{8}$ feet. Consequently, if the power by which the moon is retained in its orbit be near the surface of the earth greater than at the distance of the moon in the duplicate proportion of that distance, the number of feet a

277 Calculation of the velocity of falling bodies.

body would descend near the surface of the earth by the action of this power upon it, in one minute, would be equal to the number $16\frac{1}{8}$ multiplied twice into the number 60; that is, to 58050. But how fast bodies fall near the surface of the earth may be known by the pendulum; and by the exactest experiments, they

are

Motions of the Secondary Planets.

are found to descend the space of 16$\frac{1}{8}$ feet in one second; and the spaces described by falling bodies being in the duplicate proportion of the times of their fall, the number of feet a body would describe in its fall near the surface of the earth in one minute of time will be equal to 16$\frac{1}{8}$ twice multiplied by 60; the same as would be caused by the power which acts upon the moon.

278 Earth and moon move about their common centre of gravity.

In this computation the earth is supposed to be at rest: but it would have been more exact to have supposed it to move, as well as the moon, about their common centre of gravity; as will easily be understood from what has been already said concerning the motion of the sun and primary planets about their common centre of gravity. The action of the sun upon the moon is also here neglected; and Sir Isaac Newton shows, if you take in both these considerations, the present computation will best agree to a somewhat greater distance of the moon and earth, viz. to 61$\frac{1}{2}$ semidiameters of the latter, which distance is more conformable to astronomical observations; and these computations afford an additional proof that the action of the earth observes the same proportion to the distance which is here contended for. In Jupiter and Saturn this power is so far from being confined to a small extent of space, that it not only reaches to several satellites at very different distances, but also from one planet to another, nay, even through the whole planetary system; consequently there is no appearance of reason why this power should not act at all distances, even at the very surfaces of these planets as well as farther off. But from hence it follows, that the power which retains the moon in her orbit is the same as that which causes bodies near the surface of the earth to gravitate: for since the power by which the earth acts on the moon will cause bodies near the surface of it to descend with all the velocity they are found to do, it is certain no other power can act upon them besides; because if it did, they must of necessity descend swifter. Now, from all this, it is at length very evident, that the power in the earth which we call *gravity* extends up to the moon, and decreases in the duplicate proportion of the increase of the distance from the earth.

279 Action of the sun upon the secondary Planets.

Thus far with respect to the action of the primary planets upon their secondaries. The next thing to be shown is, that the sun likewise acts upon them. For this purpose we must observe, that if to the motion of the satellite whereby it would be carried round its primary at rest, we superadd the same motion, both in regard to the velocity and direction, as the primary itself has, it will describe about the primary the same orbit with as great regularity as if the primary had been indeed at rest. This proceeds from the law of motion, which makes a body near the surface of the earth descend perpendicularly, though the earth be in so swift a motion, that if the falling body did not partake of it, its descent would be remarkably oblique; and that a body projected describes in the most regular manner the same parabola, whether projected in the direction in which the earth moves, or in the opposite direction, if the projecting force be the same. From this we learn, that if the satellite moved about its primary with perfect regularity, besides its motion about the primary it would have the same progressive velocity with which the primary is carried about the sun, in a direction parallel to that impulse of its primary: And, on the contrary, the want of either of these, in particular of the impulse towards the sun, will occasion great inequalities in the motion of the secondary planet. The inequalities which would arise from the absence of this impulse towards the sun are so great, that by the regularity which appears in the motion of the secondary planets, it is proved, that the sun communicates to them the same velocity by its action as it gives to their primary at the same distance. For Sir Isaac Newton informs us, that upon examination he found, that if any of the satellites of Jupiter were attracted by the sun more or less than Jupiter himself at the same distance, the orbit of that satellite, instead of being concentrical to Jupiter, would have its centre at a greater or lesser distance than the centre of Jupiter from the sun, nearly in the subduplicate proportion of the difference between the sun's action upon the satellite and upon Jupiter. Therefore, if any satellite were attracted by the sun but one hundredth part more or less than Jupiter is at the same distance, the orbit of that satellite would be distant from the centre of Jupiter no less than a fifth part of the outermost satellite from Jupiter; which is almost the whole distance of the innermost satellite. By the like argument, the satellites of Saturn gravitate towards the sun as much as Saturn itself at the same distance, and the moon as much as the earth.

280 Secondary planets equally attracted by the sun with their primaries.

281 Whence the inequalities in the motions of the secondary planets arise.

Thus it is proved, that the sun acts upon the secondary planets as much as upon the primaries at the same distance: but it has also been shown, that the action of the sun upon bodies is reciprocally in the duplicate proportion of the distance; therefore the secondary planets being sometimes nearer to the sun than to the primary, and sometimes more remote, they are not always acted upon in the same degree with their primary, but when nearer to the sun are attracted more, and when further off are attracted less. Hence arise various inequalities in the motion of the secondary planets.

282 Inequalities of the moon's motion explained.

Some of these inequalities, however, would take place, though the moon if undisturbed by the sun had moved in a circle concentrical to the earth, and in the plane of the earth's motion; others depend on the elliptical figure and oblique situation of the moon's orbit. One of the former is, that the moon does not describe equal spaces in equal times, but is continually accelerated as she passes from the quarter to the new or full, and is retarded again by the like degrees in returning from the new and full to the next quarter: but here we consider not so much the absolute as the apparent motions of the moon with respect to us. These two may be distinguished in the following manner. Let S, in fig. 123. represent the sun, A the earth moving in its orbit BC, DEFG the moon's orbit, and H the place of the moon in her orbit. Suppose the earth to have moved from A to I. Because it has been shown that the moon partakes of all the progressive motion of the earth, and likewise that the sun attracts both the earth and moon equally when they are at the same distance from it, or that the mean action of the sun upon the moon is equal to its action upon the earth; we must therefore consider the moon as carrying about with it the moon's orbit: so that when the earth is removed from A to I, the moon's orbit shall likewise

be

be removed from its former situation into that denoted by KLMN. But now the earth being in I, if the moon were found in O, so that OI should be parallel to HA, though the moon would readily have moved from H to O, yet it would not have appeared to a spectator upon the earth to have moved at all, because the earth has moved as much as itself; so that the moon would still appear in the same place with respect to the fixed stars. But if the moon be observed in P, it will then appear to have moved, its apparent motion being measured by the angle under OIP. And if the angle under PIS be less than the angle under HAS, the moon will have approached nearer its conjunction with the sun. Now, to explain particularly the inequality of the moon's motion already mentioned, let S, in fig. 124. represent the sun, A the earth, BCDE the moon's orbit, C the place of the moon when in the latter quarter. Here it will be nearly at the same distance from the sun as the earth is. In this case, therefore, they will be both equally attracted, the earth in the direction AS, and the moon in that CS. Whence, as the earth, in moving round the sun, is continually descending towards it, so the moon in this situation must in any equal portion of time descend as much; and therefore the position of the line AC in respect of AS, and the change which the moon's motion produces in the angle CAS, will not be altered by the sun; but as soon as the moon is advanced from the quarter toward the new or conjunction, suppose to G, the action of the sun upon it will have a different effect. Were the sun's action upon the moon here to be applied in the direction GH parallel to AS, if its action on the moon were equal to its action on the earth, no change would be wrought by the sun on the apparent motion of the moon round the earth. But the moon receiving a greater impulse in G than the earth receives in A, were the sun to act in the direction GH, yet it would accelerate the description of the space DAG, and cause the angle under GAD to decrease faster than it otherwise would. The sun's action will have this effect upon account of the obliquity of its direction to that in which the earth attracts the moon. For the moon by this means is drawn by two forces oblique to one another; one drawing from G towards A, the other from G towards H; therefore the moon must necessarily be impelled toward D. Again, because the sun does not act in the direction GH parallel to SA, but in the direction GS oblique to it, the sun's action on the moon will, by reason of this obliquity, farther contribute to the moon's acceleration. Suppose the earth, in any short space of time, would have moved from A to I, if not attracted by the sun, the point I being in the straight line CE, which touches the earth's orbit in A. Suppose the moon in the same time would have moved in her orbit from G to K, and besides have partook of all the progressive motion of the earth. Then, if KL be drawn parallel to AI, and taken equal to it, the moon, if not attracted to the sun, would be found in L. But the earth, by the sun's action, is removed from I. Suppose it were moved down to M in the line IMN parallel to SA, and if the moon were attracted but as much, and in the same direction, as the earth is here supposed to be attracted, so as to have descended during the same time in the line LO parallel also to AS, down as far as P, till LP were equal to IM, the angle under PMN would be equal to that under LIN; that is, the moon will appear advanced as much farther forward than if neither it nor the earth had been subject to the sun's action. But this is on the supposition that the actions of the sun upon the earth and moon are equal; whereas the moon being acted upon more than the earth, did the sun's action draw the moon in the line LO parallel to AS, it would draw it down so far as to make LP greater than IM, whereby the angle under PMN will be rendered greater than that under LIN. But, moreover, as the sun draws the earth in a direction oblique to IN, the earth will be found in its orbit somewhat short of the point M. However, the moon is attracted by the sun still more out of the line LO than the earth is out of the line IN; therefore this obliquity of the sun's action will yet farther diminish the angle under PMN. Thus the moon at the point G receives an impulse from the sun whereby her motion is accelerated; and the sun producing this effect in every place between the quarter and the conjunction, the moon will move from the quarter with a motion continually more and more accelerated; and therefore, by acquiring from time to time an additional degree of velocity in its orbit, the spaces which are described in equal times by the line drawn from the earth to the moon will not be every where equal, but those toward the conjunction will be greater than those towards the quarter. But in the moon's passage from the conjunction D to the next quarter, the sun's action will again retard the moon, till, at the next quarter at E, it be restored to the first velocity which it had in C. When the moon moves from E to the full, or opposition to the sun in B, it is again accelerated; the deficiency of the sun's action on the moon from what it has upon the earth producing here the same effect as before the excess of its action.

Let us now consider the moon in Q as moving from E towards B. Here, if she were attracted by the sun in a direction parallel to AS, yet being acted on less than the earth, as the latter descends towards the sun, the moon will in some measure be left behind. Therefore, QF being drawn parallel to SB, a spectator on the earth would see the moon move as if attracted from the point Q in the direction QF, with a degree of force equal to that whereby the sun's action on the moon falls short of its action on the earth. But the obliquity of the sun's action has here also an effect. In the time the earth would have moved from A to I without the influence of the sun, let the moon have moved in its orbit from Q to R. Drawing, therefore, RT parallel and equal to AI, the moon, by the motion of its orbit, if not attracted by the sun, must be found in T; and therefore, if attracted in a direction parallel to SA, would be in the line TV parallel to AS; suppose in W. But the moon in Q being farther off the sun than the earth, it will be less attracted; that is, TW will be less than IM; and if the line SM be prolonged towards X, the angle under XMW will be less than XIT. Thus, by the sun's action, the moon's passage from the quarter to the full would be accelerated, if the sun were to act on the earth and moon in a direction parallel to AS: and the obliquity of the sun's action will still increase this acceleration: For

For the action of the sun on the moon is oblique to the line SA the whole time of the moon's passage from Q to T, and will carry her out of the line TV towards the earth. Here we suppose the time of the moon's passage from Q to T so short, that it shall not pass beyond the line SA. The earth will also come a little short of the line IN, as was already mentioned; and from these causes the angle under XMW will be still farther lessened. The moon, in passing from the opposition B to the next quarter, will be retarded again by the same degrees as it was accelerated before its appulse to the opposition; and thus the moon, by the sun's action upon it, is twice accelerated and twice restored to its first velocity every circuit it makes round the earth; and this inequality of the moon's motion about the earth is called by astronomers its variation.

283 Effect of the sun's attraction in different parts of the moon's orbit.

The next effect of the sun upon the moon is, that it gives the orbit of the latter in the quarters a greater degree of curvature than it would receive from the earth alone; and, on the contrary, in the conjunction and opposition the orbit is less inflected. When the moon is in the conjunction with the sun at D, the latter attracting her more forcibly than it does the earth, the moon is by that means impelled less to the earth than otherwise it would be, and thus the orbit less incurvated: for the power by which the moon is impelled towards the earth being that by which it is inflected from a rectilinear course, the less that power is the less it will be inflected. Again, when the moon is in the opposition in B farther removed from the sun than the earth is, it follows then, that though the earth and moon are both continually descending toward the sun, that is, are drawn by the sun towards itself out of the place they would otherwise move into, yet the moon descends with less velocity than the earth; insomuch that, in any given space of time from its passing the point of opposition, it will have less approached the earth than otherwise it would have done; that is, its orbit, in respect to the earth, will approach nearer to a straight line. Lastly, when the moon is in the quarter in F, and equally distant from the sun as the earth, it was before observed, that they would both descend with equal velocity towards the sun, so as to make no change in the angle FAS; but the length of the line FA must necessarily be shortened. Therefore the moon, in moving from F toward the conjunction with the sun, will be impelled more toward the earth by the sun's action than it would have been by the earth alone, if neither the earth nor the moon had been acted upon by the sun; so that, by this additional impulse, the orbit is rendered more curve than it otherwise should be. The same effect will also be produced in the other quarter.

A third effect of the sun's action, and which follows from that just now explained, is, that though the moon undisturbed by the sun might move in a circle, having the earth for its centre, by the sun's action, if the earth were to be in the very middle or centre of the moon's orbit, yet the moon would be nearer the

284 Moon comes nearest the earth when least attracted by it.

earth at the new and full than in the quarters. This may at first appear somewhat difficult to be understood, that the moon should come nearest to the earth where it is least attracted by it: yet, upon a little consideration, it will evidently appear to flow from that very cause, because her orbit, in the conjunction and opposition, is rendered less curve; for the less curve the orbit is, the less will the moon have descended from the place it would move into without the action of the earth. Now, if the moon were to move from any place without farther disturbance from that action, since it would proceed on the line touching the orbit in that place, it would continually recede from the earth; and therefore, if the power of the earth upon the moon be sufficient to retain it at the same distance, this diminution of that power will cause the distance to increase, though in a less degree. But, on the other hand, in the quarters, the moon being pressed in a less degree towards the earth than by the earth's single action, will be made to approach it: so that, in passing from the conjunction or opposition to the quarters, the moon ascends from the earth; and in passing from the quarters to the opposition or conjunction, it descends again, becoming nearer in these last mentioned places than in the other.

All the inequalities we have mentioned are different in degree as the sun is more or less distant from the earth; being greatest when the earth is in its perihelion, and smallest when it is in its aphelion: for in the quarters, the nearer the moon is to the sun the greater is the addition to the earth's action upon it by the power of the sun; and in the conjunction and opposition. the difference between the sun's action upon the earth and upon the moon is likewise so much the great-

285 Cause of the dilatation of the moon's orbit.

er. This difference in the distance between the earth and the sun produces a farther effect upon the moon's motion; causing her orbit to dilate when less remote from the sun, and become greater than when at a farther distance: For it is proved by Sir Isaac Newton, that the action of the sun by which it diminishes the earth's power over the moon in the conjunction or opposition, is about twice as great as the addition to the earth's action by the sun in the quarters; so that, upon the whole, the power of the earth on the moon is diminished by the sun, and therefore is most diminished when that action is strongest: but as the earth, by its approach to the sun, has its influence lessened, the moon, being less attracted, will gradually recede from the earth; and as the earth, in its recess from the sun, recovers by degrees its former power, the orbit of the moon must again contract. Two consequences follow from hence, viz. that the moon will be more remote from the earth when the latter is nearest the sun, and also will take up a longer time in performing its revolution through the dilated orbit than through the more contracted.

These irregularities would be produced if the moon, without being acted upon unequally by the sun, should describe a perfect circle about the earth and in the plane of its motion; but though neither of these circumstances take place, yet the abovementioned inequalities occur only with some little variation with regard to the degree of them; but some others are observed to take place from the moon's motion being performed in the manner already described: For, as the moon describes an ellipsis, having the earth in one of its foci, this curve will be subjected to various changes, neither preserving constantly the same figure nor position; and because the plane of this ellipsis is not the same with that of the earth's orbit, it thence follows, that the former will continually change; so

Motions of the Secondary Planets.

that neither the inclination of the two planes towards each other, nor the line in which they interfect, will remain for any length of time unaltered.

286 Action of the fun caufes the plane of the moon's orbit to change.

As the moon does not move in the fame plane with the earth, the fun is but feldom in the plane of her orbit, viz. only when the line made by the common interfection of the two planes, if produced, will pafs through the fun. Thus, let S, in fig. 125. denote the fun, T the earth, ATB the plane of the earth's orbit, CDEF the moon's orbit; the part CDE being raifed above, and the part CFE depreffed under the former. Here the line CE, in which the two planes interfect each other, being continued, paffes through the fun in S. When this happens, the action of the fun is directed in the plane of the moon's orbit, and cannot draw her out of this plane, as will evidently appear from an infpection of the figure; but in other cafes the obliquity of the fun's action to the plane of the orbit will caufe this plane continually to change.

Let us now fuppofe, in the firft place, the line in which the two planes interfect each other to be perpendicular to the line which joins the earth and fun. Let T, in fig. 126, 127, 128, 129. reprefent the earth; S the fun; the plane of the fcheme the plane of the earth's orbit, in which both the fun and earth are placed. Let AC be perpendicular to ST, which joins the earth and fun; and let the line AC be that in which the plane of the moon's orbit interfects the orbit of the earth. On the centre T defcribe in the plane of the earth's motion the circle ABCD; and in the plane of the moon's orbit defcribe the circle AECF; one-half of which, AEC, will be elevated above the plane of this fcheme, and the other half, AFC, as much depreffed below it. Suppofe then the moon to fet out from the point A, in fig. 127. in the direction of the plane AEC. Here fhe will be continually drawn out of this plane by the action of the fun; for this plane AEC, if extended, will not pafs through the fun, but above it; fo that the fun, by drawing the moon directly toward itfelf, will force it continually more and more from that plane towards the plane of the earth's motion in which itfelf is, caufing it to defcribe the line AKGHI, which will be convex to the plane AEC and concave to the plane of the earth's motion. But here this power of the fun, which is faid to draw the moon toward the plane of the earth's motion, muft be underftood principally of as much only of the fun's action upon the moon as it exceeds the action of the fame upon the earth: For fuppofe the laft mentioned figure to be viewed by the eye placed in the plane of that fcheme; and in the line CTA, on the fide A, will appear as the ftraight line TDB in fig. 130. and the plane AECF as another ftraight line FE, and the curve line AKGHI under the form of the line TKGHI. Now it is plain, that the earth and moon being both attracted by the fun, if the fun's action upon both was equally ftrong, the earth T, and with it the plane AECF, or the line FTE, would be carried towards the fun with as great velocity as the moon, and therefore the moon not drawn out of it by the fun's action, except only from the fmall obliquity of direction of this action upon the moon to that of the fun's action upon the earth, which arifes from the moon being out of the plane of the earth's motion, and is not confiderable; but the action of the fun upon the moon being greater than upon the earth all the time the moon is nearer to the fun than the earth is, it will be drawn from the plane AEC, or the line TE, by that excefs, and made to defcribe the curve line AGI or TGI. But it is the cuftom of aftronomers, inftead of confidering the moon as moving in fuch a curve line, to refer its motion continually to the plane which touches the true line wherein it moves at the point where at any time the moon is. Thus, when the moon is in the point A, its motion is confidered as being in the plane AEC, in whofe direction it then attempts to move; and when in the point K, fig. 127. its motion is referred to the plane which paffes through the earth and touches the line AKGHI in the point K. Thus the moon, in paffing from A to I, will continually change the plane of her motion in the manner we fhall now more particularly explain.

Let the plane which touches the line AKI in the point K, fig. 127. interfect the plane of the earth's orbit in the line LTM. Then, becaufe the line AKI is concave to the plane ABC, it falls wholly between that plane and the plane which touches it in K; fo that the plane MKL will cut the plane AEC before it meets the plane of the earth's motion, fuppofe in the line YT, and the point A will fall between K and L. With a radius equal to TY or TL defcribe the femicircle LYM. Now, to a fpectator on the earth, the moon when in A will appear to move in the circle AECF; and when in K, will appear to be moving in the femicircle LYM. The earth's motion is performed in the plane of this fcheme; and to a fpectator on the earth the fun will always appear to move in that plane. We may therefore refer the apparent motion of the fun to the circle ABCD defcribed in this plane about the earth. But the points where this circle in which the fun feems to move interfects the circle in which the moon is feen at any time to move, are called the nodes of the moon's orbit at that time. When the moon is feen moving in the circle AECD, the points A and C are the nodes of the orbit; when fhe appears in the femicircle LYM, then L and M are the nodes. It will now appear, from what has been faid, that while the moon has moved from A to K, one of the nodes has been carried from A to L, and the other as much from C to M. But the motion from A to L and from C to M is backward in regard to the motion of the moon, which is the other way from A to K, and from thence toward C. Again, the angle which the plane wherein the moon at any time appears makes with the plane of the earth's motion, is called the inclination of the moon's orbit at that time: we fhall now therefore proceed to fhow, that this inclination of the orbit, when the moon is in K, is lefs than when fhe was in A; or, that the plane LYM, which touches the line of the moon's motion in K, makes a lefs angle with the plane of the earth's motion, or with the circle ABCD, than the plane AEC makes with the fame. The femicircle LYM interfects the femicircle AEC in Y, and the arch AY is lefs than LY, and both together lefs than half a circle. But it is demonftrated by fpheric geometry, that when a triangle is made as here, by three arches of circles AL, AY, and YL, the angle under YAB without the triangle is greater than the angle YLA within, if the two arches AY, YL, taken together,

287 Nodes of the moon's orbit.

288 Inclination of her orbit.

ther,

Motions of the Secondary Planets.

ther, do not amount to a semicircle. If the two arches make a complete semicircle, the two angles will be equal; but if the two arches taken together exceed a semicircle, the inner angle YLA is greater than the other. Here then the two arches AY and LY together being less than a semicircle, the angle under ALY is less than the angle under BAE. But from the doctrine of the sphere it is also evident, that the angle under ALY is equal to that in which the plane of the circle LYKM, that is, the plane which touches the line AKGHI in K is inclined to the plane of the earth's motion ABC; and the angle under BAE is equal to that in which the plane AEC is inclined to the same plane. Therefore the inclination of the former plane is less than that of the latter. Suppose, now, the moon to be advanced to the point G in fig. 128. and in this point to be distant from its node a quarter part of the whole circle; or, in other words, to be in the mid-way between its two nodes. In this case the nodes will have receded yet more, and the inclination of the orbit be still more diminished: for suppose the line AKGHI to be touched in the point G by a plane passing through the earth T, let the intersection of this plane with the plane of the earth's motion be the line WTO, and the line TP its intersection with the plane LKM. In this plane let the circle NGO be described with the semidiameter TP or NT cutting the other circle LKM in P. Now, the line AKGI is convex to the plane LKM which touches it in K; and therefore the plane NGO, which touches it in G, will intersect the other touching plane between G and K; that is, the point P will fall between these two points, and the plane continued to the plane of the earth's motion will pass beyond L; so that the points N and O, or the places of the nodes when the moon is in G, will be farther from A and C than L and M; that is, will have moved farther backward. Besides, the inclination of the plane NGO to the plane of the earth's motion ABC is less than the inclination of the plane LKM to the same; for here also the two arches LP and NP, taken together, are less than a semicircle, each of them being less than a quadrant, as appears, because GN, the distance of the moon in G from its node N, is here supposed to be a quarter part of a circle. After the moon is passed beyond G, the case is altered: for then these arches will be greater than quarters of a circle; by which means the inclination will be again increased, though the nodes still go on to move the same way. Suppose the moon in H (fig. 129), and that the plane which touches the lines AKGI in H intersects the plane of the earth's motion in the line QTR, and the plane NGO in the line TV, and besides, that the circle QHR be described in that plane: then, for the same reason as before, the point V will fall between H and G, and the plane RVQ will pass beyond the last plane OVN, causing the points Q and K to fall farther from A and C than N and O. But the arches NV, VQ are each greater than the quarter of a circle; consequently the angle under BQV will be greater than that under BNV. Lastly, when the moon is by this attraction of the sun drawn at length into the plane of the earth's orbit, the node will have receded yet more, and the inclination be so much increased, as to become somewhat more than at first: for the line AKGHI being convex to all the planes which touch it, the part HI will wholly fall between the plane QVR and the plane ABC; so that the point I will fall between B and R; and, drawing ITW, the point W, will be farther removed from A than Q. But it is evident, that the plane which passes through the earth T and touches the line AGI in the point I, will cut the plane of the earth's motion ABCD in the line ITW, and be inclined to the same in the angle under HIB; so that the node which was first in A, after having passed into L, N, and Q, comes at last into the point W, as the node which was at first in C has passed from thence successively through the points M, O, and R, to I. But the angle HIB, which is now the inclination of the orbit to the plane of the ecliptic, is manifestly not less than the angle under ECB or EAB, but rather something greater. Thus the moon, while it passes from the plane of the earth's motion in the quarter, till it comes again into the same plane, has the nodes of its orbit continually moved backward, and the inclination of it at first diminished till it comes to G in fig. 128, which is near to its conjunction with the sun, but afterwards is increased again almost by the same degrees, till upon the moon's arrival again to the plane of the earth's motion the inclination of the orbit is restored to something more than its first magnitude, though the difference is not very great, because the points I and C are not so far distant from each other.

In like manner, if the moon had departed from the quarter at C, it should have described the curve line CXW in fig. 126. between the planes AFC and ADC, which would be convex to the former planes and concave to the latter; so that here also the nodes would continually recede, and the inclination of the orbit gradually diminish more and more, till the moon arrived near its opposition to the sun in X; but from that time the inclination should again increase till it become a little greater than at first. This will easily appear by considering, that as the action of the sun upon the moon, by exceeding its action upon the earth, drew it out of the plane AEC towards the sun, while the moon passed from A to I; so during its passage from C to W, the moon being all that time farther from the sun than the earth, it will be attracted less; and the earth together with the plane AECF, will as it were be drawn from the moon, in such a manner, that the path the moon describes shall appear from the earth as it did in the former case by the moon being drawn away. 286

Motion of the nodes explained.

Such are the changes which the nodes and inclination of the moon's orbit undergo when the nodes are in the quarters; but when the nodes by their motion, and the motion of the sun together, come to be situated between the quarter and conjunction or opposition, their motion and the change made in the inclination of the orbit are somewhat different.—Let AGH, in fig. 131. be a circle described in the plane of the earth's motion, having the earth in T for its centre, A the point opposite to the sun, and G a fourth part of the circle distant from A. Let the nodes of the moon's orbit be situated in the line BTD, and B the node falling between A, the place where the moon would be in the full, and G the place where she would be in the quarter. Suppose BEDF to be the plane in which the moon attempts to move when it proceeds from the point B; then, because the moon in B is more distant

Motions of the Secondary Planets.

distant from the sun than the earth, it will be less attracted by the sun, and will not descend towards the sun so fast as the earth, consequently it will quit the plane BEDF, which is supposed to accompany the earth, and describe the line BIK convex to it, till such time as it comes to the point K, where it will be in the quarter; but from thenceforth being more attracted than the earth, the moon will change its course, and the following part of the path it describes will be concave towards the plane BED or BGD, and continue concave to the plane BGD till it crosses that plane in L, just as in the preceding case. Now, to show that the nodes, while the moon is passing from B to K, will proceed forward, or move the same way with the moon, and at the same time the inclination of the orbit will increase when the moon is in the point I, let the line MIN pass through the earth T, and touch the path of the moon in I, cutting the plane of the earth's motion in the line MTN, and the line BED in TO. Because the line BIK is convex to the plane BED, which touches it in B, the plane NIM must cross the plane DEB before it meets the plane CGB; and therefore the point M will fall from G towards B; and the node of the moon's orbit being translated from B towards M is moved forward.

Again, the angle under OMG, which the plane MON makes with the plane BGC, is greater than the angle OBG, which the plane BOD makes with the same. This appears from what has been already demonstrated, because the arches BO and OM are each of them less than the quarter of a circle; and therefore, taken both together are less than a semicircle. But further, when the moon is come to the point K in its quarter, the nodes will be advanced yet further forward, and the inclination of the orbit also more augmented. Hitherto we have referred the moon's motion to the plane which, passing through the earth, touches the path of the moon in the point where the moon is, as we have already said that the custom of astronomers is. But in the point K no such plane can be found: on the contrary, seeing the line of the moon's motion on one side the point K is convex to the plane BED, and on the other side concave to the same, so that no plane can pass through the points T and K, but will cut the line BKL in that point; therefore, instead of such a touching plane, we must make use of PKQ, which is equivalent, and with which the line BKL shall make a less angle than with any other plane; for this does as it were touch the line BK in the point K, since it cuts it in such a manner that no other plane can be drawn so as to pass between the line BK and the plane PKQ. But now it is evident, that the point P, or the node, is removed from M towards G, that is, has moved yet farther forwards; and it is likewise as manifest, that the angle under KPG, or the inclination of the moon's orbit in the point K, is greater than the angle under IMG for the reason already given.

After the moon has passed the quarter, her plane being concave to the plane AGCH, the nodes will recede as before till she arrives at the point L; which shows, that, considering the whole time of the moon's passing from B to L, at the end of that time the nodes shall be found to have receded, or to be placed more backward, when the moon is in L than when it was in B: for the moon takes a longer time in passing from K to L than in passing from B to K; and therefore the nodes continue to recede a longer time than they moved forwards; so that their recess must surmount their advance. In the same manner, while the moon is in its passage from K to L, the inclination of the orbit shall diminish till the moon come to the point in which it is one quarter part of a circle distant from its node, suppose in the point R; and from that time the inclination will again increase. Since, therefore, the inclination of the orbit increases while the moon is passing from B to K, and diminishes itself again only while the moon is passing from K to R, then augments again while the moon passes from B to L; it thence comes to be much more increased than diminished, and thus will be distinguishably greater, when the moon comes to L than when it sets out from B. In like manner, when the moon is passing from L on the other side the plane AGCH, the node will advance forward as long as the moon is between the point L and the next quarter; but afterwards it will recede till the moon comes to pass the plane AGCH again, in the point V between B and A: and because the time between the moon's passing from L to the next quarter is less than the time between that quarter and the moon's coming to the point V, the node will have receded more than it has advanced; so that the point V will be nearer to A than L is to C. So also the incination of the orbit, when the moon is in V, will be greater than when she was in L: for this inclination increases all the time the moon is betwixt L and the next quarter, decreasing only when she is passing from this quarter to the mid-way between the two nodes, and from thence increases again during the whole passage through the other half of the way to the next node.

In this manner we see, that at every period of the moon the nodes will have receded, and thereby have approached towards a conjunction with the sun; but this will be much forwarded by the motion of the earth, or the apparent motion of the sun himself. In the last scheme the sun will appear to have moved from S towards W. Let us suppose it had appeared to have moved from S to W while the moon's node has receded from B to V: then drawing the line WTX, the arch VX will represent the distance of the line drawn between the nodes from the sun when the moon is in V; whereas the arch BA represented that distance when the moon was in B. This visible motion of the sun is much greater than that of the node; for the sun appears to revolve quite round in one year, while the node is near nineteen in making its revolution. We have also seen, that when the moon was in the quadrature, the inclination of her orbit decreased till she came to the conjunction or opposition, according to the node it set out from; but that afterwards it again increased till it became at the next node rather greater than at the former. When the node is once removed from the quarter nearer to a conjunction with the sun, the inclination of the moon's orbit when she comes into the node is more sensibly greater than it was in the node preceding; the inclination of the orbit by this means more and more increasing till the node comes into conjunction with the sun: at which time it has been shown that the latter has no power to

Motions of the Secondary Planets.

change the plane of her orbit. As soon, however, as the nodes are got out of conjunction towards the other quarters, they begin to recede as before; but the inclination of the orbit in the appulse of the moon to each succeeding node is less than at the preceding, till the nodes come again into the quarters. This will appears as follows: Let A, in fig. 132. represent one of the moon's nodes placed between the point of opposition B and the quarter C. Let the plane ADE pass through the earth T, and touch the path of the moon in A. Let the line AFGH be the path of the moon in her passage from A to H, where she crosses again the plane of the earth's motion. This line will be convex towards the plane ADE, till the moon comes to G, where she is in the quarter; and after this, between G and H, the same line will be concave towards this plane. All the time this line is convex towards the plane ADE, the nodes will recede; and, on the contrary, move forward when the line is concave towards that plane. But the moon is longer in passing from A to G, and therefore the nodes go backward farther than they proceed; and therefore, on the whole, when the moon has arrived at H, the nodes will have receded, that is, the point H will fall between B and E. The inclination of the orbit will decrease till the moon is arrived at the point F in the middle between A and H. Through the passage between F and G the inclination will increase, but decrease again in the remaining part of the passage from G to H, and consequently at H must be less than at A. Similar effects, both with respect to the nodes and inclination of the orbit, will take place in the following passage of the moon on the other side of the plane ABEC from H, till it comes over that plane again in I.

Thus the inclination of the orbit is greatest when the line drawn between the moon's nodes will pass through the sun, and least when this line lies in the quarters; especially if the moon at the same time be in conjunction with the sun, or in the opposition. In the first of these cases the nodes have no motion; in all others, the nodes will each month have receded: and this retrograde motion will be greatest when the nodes are in the quarters, for in that case they will have no progressive motion during the whole month; but in all other cases they at some times go forward, viz. whenever the moon is between either of the quarters and the node which is less distant from that quarter than the fourth part of a circle.

290 Irregularities arising from the moon's motion in an ellipsis.

We have now only to explain those irregularities of the lunar motion which arise from her motion in an ellipsis. From what has been already said it appears, that the earth acts on the moon in the reciprocal duplicate proportion of the distance; therefore the moon, if undisturbed by the sun, would move round the earth in a true ellipsis, and a line drawn from the earth to the sun would pass over equal spaces in equal times. We have, however, already shown, that this equality is disturbed by the sun, and likewise how the figure of the orbit is changed each month; that the moon is nearer the earth at the new and full, and more remote in the quarters, than it would be without the sun. We must, however, pass by those monthly changes, and consider the effect which the sun will have in the different situations of the axis of the orbit in respect of that luminary. This action varies the force wherewith the moon is drawn towards the earth. In the quarters the force of the earth is directly increased by the sun, but diminished at the new and full; and in the intermediate places the influence of the earth is sometimes lessened, sometimes assisted, by the action of that luminary. In these intermediate places, however, between the quarters and the conjunction or opposition, the sun's action is so oblique to that of the earth on the moon, as to produce that alternate acceleration and retardation of her motion so oftened mentioned. But besides this effect, the power by which the moon attracts the earth towards itself, will not be at full liberty to act with the same force as if the sun acted not at all on the moon; and this effect of the sun's action, whereby it corroborates or weakens the action of the earth, is here only to be considered; and by means of this influence it comes to pass, that the power by which the moon is impelled towards the earth is not perfectly in the reciprocal duplicate proportion of the distance, and of consequence the moon will not describe a perfect ellipsis. One particular in which the lunar orbit will differ from a perfect elliptical figure, consists in the places where the motion of the moon is perpendicular to the line drawn from itself to the earth. In an ellipsis, after the moon should have set out in the direction perpendicular to this line, drawn from itself to the earth, and at its greatest distance from the earth, its motion would again become perpendicular to this line drawn between itself and the earth, and the moon be at its nearest distance from the earth, when it should have performed half its period; after having performed the other half period of its motion, would again become perpendicular to the forementioned line, and the moon return to the place whence it set out, and have recovered again its greatest distance. But the moon in its real motion, after setting out as before, sometimes makes more than half a revolution before its motion comes again to be perpendicular to the line drawn from itself to the earth, and the moon is at its nearest distance; and then performs more than another half of an entire revolution before its motion can a second time recover its perpendicular direction to the line drawn from the moon to the earth, and the former arrive again at its greatest distance from the earth. At other times the moon will descend to her nearest distance before she has made half a revolution, and recover again its greatest distance before it has made an entire revolution. The place where the moon is at its greatest distance is called the *moon's apogeon*, and the place of her nearest distance her *perigeon*; and this change of place, where the moon comes successively to its greatest distance from the earth, is called the *motion of the apogeon*. The manner in which this motion of the apogeon is caused by the sun comes now to be explained. 291

291 Apogeon and perigeon of the moon.

Sir Isaac Newton has shown, that if the moon were attracted toward the earth by a composition of two powers, one of which were reciprocally in the duplicate proportion of the distance from the earth, and the other reciprocally in the triplicate proportion of the same distance; then, though the line described by the moon would not be in reality an ellipsis, yet the moon's motion might be perfectly explained by an ellipsis whose axis should be made to move round the earth; this motion being in consequence, as astronomers express themselves, that is, the same way as the moon itself moves,

Motions of the Secondary Planets.

moves, if the moon be attracted by the sum of the two powers; but the axis must move in antecedence, or the contrary way, if the moon be acted upon by the difference of these forces. We have already explained what is meant by duplicate proportion, namely, that if three magnitudes, as A, B, and C, are so related that the second B bears the same proportion to the third C as the first A bears to the second B; then the proportion of the first A to the third C is the duplicate of the proportion of the first A to the second B. Now if a fourth magnitude as D be assumed, to which C shall bear the same proportion as A bears to B, and B to C; then the proportion of A to D is the triplicate of the proportion of A to B.

292 Motion in antecedence and consequence explained.

293 Triplicate proportion explained.

294 Motion of the moon's apogeon determined.

Let now T (fig. 133. 134.) denote the earth, and suppose the moon in the point A its apogeon or greatest distance from the earth, moving in the direction AF perpendicular to AB, and acted upon from the earth by two such forces as already mentioned. By that power alone, which is reciprocally in the duplicate proportion of the distance, if the moon set out with a proper degree of velocity, the ellipsis AMB may be described: but if the moon be acted upon by the sum of the forementioned powers, and her velocity in the point A be augmented in a certain proportion; or if that velocity be diminished in a certain proportion *, and the moon be acted upon by the difference of those powers; in both these cases the line AE, which shall be described by the moon, shall thus be determined. Let the point M be that into which the moon would have arrived in any given point of time, had it moved in the ellipsis AMB; draw MT and likewise CTD in such a manner that the angle ATM shall bear the same proportion to the angle under ATC as the velocity with which the ellipsis must have been described bears to the difference between this velocity and that with which the moon must set out from the point A, in order to describe the path AE. Let the angle ATC be taken toward the moon, as in fig. 133. if the moon be attracted by the sum of the powers; but the contrary way (as in fig. 134.) if by their difference. Then let the line AB be moved into the position CD, and the ellipsis AMB into the situation CND, so that the point M be translated to L; then the point L shall fall upon the path of the moon AE. Now the angular motion of the line AT, whereby it is removed into the situation CT, represents the motion of the apogeon; by the means of which the motion of the moon might be fully explained by the ellipsis AMB, if the action of the sun upon it was directed to the centre of the earth, and reciprocally in the triplicate proportion of the moon's distance from it; but that not being so, the motion of the apogeon will not proceed in the regular manner now described. It is, however, to be observed here, that in the first of the two preceding cases, where the apogeon moves forward, the whole centripetal power increases faster, with the decrease of distance, than if the entire power were reciprocally in the duplicate proportion of the distance; because one part only is already in that proportion, and the other part, which is added to this to make up the whole power, increases faster with the decrease of distance. On the other hand, when the centripetal power is the difference between these two bodies, it increases less with the decrease of the distance, than if it were simply in the reciprocal duplicate proportion of the distance. Therefore, if we choose to explain the moon's motion by an ellipsis, which may be done without any sensible error, we may collect in general, that when the power by which the moon is attracted to the earth, by varying the distance, increases in a greater than the duplicate proportion of the distance diminished, a motion in consequence must be ascribed to the apogeon; but that when the attraction increases in a smaller proportion than that just mentioned, the apogeon must have given to it a motion in antecedence. It is then observed by Sir Isaac Newton, that the former of these cases obtains when the moon is in the conjunction and opposition, and the latter when she is in the quarters; so that in the former the apogeon moves according to the order of the signs; in the other, the contrary way. But, as has been already mentioned, the disturbance given to the action of the earth by the sun in the conjunction and opposition, being near twice as great as in the quarters, the apogeon will advance with a greater velocity than recede, and in the compass of a whole revolution of the moon will be carried in consequence.

* See *Newton's Principia*, book i. prop. 44. corol. 2.

295 Inequality of the motion of the apogeon.

Sir Isaac shows, in the next place, that when the line AB coincides with the line that joins the sun and earth, the progressive motion of the apogeon, when the moon is in conjunction or opposition, exceeds the retrograde, in the quadratures, more than in any other situation of the line AB. On the contrary, when the line AB makes right angles with that which joins the earth and sun, the retrograde motion will be more considerable, nay, is found so great as to exceed the progressive; so that in this case the apogeon, in the compass of an entire revolution of the moon, is carried in antecedence. Yet from the considerations already mentioned, the progressive motion exceeds the other; so that on the whole, the motion of the apogeon is in consequence. The line AB also changes its situation with that which joins the earth and sun by such slow degrees, that the inequalities of the motion of the apogeon, arising from this last consideration, are much greater than what arise from the other.

296 Occasions another inequality in the eccentricity of the moon's orbit.

This unsteady motion of the apogeon gives rise to another inequality in the motion of the moon herself, so that it cannot at all times be explained by the same ellipsis. For whenever the apogeon moves in consequence, the motion of the luminary must be referred to an orbit more eccentric than what the moon would describe, if the whole power by which the moon was acted upon in its passing from the apogeon changed according to the reciprocal duplicate proportion of its distance from the earth, and by that means the moon did describe an immoveable ellipsis: and when the apogeon moves in antecedence, the moon's motion must be referred to an orbit less eccentric. In the former of the two figures last referred to, the true place of the moon L falls without the orbit AMB, to which its motion is referred: whence the orbit ALE truly described by the moon, is less incurvated in the point A than is the orbit AMB; therefore this orbit is more oblong, and differs farther from a circle than the ellipsis would, whose curvature in A were equal to that of the line ALB: that is, the proportion of the distance of the earth T from the centre of the ellipsis to its axis, will be greater in AMB than in the other; but that

Motions of the Secondary Planets.

that other is the ellipsis which the moon would describe, if the power acting upon it in the point A were altered in the reciprocal duplicate proportion of the distance; and consequently the moon being drawn more forcibly towards the earth, it will descend nearer to it. On the other hand, when the apogeon recedes, the power acting on the moon increases with the decrease of distance, in less than the duplicate proportion of the distance, and therefore the moon is less impelled towards the earth, and will not descend so low. Now, suppose, in the former of these figures, that the apogeon A is in the situation where it is approaching towards the conjunction or opposition of the sun; in this case its progressive motion will be more and more accelerated. Here suppose the moon, after having descended from A through the orbit AE as far as F, where it is come to its nearest distance from the earth, ascends again up the line FG. As the motion of the apogeon is here more and more accelerated, it is plain that the cause of its motion must also be on the increase; that is, the power by which the moon is drawn to the earth, will decrease with the increase of the moon's distance in her ascent from F, in a greater proportion than that wherewith it is increased with the decrease of distance in the moon's descent to it. Consequently the moon will ascend to a greater distance than AT from whence it is descended; therefore the proportion of the greatest distance of the moon to the least is increased. But further, when the moon again descends, the power will increase yet farther with the decrease of distance than in the last ascent it increased with the agmentation of distance. The moon therefore must descend nearer to the earth than it did before, and the proportion of the greatest distance to the least be yet more increased. Thus, as long as the apogeon is advancing to the conjunction or opposition, the proportion of the greatest distance of the moon from the earth to the least will continually increase; and the elliptical orbit to which the moon's motion is referred, will become more and more eccentric. As soon, however, as the apogeon is passed the conjunction or opposition with the sun, its progressive motion abates, and with it the proportion of the greatest distance of the moon from the earth to the least will also diminish: and when the apogeon becomes retrograde, the diminution of this proportion will be still farther continued on, till the apogeon comes into the quarter; from thence this proportion, and the eccentricity of the orbit, will increase again. Thus the orbit of the moon is most eccentric when the apogeon is in conjunction with the sun, or in opposition to it, and least of all when the apogeon is in the quarters. These changes in the nodes, the inclination of the orbit to the plane of the earth's motion, in the apogeon and in the eccentricity, are varied like the other inequalities in the motion of the moon, by the different distance of the earth from the sun being greatest when their cause is greatest; that is, when the earth is nearest the sun. Sir Isaac

297 Computation of the lunar inequalities

Newton has computed the very quantity of many of the moon's inequalities. That acceleration of the moon's motion which is called the variation, when greatest, removes the luminary out of the place in which it would otherwise be found, somewhat more than half a degree. If the moon, without disturbance from the sun, would have described a circle concentrical to the earth, his action would cause her approach nearer in the conjunction and opposition than in the quarters, nearly in the proportion of 69 to 70. It has already been mentioned, that the nodes perform their period in almost 19 years. This has been found by observation; and the computations of Sir Isaac assign to them the same period. The inclination of the moon's orbit, when least, is an angle about one-eighteenth of that which constitutes a right angle; and the difference between the greatest and least inclination is about one-eighteenth of the least inclination, according to our author's computations: which is also agreeable to the general observations of astronomers. The motion of the apogeon and the changes in the eccentricity have not been computed by Sir Isaac.

298 How to compute the inequalities of the motions of Jupiter's satellites.

The same incomparable geometer shows how, by comparing the periods of the motions of the satellites which revolve round Jupiter and Saturn with the period of our moon round the earth, and the periods of those planets round the sun with our earth's motion, the inequalities in the motion of those satellites may be computed from those of our moon, excepting only the motion of the apogeon; for the orbits of those satellites, as far as can be discerned by us at this distance, appearing little or nothing eccentric, this motion, as deduced from the moon, must be diminished.

Nature and Motions of the Comets.

§ 4. *Of the Nature and Motions of the Comets.*

That these bodies are not meteors in our air is manifest, because they rise and set in the same manner as the moon and stars. The astronomers have gone so far in their inquiries concerning them as to prove by their observations that they moved in the celestial spaces beyond the moon; but they had no notion of the path which they described. Before the time of our author, it was supposed that they moved in straight lines; and Des Cartes, finding that such a motion would interfere with his vortices, removed them entirely out of the solar system. Sir Isaac Newton, however, distinctly proves from astronomical observation, that the comets pass through the planetary regions, and are generally invisible at a smaller distance than that of Jupiter. Hence, finding that they were evidently within the sphere of the sun's action, he concludes, that they must necessarily move about the sun as the planets do; and he proves, that the power of the sun being reciprocally in the duplicate proportion of the distance, every body acted upon by him must either fall directly down, or move about him in one of the conic sections, viz. either the ellipsis, parabola, or hyperbola. If a body which descends towards the sun as low as the orbit of any planet, move with a swifter motion than the planet, it will describe an orbit of a more oblong figure than that of the planet, and have at least a longer axis. The velocity of the body may be so great, that it shall move in a parobola; so that having once passed the sun, it shall ascend for ever without returning, though the sun will still continue in the focus of that parabola; and with a velocity still greater, they will move in an hyberbola. It is, however, most probable, that the comets move in very eccentric ellipsis, such as is represented in fig. 135. where S represents the sun, C the comet, and ABDE its orbit; wherein the distance of S and D far exceeds that of S and A. Hence those bodies are sometimes found at a moderate distance from the sun, and appear within

299 Comets generally invisible until they come nearer than Jupiter.

Nature and Motions of the Comets.

within the planetary regions; at other times they aſcend to vaſt diſtances, far beyond the orbit of Saturn, and thus become inviſible.

300 *They move in eccentric ellipſes.*

That the comets do move in this manner is proved by our author from computations built upon the obſervations made by many aſtronomers. Theſe computations were made by Sir Iſaac Newton himſelf upon the comet which appeared toward the latter end of the year 1680 and beginning of 1681, and the ſame were proſecuted more at large by Dr Halley upon this and other comets. They depend on this principle, that the eccentricity of the orbits of the comets is ſo great, that if they are really elliptical, yet that part of them which comes under our view approaches ſo near to a parabola that they may be taken for ſuch without any ſenſible error, as in the foregoing figure the parabola FAG, in the lower part of it about A, differs very little from the ellipſis DEAB; on which foundation Sir Iſaac teaches a method of finding the parabola in which any comet moves, by three obſervations made upon it in that part of its orbit where it agrees neareſt with a parabola: and this theory is confirmed by aſtronomical obſervations; for the places of the comets may thus be computed as exactly as thoſe of the primary planets.

301 *How to calculate the motion of a comet.*

Our author afterwards ſhows how to make uſe of any ſmall deviation from the parabola which may be obſerved, to determine whether the orbits of the comets be elliptical or not; and thus to know whether or not the ſame comet returns at different ſeaſons. On examining by this rule the comet of 1680, he found its orbit to agree more exactly with an ellipſis than a parabola, tho' the ellipſis be ſo very eccentric, that it cannot perform its revolution in 500 years. On this Dr Halley obſerved, that mention is made in hiſtory of a comet with a ſimilar large tail, which appeared three ſeveral times before. The firſt was before the death of Julius Cæſar; and each appearance happened at the interval of 575 years, the laſt coinciding with the year 1680. He therefore calculated the motion of this comet to be in ſuch an eccentric orbit, that it could not return in leſs than 575 years; which computations agree yet more perfectly with the obſervations made on this comet than any parabolic orbit will do. To compare together different appearances of the ſame comet, is indeed the only method of diſcovering with certainty the form of its orbit; for it is impoſſible to diſcover the form of one ſo exceedingly eccentric from obſervations taken in a ſmall part of it. Sir Iſaac Newton therefore propoſes to compare the orbits, on the ſuppoſition that they are parabolical, of ſuch comets as appear at different times, for if we find the ſame orbit deſcribed by a comet at different times, in all probability it will be the ſame comet that deſcribes it. Here he remarks from Dr Halley, that the ſame orbit very nearly agrees to two appearances of a comet about the ſpace of 75 years diſtance; ſo that if theſe two appearances were really of the ſame comet, the tranſverſe axis of its orbit would be 18 times that of the axis of the earth's orbit; and therefore, when at its greateſt diſtance from the ſun, this comet would be removed not leſs than 35 times the mean diſtance of the earth from the ſame luminary.

Even this is the leaſt diſtance aſſigned by our author to any comet in its greateſt elongation from the ſun; and on the foundation of Dr Halley's computations it was expected in the year 1758 or 1759.

I

The Aſtronomer Royal advertiſes us of the expected return of the comet of 1532 and 1661, in the latter end of the year 1788, or beginning of 1789, in the following particulars.

"The elements of the orbits of the comets obſerved by Apian in 1532, and by Hevelius in 1661, are ſo much alike as to have induced Mr Halley to ſuppoſe them to be one and the ſame comet; and aſtronomers ſince have joined in the ſame opinion. Hence it ſhould return to its perihelium the 27th of April 1789. But from the diſturbances of the planets, it will probably come a few months ſooner. It will firſt be ſeen in the ſouthern parts of the heavens, if any aſtronomers ſhould watch for it in ſituations near the line, or in ſouthern climates, in the courſe of the year 1788, and probably not before the month of *September*. Aſtronomers who may happen to be in thoſe parts will be enabled to direct their teleſcopes for diſcovering it as early as poſſible, by being furniſhed with the following elements of its orbit:

The perihelium diſtance	0.44851
Place of aſcending node	$2^s\ 24^\circ\ 18'$
Inclination of the orbit to the ecliptic	$32^\circ\ 36'$
Perihelium forwarder in the orbit than the aſcending node	$33^\circ\ 28'$

time of the perihelium in the latter end of the year 1788, or beginning of 1789. Its motion is direct. If it ſhould come to its perihelium on *January* 1, 1789, it might be ſeen in the ſouthern parts of the world with a good achromatic teleſcope about the middle of *September*, towards the middle of *Piſces*, with 55° ſouth latitude, and 53 ſouth declination."

Sir Iſaac Newton obſerves, that as the great eccentricity of the orbits of comets renders them very liable to be diſturbed by the attraction of the planets and other comets, it is probably, to prevent too great diſturbances from theſe, that while all the planets revolve nearly in the ſame plane, the comets are diſpoſed in very different ones, and diſpoſed all over the heavens; that when in their greateſt diſtance from the ſun, and moving ſloweſt, they might be removed as far as poſſible out of the reach of each other's action. The ſame end is likewiſe anſwered in theſe comets, which by moving ſloweſt in the aphelion or remoteſt diſtance from the ſun, deſcend neareſt to it by placing their aphelion at the greateſt height from the ſun. See more on the ſubject of comets by Sir Iſaac, Sect. III. n° 169.

§ 5. *Of the Bodies of the Sun and Planets, with the Method of computing the Quantity of Matter they contain.*

Our author having proved, as has been related, that the primary planets and comets are retained in their orbits by a power directed towards the ſun, and that the ſecondaries are alſo retained by a power of the like kind directed to the centre of their primaries, 302

Attractive power diffuſed throughout the ſubſtance of all matter.

proceeds next to demonſtrate, that the ſame power is diffuſed through their whole ſubſtance and inherent in every particle. For this purpoſe he ſhows firſt, that each of the heavenly bodies attracts the reſt and other bodies with ſuch different degrees of force, as that the force of the ſame attracting body is exerted on others exactly in proportion to the quantity of matter contained in the body attracted. The firſt proof of this he brings from experiments made on bodies here on

earth

Of the Bodies of the Sun and Planets.

earth. The power by which the moon is influenced has been already shown to be the same with that which we call *gravity*. Now, one of the effects of the principle of gravity is, that all bodies descend by this force from equal heights in equal times. This was taken notice of long ago; and particular methods have been invented to show, that the only cause why some bodies were observed to fall in a shorter time than others was the resistance of the air. As these methods, however, have been found liable to some uncertainty, Sir Isaac Newton had recourse to experiments made on pendulums. These vibrate by the same power which makes heavy bodies fall to the ground; but if the ball of any pendulum of the same length with another were more or less attracted in proportion to the quantity of solid matter it contains, that pendulum must then vibrate faster or slower than the other. Now the vibrations of pendulums continue for a long time, and the number of vibrations they make may be easily determined without any suspicion of error; so that this experiment may be extended to what exactness we please: and Sir Isaac assures us, that he examined in this way several substances, as gold, silver, lead, glass, sand, common salt, wood, water, and wheat; in all which he found not the least deviation from the theory, tho' he made the experiment in such a manner, that in bodies of the same weight, a difference in the quantity of their matter less than the thousandth part of the whole would have discovered itself. It appears, therefore, that all bodies are made to descend here by the power of gravity with the same degree of swiftness. This descent has already been determined at $16\frac{1}{8}$ feet in a second from the beginning of their fall. It has also been observed, that if any terrestrial body could be conveyed as high up as the moon, it would descend with the very same degree of velocity with which the moon is attracted toward the earth; and therefore that the power of the earth upon the moon bears the same proportion it would have upon those bodies at the same distance as the quantity of matter in the moon bears to the quantity in those bodies. Thus the assertion is proved in the earth, that its power on every body it attracts is, at the same distance from the earth, proportional to the quantity of solid matter in the body acted upon. As to the sun, it has been shown, that the power of his action upon the same primary planet is reciprocally in the duplicate proportion of its distance; and that the power of the sun decreases throughout in the same proportion, is testified by the motion of the planets traversing the whole planetary region. This proves, that if any planet were removed from the sun to any distance whatever, the degree of its acceleration towards the sun would yet be reciprocally in the duplicate proportion of their distance. But it has already been proved, that the degree of acceleration given to the planets by the sun is reciprocally in the duplicate proportion of their respective distances; all which compared together, puts it out of doubt, that the power of the sun upon any planet removed into the place of any other, would give it the same velocity of descent as it gives that other; and consequently that the sun's action upon different planets at the same distance would be proportionable to the quantity of matter in each. It has likewise been shown, that the sun attracts the primary planets and their respective secondaries, when at the same distance, in such a manner as to communicate to both the same degree of velocity; and therefore the force wherewith the sun acts on the secondary planet bears the same proportion to the force wherewith it attracts the primary, as the quantity of matter in the secondary planet bears to the quantity of matter in the primary. This property therefore is found in the sun with regard to both kinds of planets; so that he possesses the same quality found in the earth, viz. that of acting on bodies with a degree of force proportional to the quantity of matter they contain.

303 Properties of gravity demonstrated by pendulums.

304 Attraction proportioned to the quantity of matter

This point being granted, it is hardly to be supposed that the power of attraction with which the other planets are endowed, should be different fom that of the earth, if we consider the similitude of these bodies: and that it does not in this respect, is farther evident from the satellites of Saturn and Jupiter which are attracted according to this law; that is, in the same proportion to their distances that their primaries are attracted by the sun. So that what has been concluded of the sun in relation to the primary planets may be justly concluded of those primaries in respect to their secondaries; and in consequence of that likewise in regard to all other bodies, viz. that they will attract every other body in proportion to the quantity of solid matter it contains. Hence it follows, that this attraction extends itself to every particle of matter in the attracted body, and that no proportion of matter is exempted from the influence of these bodies to which this attractive power has been proved to belong.

305 Attraction acts equally throughout the bodies in the universe.

Here we may remark, that the attractive power both of the sun and planets appears to be the same in all; for it acts in each in the same proportion to the distance, and in the same manner acts alike upon every particle of matter. This power, therefore, in the sun and planets, is not of a different nature from the power of gravity in the earth: and this enables us to prove, that the attracting power lodged in the sun and planets belongs likewise to every part of them; and that their respective powers upon the same body are proportional to the quantity of matter of which they are composed; for instance, that the force with which the earth attracts the moon, is to the force with which the sun would attract it at the same distance, as the quantity of solid matter in the earth is to that in the sun.

Before we proceed to a full proof of these assertions, it will be necessary to show that the third law of motion, viz. That action is equal to reaction, holds good in attractive powers as well as in any other. The most remarkable force of this kind with which we are acquainted, next to that of gravity, is the attraction the loadstone has for iron. Now if a loadstone and piece of iron were both made to swim on water, both of them would move towards each other, and thus the attraction would be shown to be mutual; and when they meet, they will mutually stop each other: which shows that their velocities are reciprocally proportioned to the quantities of solid matter in each; and that by the stone's attracting the iron, it receives as much motion itself, in the strict philosophic sense of the word, as it communicates to the iron: for it is proved from experiments on the percussion of bodies, that if two meet with velocities reciprocally proportional to the respective bodies, they will be stopt by the concourse, unless they meet with some other velocity, or their elasticity

Of the Bodies of the Sun and Planets.

city put them into freſh motion. Hitherto, however, for the ſake of brevity, in ſpeaking of theſe forces, we have aſcribed them to the body which is leaſt moved; as when we called the power which exerts itſelf between the ſun and planets, *the attractive power of the ſun:* but to ſpeak more correctly, we ſhould rather call this power in any caſe the force which acts between the ſun and earth, between the earth and moon, &c. for both the bodies are moved by the power acting between them, in the ſame manner as when two bodies are tied together by a rope, if that ſhould ſhrink by being wet or otherwiſe, and thereby cauſe the bodies to approach; by drawing both, it will communicate to

306 Why the ſun and planets revolve about their common centre of gravity.

both the ſame degree of motion, and cauſe them to approach each other with velocities proportional to their quantities of matter. From this mutual action of the ſun and planets upon each other, it follows, as has been already mentioned, that they both revolve about their common centre of gravity. Thus let A (in fig. 136.) repreſent the ſun, B, a planet and C their common centre of gravity. If theſe bodies were once at reſt, they would directly approach each other by their mutual attraction, and that with ſuch velocities, that their common centre of gravity would remain at reſt, and they would meet in that point. Were the planet B to receive an impulſe, as in the direction DE, this would prevent the two bodies from falling together; but their common centre of gravity would be put into motion in the direction of the line CF, equidiſtant from BE. In this caſe Sir Iſaac Newton proves, that the ſun and planet would deſcribe round their common centre of gravity ſimilar orbits, while that centre would proceed with an uniform velocity in the line CF, and ſo the ſyſtem of the two bodies would move on with the centre of gravity without end. In order to keep the ſyſtem in the ſame place, it is neceſſary, that when the planet received its impulſe in the direction BE, the ſun ſhould receive ſuch another the contrary way, ſo as to keep the centre of gravity C without any motion, in which caſe it would always remain fixed.

Thus we may underſtand in what manner the action between the ſun and planets is mutual. It has alſo been ſhown, that the power which acts between the ſun and primary planets is altogether of the ſame nature with that which acts between the ſecondary planets and their primaries, or which acts between the earth and bodies near its ſurface. It has alſo been already proved, that in different planets the force of the ſun's action upon each at the ſame diſtance would be proportional to the quantity of ſolid matter contained in the planet: therefore the reaction of the planet on the ſun at the ſame diſtance, or the motion which he would receive from each planet, would alſo be proportional to the quantity of matter in the planet; that is, theſe planets, at the ſame diſtance, would act on the ſame body with degrees of ſtrength proportioned to the quantity of ſolid matter contained in each.

307 The ſmalleſt particles of matter attract each other according to the ſame law.

In the next place, our author deduces from the principles above demonſtrated, that each of the particles out of which the ſun, moon, and planets, are formed, exert their power of gravitation by the ſame law, and in the ſame proportion to the diſtance, as the great bodies they compoſe. For this purpoſe, he firſt demonſtrates, that if a globe were compounded of particles which will attract the particles of any other body reciprocally in the duplicate proportion of their diſtances, the whole globe will attract the ſame in the reciprocal duplicate proportion of their diſtances from the centre of the globe, provided it be of equal denſity throughout. Hence alſo he deduces the reverſe; that if a globe acts upon diſtant bodies by the law juſt now ſpecified, and the power of the globe be derived from its being compoſed of attracting particles, each of theſe will attract after the ſame proportion. The manner of deducing this is as follows: The globe is ſuppoſed to act upon the particles of a body without it conſtantly in the reciprocal duplicate proportion of their diſtances from the centre; and therefore, at the ſame diſtance from the globe, on which ſide ſoever the body be placed, the globe will act equally upon it. Now, becauſe if the particles of which the globe is compoſed acted upon thoſe without in the reciprocal duplicate proportion of their diſtances, the whole globe would act upon them in the ſame manner as it does; therefore, if the particles of the globe have not all of them that property, ſome muſt act ſtronger than in that proportion, whilſt others act weaker: and if this be the condition of the globe, it is plain, that when the body attracted is in ſuch a ſituation in reſpect of the globe that the greater number of the ſtrongeſt particles are neareſt to it, the body will be more forcibly attracted than when, by turning the globe about, the greater quantity of weak particles would be neareſt, though the diſtance of the body ſhould remain the ſame from the centre of the globe; which is contrary to what was at firſt remarked, that the globe acts equally on all ſides.

It is farther deduced from theſe propoſitions, that if all the particles of one globe attract all the particles of another in the proportion already mentioned, the attracting globe will act upon the other in the ſame proportion to the diſtance between the centre of the globe which attracts and the centre of that which is attracted: and farther, that the proportion holds true, though either or both of the globes be compoſed of diſſimilar parts, ſome rarer, and ſome more denſe; provided only, that all the parts in the ſame globe, equally diſtant from the centre, be homogeneous, and likewiſe if both globes attract each other.

308 Attraction an univerſal property of matter.

Thus has our author ſhown that this power in the great bodies of the univerſe is derived from the ſame being lodged in every particle of the matter which compoſes them; and conſequently that it is no leſs than univerſal in matter, though the power be too minute to produce any viſible effects on the ſmall bodies with which we are converſant by their action on one another. In the fixed ſtars indeed we have no particular proof that they have this power, as we find no appearance to demonſtrate that they either act or are acted upon by it. But ſince this power is found to belong to all bodies whereon we can make obſervation, and we find that it is not to be altered by any change in the ſhape of bodies, but accompanies them in every form, without diminution, remaining ever proportional to the quantity of ſolid matter in each; ſuch a power muſt without doubt univerſally belong to matter.

Of the Bodies of the Sun and Planets.

All this naturally follows from a consideration of the phenomena of those planets which have secondaries revolving about them. By the times in which these satellites perform their revolutions, compared with

309 How to determine the power of gravity on any of the planets.

their distances from their respective primaries, the proportion between the power with which one primary attracts his satellites and the force with which any other attracts his will be known; and the proportion of the power with which any planet attracts his secondary to the power with which it attracts a body at its surface, is found by comparing the distance of the secondary planet from the centre of the primary to the distance of the primary planet's surface from the same: and from hence is deduced the proportion between the power of gravity upon the surface of one planet to the gravity upon the surface of another. By the like method of comparing the periodical time of a primary planet about the sun with the revolution of a satellite about its primary, may be found the proportion of gravity or of the weight of any body on the surface of the sun, to the gravity or to the weight of the same body upon the surface of the planet which carries about the satellite. By computations of this kind it is found, that the weight of any body on the surface of the sun will be about 23 times as great as on the surface of the earth; about 10 times as great as on the surface of Jupiter; and near 19 times as great as on Saturn. The quantity of matter contained in each of these bodies is proportional to the power it has upon a body at a given distance. Thus it is found, that the sun contains 1067 times as much matter as Jupiter; Jupiter $158\frac{1}{3}$ times as the earth, and $2\frac{1}{3}$ times as much as Saturn. The diameter of the sun, according to the data with which Sir Isaac Newton was furnished, was calculated at 92 times, that of Jupiter about 9 times, and that of Saturn about 7 times as large as the diameter of the earth.

310 Densities of the heavenly bodies.

By comparing the quantities of matter in each of these bodies with their respective magnitudes their densities are likewise easily discovered; the density of every body being measured by the quantity of matter contained under the same bulk. Thus the earth is found $4\frac{1}{4}$ times more dense than Jupiter, while Saturn has only between two-thirds and three-fourths of the density of the latter, and the sun has only one-fourth part of the density of the earth. From all this our author draws the following conclusions, viz. That the sun is rarefied by its great heat; and of the three planets above-mentioned, the most dense is that nearest the sun. This it was highly reasonable to expect, the densest bodies requiring the greatest heat to agitate and keep their parts in motion; as on the contrary, the planets which are more rare would be rendered unfit for their office by the intense heat to which the denser are exposed. Thus the waters of our seas, if removed to the distance of Saturn would remain perpetually frozen, and at Mercury would constantly boil. The densities of the planets Mars, Venus, Mercury, and the *Georgium Sidus*, as they are not attended with planets on which many observations have been made, cannot be ascertained. From analogy, however, we ought to conclude, that the inferior planets, Venus and Mercury are more dense than the earth, Mars more rare, and the Georgium Sidus much more rare, than any of the rest.

SECT. V. *The Newtonian Doctrine applied more particularly to the Explication of the Celestial Phenomena.*

Particular Explication of the Celestial Phenomena.

FROM the general account of those laws by which the universe is upheld, we now proceed to give an explanation of the particular parts of which it is composed. Those which are most exposed to our researches, besides the Earth we inhabit, are the Sun, Moon, Mercury, Venus, Mars, Jupiter, Saturn, and the Georgium Sidus (see fig. 119.). The sun, an immense globe of fire, is situated near the centre of the system, round which he turns by a small and irregular motion, according as the common centre of gravity betwixt him and the planets, which is the true centre of the system, varies by their different positions on this or that side of him. All the planets move round this common centre of gravity together with the sun; but the latter, by reason of his vast bulk, is so near the true centre, that the motions of the celestial bodies are by astronomers always referred to the centre of the sun as the point round which they are directed. The motions of all of them are performed the same way, viz. from west to east; and some comets have been observed to move also in this way, though the motion of others has been directly contrary. This motion, from west to east, is said to be in the order of the signs, or *in consequence*, as has been already mentioned, with regard to the moon; while that from east to west is in *antecedence*, or contrary to the order of the signs. Though all of them, however, revolve round the sun, their motions, as we have already observed, are not in the same plane, but inclined to one another by small angles: and the way in which we compute this inclination is by considering the orbit of the earth as a standard, and calculating the angle which each of their orbits makes with it.

311 Heliocentric circles of the planets.

To a spectator placed in the sun, all the planets would appear to describe circles annually in the heavens; for though their motions are really elliptical, the eccentricity is so small, that the difference between them and true circles is not easily perceived even on earth; and at the sun, whether great or small, it would entirely vanish. These circles, which in such a situation would appear to be annually described among the fixed stars are called the *heliocentric circles* of the planets; and if we suppose the orbits of the planets to be extended to the extreme bounds of the creation, they would describe among the fixed stars those circles just mentioned. To a spectator in the sun, the comets, though moving in the most eccentric orbits, would also appear to describe circles in the heavens; for though their orbits are in reality very long ellipses, the planes of them extended to the heavens would mark a great circle thereon, whereof the eye would be the centre; only, as the real motion is in an ellipsis, the body would appear to move much more slowly in some part of the circle than another, and to differ excessively in magnitude. To an inhabitant of any planet, however, the sun appears to go round in its own heliocentric circle, or to describe in the heavens that same curve which the planet would appear to do if seen from the sun. Thus (fig. 137), when the earth is at *a*, if we

Fig. 158.

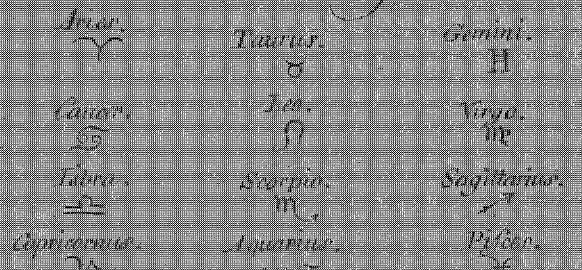

Fig. 159.

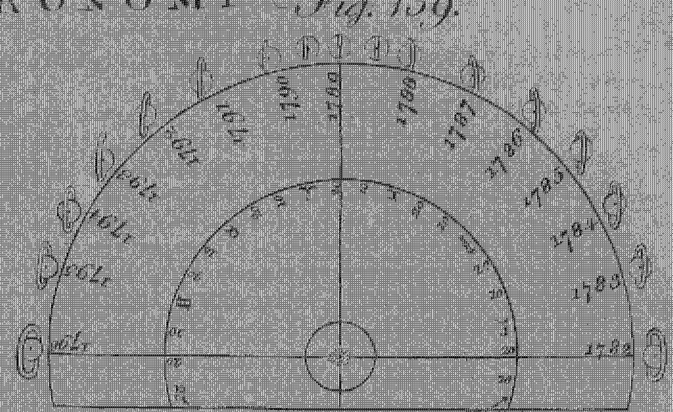

Fig. 160.

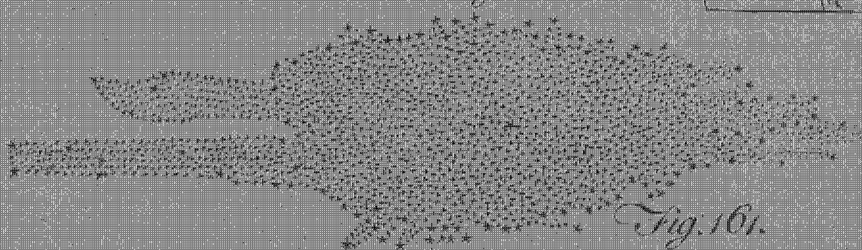

Fig. 161.

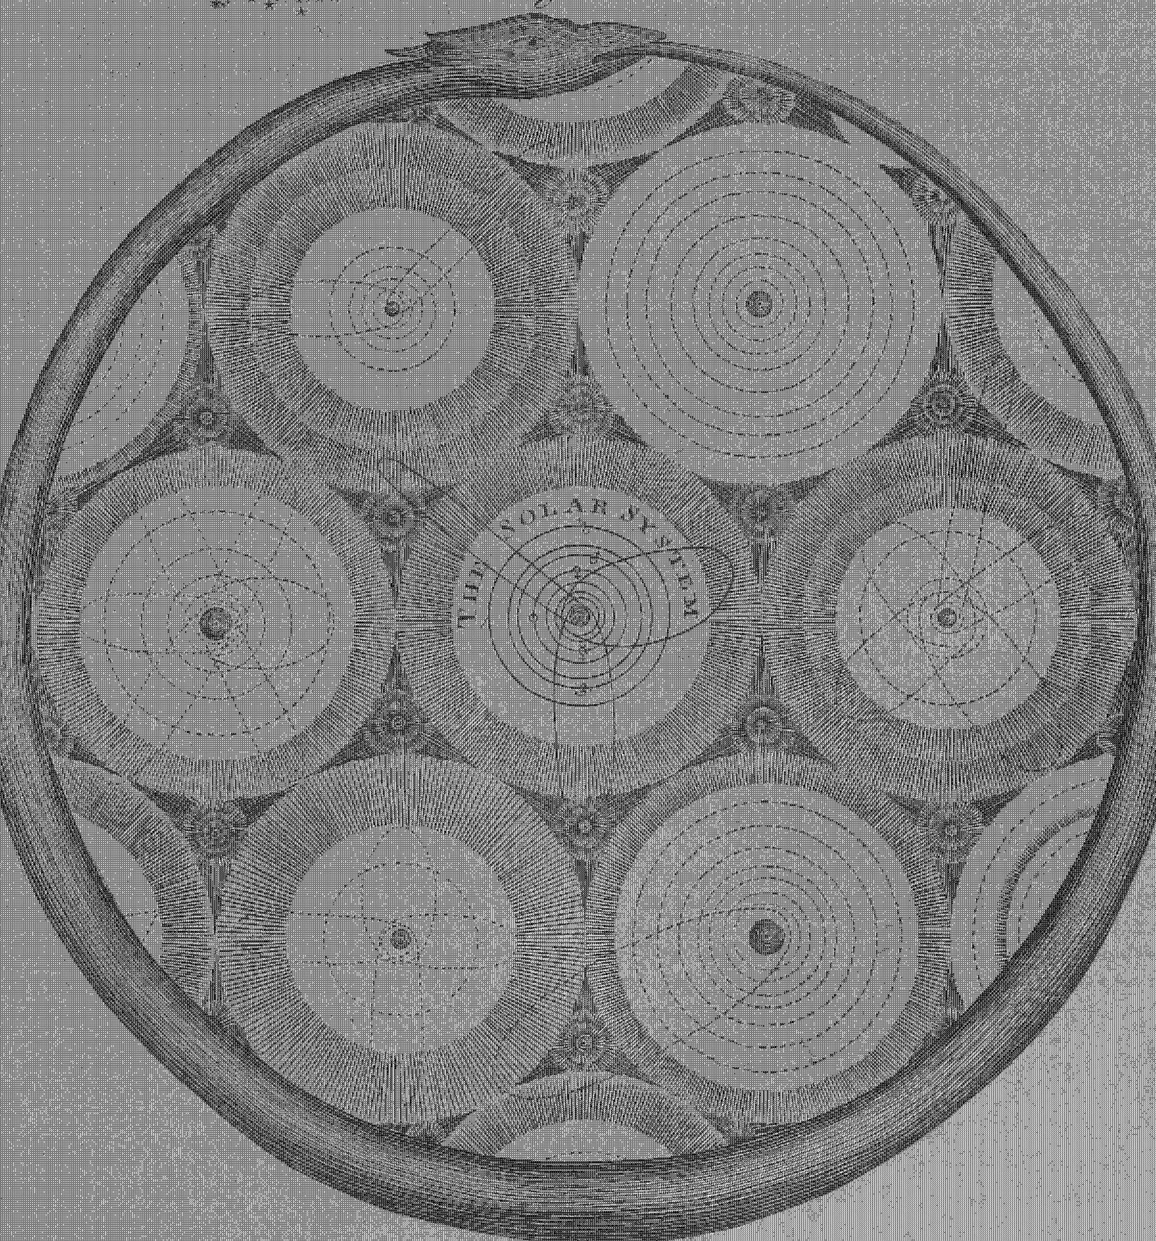

we draw a line from *a* through the ſun at S, the point G, in the ſphere of the heavens where the line terminates, is the place where the ſun then appears to an inhabitant of the earth. In a month's time the earth will be got from *a* to *b*; draw a line then through the ſun, and its extremity at H will point out his apparent place at that time. In like manner, if we draw lines from the earth in the twelve ſeveral ſituations in which it is repreſented for the twelve months of the year, the ſun's apparent place will be found as above, and ſo it would be found by a ſpectator placed in Venus or any other planet.

312 Ecliptic, why ſo named.

The heliocentric circle of the earth is called the *ecliptic;* becauſe eclipſes of the ſun or moon can only happen when the latter is in or near it, as will afterwards be more particularly explained. By ſome ancient writers it has been called the circle of the ſun, or the oblique circle, becauſe it cuts the equator at oblique angles. It is alſo called by Ptolemy the circle which paſſes through the midſt of the animals; becauſe the twelve conſtellations through which it paſſes were anciently all repreſented by animals, or parts of them, though now the *balance* is introduced in place of the claws of the *ſcorpion*.

313 Zodiac.

For this reaſon, a belt or hoop taken in the concave ſphere of the heavens about 10 degrees on each ſide of the ecliptic, is called the *zodiac*, from a Greek word which ſignifies an animal; and the conſtellations through which the ecliptic is drawn, are called the conſtellations of the zodiac.

314 How to determine the ſun's place.

Though the ſun, as we have ſaid, apparently goes round the earth annually in the circle juſt mentioned, we cannot determine his place by mere inſpection as we can do that of any of the other heavenly bodies; for the fixed ſtars are the only marks by which we can determine the places of any of the celeſtial bodies, and the ſuperior brightneſs of the ſun renders them totally inviſible except in the time of a great eclipſe when his light is for a time totally obſcured. But though we cannot know the place of the ſun directly, it is eaſily found from a knowledge of thoſe fixed ſtars which are oppoſite to him. Thus, in fig. 137. ſuppoſe it the time of the year in which the earth it at *g*, if we know that the point G is then diametrically oppoſite to the ſun, we know that A, its oppoſite, is the ſun's place; and conſequently, by finding the places throughout the year diametrically oppoſite to the ſun, as GHIKLM ABCDEF, we may be aſſured that in theſe times the ſun's place was in the points ABCDEFGHIKLM. The point in the heavens diametrically oppoſite to the ſun may be known every night at twelve o'clock when the ſtars are viſible; for the ſtar which has an elevation above the horizon at that time equal to the ſun's depreſſion below it, is directly oppoſite to him.

315 Latitude, declination, &c. explained.

The ecliptic being thus found, the latitude of the moon or any ſtar is counted by its diſtance from the ecliptic, as the latitude of places on earth is counted by their diſtance from the equator; and is marked upon circles drawn through the pole of the ecliptic, and perpendicular to its plane, as the latitude of places is marked on one of the meridians of a terreſtrial globe. Theſe are called *circles of latitude*, and each of them is ſuppoſed to divide the celeſtial concave into two equal hemiſpheres; and the *declination* of any celeſtial body is its deviation from the ecliptic towards the celeſtial equator perpendicular to that of the earth.

The latitude of any planet is either heliocentric or geocentric. The heliocentric latitude is its diſtance from the ecliptic as ſeen from the ſun, and its geocentric as ſeen from the earth, and is conſiderably different from the former. With the fixed ſtars indeed it is otherwiſe; for their diſtance is ſo vaſt, that the whole diameter of the earth's orbit is but a point in compariſon with it. For this reaſon, whatever part of its orbit the earth may be in, the fixed ſtars always appear to keep the ſame place; but with reſpect to the planets, the orbit of the earth, or *magnus orbis*, as it has ſometimes been called, bears a very conſiderable proportion, excepting only to the Georgium Sidus, of whoſe diſtance the diameter of the earth's orbit forms little more than a tenth part; and therefore all calculations with regard to that ſtar are much more difficult than the reſt. The apparent places of the planets therefore are conſiderably altered by the earth's change of place as well as by their own motions; ſo that though a planet ſhould ſtand ſtill for a whole year, it would nevertheleſs appear to us to deſcribe a circle round the heavens, as in that ſpace of time we would have been carried by the earth round the ſun, and have continually taken a view of it from different ſtations. As the orbits of the planets are inclined in different angles to the ecliptic, it thence happens, that the heliocentric latitude of any planet is almoſt always different from its geocentric latitude. Thus, let AB, fig. 138. be the orbit of the earth, CD the orbit of Venus, viewed with the eye in their common ſection, wherein they appear ſtraight lines; let E and F be two oppoſite points of the ecliptic; and ſuppoſe Venus to be in the point C in her utmoſt north limit. If ſhe were at that time viewed from the ſun S, ſhe would appear in the point of the heavens marked H, and her heliocentric latitude is then FH: but if viewed from the earth in B, ſhe will appear at *g*; at which time her heliocentric latitude is FH, and her geocentric only F*g*. When at I, her apparent place is at K, her heliocentric latitude FH, and her geocentric FK; but when the earth is at A, her apparent place will then be at G, and her geocentric latitude EG, while her heliocentric is only FH as before.

316 How to find the geocentric latitude of a ſuperior planet.

The two planets, Mercury and Venus, whoſe orbits are included in that of the earth, are called *inferior;* and Mars, Jupiter, Saturn, and the Georgium Sidus, whoſe orbits include that of the earth, are called *ſuperior;* and from the circumſtance juſt mentioned, they muſt preſent very different appearances in the heavens, as will afterwards be particularly explained. The geocentric latitude of a ſuperior planet may be underſtood from fig. 139. Let AB be the orbit of the earth, CD that of Mars, both viewed with the eye in their common ſection continued, by which they appear in ſtraight lines. Let E and F be oppoſite points of the ecliptic, and ſuppoſe Mars to be in his ſouth limit at C. If he were at that time viewed from S, the centre of the ſun, he would appear in the ſphere of the heaven at the point H; in which caſe his heliocentric latitude would be FH: But when viewed in C from the earth, or from its centre, which in this caſe is ſuppoſed to be the ſtation of the ſpectator, he will appear to be in different places of the heavens according to the poſition of the

the earth. When the earth, for instance, is at B, the place of Mars will appear to be at *g*, and his geocentric latitude will be F *g*. When the earth is at A, his apparent place will be in G, and his geocentric latitude FG: and in like manner, supposing the earth to be in any other part of its orbit, as in I or K, it is easy to see, that his apparent places, as well as geocentric latitudes at those times, will be different.

317 Nodes of a planet.

The two points where the heliocentric circle of any planet cuts the ecliptic are called its *nodes*: and that which the planet passes through as it goes into north latitude, is called the *ascending* node, and is marked thus ☊; and the opposite to this is called the *descending* node, and is marked ☋. A line drawn from one node to the other is called the *line of the nodes of the planet*, which is the common section of the plane of the ecliptic, and that of the planet produced on each side to the fixed stars.

318 Zodiac and signs explained.

The zodiac, of which we have already given some account, is either *astral* or *local*. The astral is divided into 12 unequal parts, because it contains 12 celestial constellations, some of which are larger than others. This continues always invariably the same; because the same stars now go to the making up of the different constellations as formerly, excepting some small variations to be afterwards explained. The local zodiac is divided into twelve equal parts, each containing 30 degrees, called *signs*. These are counted from the point where the equator and ecliptic intersect each other at the time of the vernal equinox; and are denoted by particular marks, according to the apparent annual motion of the sun. See fig. 158. A motion in the heavens in the order of these signs, as from Aries to Taurus, is said to be a motion *in consequence*; and such are the true motions of all the planets; tho' their apparent motions are sometimes contrary, and then they are said to move in *antecedence*. The local zodiac is not always invariably the same as to the places of the several signs, though the whole always takes up the same place in the heaven, viz. 10 degrees on each side the ecliptic. The points where the celestial equator cuts into the ecliptic are found to have a motion in antecedence of about 50 seconds in a year. This change of place of the first point of the ecliptic, from whence the signs are counted, occasions a like change in the signs themselves; which though scarce sensible for a few years, has now become very considerable. Thus, since astronomy was first cultivated among the Greeks, which is about 2000 years ago, the first point of the ecliptic is removed backward above a whole sign; and though it was then about the middle of the constellation Aries, is now about the middle of Pisces. Notwithstanding this alteration, however, the signs still retain their ancient names and marks. When the zodiac is mentioned by astronomers, the local zodiac is generally meant.

319 Longitude of celestial bodies explained.

The longitude of a phenomenon in the heavens is the number of degrees counted from the first point of Aries on the ecliptic to the place where a circle of latitude drawn through the phenomenon would cut the ecliptic at right angles. Every phenomenon in the heavens, whether in the zodiac or not, is thus referred to the ecliptic by the circles of latitude, as the longitudes of terrestrial places are referred to the equator by the meridians; and whatever sign the circle of latitude passes through, the phenomenon is said to have its place in that sign, though ever so far distant from it.

Some astronomical writers have made the local zodiac invariable: for which purpose they imagine a circle of latitude drawn through the first star of the constellation Aries, marked in Bayer's catalogue by the Greek letter γ; and reckon their longitude from the point where that circle cuts the ecliptic. This star, from its use, is called the first star of the Ram; and when this method is made use of, the longitude of any phenomenon is said to be so many signs, degrees, minutes, &c. from the first star of the Ram. Thus, in Street's Caroline tables, the longitude of Jupiter's ascending node is two signs eight degrees from the first star of Aries, which is thus marked: Long. ♃ ☊ à 1 ✱ ♈ 2s 8°. The common way of reckoning the longitude of a phenemenon is to take ♈ for the first point of the ecliptic, and not to number the degrees quite round that circle as a continued series, but to make a new beginning at the first point of every sign, and to reckon from thence only the length of 30°. When this method is made use of, the longitude of any phenomenon is expressed, by saying it is in such a degree and such a minute of a sign: and thus we may express the longitude of the ascending node of Mercury, ☿ ☊ ♉ 14° 40′; and so of any other. The place of a phenomenon in the heaven is expressed by setting down its longitude and latitude as is done with places situated any where on the surface of the earth.

Having thus explained the astronomical terms commonly made use of with respect to the planets; and likewise shown how from their motions and that of the earth, there must be a considerable variation in their apparent places, as seen from the sun and from the earth; we shall now proceed to a more particular consideration of their phenomena, as derived from a composition of the two motions just mentioned, viz. that of the planets in their respective orbits, and that of the earth in the ecliptic. Every planet, like the moon, is sometimes in conjunction and sometimes in opposition with the sun. Its conjunction is when the geocentric place of the planet is the same with that of the sun; though an exact or central conjunction can only take place when the line of its nodes passes through the earth, and the planet itself is in one of its nodes at the time. It is however, in general, called a conjunction, or opposition, when the same circle of latitude passes through the sun and planet at the same time. When the geocentric place of a planet is 90°, or a quarter of a circle from the sun's place, the planet is said to be in *quadrature*, or in *quartile* aspect with the sun; and these terms are used in a like sense when applied to any two of the heavenly bodies. Thus the sun and moon, or the moon and any planet, or any two planets, may be in conjunction, opposition, or quadrature. Besides these, the ancients reckoned other two aspects, the *trine* and the *sextile*; the former when the bodies were distant 120°, and the latter when only half that distance. These aspects they marked thus:

320 Conjunctions and oppositions of the planets explained.

221 Aspects of the planets.

Conjunction.	Opposition.	Quadrature.	Trine.	Sextile.
☌	☍	□	△	✱

The aspects were supposed to influence the affairs of mankind; and many conclusions drawn from them too absurd to be mentioned here, and now indeed almost entirely buried in oblivion.

The

Particular Explication of the Celestial Phenomena.

The inferior planets have two kinds of conjunction with the sun; one in the inferior part of their semicircles, where they are nearer to the earth than the sun; the other in the superior part, where they are farther off. In the former, the planet is between the earth and the sun; and in the latter, the sun is between the earth and planet. The inferior planets can never be in opposition to the sun, nor even appear at a great distance from him. The length they go is called their *elongation*. Thus, in fig. 140. let OPQRT be part of the ecliptic; S the sun; and the three circles round him, the orbits of Mercury, Venus, and the Earth.

322 Geocentric places, &c. of the inferior planets

Suppose the earth to be at A, the sun's geocentric place will be at Q. If Mercury be then at I, his geocentric place is likewise at Q; so that he is in conjunction with the sun in his inferior semicircle: if at M, his geocentric place is likewise at Q; so that he is in conjunction in his superior semicircle. In like manner, Venus at E is in conjunction in her inferior semicircle, at G in her superior: but if we suppose the earth to be at A, and Venus at H, her geocentric place is T, and her elongation QT, which in this figure is the greatest possible; for this always takes place when a straight line from the earth touches the orbit of the planet, as is evident from the figure; that is, provided the planet be in its aphelion at the time. Thus the greatest possible elongation of Mercury is QP when he is in his aphelion at L; and the quantity of this is found by astronomical observations to be about 28 degrees, that of Venus about 48. The inferior planets in their elongations are sometimes eastward and sometimes westward of the sun: in the former case they appear in the evening, and in the latter in the morning. The smallness of Mercury and his nearness to the sun prevent him from being often taken notice of; but the largeness and beauty of Venus have made her, in all ages, celebrated as the *evening* and *morning star*.

323 Direct retrograde motions of the planets explained.

The irregular apparent motion of the planets has been already taken notice of; sometimes going forward, sometimes backward, and sometimes appearing to stand still for a little. These different conditions are by astronomers called *direct*, *retrograde*, and *stationary*. Were they to be viewed from the sun, they would always appear direct, as has been already shown; but when viewed from the earth, the inferior planets appear direct when moving in their upper semicircle, and retrograde when in their lower ones. Thus, in fig. 140. suppose the earth at rest at A, while Mercury is going on in his orbit from N to I. from I to L his motion appears to an observer at A to be retrograde, or contrary to the order of the signs, namely, from R to Q and from Q to P; but when in that part of his orbit which lies between L and N, his motion appears direct, or from P to Q and from Q to R.

When the earth is in the line of nodes of an inferior planet, the apparent motion of the former is then in a straight line, because the plane of it passes through the eye; if in a conjunction in his upper semicircle, he passes behind the sun; if in his lower semicircle, he passes before it, and will then be seen by an observer on earth to pass over the sun's disk like a round and very black spot. Were the plane of his orbit coincident with the ecliptic, this appearance would be seen every year; but by reason of the obliquity of the two planes to each other, it is much more rare. However, he was seen in this manner November 12th 1782, at 3 h. 44′ in the afternoon; May 4th 1786, at 6 h. 57′ in the morning; and will be seen again December 6th 1789, at 3 h. 55′ in the afternoon: but from that time not, in Britain at least, until the year 1799, May 7th, at 2 h. 34′ in the afternoon. In like manner, Venus sometimes appears as a black spot on the sun, but much more seldom than Mercury. She was first seen by Mr Horrox, as we have already related, in the year 1639; afterwards in the years 1761 and 1769; but will not afterwards be visible in this manner till the year 1874.

When the earth is out of the line of the nodes of an inferior planet, its orbit appears an ellipsis, more or less eccentric according to the situation of the eye of the spectator. Thus, suppose the earth to be as far as possible (that is 90°) out of the line of the nodes of Mercury, the projection of his orbit will be in such an elliptic curve as is represented fig. 141. wherein he will appear to move in the order of the letters; direct when in his upper semicircle from *a* to *b*, from *b* to *c*, being above the sun at *b* in his superior conjunction: but in his inferior semicircle his motion will appear retrograde from *c* to *d*, and from *d* to *a*; in conjunction he will be at *d* below the sun. In these cases, the motion of Mercury is unequal; faster near the inferior conjunction, but most unequal in the inferior semicircle, going through the unequal spaces into which the ellipsis is divided. The motions of the inferior planets, both direct and retrograde, are very unequal: and this inequality proceeds not from the eccentricity of their orbits, but from the projection of their orbits into long ellipsis; and is therefore a mere optical deception.

These planets appear stationary while changing their motion from direct to retrograde, or from retrograde to direct. If the earth stood still, the times of their appearing stationary would be at their greatest elongation; for though it be a property of the circle that a straight line can only touch it in one point, yet when the circle is very large the recess from the tangent is not perceptible for a considerable time. Thus, in fig. 140. suppose the earth to be at rest in A, Venus would appear stationary, her geocentric place continuing at T all the while she is going in her orbit from *a* to *b*; because her deviation from the visual line AT would scarce be perceptible so near the point of contact H.

To an inhabitant of the earth, therefore, the inferior planets appear always near the sun; alternately going from and returning to him, sometimes in straight lines, at others in elliptical curves, first on one side and then on the other; sometimes so near as to be rendered invisible by his stronger light. Sometimes, when in or near their nodes, they pass behind the sun in their superior semicircles, or pass between him and us; in which case they appear like black spots on his disk, as has been just now mentioned. For the better comprehending of these motions, however, we have hitherto supposed the earth to stand still in some part of its orbit, while they go round the sun in theirs; but as this is not the case, it now remains to consider the changes which take place in consequence of the earth's motion. Were the earth to stand still in any part of her

324 Effects of the earth's motion on the appearances of the planets.

Particular Explication of the Celestial Phenomena.

her orbit as at A, the places of conjunction both in the superior and inferior semicircle, as also of the greatest elongation; and consequently the places of direct and retrograde motion, and of the stations of an inferior planet, would always be in the same part of the heavens. Thus, in fig. 140. upon this supposition, the places of Mercury's stations would always be the points P and R, the arc of his motion PR, and of his retrograde motion RP; whereas, on account of the earth's motion, the places where these appearances happen are continually advancing forward in the ecliptic according to the order of the signs. In fig. 142, let ABCD be the orbit of the earth; *e f g h* that of Mercury; ⊙ the sun; GKI an arc of the ecliptic extended to the fixed stars. When the earth is at A, the sun's geocentric place is at F; and Mercury, in order to a conjunction, must be in the line AF; that is, in his orbit he must be at *f* or *h*. Suppose him to be at *f* in his inferior semicircle: If the earth stood still at A, his next conjunction would be when he is in his superior semicircle at *h*; the places of his greatest elongation also would be at *e* and *g*, and in the ecliptic at E and G: but supposing the earth to go on in its orbit from A to B; the sun's geocentric place is now at K; and Mercury, in order to be in conjunction, ought to be in the line BK at *m*. As by the motion of the earth the places of Mercury's conjunction with the sun are thus continually carried round in the ecliptic in consequence, so the places of his utmost elongations must be carried in consequence also. Thus, when the earth is at A, the places of his greatest elongation from the sun are in the ecliptic E and G; the motion of the earth from A to B advances them forward from G to L and from E to I. But the geocentric motion of Mercury will best be seen in fig. 146. Here we have part of the extended ecliptic marked ♈, ♉, ♊, &c. in the center of which S represents the sun, and round him are the orbits of Mercury and the earth. The orbit of Mercury is divided into 11 equal parts, such as he goes through once in eight days; and the divisions are marked by numeral figures 1, 2, 3, &c. Part of the orbit of the earth is likewise divided into 22 equal arcs, each arc being as much as the earth goes through in eight days. The points of division are marked with the letters *a, b, c, d, e, f,* &c. and show as many several stations from whence Mercury may be viewed from the earth. Suppose then the planet to be at 1 and the earth at *a*; draw a line from *a* to 1, and it shews Mercury's geocentric place at A. In eight days he will be got to 2, and the earth to *b*; draw a line from 2 to *b*, and it shows his geocentric place at B. In other eight days he will have proceeded to 3, and the earth to *c*; a line drawn from 3 to *c* will show his geocentric place at C. In this manner, going through the figure, and drawing lines from the earth at *d, e, f, g,* &c. through 4, 5, 6, 7, &c. we shall find his geocentric places successively at the points D, E, F, G, &c. where we may observe, that from A to B, and from B to C, the motion is direct; from C to D, and from D to E, retrograde. In this figure 22 stations are marked in the earth's orbit, from whence the planet may be viewed; corresponding to which there ought to be as many in the orbit of Mercury; and for this purpose the place of that planet is marked at the end of every eight days for two of his periodical revolutions; and to denote this, two numeral figures are placed at each division.

The geocentric motion of Venus may be explained in a similar manner; only as the motion of Venus is much slower than that of Mercury, his conjunctions, oppositions, elongations, and stations all return much more frequently than those of Venus.

To explain the stationary appearances of the planets, it must be remembered, that the diameter of the earth's orbit, and even that of Saturn, are but mere points in comparison of the distance of the fixed stars; and therefore, any two lines absolutely parallel, though drawn at the distance of the diameter of Saturn's orbit from each other; would, if continued to the fixed stars, appear to us to terminate in the same point. Let, then, the two circles fig. 143. represent the orbits of Venus and of the Earth; let the lines AE, BF, CG, DH, be parallel to SP, we may nevertheless affirm, that if continued to the distance of the fixed stars, they would all terminate in the same point with the line SP. Suppose then, Venus at E while the Earth is at A, the visual ray by which she is seen is the line AE. Suppose again, that while Venus goes from E to F, the Earth goes from A to B, the visual ray by which Venus is now seen is BF parallel to AE; and therefore Venus will be all that time stationary, appearing in that point of the heaven where SP extended would terminate: this station is at her changing from direct to retrograde. Again, suppose, when the Earth is at C, Venus is at G, and the visual line CG; if, while the Earth goes from C to D, Venus goes from G to H, so that she is seen in the line GH parallel to CG, she will be all that time stationary, appearing in the point where a line drawn from S through P would terminate. This station is at her changing from retrograde to direct; and both are in her inferior semicircle.

325 Perigee and apogee of the planets explained.

An inferior planet, when in conjunction with the sun in its inferior semicircle, is said to be in *perigee*, and in the other in *apogee*, on account of its different distances from the earth. Their real distances from the earth when in perigee are variable, partly owing to the eccentricities of their orbits, as well as that of the earth; and partly owing to the motions of the different bodies, by which it happens that they are in perigee in different parts of their orbits. The least possible distance is when the perigee happens when the earth is in its perihelion, and the planet in its aphelion.

326 Differences in the apparent diameters of the planets.

The difference of distance between the earth and inferior planets at different times, makes a considerable variation in their apparent diameters, which indeed is very observable in all the planets; and thus they sometimes look very considerably larger than at others. This difference in magnitude in Mercury is nearly as $5\frac{1}{4}$ to 1; and in Venus, no less than 32 to 1. A common spectator, unassisted by any instrument, may observe an inferior planet alternately approach nearer and nearer the sun, until at last it comes into conjunction with him, and then to recede farther and farther till it is at its greatest elongation, which will be first on one side and then on the other: but if we observe the apparent change of place of an inferior planet in the sphere of the heavens, its direct motions, stations, and retrogradations, measuring its diameter frequently with the micrometer,

Particular Explication of the Celestial Phenomena.

micrometer, we shall find by its decrease at some times and increase at others, that its distance from us is very considerably varied; so that, taking the whole of its course into consideration, it appears to move in a very complicated curve. See fig. 1. and C.

327 Appearances of the superior planets explained.

As the superior planets move in a larger orbit than the earth, they can only be in conjunction with the sun when they are on that side opposite to the earth; as, on the other hand, they are in opposition to him when the earth is between the sun and them. They are in quadrature with him when their geocentric places are 90° distant from that of the sun. In order to understand their apparent motions, we shall suppose them to stand still in some part of their orbit while the earth makes a complete revolution in hers; in which case, any superior planet would then have the following appearances: 1. While the earth is in her most distant semicircle, the motion of the planet will be direct. 2. While the earth is in her nearest semicircle, the planet will be retrograde. 3. While the earth is near those places of its orbit where a line drawn from the planet would be a tangent, it would appear to be stationary. Thus, in fig. 147. let *a b c d* represent the orbit of the Earth; S the Sun; EFG an arc of the orbit of Jupiter; ABC an arc of the ecliptic projected on the sphere of the fixed stars. Suppose Jupiter to continue at F, while the earth goes round in her orbit according to the order of the letters *a b c d*. While the earth is in the semicircle most distant from Jupiter going from *a* to *b* and from *b* to *c*, his motion in the heaven would appear direct, or from A to B and from B to C: but while the earth is in its nearest semicircle *c d e*, the motion of Jupiter would appear retrograde from C to B and from B to A; for *a*, *b*, *c*, *d*, may be considered as so many different stations from whence an inhabitant of the earth would view Jupiter at different seasons of the year, and a straight line drawn from each of these stations, through F the place of Jupiter, and continued to the ecliptic, would show his apparent place there to be successively at A, B, C, B, A. While the earth is near the points of contact *a* and *c*, Jupiter would appear stationary, because the visual ray drawn through both planets does not sensibly differ from the tangent F*a* or F*c*. When the earth is at *b*, a line drawn from *b* through S and F to the ecliptic, shows Jupiter to be in conjunction with the sun at B. When the earth is at *d*, a line drawn from *d* through S, continued to the ecliptic, would terminate in a point opposite to B; which shows Jupiter then to be in opposition to the sun: and thus it appears that his motion it direct in the conjunction, but retrograde when in opposition with the sun.

The direct motion of a superior planet is swifter the nearer it is to a conjunction, and slower as it approaches to a quadrature with the sun. Thus, in fig. 144. let ☉ be the sun; the little circle round it, the orbit of the earth, whereof *a b c d e f g* is the most distant semicircle: OPQ, an arc of the orbit of Jupiter; and ABCDEFG, an arc of the ecliptic in the sphere of the fixed stars. If we suppose Jupiter to stand still at P, by the earth's motion from *a* to *g*, he would appear to move direct from A to G, describing the unequal arcs AB, BC, CD, DE, EF, FG, in equal times. When the earth is at *d*, Jupiter is in conjunction with the sun at D, and there his direct motion is swiftest. When the earth is in that part of her orbit where a line drawn from Jupiter would touch it, as in the points *e* or *g*, Jupiter is nearly in quadrature with the sun; and the nearer the earth is to any of those points, the slower is the geocentric motion of Jupiter; for the arcs CD and DE are greater than BC or EF, and the arcs BC and EF are greater than AB or FG.

The retrograde motion of a superior planet is swifter the nearer it is to an opposition, and slower as it approaches to a quadrature with the sun. Thus, let ☉, fig. 145. be the sun; the little circle round it the orbit of the earth, whereof *g h i k l m n* is the nearest semicircle; OPQ, an arc of the orbit of Jupiter; NKG an arc of the ecliptic: If we suppose Jupiter to stand still at P, by the earth's motion from *g* to *n*, he would appear to move retrograde from G to N, describing the unequal arcs GH, HI, IK, KL, LM, MN, in equal times. When the earth is at *k*, Jupiter appears at K, in opposition to the sun, and there his retrograde motion is swiftest. When the earth is either at *g* or *n*, the points of contact of the tangents P*g* and P*n*, Jupiter is nearly in quadrature with the sun: and the nearer he is to either of these points, the slower is his retrogradation, for the arcs IK and KL are greater than HI or LM; and the arcs HI and LM are greater than GH or MN. Since the direct motion is swiftest when the earth is at *d*, and continues diminishing till it changes to retrogade, it must be insensible near the time of change: and, in like manner, the retrograde motion being swiftest when the earth is in *k*, and diminishing gradually till it changes to direct, must also at the time of that change be insensible; for any motion gradually decreasing till it changes into a contrary one gradually increasing, must at the time of the change be altogether insensible.

The same changes in the apparent motions of this planet will also take place if we suppose him to go on slowly in his orbit; only they will happen every year when the earth is in different parts of her orbit, and consequently different times of the year. Thus, (fig. 147.) let us suppose, that while the earth goes round her orbit Jupiter goes from F to G, the points of the earth's orbit from which Jupiter will now appear to be stationary will be *a* and *y*; and consequently his stations must be at a time of the year different from the former. Moreover, the conjunction of Jupiter with the sun will now be when the earth is at *f*, and his opposition when it is at *e*; for which reason these also will happen at times of the year different from those of the preceding opposition and conjunction. The motion of Saturn is so slow, that it makes but little alteration either in the times or places of his conjunction or opposition; and no doubt the same will take place in a more eminent degree in the Georgium Sidus; but the motion of Mars is so much swifter than even that of Jupiter, that both the times and places of his conjunctions and oppositions are thereby very much altered.

Fig. 148. exemplifies the geocentric motion of Jupiter in a very intelligible manner: where ☉ represents the sun; the circle 1, 2, 3 4, the orbit of the earth, divided into twelve equal arcs for the twelve months of the year; PQ an arc of the orbit of Jupiter, containing as much as he goes through in a year, and divided in in like manner into twelve equal parts each as much

Particular Explication of the Celestial Phenomena.

as he goes through in a month. Now, suppose the earth to be at 1 when Jupiter is at *a*, a line drawn through 1 and *a* shows Jupiter's place in the celestial ecliptic to be at A. In a month's time the earth will have moved from 1 to 2, Jupiter from *a* to *b*; and a line drawn from 2 to *b* will show his geocentric place to be in B. In another month, the earth will be in 3, and Jupiter at C, and consequently his geocentric place will be at C; and in like manner his place may be found for the other months at D, E, F, &c. It is likewise easy to observe, that his geocentric motion is direct in the arcs AB, BC, ED, DE; retrograde in EF, FG, GH, HI; and direct again in IK, KL, LM, MN. The inequality of his geocentric motion is likewise apparent from the figure.

A superior planet is in apogee when in conjunction with the sun, and in perigee when in opposition; and every one of the superior planets is at its least possible distance from the earth where it is in perigee and perihelion at the same time. Their apparent diameters are variable, according to their distances, like those of the inferior planets; and this, as might naturally be expected, is most remarkable in the planet Mars, who is nearest us. In his nearest approach, this planet is 25 times larger than when farthest off, Jupiter twice and a half, and Saturn once and a half.

328 Of the Georgium Sidus.

The honour of discovering the new attendant of the sun, called the *Georgium Sidus*, is undoubtedly due to Mr Herschel; though Mr Robison, professor of Natural Philosophy in Edinburgh, has given strong reasons for supposing that it had been marked by several astronomers as a fixed star. It was first observed by Mr Herschel on the 13th of March 1781, near the foot of Castor, and his attention was drawn by its steady light. On applying an higher magnifying power to his telescope, it appeared manifestly to increase in diameter; and two days after, he observed that its place was changed. From these circumstances he concluded, that it was a comet: and sent an account of it as such to the astronomer-royal, which very soon spread all over Europe. It was not long, however, before it was known, by the English astronomers especially, to be a planet.

329 How discovered to be a planet.

The circumstances which led to this discovery were, its vicinity to the ecliptic, the direction of its motion, and its being nearly stationary at the time, in such a manner as corresponds with the like appearances of the other planets. The French astronomers, however, still imagined it to be a comet, although it had not that faint train of light which usually accompanies these bodies, nor would its successive appearances correspond with such an hypothesis; so that they were at last obliged to own that it went round the sun in an orbit nearly circular.

330 Computation of its distance, &c.

Its motion was first computed on this principle by Mr Lexel professor of astronomy at St Petersburgh; who showed, that a circular orbit, whose radius is about 19 times the distance of the earth from the sun, would agree very well with all the observations which had been made during the year 1781. On the 1st of December that year it was in opposition with the sun; whence one of its stations was certainly determined. In the mean time, however, as astronomers were every where engaged in making observations on the same star, it occurred to some, that it might possibly have been observed before, though not known to be a planet. Mr Bade of Berlin, who had just published a work containing all the catalogues of zodiacal stars which had appeared, was induced, by the observations which had been already made on the new planet, to consult these catalogues, in order to discover whether any star, marked by one astronomer and omitted by another, might not be the new planet in question. In the course of this inquiry, he found, that the star, N° 964 of Mayer's catalogue, had been unobserved by others, and only once by Mr Mayer himself, so that no motion could have been perceived by him. On this Mr Bade immediately directed his telescope to that part of the heavens where he might expect to find the star marked in Mayer's catalogue, but without success. At the same time, by the calculations already made concerning the new planet, he discovered, that its apparent place in the year 1756 ought to have been that of Mayer's star, and this was one of the years in which he was busied in his observations; and on farther inquiry it was found, that the star 964 had been discovered by Mr Mayer on the 15th of September 1756: So that it is now generally believed, that the star N° 964 of Mayer's catalogue was the new planet of Herschel.

Before the end of the year 1782, it was found, that the angular motion of the planet was increasing; which showed, that it was not moving in a circle, but in an eccentric orbit, and was approaching towards the sun. Astronomers, therefore, began to investigate the inequality of this angular heliocentric motion, in order to discover the form and position of the ellipsis described. This was a very difficult task, as the small inequality of motion showed that the orbit was nearly circular, and the arch already described was no more than one-fiftieth part of the whole circumference. It was, however, by no means easy, from the variation of curvature discoverable in this small arch, to determine to what part of the circumference it belongs: though the Professor is of opinion, that the supposition of its being the star 964 of Mayer's catalogue renders the calculation easy. On this supposition, its motion has been calculated by several astronomers, as well as by Mr Robison himself. He observes, however, that if we do not admit the identity of these stars, near half a century must elapse before we can determine the elements of this planet's motion with a precision equal to that of the others.

Some astronomers are of opinion, that the new planet is the same with the star N° 34 Tauri of the Britannic catalogue. "In this case (says Mr Robison), the elements will agree very well with Flamstead's observation of that star on December 13th 1690, being only 40″, or perhaps only 12″, to the westward of it; but the latitude differs more than two minutes from Flamstead's latitude, which is properly deduced from the zenith distance. This is too great an error for him to commit in the observation; and we should therefore reject the supposition on this account alone: But there are stronger reasons for rejecting it, arising from the disagreement of those elements with the observations made on the stations of the planet in October 1781 and in March and October 1782, which give a very near approximation of its distance from the sun. When compared with observations of the planet near its stationary

Particular Explication of the Celestial Phenomena.

tionary points in the spring, they give the geocentric latitude considerably too great, while they give it too small for the similar observations in autumn."

331 To find the time when any planet will return into the same apparent situation.

As the times of conjunction, utmost elongation, direct or retrograde motions of the inferior planets, depend on the combinations of their motions in their orbits with the motion of the earth in its orbit; any of these appearances will be more frequent in Mercury than in Venus, because the former moves with a swifter motion in his orbit, and consequently must more frequently pass through those places where he is in conjunction, &c. The time in which any of the inferior planets will return into a given situation, may be known by the following examples. Let fig. 149. represent the orbits of Venus and the earth. Let the earth be at E, Venus at V, when she is in the inferior conjunction with the sun in ♈. From S, Venus and the earth would appear in conjunction in ♎: let Venus go round her orbit, and return to V; the earth taking longer time to go round than Venus, will, in the mean time, go from E, only through a part of her orbit, and Venus must overtake the earth before she can have another inferior conjunction; that is, she must, besides an entire revolution, which is equal to four right angles, go through as much more angular motion round the sun as the earth has done in the mean time, so as to be in a right line between the sun and the earth. Suppose this is to happen when the earth is got to F and Venus to T, the angular motions of the earth and Venus performed in the same times are reciprocally as their periodical times: and therefore as the periodical time of the earth is to the periodical time of Venus; so is the angular motion of Venus, which is equal to four right angles, added to the angular motion of the earth, in the time between two like conjunctions of Venus, to the angular motion of the earth in the same time: and therefore, by division of proportion, as the difference between the periodical times of Venus and the earth is to the periodical time of Venus; so are four right angles, or 360°, to a fourth quantity; namely, to the angular motion or number of degrees which the earth goes in her orbit from the time of one conjunction of Venus to the next conjunction of the same kind. Now the periodical time of the earth is 365 days 6 hours or 8766 hours; the period of Venus 224 days 16 hours or 5392 hours; the difference is 3374 hours. Say then, As 3374 is to 5392, so are four right angles, or 360 degrees, to a fourth number, which is 575°; which the earth goes through in a year and 218 days. Were Venus therefore this day in an inferior conjunction with the sun, it would be a year and 218 days before she come into another conjunction of the same kind; and this alteration in time occasions a proportionable change in place: so that if one conjunction be in ♈, the next similar conjunction will be in ♍. The time between any situation of Mercury, with regard to the sun and the earth, and another like situation, may be found by the same method. The periodical time of the earth is 8766 hours; the period of Mercury 87 days 23 hours or 2111 hours; the difference 6655 hours. Say then, As 6655 is to 2111, so are four right angles or 360° to 114°, through which the earth passes in 116 days. If therefore Mercury were to be this day in his inferior conjunction, it would be 116 days before he were in a similar situation.

Eucl. Elm. 5. prop 17.

This problem is commonly resolved in another manner. Astronomers compute the diurnal heliocentric motions of Venus and of the earth: the difference of these motions is the diurnal motion of Venus from the earth, or the quantity by which Venus would be seen to recede from the earth every day by a spectator placed in the sun: thus the mean motion of Venus is, every day about 59 minutes and 8 seconds; the difference is 37 minutes. Say, therefore, As 37 minutes is to 36°, or to 21,600 minutes, so is one day to the time wherein Venus, having left the earth, recedes from her 360 degrees; that is, to the time wherein she returns to the earth again, or the time between two conjunctions of the same kind.

332 To find the true times of the conjunctions, oppositions, &c of the planets.

The times are here computed according to the mean or equable motions of the planets; and this is therefore called a mean conjunction: but because Venus and the earth are really carried in elliptic orbits, in which their motions are sometimes swifter and sometimes slower, the true conjunctions may happen some days either sooner or later than what these rules will give. The time of the true conjunction is to be computed from that of the mean conjunction in the following manner. Find by astronomical tables the places of Venus and the earth in the ecliptic, from which we shall have the distance of the two as seen from the sun; compute also for the same time the triangular motions of these two planets for any given time, suppose six hours; the difference of these two motions will give the access of Venus to the earth, or her recess from it in six hours: then say, as this difference is to the arc between the places of Venus and the earth at the time of a mean conjunction, so is six hours to the time between the mean conjunction and the true. This time added to or subtracted from the time of the mean conjunction, according as Venus is in antecedence or consequence from the earth, shows the time of their true conjunction.

With regard to the conjunctions, oppositions, direct and retrograde motions, &c. of the superior planets, as they depend on the combinations of their motions with that of the earth, they will be more frequent in Saturn than in Jupiter, in Jupiter than in Mars, but most frequent of all in the Georgium Sidus; because the slower the motion of the planet is, the sooner the earth will overtake it, so as to have it again in any given situation. Thus, suppose Saturn to be in conjunction with the sun in ♈, if he were to stand still for one year, then he would again be in conjunction in ♈; but as he goes on slowly, according to the order of the signs, about 12° annually, the earth must go through almost 13° more than an entire revolution; so that there will be almost a year and 13 days between any conjunction between the Sun and Saturn and the conjunction immediately following. As Jupiter moves in his orbit with greater velocity than Saturn, the earth must have a proportionably larger space added to the year; and as Mars moves swifter still, the time betwixt any two of his conjunctions must be still longer.

The time when a superior planet will return into any given situation may be found by the methods already

Particular Explication of the Celestial Phenomena.

ready laid down for the inferior planets. Thus, the mean diurnal motion of the earth is about 59′ 8″; the mean motion of Saturn in a day is only two minutes; the difference 57′ 8″. Say therefore, As 57′ 8″ are to 360°, or 21,600 minutes, so is one day to the space of time wherein the earth having left Saturn recedes from him 360°; that is, to the time of her return to Saturn again, or the time between two conjunctions, oppositions, or other like aspects. This time will be found 378 days, or one year and 13 days. The mean motion of Jupiter in a day is 4′ 59″; the difference between this and the earth's diurnal motion is 54′ 59″. Say then, As 54′ 59″ are to 360° or 21,600′, so is one day to the space of time when the earth, having left Jupiter, will overtake him again; which will be found to be 398 days, or one year and 33 days. The mean motion of Mars is 31′ 27″; the difference between which and the earth's diurnal motion is 27′ 41″. Say then, As 27′ 41″ are to 360° or 21,600′, so is one day to the space of time wherein the earth, having left Mars, recedes from him 360°; which will be found two years and 50 days. The true conjunctions, &c. may be found in the superior planets as in the inferior.

333 Distance, &c. of the earth.

The earth is the next planet above Venus in the system. It is 95,173,000 miles from the sun; and goes round him in 365 days 5 hours 49 minutes, from any equinox or solstice to the same again; but from any fixed star to the same again, as seen from the sun, in 365 days 6 hours 9 minutes; the former being the length of the tropical year, and the latter the length of the sidereal. It travels at the rate of 68,000 miles every hour; which motion, though upwards of 140 times swifter than that of a cannon ball, is little more than half as swift as Mecury's motion in his orbit. The earth's diameter is 7970 miles; and by turning round its axis every 24 hours from west to east, it causes an apparent diurnal motion of all the heavenly bodies from east to west. By this rapid motion of the earth on its axis, the inhabitants about the equator are carried 1042 miles every hour, whilst those on the parallel of London are carried only about 580, besides the 68,000 miles by the annual motion abovementioned, which is common to all places whatever.

That the earth is of a globular figure may be proved from several different and evident circumstances. 1. When we are at sea on board a ship, we may be out of sight of land when the land is near enough to be visible if it were not hid from our eye by the convexity of the water. Thus, let ABCD (fig. 154.) represent a portion of the globe of our earth. Let M be the top of a mountain; this cannot be seen by a person on board the ship at B, because a line drawn from M to his eye at E is intercepted by the convexity of the water, but let the ship come to C, then the mountain will be visible, because a line may be drawn from M to his eye at E. 2. The higher the eye, the further will the view be extended. It is very common for sailors from the top of the mast of a ship to discover land or ships at a much greater distance than they can do when they stand upon deck. 3. When we stand on shore, the highest part of a ship is visible at the greatest distance. If a ship is going from us out to sea, we shall continue to see the mast after the hull or body of the ship disappears, and the top of the mast will continue to be seen the longest. If a ship is coming towards us, the top of the mast comes first in view, and we see more and more till at last the hull appears. If the surface of the sea were a flat plain (fig. 155.), a line might be drawn from any object situated upon it, as the ship D, to the eye, whether placed high or low, at A or B. In this case, any object upon the earth or sea, would be visible at any distance which was not so great as to make the appearance of it too faint, or the angle under which it appears too small, to be seen by us. An object would be visible at the same distance, whether the eye were high or low. Not the highest, but the largest, objects would be visible to the greatest distance, so that we should be able to see the hulk of a ship further off than the mast: All which is contrary to experience. 4. Several navigators, such as Ferdinand Magellan, Sir Francis Drake, Captain Cook, have sailed round the globe; not in an exact circle, the land preventing them, but by going in and out as the shores happened to lie. 5. All the appearances in the heavens are the same, whether at land or sea. 6. Eclipses of the moon arise from the shadow of the earth, and this shadow is always circular. Although the earth presents, during several hours, different portions of its surface to the moon, yet still the shadow is round. The small inequalities upon the surface of the earth bear no kind of proportion to its magnitude sufficient to alter the appearance of its shadow.

The earth's axis makes an angle of 23½ degrees with the axis of its orbit, and keeps always the same oblique direction, inclining nearly to the same fixed stars (A) throughout its annual course, which causes the returns of spring, summer, autumn, and winter.

334 Demonstration of the earth's motion.

That the sun, and not the earth, is the centre of our solar system, may be demonstrated beyond a possibility of doubt, from considering the forces of gravitation and projection, by which all the celestial bodies are retained in their orbits. For, if the sun moves about the earth, the earth's attractive power must draw the sun towards it from the line of projection so as to bend its motion into a curve: But the sun being at least 227,000 times as heavy as the earth, by being so much weightier as its quantity of matter is greater, it must move 227,000 times as slowly towards the earth as the earth does towards the sun; and consequently the earth would fall to the sun in a short time, if it had not a very strong projectile motion to carry it off. The earth, therefore, as well as every other planet in the system, must have a rectilineal impulse, to prevent its falling into the sun. To say, that gravitation retains

(A) This is not strictly true, as will appear when we come to treat of the recession of the equinoctial points in the heavens, which recession is equal to the deviation of the earth's axis from its parallelism: but this is rather too small to be sensible in an age, except to those who make very nice observations.

Particular Explication of the Celeſtial Phenomena.

tains all the other planets in their orbits without affecting the earth, which is placed between the orbits of Mars and Venus, is as abſurd as to ſuppoſe that ſix cannon-bullets might be projected upwards to different heights in the air, and that five of them ſhould fall down to the ground; but the ſixth, which is neither the higheſt nor the loweſt, ſhould remain ſuſpended in the air without falling, and the earth move round about it.

There is no ſuch thing in nature as a heavy body moving round a light one as its center of motion. A pebble faſtened to a mill-ſtone by a ſtring, may by an eaſy impulſe be made to circulate round the mill-ſtone: but no impulſe can make a mill-ſtone circulate round a looſe pebble; for the mill-ſtone would go off, and carry the pebble along with it.

The ſun is ſo immenſely bigger and heavier than the earth, that, if he was moved out of his place, not only the earth, but all the other planets, if they were united into one maſs, would be carried along with the ſun as the pebble would be with the mill-ſtone.

335
From the proportional decreaſe of gravity, &c.

By conſidering the law of gravitation, which takes place throughout the ſolar ſyſtem, in another light, it will be evident that the earth moves round the ſun in a year, and not the ſun round the earth. It has been obſerved, that the power of gravity decreaſes as the ſquare of the diſtance increaſes; and from this it follows with mathematical certainty, that when two or more bodies move round another as their centre of motion, the ſquares of their periodic times would be to one another in the ſame proportion as the cubes of their diſtances from the central body. This holds preciſely with regard to the planets round the ſun, and the ſatellites round the planets; the relative diſtances of all which are well known. But, if we ſuppoſe the ſun to move round the earth, and compare its period with the moon's by the above rule, it will be found that the ſun would take no leſs than 173,510 days to move round the earth; in which caſe our year would be 475 times as long as it now is. To this we may add, that the aſpects of increaſe and decreaſe of the planets, the times of their ſeeming to ſtand ſtill, and to move direct and retrograde, anſwer preciſely to the earth's motion, but not at all to the ſun's, without introducing the moſt abſurd and monſtrous ſuppoſitions, which would deſtroy all harmony, order, and ſimplicity, in the ſyſtem. Moreover, if the earth be ſuppoſed to ſtand ſtill, and the ſtars to revolve in free ſpaces about the earth in 24 hours, it is certain that the forces by which the ſtars revolve in their orbits are not directed to the earth, but to the centres of the ſeveral orbits, that is, of the ſeveral parallel circles which the ſtars on different ſides of the equator deſcribe every day: and the like inferences may be drawn from the ſuppoſed diurnal motion of the planets, ſince they are never in the equinoctial but twice, in their courſes with regard to the ſtarry heavens. But, that forces ſhould be directed to no central body, on which they phyſically depend, but to innumerable imaginary points in the axis of the earth produced to the poles of the heavens, is an hypotheſis too abſurd to be allowed of by any rational creature. And it is ſtill more abſurd to imagine, that theſe forces ſhould increaſe exactly in proportion to the diſtances from this axis; for this is an indication of an increaſe to infinity; whereas the force of attraction is found to decreaſe in receding from the fountain from whence it flows. But the farther any ſtar is from the quieſcent pole, the greater muſt be the orbit which it deſcribes; and yet it appears to go round in the ſame time as the neareſt ſtar to the pole does. And if we take into conſideration the twofold motion obſerved in the ſtars, one diurnal round the axis of the earth in 24 hours, and the other round the axis of the ecliptic in 25,920 years, it would require an explication of ſuch a perplexed compoſition of forces, as could by no means be reconciled with any phyſical theory.

336
Objection againſt the earth's motion anſwered.

The ſtrongeſt objection that can be made againſt the earth's motion round the ſun is, that in oppoſite points of the earth's orbit, its axis, which always keeps a parallel direction, would point to different fixed ſtars; which is not found to be fact. But this objection is eaſily removed, by conſidering the immenſe diſtance of the ſtars in reſpect of the diameter of the earth's orbit; the latter being no more than a point when compared to the former. If we lay a ruler on the ſide of a table, and along the edge of the ruler view the top of a ſpire at ten miles diſtance; then lay the ruler on the oppoſite ſide of the table, in a parallel ſituation to what it had before, and the ſpire will ſtill appear along the edge of the rule; becauſe our eyes, even when aſſiſted by the beſt inſtruments, are incapable of diſtinguiſhing ſo ſmall a change at ſo great a diſtance.

337
Earth's motion demonſtrated from the aberration of light.

Dr Bradley, our late aſtronomer-royal, found by a long ſeries of the moſt accurate obſervations, that there is a ſmall apparent motion of the fixed ſtars, occaſioned by the aberration of their light; and ſo exactly anſwering to an annual motion of the earth, as evinces the ſame, even to a mathematical demonſtration. He conſidered this matter in the following manner: he imagined CA, fig. 33. to be a ray of light falling perpendicularly upon the line BD; that if the eye is at reſt at A, the object muſt appear in the direction AC, whether light be propagated in time or in an inſtant. But if the eye is moving from B towards A, and light is propagated in time, with a velocity that is to the velocity of the eye, as CA to BA; then light moving from C to A, whilſt the eye moves from B to A, that particle of it by which the object will be diſcerned when the eye comes to A, is at C when the eye is at B. Joining the points BC, he ſuppoſed the line CB to be a tube, inclined to the line BD in the angle DBC, of ſuch diameter as to admit but one particle of light. Then it was eaſy to conceive, that the particle of light at C, by which the object muſt be ſeen, when the eye, as it moves along, arrives at A, would paſs through the tube BC, if it is inclined to BD in the the angle BDC, and accompanies the eye in its motion from B to A; and that it could not come to the eye placed behind ſuch a tube, if it had any other inclination to the line BD. If, inſtead of ſuppoſing CB ſo ſmall a tube, we imagine it to be the axis of a larger; then, for the ſame reaſon, the particle of light at C would not paſs through the axis, unleſs it is inclined to BD in the angle CBD. In like manner, if the eye moved the contrary way, from D towards A, with the ſame velocity, then the tube muſt be inclined in the angle BCD. Although, therefore, the true or real place of an object is perpendicular to the line in which the eye is moving, yet the viſible place will not be ſo; ſince that, no doubt, muſt be in the direction of the tube;

Particular Explication of the Celestial Phenomena.

tube; but the difference between the true and apparent place will be *cæteris paribus*, greater or less, according to the different proportion between the velocity of light and that of the eye. So that, if we could suppose that light was propagated in an instant, then there would be no difference between the real and visible place of an object, although the eye was in motion: for in that case, AC being infinite with respect to AB, the angle ACB, the difference between the true and visible place, vanishes. But if light be propagated in time, it is evident, from the foregoing considerations, that there will be always a difference between the real and visible place of an object, unless the eye is moving either directly towards or from the object. And in all cases the sine of the difference between the real and visible place of the object will be to the sine of the visible inclination of the object to the line in which the eye is moving, as the velocity of eye is to the velocity of light.

He then shows, that if the earth revolve round the sun annually, and the velocity of light be to the velocity of the earth's motion in its orbit, as 1000 to 1, that a star really placed in the very pole of the ecliptic would, to an eye carried along with the earth, seem to change its place continually; and, neglecting the small difference on the account of the earth's diurnal revolution on its axis, would seem to describe a circle round that pole every way distant from it $3\frac{1}{2}$; so that its longitude would be varied through all the points of the ecliptic every year, but its latitude would always remain the same. Its right ascension would also change, and its declination, according to the different situation of the sun with respect to the equinoctial points, and its apparent distance from the north pole of the equator, would be 7′ less at the autumnal than at the vernal equinox.

338
Velocity of light.

By calculating exactly the quantity of abberration of the fixed stars from their place, he found that light came from the sun to us in 8′ 13″; so that its velocity is to the velocity of the earth in its orbit as 10,201 to 1.

339
Errors in the observation of small angles.

It must here be taken notice of, however, that Mr Nevil Maskelyne, in attempting to find the parallax of Sirius, with a ten-feet sector, observed that by the friction of the plummet line on the pin which suspended it, and error of 10″, 20″, and sometimes 30″, was committed. The pin was $\frac{1}{20}$ of an inch diameter; and though he reduced it to $\frac{1}{70}$ of an inch, the error still amounted to 3″. All observations, therefore, that have hitherto been made in order to discover the parallax of the fixed stars, are to be disregarded.

340
Another objection against the earth's motion answered.

It is also objected, that the sun seems to change his place daily, so as to make a tour round the stary heavens in a year. But whether the sun or earth moves, this appearance will be the same, for when the earth is in any part of the heavens, the sun will appear in the opposite. And therefore, this appearance can be no objection against the motion of the earth.

It is well known to every person who has sailed on smooth water, or been carried by a stream in a calm, that, however fast the vessel goes, he does not feel its progressive motion. The motion of the earth is incomparably more smooth and uniform than that of a ship, or any machine made and moved by human art; and therefore it is not to be imagined that we can feel its motion.

We find that the sun, and those planets on which there are visible spots, turn round their axis: for the spots move regularly over their disks (B.) From hence we may reasonably conclude, that the other planets on which we see no spots, and the earth, which is likewise a planet, have such rotations. But being incapable of leaving the earth, and viewing it at a distance, and its rotation being smooth and uniform, we can neither see it move on its axis as we do the planets, nor feel ourselves affected by its motion. Yet there is one effect of such a motion, which will enable us to judge with certainty whether the earth revolves on its axis or not. All globes which do not turn round their axis will be perfect spheres, on account of the equality of the weight of bodies on their surfaces; especially of the fluid parts. But all globes which turn on their axes will be oblate spheroids; that is, their surfaces will be higher or farther from the centre in the equatorial than in the polar regions: for as the equatorial parts move quickest, they will recede farthest from the axis of motion, and enlarge the equatorial diameter. That our earth is really of this figure, is demonstrable from the unequal vibrations of a pendulum, and the unequal lengths of degrees in different latitudes. Since then the earth is higher at the equator than at the poles, the sea, which naturally runs downward, or toward the places which are nearest the centre, would run towards the polar regions, and leave the equatorial parts dry, if the centrifugal force of these parts, by which the waters were carried thither, did not keep them from returning. The earth's equatorial diameter is 36 miles longer than its axis.

341
Argument for the earth's motion from its spheroidal figure.

342
Weight of bodies increases towards the poles.

Bodies near the poles are heavier than those towards the equator, because they are nearer the earth's centre, where the whole force of the earth's attraction is accumulated. They are also heavier, because their centrifugal force is less, on account of their diurnal motion being slower. For both these reasons, bodies carried from the poles toward the equator gradually lose their weight. Experiments prove, that a pendulum which vibrates seconds near the poles vibrates slower near the equator, which shows that it is lighter or less attracted there. To make it oscillate in the same time, it is found necessary to diminish its length. By comparing the different lengths of pendulums swinging seconds at the equator and at London, it is found that a pendulum must be $2\frac{169}{1000}$ lines shorter at the equator than at the poles. A line is a twelfth part of an inch.

If the earth turned round its axis in 84 minutes 43 seconds, the centrifugal force would be equal to the power of gravity at the equator: and all bodies there would entirely lose their weight. If the earth revolved quicker, they would all fly off and leave it,

A person on the earth can no more be sensible of its undisturbed motion on its axis, than one in the cabbin of

(B.) This, however, must be understood with some degree of limitation, as will evidently appear from what has been already said concerning the variable motion both of the spots of the sun and planets.

Particular Explication of the Celeſtial Phenomena.

of a ſhip on ſmooth water can be ſenſible of the ſhip's motion when it turns gently and uniformly round. It is therefore no argument againſt the earth's diurnal motion, that we do not feel it: nor is the apparent revolutions of the celeſtial bodies every day a proof of the reality of theſe motions; for whether we or they revolve, the appearance is the very ſame. A perſon looking through the cabin-windows of a ſhip, as ſtrongly fancies the objects on land to go round when the ſhip turns as if they were actually in motion.

343
Earth's motion proved from the celeſtial appearances from different planets.

If we could tranſlate ourſelves from planet to planet, we ſhould ſtill find that the ſtars would appear of the ſame magnitudes, and at the ſame diſtances from each other, as they do to us here; becauſe the width of the remoteſt planet's orbit bears no ſenſible proportion to the diſtance of the ſtars. But then the heavens would ſeem to revolve about very different axes; and conſequently, thoſe quieſcent points, which are our poles in the heavens, would ſeem to revolve about other points, which, though apparently in motion as ſeen from the earth, would be at reſt as ſeen from any other planet. Thus the axis of Venus, which lies at right angles to the axis of the earth, would have its motionleſs poles in two oppoſite points of the heavens lying almoſt in our equinoctial, where the motion appears quickeſt, becauſe it is ſeemingly performed in the greateſt circle: and the very poles, which are at reſt to us, have the quickeſt motion of all as ſeen from Venus. To Mars and Jupiter the heavens appear to turn round with very different velocities on the ſame axis, whoſe poles are about 23½ degrees from ours. Were we on Jupiter, we ſhould be at firſt amazed at the rapid motion of the heavens; the ſun and ſtars going round in 9 hours 56 minutes. Could we go from thence to Venus, we ſhould be as much ſurpriſed at the ſlowneſs of the heavenly motions; the ſun going but once round in 584 hours, and the ſtars in 540. And could we go from Venus to the moon, we ſhould ſee the heavens turn round with a yet ſlower motion; the ſun in 708 hours, the ſtars in 655. As it is impoſſible theſe various circumvolutions in ſuch different times, and on ſuch different axes, can be real, ſo it is unreaſonable to ſuppoſe the heavens to revolve about our earth more than it does about any other planet. When we reflect on the vaſt diſtance of the fixed ſtars, to which 190,000,000 of miles, the diameter of the earth's orbit, is but a point, we are filled with amazement at the immenſity of their diſtance. But if we try to frame an idea of the extreme rapidity with which the ſtars muſt move, if they move round the earth in 24 hours, the thought becomes ſo much too big for our imagination, that we can no more conceive it than we do infinity or eternity. If the ſun was to go round the earth in 24 hours, he muſt travel upwards of 300,000 miles in a minute: but the ſtars being at leaſt 400,000 times as far from the ſun as the ſun is from us, thoſe about the equator muſt move 400,000 times as quick. And all this to ſerve no other purpoſe than what can be as fully and much more ſimply obtained by the earth's turning round eaſtward, as on an axis, every 24 hours, cauſing thereby an apparent diurnal motion of the ſun weſtward, and bringing about the alternate returns of day and night.

344
Another objection anſwered.

As to the common objections againſt the earth's motion on its axis, they are all eaſily anſwered and ſet aſide. That it may turn without being ſeen or felt by us to do ſo, has been already ſhown. But ſome are apt to imagine, that if the earth turns eaſtward (as it certainly does if it turns at all), a ball fired perpendicularly upward in the air muſt fall conſiderably weſtward of the place it was projected from. The objection, which at firſt ſeems to have ſome weight, will be found to have none at all, when we conſider that the gun and ball partake of the earth's motion; and therefore the ball being carried forward with the air as quick as the earth and air turn, muſt fall down on the ſame place. A ſtone let fall from the top of a mainmaſt, if it meets with no obſtacle, falls on the deck as near the foot of the maſt when the ſhip ſails as when it does not. If an inverted bottle full of liquor be hung up to the ceiling of the cabin, and a ſmall hole be made in the cork to let the liquor drop through on the floor, the drops will fall juſt as far forward on the floor when the ſhip ſails as when it is at reſt. And gnats or flies can as eaſily dance among one another in a moving cabin as in a fixed chamber. As for thoſe ſcripture expreſſions which ſeem to contradict the earth's motion, this general anſwer may be made to them all, viz. It is plain from many inſtances, that the ſcriptures were never intended to inſtruct us in philoſophy or aſtronomy; and therefore on thoſe ſubjects expreſſions are not always to be be taken in the literal ſenſe, but for the moſt part as accommodated to the common apprehenſions of mankind. Men of ſenſe in all ages, when not treating of the ſciences purpoſely, have followed this method: and it would be in vain to follow any other in addreſſing ourſelves to the vulgar, or bulk of any community.

345
Diurnal motion of the earth, and different changes of the ſeaſons, illuſtrated by experiment Fig. 172.

The following experiment will give a plain idea of the diurnal or annual motions of the earth, together with the different lengths of days and nights, and all the beautiful variety of ſeaſons, depending on thoſe motions.

Take about ſeven feet of ſtrong wire, and bend it into a circular form, as a b c d, which being viewed obliquely, appears elliptical, as in the figure. Place a lighted candle on a table; and having fixed one end of a ſilk thread K to the north pole of a ſmall terreſtrial globe H, about three inches diameter, cauſe another perſon to hold the wire circle, ſo that it may be parallel to the table, and as high as the flame of the candle I, which ſhould be in or near the centre. Then having twiſted the thread as towards the left hand, that by untwiſting it may turn the globe round eaſtward, or contrary to the way that the hands of a watch move, hang the globe by the thread within this circle, almoſt contiguous to it; and as the thread untwiſts, the globe (which is enlightened half round by the candle as the earth is by the ſun) will turn round its axis, and the different places upon it will be carried through the light and dark hemiſpheres, and have the appearance of a regular ſucceſſion of days and nights, as our earth has in reality by ſuch a motion. As the globe turns, move your hand ſlowly, ſo as to carry the globe round the candle according to the order of the letters a b c d, keeping its centre even with the wire circle; and you will perceive, that the candle, being ſtill perpendicular to the equator, will enlighten the globe from pole to pole in its whole motion round the circle; and that every place on the globe goes equally through the light and the dark, as it turns round by the untwiſting

Particular Explication of the Celestial Phenomena.

ing of the thread, and therefore has a perpetual equinox. The globe thus turning round represents the earth turning round its axis; and the motion of the globe round the candle represents the earth's annual motion round the sun; and shows, that if the earth's orbit had no inclination to its axis, all the days and nights of the year would be equally long, and there would be no different seasons. Hence also it appears why the planets Mars and Jupiter have a perpetual equinox, namely, because their axes are perpendicular to the planes of their orbits, as the thread round which the globe turns in this experiment is perpendicular to the plane of the area inclosed by the wire.—But now desire the person who holds the wire to hold it obliquely in the position ABCD, raising the side ♋ just as much as he depresses the side ♑, that the flame may be still in the plane of the circle; and twisting the thread as before, that the globe may turn round its axis the same way as you carry it round the candle; that is, from west to east; let the globe down into the lowermost part of the wire circle at ♑: and if the circle be properly inclined, the candle will shine perpendicularly on the tropic of Cancer; and the frigid zone, lying within the arctic or north polar circle, will be all in the light, as in the figure: and will keep in the light let the globe turn round its axis ever so often. From the equator to the north polar circle, all the places have longer days and shorter nights; but from the equator to the south polar circle, just the reverse. The sun does not set to any part of the north frigid zone, as shown by the candle's shining on it, so that the motion of the globe can carry no place of that zone into the dark; and at the same time the south frigid zone is involved in darkness, and the turning of the globe brings none of its places into the light. If the earth were to continue in the like part of its orbit, the sun would never set to the inhabitants of the north frigid zone, nor rise to those of the south. At the equator, it would be always equal day and night; and as places are gradually more and more distant from the equator towards the arctic circle, they would have longer days and shorter nights; whilst those on the south side of the equator would have their nights longer than their days. In this case, there would be continual summer on the north side of the equator, and continual winter on the south side of it.

But as the globe turns round its axis, move your hand slowly forward, so as to carry the globe from H towards E, and the boundary of light and darkness will approach towards the north pole, and recede towards the south pole; the northern places will go through less and less of the light, and the southern places through more and more of it; showing how the northern days decrease in length and the southern days increase, whilst the globe proceeds from H to E. When the globe is at E, it is at a mean state between the lowest and highest parts of its orbit; the candle is directly over the equator, the boundary of light and darkness just reaches to both the poles, and all places on the globe go equally through the light and dark hemispheres, showing that the days and nights are then equal to all places of the earth, the poles only excepted; for the sun is then setting to the north pole and rising to the south pole.

Continue moving the globe forward, and as it goes through the quarter A, the north pole recedes still farther into the dark hemisphere, and the south pole advances more into the light, as the globe comes nearer to ♋: and when it comes there at F, the candle is directly over the tropic of Capricorn; the days are at the shortest and nights at the longest, in the northern hemisphere, all the way from the equator to the arctic circle; and the reverse in the southern hemisphere from the equator to the antarctic circle; within which circles it is dark to the north frigid zone and light to the south.

Continue both motions; and as the globe moves through the quarter B, the north pole advances towards the light, and the south pole recedes towards the dark; the days lengthen in the northern hemisphere and shorten in the southern; and when the globe comes to G, the candle will be again over the equator (as when the globe was at E), and the days and nights will again be equal as formerly; and the north pole will be just coming into the light, the south pole going out of it.

Thus we see the reason why the days lengthen and shorten from the equator to the polar circles every year; why there is sometimes no day or night for many turnings of the earth, within the polar circles; why there is but one day and one night in the whole year at the poles; and why the days and nights are equally long all the year round at the equator, which is always equally cut by the circle bounding light and darkness.

The inclination of an axis or orbit is merely relative, because we compare it with some other axis or orbit which we consider as not inclined at all. Thus, our horizon being level to us, whatever place of the earth we are upon, we consider it as having no inclination; and yet, if we travel 90 degrees from that place, we shall then have an horizon perpendicular to the former; but it will still be level to us.

346 Different seasons particularly explained.

Let us now take a view of the earth in its annual course round the sun, considering its orbit as having no inclination; and its axis as inclining $23\frac{1}{2}$ degrees from a line perpendicular to the plane of its orbit, and keeping the same oblique direction in all parts of its annual course; or, as commonly termed, keeping always parallel to itself.

Let *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, be the earth in eight different parts of its orbit, equidistant from one another; N*s* its axis, N its north pole, *s* its south pole, and S the sun nearly in the centre of the earth's orbit. As the earth goes round the sun according to the order of the letters *abcd*, &c. its axis N*s* keeps the same obliquity, and is still parallel to the line MN*s*. When the earth is at *a*, its north pole inclines towards the sun S, and brings all the northern places more into the light than at any other time of the year. But when the earth is at *e* in the opposite time of the year, the north pole declines from the sun, which occasions the northern places to be more in the dark than in the light, and the reverse at the southern places; as is evident by the figure which is taken from Dr Long's astronomy. When the earth is either at *c* or *g*, its axis inclines not either to or from the sun, but lies sidewise to him, and then the poles are in the boundary of light and darkness; and the sun, being directly over the equator, makes equal day and night at all places. Fig. 174.

When

Particular Explication of the Celeſtial Phenomena.

When the earth is at *b*, it is half-way between the ſummer ſolſtice and harveſt equinox; when it is at *d*, it is half-way from the harveſt equinox to the winter ſolſtice; at *f*, half-way from the winter ſolſtice to the ſpring equinox; and at *h*, half-way from the ſpring equinox to the ſummer ſolſtice.

From this oblique view of the earth's orbit, let us ſuppoſe ourſelves to be raiſed far above it, and placed juſt over its centre S, looking down upon it from its north pole; and as the earth's orbit differs but very little from a circle, we ſhall have its figure in ſuch a view repreſented by the circle ABCDEFG. Let us ſuppoſe this circle to be divided into 12 equal parts, called *ſigns*, having their names affixed to them; and each ſign into 30 equal parts, called *degrees*, numbered 10, 20, 30, as in the outermoſt circle of the figure, which repreſents the great ecliptic in the heavens. The earth is ſhown in eight different poſitions in this circle; and in each poſition Æ is the equator, T the tropic of Cancer, the dotted circle the parallel of London, U the arctic or north polar circle, and P the north pole, where all the meridians or hour-circles meet. As the earth goes round the ſun, the north pole keeps conſtantly towards one part of the heavens, as it keeps in the figure towards the right-hand ſide of the plate.

Fig. 177.

When the earth is at the beginning of Libra, namely on the 20th of March, in this figure the ſun S as ſeen from the earth, appears at the beginning of Aries in the oppoſite part of the heavens, the north pole is juſt coming into the light, and the ſun is vertical to the equator; which, together with the tropic of Cancer, parallel of London, and arctic circle, are all equally cut by the circle bounding light and darkneſs, coinciding with the ſix-o'clock hour-circle, and therefore the days and nights are equally long at all places: for every part of the meridian ÆTL*a* comes into the light at ſix in the morning, and, revolving with the earth according to the order of the hour-letters, goes into the dark at ſix in the evening. There are 24 meridians or hour-circles drawn on the earth in this figure, to ſhow the time of ſun-riſing and ſetting at different ſeaſons of the year.

As the earth moves in the ecliptic according to the order of the letters ABCD, &c. through the ſigns Libra, Scorpio, and Sagittarius, the north pole P comes more and more into the light; the days increaſe as the nights decreaſe in length, at all places north of the equator Æ; which is plain by viewing the earth at *b* on the 5th of May, when it is in the 15th degree of Scorpio, and the ſun as ſeen from the earth appears in the 15th degree of Taurus. For then the tropic of Cancer T is in the light from a little after five in the morning till almoſt ſeven in the evening; the parallel of London, from half an hour paſt four till half an hour paſt ſeven; the polar circle U, from three till nine; and a large track round the north pole P has day all the 24 hours, for many rotations of the earth on its axis.

When the earth comes to *c* (fig. 174.) at the beginning of Capricorn, and the ſun as ſeen from the earth appears at the beginning of Cancer, on the 21ſt of June, as in this figure, it is in the poſition C in fig. 177; and its north pole inclines towards the ſun, ſo as to bring all the north frigid zone into the light, and the northern parallels of latitude more into the light than the dark from the equator to the polar circle; and the more ſo as they are farther from the equator. The tropic of Cancer is in the light from five in the morning till ſeven at night, the parallel of London from a quarter before four till a quarter after eight; and the polar circle juſt touches the dark, ſo that the ſun has only the lower half of his diſk hid from the inhabitants on that circle for a few minutes about midnight, ſuppoſing no inequalities in the horizon, and no refractions.

A bare view of the figure is enough to ſhow, that as the earth advances from Capricorn towards Aries, and the ſun appears to move from Cancer towards Libra, the north pole recedes from the light, which cauſes the days to decreaſe and the nights to increaſe in length, till the earth comes to the beginning of Aries, and then they are equal as before; for the boundary of light and darkneſs cuts the equator and all its parallels equally, or in halves. The north pole then goes into the dark, and continues therein until the earth goes halfway round its orbit; or, from the 23d of September till the 20th of March. In the middle between theſe times, viz. on the 22d of December, the north pole is as far as it can be in the dark, which is 23½ degrees, equal to the inclination of the earth's axis from a perpendicular to its orbit: and then the northern parallels are as much in the dark as they were in the light on the 21ſt of June; the winter nights being as long as the ſummer days, and the winter days as ſhort as the ſummer nights. Here it muſt be noted, that of all that has been ſaid of the northern hemiſphere, the contrary muſt be underſtood of the ſouthern; for on different ſides of the equator the ſeaſons are contrary, becauſe, when the northern hemiſphere inclines towards the ſun, the ſouthern declines from him.

347 Why the ſun appears bigger in winter than in ſummer.

The earth's orbit being elliptical, and the ſun conſtantly keeping in its lower focus, which is 1,617,941 miles from the middle point of the longer axis, the earth comes twice ſo much, or 3,235,882 miles nearer the ſun at one time of the year than at another; for the ſun appearing under a larger angle in our winter than ſummer, proves that the earth is nearer the ſun in winter. But here this natural queſtion will ariſe, Why have we not the hotteſt weather when the earth is neareſt the ſun? In anſwer it muſt be obſerved, that the eccentricity of the earth's orbit, or 1,617,941 miles, bears no greater proportion to the earth's mean diſtance from the ſun than 17 does to 1000; and therefore this ſmall difference of diſtance cannot occaſion any great difference of heat or cold. But the principal cauſe of this difference is, that in winter the ſun's rays fall ſo obliquely upon us, that any given number of them is ſpread over a much greater portion of the earth's ſurface where we live; and therefore each point muſt then have fewer rays than in ſummer. Moreover, there comes a greater degree of cold in the long winter-nights than there can return of heat in ſo ſhort days; and on both theſe accounts the the cold muſt increaſe. But in ſummer the ſun's rays fall more perpendicularly upon us; and therefore come with greater force, and in greater numbers, on the ſame place; and by their long continuance, a much greater degree of heat it imparted by day than can fly off by night. Beſides, thoſe parts which are once heated, retain the heat for ſome time; which, with the additional heat daily imparted, makes

Particular Explication of the Celestial Phenomena.

makes it continue to increase, though the sun declines towards the south: and this is the reason why July is hotter than June, although the sun has withdrawn from the summer tropic; as we find it is generally hotter at three in the afternoon, when the sun has gone towards the west, than at noon when he is on the meridian. Likewise those places which are well cooled require time to be heated again; for the sun's rays do not heat even the surface of any body till they have been some time upon it. And therefore we find January for the most part colder than December, although the sun has withdrawn from the winter tropic, and begins to dart his beams more perpendicularly upon us. An iron bar is not heated immediately upon being in the fire, nor grows cold till some time after it has been taken out.

It has been already observed, that by the earth's motion on its axis, there is more matter accumulated all around the equatorial parts than any where else on the earth.

The sun and moon, by attracting this redundancy of matter bring the equator sooner under them in every return towards it, than if there was no such accumulation. Therefore, if the sun sets out, as from any star or other fixed point in the heavens, the moment when he is departing from the equinoctial or from either tropic, he will come to the same equinox or tropic again 20 min. 17$\frac{1}{7}$ sec. of time, or 50 seconds of a degree, before he completes his course, so as to arrive at the same fixed star or point from whence he set out. For the equinoctial points recede 50 seconds of a degree westward every year, contrary to the sun's annual progressive motion.

When the sun arrives at the same equinoctial or solstitial point, he finishes what we call the *Tropical Year;* which, by observation, is found to contain 365 days 5 hours 48 minutes 57 seconds: and when he arrives at the same fixed star again, as seen from the earth, he completes the sidereal year, which contains 365 days 6 hours 9 minutes 14$\frac{1}{2}$ seconds. The sidereal year is therefore 20 minutes 17$\frac{1}{7}$ seconds longer than the solar or tropical year, and 9 minutes 14$\frac{1}{2}$ seconds longer than the Julian or the civil year, which we state at 365 days 6 hours, so that the civil year is almost a mean between the sidereal and tropical.

As the sun describes the whole ecliptic, or 360 degrees, in a tropical year, he moves 50′ 8″ of a degree every day at a mean rate; and consequently 50″ of a degree in 20 minutes 17$\frac{1}{7}$ seconds of time: therefore he will arrive at the same equinox or solstice when he is 50″ of a degree short of the same star or fixed point in the heavens from which he set out the year before. So that, with respect to the fixed stars, the sun and equinoctial points fall back (as it were) 30 degrees in 2160 years, which will make the stars appear to have gone 30 deg. forward with respect to the signs of the ecliptic in that time: for the same signs always keep in the same points of the ecliptic, without regard to the constellations.

348 Precession of the equinoxes explained. Fig. 181.

To explain this by a figure, let the sun be in conjunction with a fixed star at S, suppose in the 30th degree of ♉, at any given time. Then, making 2160 revolutions through the ecliptic VWX, at the end of so many sidereal years, he will be found again at S: but at the end of so many Julian years, he will be found at M, short of S: and at the end of so many tropical years he will be found short of M, in the 30th deg. of Taurus at T, which has receded back from S to T in that time, by the precession of the equinoctial points ♈ Aries and ♎ Libra. The arc ST will be equal to the amount of the precession of the equinox in 2160 years, at the rate of the 50″ of a degree, or 20 minutes 17$\frac{1}{7}$ seconds of time annually; this, in so many years, makes 30 days 10$\frac{1}{2}$ hours, which is the difference between 2160 sidereal and tropical years; and the arc MT will be equal to the space moved through by the sun in 2160 times 11 min. 8 sec. or 16 days 13 hours 48 minutes, which is the difference between 2160 Julian and tropical years.

349 Anticipation of the equinoxes explained.

The anticipation of the equinoxes, and consequently of the seasons, is by no means owing to the precession of the equinoctial and solstitial points in the heavens (which can only affect the apparent motions, places, and declinations, of the fixed stars), but to the difference between the civil and solar year, which is 11 minutes 3 seconds; the civil year containing 365 days 6 hours, and the solar year 365 days 5 hours 48 minutes 57 seconds.

The above 11 minutes 3 seconds, by which the civil or Julian year exceeds the solar, amounts to 11 days in 1433 years; and so much our seasons have fallen back with respect to the days of the months, since the time of the Nicene council in A. D. 325; and therefore, in order to bring back all the fasts and festivals to the days then settled, it was requisite to suppress 11 nominal days: and, that the same seasons might be kept to the same times of the year for the future, to leave out the bissextile-day in February at the end of every century of years not divisible by 4; reckoning them only common years, as the 17th, 18th, and 19th centuries, viz. the years 1700, 1800, 1900, &c. because a day intercalated every fourth year was too much; and retaining the bissextile-day at the end of those centuries of years which are divisible by 4, as the 16th, 20th, and 24th centuries, viz. the years 1600, 2000, 2400, &c. otherwise, in length of time, the seasons should be quite reversed with regard to the months of the year; though it would have required near 23,783 years to have brought about such a total change. If the earth had made exactly 365$\frac{1}{4}$ diurnal rotations on its axis, whilst it revolved from any equinoctial or solstitial point to the same again, the civil and solar years would always have kept pace together, and the style would never have needed any alteration.

Having thus mentioned the cause of the precession of the equinoctial points in the heavens, which occasions a slow deviation of the earth's axis from its parallelism, and thereby a change of the declination of the stars from the equator, together with a slow apparent motion of the stars forward with respect to the signs of the ecliptic, we shall now explain the phenomena by a diagram.

Let NZSVL be the earth, SONA its axis produced to the starry heavens, and terminating in A, the present north pole of the heavens, which is vertical to N the north pole of the earth. Let EOQ be the equator, T♋Z the tropic of Cancer, and VT ♑ the tropic of Capicorn; VOZ the ecliptic, and BO its axis, both which are immoveable among the stars. But as the equinoctial points recede in the ecliptic, the earth's Fig. 182.

axis

Particular Explication of the Celestial Phenomena.

axis SON is in motion upon the earth's centre O, in such a manner as to describe the double cone NO*n* and SO*s*, round the axis of the ecliptic BO, in the time that the equinoctial points move quite round the ecliptic, which is 25,920 years; and in that length of time, the north pole of the earth's axis produced, describes the circle ABCDA in the starry heavens, round the pole of the ecliptic, which keeps immoveable in the centre of that circle. The earth's axis being $23\frac{1}{2}$ degrees inclined to the axis of the ecliptic, the circle ABCDA described by the north pole of the earth's axis produced to A, is 47 degrees in diameter, or double the inclination of the earth's axis. In consequence of this, the point A, which at present is the north pole of the heavens, and near to a star of the second magnitude in the tail of the constellation called the *Little Bear*, must be deserted by the earth's axis; which moving backwards a degree every 72 years, will be directed towards the star or point B in 6480 years hence; and in double of that time, or in 12,960 years, it will be directed towards the star or point C, which will then be the north pole of the heavens, although it is at present $8\frac{1}{2}$ degrees south of the zenith of London L. The present position of the equator EOQ will then be changed into *e*O*q*, the tropic of Cancer T ♋ Z; into V*t*♋, and the tropic of Capricorn VT ♑ into *t*♑ Z; as is evident by the figure. And the sun, in the same part of the heavens where he is now over the earthly tropic of Capricorn, and makes the shortest days and longest nights in the northern hemisphere, will then be over the earthly tropic of Cancer, and make the days longest and nights shortest. So that it will require 12,960 years yet more, or 25,920 from the then present time, to bring the north pole N quite round, so as to be directed toward that point of the heavens which is vertical to it at present. And then, and not till then, the same stars which at present describe the equator, tropics, and polar circles, &c. by the earth's diurnal motion, will describe them over again.

From the shifting of the equinoctial points, and with them all the signs of the ecliptic, it follows that those stars which in the infancy of astronomy were in Aries are now got into Taurus; those of Taurus into Gemini, &c. Hence likewise it is that the stars which rose or set at any particular season of the year, in the times of Hesiod, Eudoxus, Virgil, Pliny, &c. by no means answer at this time to their descriptions.

350 Of the moon.

The moon is not a planet, but only a satellite or attendant of the earth, going round the earth from change to change in 29 days 12 hours and 44 minutes, and round the sun with it every year. The moon's diameter is 2,180 miles; and her distance from the earth's centre is 240,000. She goes round her orbit in 27 days 7 hours 43 minutes, moving about 2290 miles every hour; and turns round her axis exactly in the time that she goes round the earth, which is the reason of her keeping always the same side towards us, and that her day and night taken together is as long as our lunar month.

351 Reflects the sun's light.

The moon is an opaque globe like the earth, and shines only by reflecting the light of the sun: therefore, whilst that half of her which is towards the sun is enlightened, the other half must be dark and invisible. Hence she disappears when she comes between us and the sun; because her dark side is then towards us. When she is gone a little way forward, we see a little of her enlightened side: which still increases to our view as she advances forward, until she comes to be opposite to the sun; and then her whole enlightened side is towards the earth, and she appears with a round illumined orb, which we call the *full moon*; her dark side being then turned away from the earth. From the full she seems to decrease gradually as she goes through the other half of her course; showing us less and less of her enlightened side every day, till her next change or conjunction with the sun, and then she disappears as before.

The moon has scarce any difference of seasons: her axis being almost perpendicular to the ecliptic. What is very singular, one half of her has no darkness at all; the earth constantly affording it a strong light in the sun's absence; while the other half has a fortnight's darkness and a fortnight's light by turns.

352 Earth appears a moon to our moon.

Our earth is thought to be a moon to the moon; waxing and waning regularly, but appearing 13 times as big, and affording her 13 times as much light as she does us. When she changes to us, the earth appears full to her: and when she is in her first quarter to us, the earth is in its third quarter to her; and *vice versa*.

But from one half of the moon the earth is never seen at all: from the middle of the other half, it is always seen over head; turning round almost 30 times as quick as the moon does. From the circle which limits our view of the moon, only one half of the earth's side next her is seen; the other half being hid below the horizon of all places on that circle. To her the earth seems to be the biggest body in the universe; for it appears 13 times as big as she does to us.

As the earth turns round its axis, the several continents, seas, and islands, appear to the moon's inhabitants like so many spots of different forms and brightness, moving over its surface; but much fainter at some times than others, as our clouds cover them or leave them. By these spots the Lunarians can determine the time of the earth's diurnal motion, just as we do the motion of the sun: and perhaps they measure their time by the motion of the earth's spots; for they cannot have a truer dial.

353 How the Lunar inhabitants can measure their year.

The moon's axis is so nearly perpendicular to the ecliptic, that the sun never removes sensibly from her equator; and the obliquity of her orbit, which is next to nothing as seen from the sun, cannot cause the sun to decline sensibly from her equator. Yet her inhabitants are not destitute of means for ascertaining the length of their year, though their method and ours must differ. For we can know the length of our year by the return of our equinoxes; but the Lunarians, having always equal day and night, must have recourse to another method: and we may suppose, they measure their year by observing when either of the poles of our earth begins to be enlightened and the other to disappear, which is always at our equinoxes; they being conveniently situated for observing great tracts of land about our earth's poles, which are entirely unknown to us. Hence we may conclude, that the year is of the same absolute length both to the earth and the moon, though very different as to the number of days: we having $365\frac{1}{4}$ natural days, and the Lunarians only $12\frac{7}{19}$, every day and night in the moon being as long as $29\frac{1}{2}$ on the earth.

The moon's inhabitants on the side next the earth

Particular Explication of the Celestial Phenomena.

may as easily find the longitude of their places as we can find the latitude of ours. For the earth keeping constantly, or very nearly so, over one meridian of the moon, the east or west distances of places from that meridian are as easily found as we can find our distance from the equator by the altitude of our celestial poles.

354 Longitude easily found.

As the sun can only enlighten that half of the earth which is at any moment turned towards him, and, being withdrawn from the opposite half, leaves it in darkness; so he likewise doth to the moon: only with this difference, that as the earth is surrounded by an atmosphere, we have twilight after the sun sets; but if the moon has none of her own, nor is included in that of the earth, the lunar inhabitants have an immediate transition from the brightest sun-shine to the blackest darkness. For, let t r k s w be the earth, and A, B, C, D, E, F, G, H, the moon in eight different parts of her orbit. (Fig. 183.) As the earth turns round its axis from west to east, when any place comes to t, the twilight begins there, and when it revolves from thence to r the sun S rises; when the place comes to s the sun sets, and when it comes to w the twilight ends. But as the moon turns round her axis, which is only once a month, the moment that any point of her surface comes to *r* (see the moon at G), the sun rises there without any previous warning by twilight; and when the same point comes to *s* the sun sets, and that point goes into darkness as black as at midnight.

355 Her phases explained.

The moon being an opaque spherical body (for her hills take off no more from her roundness than the inequalities on the surface of an orange takes off from its roundness), we can only see that part of the enlightened half of her which is towards the earth. And therefore, when the moon is at A, in conjunction with the sun S, her dark half is towards the earth, and she disappears, as at *a*, there being no light on that half to render it visible. When she comes to her first octant at B, or has gone an eighth part of her orbit from her conjunction, a quarter of her enlightened side is towards the earth, and she appears horned, as at *b*. When she has gone a quarter of her orbit from between the earth and sun to C, she shows us one half of her enlightened side, as at *c*, and we say she is a quarter old. At D, she is in her second octant; and by showing us more of her enlightened side she appears gibbous, as at *d*. At E, her whole enlightened side is towards the earth; and therefore she appears round, as at *e*; when we say it is full moon. In her third octant at F, part of her dark side being towards the earth, she again appears gibbous, and is on the decrease, as at *f*. At G, we see just one half of her enlightened side; and she appears half decreased, or in her third quarter, as at *g*. At H, we only see a quarter of her enlightened side, being in her fourth octant; where she appears horned, as at *h*. And at A, having completed her course from the sun to the sun again, she disappears; and we say it is new moon. Thus, in going from A to E, the moon seems continually to increase; and in going from E to A, to decrease in the same proportion; having like phases at equal distances from A to E, but as seen from the sun S she is always full.

356 Never appears perfectly round.

The moon appears not perfectly round when she is full in the highest or lowest part of her orbit, because we have not a full view of her enlightened side at that time. When full in the highest part of her orbit, a small deficiency appears on her lower edge; and the contrary when full in the lowest part of her orbit.

Particular Explication of the Celestial Phenomena.

It is plain by the figure, that when the moon changes to the earth, the earth appears full to the moon; and *vice versa*. For when the moon is at A, new to the earth, the whole enlightened side of the earth is towards the moon; and when the moon is at E, full to the earth, its dark side is towards her. Hence a new moon answers to a full earth, and a full moon to a new earth. The quarters are also reversed to each other.

357 Agreeable representation of her phases.

Between the third quarter and change, the moon is frequently visible in the forenoon, even when the sun shines; and then she affords us an opportunity of seeing a very agreeable appearance, wherever we find a globular stone above the level of the eye, as suppose on the top of a gate. For, if the sun shines on the stone, and we place ourselves so as the upper part of the stone may just seem to touch the point of the moon's lowermost horn, we shall then see the enlightened part of the stone exactly of the same shape with the moon; horned as she is, and inclined the same way to the horizon. The reason is plain: for the sun enlightens the stone the same way as he does the moon: and both being globes, when we put ourselves into the above situation, the moon and stone have the same position to our eyes; and therefore we must see as much of the illuminated part of the one as of the other.

The position of the moon's cusps, or a right line touching the points of her horns, is very differently inclined to the horizon at different hours of the same days of her age. Sometimes she stands, as it were, upright on her lower horn, and then such a line is perpendicular to the horizon: when this happens, she is in what the astronomers call *the nonagesimal degree*; which is the highest point of the ecliptic above the horizon at that time, and is 90 degrees from both sides of the horizon where it is then cut by the ecliptic. But this never happens when the moon is on the meridian, except when she is at the very beginning of Cancer or Capricorn. 358

358 Nonagesimal degree.

That the moon turns round her axis in the time that she goes round her orbit, is quite demonstrable; for, a spectator at rest, without the periphery of the moon's orbit, would see all her sides turned regularly towards him in that time. She turns round her axis from any star to the same star again in 27 days 8 hours; from the sun to the sun again in $29\frac{1}{2}$ days: the former is the length of the sidereal day, and the latter the length of her solar day. A body moving round the sun would have a solar day in every revolution, without turning on its axis; the same as if it had kept all the while at rest, and the sun moved round it: but without turning round its axis it could never have one sidereal day, because it would always keep the same side towards any given star.

If the earth had no annual motion, the moon would go round it so as to complete a lunation, a sidereal, and a solar day, all in the same time. But, because the earth goes forward in its orbit while the moon goes round the earth in her orbit, the moon must go as much more than round her orbit from change to change

in

Particular Explication of the Celestial Phenomena.

in completing a solar day, as the earth has gone forward in its orbit during that time, i. e. almost a twelfth part of a circle.

359 Delineation of her path round the sun.

If the earth had no annual motion, the moon's motion round the earth, and her track in open space, would be always the same (c). But as the earth and moon move round the sun, the moon's real path in the heavens is very different from her visible path round the earth; the latter being in a progressive circle, and the former in a curve of different degrees of concavity, which would always be the same in the same parts of the heavens, if the moon performed a complete number of lunations in a year without any fraction.

Let a nail in the end of the axle of a chariot-wheel represent the earth, and a pin in the nave the moon; if the body of the chariot be propped up so as to keep that wheel from touching the ground, and the wheel be then turned round by hand, the pin will describe a circle both round the nail and in the space it moves through. But if the props be taken away, the horses put to, and the chariot driven over a piece of ground which is circularly convex; the nail in the axle will describe a circular curve, and the pin in the nave will still describe a circle round the progressive nail in the axle, but not in the space through which it moves. In this case, the curve described by the nail will resemble in miniature as much of the earth's annual path round the sun, as it describes whilst the moon goes as often round the earth as the pin does round the nail: and the curve described by the pin will have some resemblance of the moon's path during so many lunations.

Fig. 184.

Let us now suppose that the radius of the circular curve described by the nail in the axle is to the radius of the circle which the pin in the nave describes round the axle, as 337½ to 1; (D) which is the proportion of the radius or semidiameter of the earth's orbit to that of the moon's, or of the circular curve A 1 2 3 4 5 6 7 B, &c. to the little circle *a*; and then, whilst the progressive nail describes the said curve from A to E, the pin will go once round the nail with regard to the centre of its path, and in so doing will describe the curve *a b c d e*. The former will be a true representation of the earth's path for one lunation, and the latter of the moon's for that time. Here we may set aside the inequalities of the moon's motion, and also the earth's moving round its common centre of gravity and the moon's: all which, if they were truly copied in this experiment, would not sensibly alter the figure of the paths described by the nail and pin, even though they should rub against a plain upright surface all the way, and leave their tracts visible upon it. And if the chariot was driven forward on such a convex piece of ground, so as to turn the wheel several times round, the track of the pin in the nave would still be concave towards the centre of the circular curve described by the nail in the axle; as the moon's path is always concave to the sun in the centre of the earth's annual orbit.

In this diagram, the thickest curve line ABCDE, with the numeral figures set to it, represents as much of the earth's annual orbit as it describes in 32 days from west to east; the little circles at A, B, C, D, E, show the moon's orbit in due proportion to the earth's; and the smallest curve *a* C *f* represents the line of the moon's path in the heavens for 32 days, accounted from any particular new moon at *a*. The sun is supposed to be in the centre of the curve A 1 2 3 4 5 6 7 B, &c. and the small dotted circles upon it represent the moon's orbit, of which the radius is in the same proportion to the earth's path in this scheme, that the radius of the moon's orbit in the heavens was supposed to bear to the radius of the earth's annual path round the sun; that is, as 240,000, to 81,000,000, or as 1 to 337½.

When the earth is at A, the new moon is at *a*; and in the seven days that the earth describes the curve 1 2 3 4 5 6 7, the moon in accompanying the earth describes the curve *a b*; and is in her first quarter at *b* when the earth is at B. As the earth describes the curve B 8 9 10 11 12 13 14, the moon describes the curve *b c*; and is at *c*, opposite to the sun, when the earth is at C. Whilst the earth describes the curve C 15 16 17 18 19 20 21 22, the moon describes the curve *c d*; and is in her third quarter at *d* when the earth is at D. And lastly, whilst the earth describes the curve D 23 24 25 26 27 28 29, the moon describes the curve *d e*; and is again in conjunction at *e* with the sun when the earth is at E, between the 29th and 30th day of the moon's age, accounted by the numeral figures from the new moon at A. In describing the curve *a* C *e*, the moon goes round the progressive earth as really as if she had kept in the dotted circle A, and the earth continued immoveable in the centre of that circle.

360 Her path always concave to the sun.

And thus we see, that although the moon goes round the earth in a circle, with respect to the earth's centre, her real path in the heavens is not very different in appearance from the earth's path. To show that the moon's path is concave to the sun, even at the time of change, it is carried on a little farther into a second lunation as to *f*.

Fig. 185.

The curves which Jupiter's satellites describe, are all of different sorts from the path described by our moon, although these satellites go round Jupiter as the moon goes round the earth. Let ABCDE, &c. be as much of Jupiter's orbit as he describes in 18 days from A to T; and the curves *a*, *b*, *c*, *d*, will be the paths of his four moons going round him in his progressive motion. Now let us suppose all these moons to set out from a conjunction with the sun, as seen from Jupiter at A; then, his first or nearest moon will be at *a*, his second at *b*, his third at *c*, and his fourth at *d*. At the end of 24 terrestrial hours after this con-

(c) In this place, we may consider the orbits of all the satellites as circular, with respect to their primary planets; because the eccentricities of their orbits are too small to affect the phenomena here described.

(D) The figure by which this is illustrated is borrowed from Mr Ferguson. Later observations have determined the proportions to be different: but we cannot find that any delineation of this kind hath been given by astronomers, according to the new proportions.

Particular Explication of the Celestial Phenomena.

conjunction, Jupiter has moved to B, his first moon or satellite has described the curve *a* 1, his second the curve *b* 1, his third *c* 1, and his fourth *d* 1. The next day, when Jupiter is at C, his first satellite has described the curve *a* 2, from its conjunction, his second the curve *b* 2, his third the curve *c* 2, and his fourth the curve *d* 2, and so on. The numeral figures under the capital letters show Jupiter's place in his path every day for 18 days, accounted from A to T; and the like figures set to the paths of his satellites, show where they are at the like times. The first satellite, almost under C, is stationary at + as seen from the sun, and retrograde from + to 2: at 2 it appears stationary again, and thence it moves forward until it has past 3, and is twice stationary and once retrograde between 3 and 4. The path of this satellite intersects itself every $42\frac{1}{2}$ hours, making such loops as in the diagram at 2. 3. 5. 9. 10. 12. 14. 16. 18. a little after every conjunction. The second satellite *b*, moving slower, barely crosses its path every 3 days 13 hours; as at 4. 7. 11. 14. 18, making only five loops and as many conjunctions in the time that the first makes ten. The third satellite *c* moving still slower, and having described the curve *c* 1. 2. 3. 4. 5. 6. 7. comes to an angle at 7 in conjunction with the sun at the end of 7 days 4 hours; and so goes on to describe such another curve 7. 8. 9. 10. 11. 12. 13. 14. and is at 14 in its next conjunction. The fourth satellite *d* is always progressive, making neither loops nor angles in the heavens; but comes to its next conjunction at *e* between the numeral figures 16 and 17, or in 16 days 18 hours.

The method used by Mr Ferguson to delineate the paths of these satellites was the following. Having drawn their orbits on a card, in proportion to their relative distances from Jupiter, he measured the radius of the orbit of the fourth satellite, which was an inch and $\frac{14}{100}$ parts of an inch; then multiplied this by 424 for the radius of Jupiter's orbit, because Jupiter is 424 times as far from the sun's centre as his fourth satellite is from his centre; and the product thence arising was $483\frac{36}{100}$ inches. Then taking a small cord of this length, and fixing one end of it to the floor of a long room by a nail, with a black-lead pencil at the other end, he drew the curve ABCD, &c. and set off a degree and half thereon from A to T; because Jupiter moves only so much, whilst his outermost satellite goes once round him, and somewhat more; so that this small portion of so large a circle differs but very little from a straight line. This done, he divided the space AT into 18 equal parts, as AB, BC, &c. for the daily progress of Jupiter; and each part into 24 for his hourly progress. The orbit of each satellite was also divided into as many equal parts as the satellite is hours in finishing its synodical period round Jupiter. Then drawing a right line through the centre of the card, as a diameter to all the four orbits upon it, he put the card upon the line of Jupiter's motion, and transferred it to every horary division thereon, keeping always the said diameter-line on the line of Jupiter's path; and running a pin through each horary division in the orbit of each satellite as the card was gradually transferred along the line ABCD, &c. of Jupiter's motion, he marked points for every hour through the card for the curves described by the satellites, as the primary planet in the centre of the card was carried forward on the line; and so finished the figure, by drawing the lines of each satellite's motion through those (almost innumerable) points: by which means, this is perhaps as true a figure of the paths of the satellites as can be desired. And in the same manner might those of Saturn's satellites be delineated.

It appears by the scheme, that the three first satellites come almost into the same line or position every seventh day; the first being only a little behind with the second, and the second behind with the third. But the period of the fourth satellite is so incommensurate to the periods of the other three, that it cannot be guessed at by the diagram when it would fall again into a line of conjunction with them, between Jupiter and the sun. And no wonder; for supposing them all to have been once in conjunction, it will require 3,087,043,493,260 years to bring them in conjunction again.

The moon's absolute motion from her change to her first quarter, or from *a* to *b*, is so much slower than the earth's that she falls 240,000 miles (equal to the semidiameter of her orbit) behind the earth at her first quarter in *b*, when the earth is in B; that is, she falls back a space equal to her distance from the earth. From that time her motion is gradually accelerated to her opposition or full at *c*; and then she is come up as far as the earth, having regained what she lost in her first quarter from *a* to *b*. From the full to the last quarter at *d*, her motion continues accelerated so as to be just as far before the earth at *d* as she was behind it at her first quarter in *b*. But from *d* to *e* her motion is retarded so, that she loses as much with respect to the earth as is equal to her distance from it, or to the semidiameter of her orbit; and by that means she comes to *e*, and is then in conjunction with the sun as seen from the earth at E. Hence we find, that the moon's absolute motion is slower than the earth's from her third quarter to her first, and swifter than the earth's from her first quarter to her third; her path being less curved than the earth's in the former case and more in the latter. Yet it is still bent the same way towards the sun; for if we imagine the concavity of the earth's orbit to be measured by the length of a perpendicular line G *g*, let down from the earth's place upon the straight line *b g d* at the full of the moon, and connecting the places of the earth at the end of the moon's first and third quarters, that length will be about 640,000 miles; and the moon when new only approaching nearer to the sun by 240,000 miles than the earth is, the length of the perpendicular let down from her place at that time upon the same straight line, and which shows the concavity of that part of her path, will be about 400,000 miles.

561
A difficulty concerning attraction solved.

The moon's path being concave to the sun throughout, demonstrates that her gravity towards the sun, at her conjunction, exceeds her gravity towards the earth; and if we consider that the quantity of matter in the sun is vastly greater than the quantity of matter in the earth, and that the attraction of each body diminishes as the square of the distance from it increases, we shall soon find, that the point of equal attraction between the earth and the sun, is much nearer the earth than the moon is at her change. It may then appear surprising that the moon does not abandon the earth when

Particular Explication of the Celestial Phenomena.

when she is between it and the sun, because she is considerably more attracted by the sun than by the earth at that time. But this difficulty vanishes when we consider, that a common impulse on any system of bodies affects not their relative motions; but that they will continue to attract, impel, or circulate round one another, in the same manner as if there was no such impulse. The moon is so near the earth, and both of them so far from the sun, that the attractive power of the sun may be considered as equal on both; and therefore the moon will continue to circulate round the earth in the same manner as if the sun did not attract them at all: like bodies in the cabin of a ship, which may move round or impel one another in the same manner when the ship is under sail as when it is at rest; because they are all equally affected by the common motion of the ship. If by any other cause, such as the near approach of a comet, the moon's distance from the earth should happen to be so much increased, that the difference of their gravitating forces towards the sun should exceed that of the moon towards the earth; in that case, the moon, when in conjunction, would abandon the earth, and be either drawn into the sun, or comet, or circulate round about it.

The ruggedness of the moon's surface mentioned n° 146, 147. is of great use to us, by reflecting the sun's light to all sides: for if the moon were smooth and polished like a looking-glass, or covered with water, she could never distribute the sun's light all round; only in some positions she would show us his image, no bigger than a point, but with such a lustre as would be hurtful to our eyes.

362
Why her edge appears always even.

The moon's surface being so uneven, many have wondered why her edge appears not jagged, as well as the curve bounding the light and dark places. But if we consider, that what we call the *edge* of the moon's disk is not a single line set round with mountains, in which case it would appear irregularly indented, but a large zone having many mountains lying behind one another from the observer's eye, we shall find that the mountains in some rows will be opposite to the vales in others; and so fill up the inequalities as to make her appear quite round: just as when one looks at an orange, although its roughness be very discernible on the side next the eye, especially if the sun or a candle shines obliquely upon that side, yet the line terminating the visible part still appears smooth and even.

Having said thus much of the moon's Period, Phases, Path, &c. it may not be amiss to describe, in a summary manner, the irregularities of her motion; and though these have been already treated of on the principles of the Newtonian system, yet as the subject has much embarrassed the astronomical world, it is hoped, that the following explanation of the planetary irregularities upon common mechanical principles, from Mr Nicholson's Natural Philosophy, may not appear superfluous to uninformed readers.

Philadelphia Edition, 184 et seq.

"If the sun were at rest, and the planets did not mutually gravitate towards each other, they would describe ellipses, having the sun in the common focus: But since they mutually act on the sun and on each other, it must follow that the sun is perpetually moved about the centre of gravity of all the planets; which centre is the common focus of all their orbits. This centre, by reason of the sun's very great bulk, can in no situation exceed the distance of its semidiameter from its surface. Some small irregularities arise from these mutual actions, but much less would ensue if the sun were at rest, or not subject to the reaction of the other planets. The irregularities in the motions of the primary planets are scarcely considerable enough to come under observation in the course of many revolutions; but those of the moon are very perceptible on account of its nearness to us, and from other causes. It will therefore be sufficient to explain the latter, and apply the explanation to the former, being effects of the same kind.

"If the actions of the sun upon the earth and moon were equal upon each, according to their masses, and tended to produce motions in parallel directions, their relative motions would be the same as if no such force acted upon them. But these forces vary both in quantity and direction according to the various relative situations of the earth and moon.

"Let the point S (fig. 162) represent the sun, and ADBC the orbit of the moon. Then if the moon be at the quadrature A, the distances ES and AS of the earth and moon from the sun being equal, their gravities towards S will also be equal, and may be represented by those lines ES and AS. Draw the line A parallel and equal to ES, and join LS, which will be parallel to AE. The force AS may be resolved (from *principles of compound motion*) into the two forces AL and AE; of which AL, by reason of its parallelism and equality to ES, will not disturb their relative motions or situation: but the force AE conspiring with that of gravity, will cause the moon to fall farther below the tangent of its orbit than it would have done if no such disturbing force had existed. Therefore, at or near the quadratures, the moon's gravity towards the earth is increased more than according to the regular course, and its orbit is rendered more curve.

"When the moon is at the conjunction C, the distances ES and CS not being equal, the moon's gravitation towards the sun exceeds that of the earth in the same proportion as the square of ES exceeds the square of CS. And because the excess acts contrary to the direction of the moon's gravity towards the earth, it diminishes the effect thereof, and causes the moon to fall less below the tangent of its orbit than it would if no such disturbing force existed. A like and very nearly equal effect follows, when the moon is at the opposition D, by the earth's gravitation towards the sun being greater than that of the moon; whence their mutual gravitation is diminished as in the former case. Therefore, at or near the conjunction or opposition, the moon's gravity is diminished, and its orbit rendered less curve.

"It is found that the force added to the moon's gravity at the quadratures, is to the gravity with which it would revolve about the earth in a circle, at its present mean distance, if the sun had no effect on its motion, as 1 to 190; and that the force subducted from its gravity at the conjunction or opposition is about double this quantity. The influence of the sun, then, on the whole, increases the moon's distance from the earth, and augments its periodical time: and since this influence is most considerable when the earth is nearest the sun, or in its perihelium, its periodical time must then be the greatest;" and it is so found by observation.

"To

Particular Explication of the Celestial phenomena.

"To show the effect of the sun in disturbing the moon's motion at any situation between the conjunction and one of the quadratures, suppose at M, let ES represent the earth's gravity towards the sun, draw the line MS, which continue towards G; from M set off MG, so that MG may be to ES as the square of the earth's distance ES is to the square of the moon's distance MS; and MG will represent the moon's gravity towards the sun. From M draw MF parallel and equal to ES; join FG, and draw MH parallel and equal to FG. The force MG may be resolved into MF and MH; of which MF, by reason of its parallelism and equality to ES, will not disturb the relative motions or situations of the moon and earth: MH then is the disturbing force. Draw the tangent MK to the moon's orbit, and continue the radius EM towards I; draw HI parallel to KM, and intersecting MI in I, and complete the parallelogram by drawing HK parallel to IM, and intersecting MK in K. The force MH may be resolved into MI and MK; of which MI affects the gravity, and MK the velocity, of the moon. When the force MH coincides with the tangent, that is, when the moon is 35° 16′ distant from the quadrature, the force MI which affects the gravity, vanishes; and when the force MH coincides with the radius, that is, when the moon is either in the conjunction or quadrature, the force MK vanishes. Between the quadrature and the distance of 35° 16′ from it, the line or force MH falls within the tangent, and consequently the force MI is directed towards E, and the moon's gravity is increased: but, at any greater distance from the quadrature, the line MH falls without the tangent, and the force MI is directed from E, the moon's gravity being diminished. It is evident that the force MK is always directed to some point in the line which passes through the sun and earth; therefore it will accelerate the moon's motion while it is approaching towards that line, or the conjunction, and similarly retard it as it recedes from it, or approaches towards the quadrature, by conspiring with the motion in one case, and subducting from it in the other.

"As the moon's gravity towards the sun, at the conjunction, is diminished by a quantity which is as the difference of the squares of their distances; and as this difference, on account of the very great distance of the sun, is nearly the same when the moon is at the opposition, the mutual tendency to separate, or diminution of gravity, will be very nearly the same. Whence it easily follows, that all the irregularities which have been explained as happening between the quadratures and conjunction, must, in like circumstances, take place between the quadratures and opposition.

"If the moon revolved about the earth in a circular orbit, the sun's disturbing influence being supposed not to act, then this influence being supposed to act would convert the orbit into an ellipsis. For the increase of gravity renders it more curve at the quadratures, by causing the moon to fall further below the tangent; and the diminution of gravity, as well as the increased velocity, render the orbit less curve at the conjunction and opposition, by causing the moon to fall less below the tangent in a given time. Therefore, an ellipsis would be described whose less or more convex parts would be at the quadratures, and whose longest diameter would pass through them: Consequently the moon would be farthest from the earth at the quadratures, and nearest at the conjunction and opposition. Neither is it strange that the moon should approach or come nearer to the earth at the time when its gravity is the least, since that approach is not the immediate consequence of the decrease of gravity, but of the curvity of its orbit near the quadratures; and in like manner, its recess from the earth does not arise immediately from its diminished gravity, from the velocity and direction acquired at the conjunction or opposition. But as the moon's orbit is, independent of the sun's action, an ellipsis, then effects take place only as far as circumstances permit. The moon's gravity towards the earth being thus subject to a continual change in its ratio, its orbit is of no constant form. The law of its gravity being nearly in the inverse proportion of the squares of the distances, its orbit is nearly a quiescent ellipsis; but the deviation from this law occasions its apsides to move direct or retrograde, according as those deviations are in defect or in excess. Astronomers, to reduce the motion of the apsides to computation, suppose the revolving body to move in an ellipsis, whose transverse diameter, or line of the apsides, revolves at the same time about the focus of the orbit. When the moon is in the conjunction or opposition, the sun subducts from its gravity, and that the more the greater its distance is from the earth; so that its gravity follows a greater proportion than the inverted ratio of the square of the distance, and consequently the apsides of its orbit must then move in consequentia or direct. In the quadratures the sun adds to the moon's gravity; and that the more the greater its distance is from the earth: so that its gravity follows a less proportion than the inverted ratio of the square of her distance, and consequently the apsides of its orbit must then move in antecedentia or retrograde. But because the action of the sun subducts more from the moon's gravity in the conjunction and opposition than it adds to it in the quadratures, the direct motion exceeds the retrograde, and at the end of each revolution the apsides are found to be advanced according to the order of the signs.

"If the plane of the moon's orbit coincided with that of the ecliptic, these would be the only irregularities arising from the sun's action; but because it is inclined to the plane of the ecliptic in an angle of about 5 degrees, the whole disturbing force does not act upon the moon's motion in its orbit; a small part of the force being employed to draw it out of the plane of the orbit into that of the ecliptic.

"Of the forces MK and MI (fig. 162.) which disturb the moon's motion, MI, being always in the direction of the radius, can have no effect in drawing it out of the plane of its orbit: and if the force MK really coincided with the tangent, as we, neglecting the small deviation arising from the obliquity of the moon's orbit, have hitherto supposed, it is evident that its only effect would be that of accelerating or retarding the moon's motion, without affecting the plane of its orbit: But because that force is always directed to some point in the line which passes through the centres of the sun and earth, it is evident that it can coincide with the tangent only when that line is in the plane of the moon's orbit; that is to say, when the nodes are in the conjunction and opposition. At all other times

times the force MK must decline to the northward or southward of the tangent, and, compounding itself with the moon's motion, will not only accelerate or retard it, according to the circumstances before explained, but will likewise alter its direction, deflecting it towards that side of the orbit on which the point, the force MK, tends to is situated. This deflection causes the moon to arrive at the ecliptic either sooner or later than it would otherwise have done; or, in other words, it occasions the intersection of its orbit with the ecliptic to happen in a point of the ecliptic, either nearer to or farther from the moon, than that in which it would have happened if such deflection had not taken place.

"To illustrate this, let the elliptical projection COQN (fig. 163.) represent a circle in the plane of the ecliptic, MOPN the moon's orbit intersecting the ecliptic in the nodes N and O. Suppose the moon to be in the northern part of its orbit at M and moving towards the node O; the disturbing force MK, which tends towards a point in the line SE to the southward of the tangent MT, will be compounded with the tangental force, and will cause the moon to describe the arc Mm, to which MR is tangent, instead of the arc MO; whence the node O is said to be moved to m. In this manner the motion of the nodes may be explained for any other situation.

"This motion evidently depends on a twofold circumstance; namely, the quantity and direction of the force MK. If the force MK be increased, its direction remaining the same, it will deflect the curve of the moon's path from its orbit in a greater degree; and, on the other hand, if its direction be altered so as to approach nearer to a right angle with the tangent, it will cause a greater deflection, though its quantity remain the same. When the moon is in the quadratures, the force MK vanishes, consequently the nodes are then stationary. When the moon is at the octant, or 45 degrees from the quadrature, the force MK is the greatest of all; and therefore the motion of the nodes is then most considerable, as far as it depends on the quantity of MK: But the direction of this force in like circumstances depends on the situation of the line of the nodes. If the line of the nodes coincides with the line passing through the centres of the sun and earth, the force MK coincides with the tangent of the moon's orbit, and the nodes are stationary; and the farther the node is removed from that line, the farther is that line removed from the plane of the moon's orbit, till the line of the nodes is in the quadratures; at which time the line passing through the centres of the sun and earth, makes an angle with the plane of the moon's orbit equal to its whole inclination, or 5 degrees; consequently the angle formed between MK and the tangent, in like circumstances, is then greatest, MK being directed to a point in a line which is further from the plane of the moon's orbit than at any other time, and of course the motion of the nodes is then most considerable.

"To determine the quantity and direction of the motion of the nodes, suppose the moon in the quarter preceding the conjunction, and the node towards which it is moving to be between it and the conjunction; in this case its motion is directed to a point in the ecliptic which is less distant than the point towards which the force MK is directed: the force MK then compounding with the moon's motion, causes it to be directed to a point more distant than it would otherwise have been; that is to say, the node towards which the moon moves is moved towards the conjunction. When the moon has passed the node, its course is directed to the other node, which is a point in the ecliptic more distant than the point to which MK is directed, and therefore MK compounding with its motion causes it to be directed to a point less distant than it would otherwise have been; so that in this case, likewise, the ensuing node is moved towards the conjunction. After the moon has passed the conjunction, the force MK still continues to deflect its course towards the ecliptic; and consequently the motion of the node is the same way till its arrival at the quadrature. Suppose, again, the moon to be at the conjunction, and the node towards which it is moving to be between it and the quadrature; in this case, the force MK compounding with the moon's motion, causes it to move towards a point in the ecliptic less distant than it would otherwise have done; so that the ensuing node is brought towards the conjunction.

"When the moon has passed the node, the force MK still continuing to deflect its course towards the same side of its orbit, produces a contrary effect; namely, as it before occasioned it to converge to the ecliptic, so it now causes it to diverge from it; and its motion, in consequence, tends continually to a point in the ecliptic more distant than it would otherwise have done; the ensuing node in this instance being also brought towards the conjunction.

"As the disturbing forces are very nearly the same in the half of the moon's orbit which is farthest from the sun, this last paragraph is true when it moves in that part of its orbit, if the word *opposition* be every where inserted instead of the word *conjunction*.

"Whence it is easy to deduce this general rule: That when the moon is in the part of its orbit nearest the sun, the node towards which it is moving is made to move towards the conjunction; and when it is in the part of its orbit farthest from the sun, the node towards which it is moving is made to move towards the opposition.

"Suppose the moon at Q (fig. 176.), or the quadrature preceding the conjunction, then the ensuing node, if at 90° distance, or at the conjunction C, will be stationary (as before observed); but if it be at a greater or less distance it will be brought towards C. Thus, if the nodes be in the position MN, the ensuing node M, being at a less distance from Q than 90°, will move towards C, or direct, while the moon moves through the arc QM; after which N becomes the ensuing node and likewise moves towards the conjunction C, or retrograde during the moon's motion through the arc MR; and because the arc MR exceeds QM, the retrograde motion exceeds the direct. Again, if the nodes be in the position *nm*, the ensuing node *n* being at a greater distance from Q than 90°, will move towards C, or retrograde during the moon's motion through the arc Q*n*; after which the node *m* becomes the ensuing node, and likewise moves towards the conjunction C, or direct, during the moon's motion through the arc *n*R; and because the arc Q*n* exceeds NR, the retrograde motion here also exceeds the

Particular Explication of the Celestial Phenomena.

the direct. If the nodes be in the quadratures QR, the ensuing node R removes towards C, or retrograde, during the moon's motion through the arc QR, or almost the whole semiorbit. The same may be shown in the other half of the orbit ROQ with respect to the opposition O; and therefore in every revolution of the moon, the retrograde motion of the nodes exceeds the direct; and, on the whole, the nodes are carried round contrary to the order of the signs.

"The line of the conjunction is by the earth's annual motion brought into every possible situation with respect to the nodes in the course of a year, independent of their own proper motion; which last occasions the change of situation to be performed in about nineteen days less.

"The inclination of the moon's orbit being the angle which its course makes with the plane of the ecliptic, it is evident from what has been said, that this angle is almost continually changing. Suppose the line of the nodes, by its retrograde motion, to leave the conjunction C (fig. 175.) and become in the second and fourth quarters as in the position MN, and the moon to move from the node M to the node N; then, because the ensuing node N moves towards the conjunction C, while the moon is in the nearer half of its orbit, the moon's course must be continually more and more inflected towards the ecliptic till its arrival at R. This inflection in the first 90°, or MA from M, prevents its diverging so much from the ecliptic, as it would otherwise have done; that is to say, it diminishes the angle of the moon's inclination. From A to R its course begins to converge towards the ecliptic; and this convergence is increased by the inflection which, in the preceding 90°, prevented its divergence: in the arc AR, then, their inclination is increased. During the moon's motion from R to N, the node is moved towards the opposition O, and consequently the angle of its course to N, is rendered less than it would have been if the node has not moved; or, in other words, the inclination is diminished. And because the arc MA added to the arc RN is greater than the arc AR, the inclination at the subsequent node is less than at the precedent node; and the same may be shown in the other half revolution NQM.

"Therefore, while the nodes are moving from the conjunction and opposition to the quadratures, the inclination of the moon's orbit on the whole diminishes in every revolution till they arrive in the quadratures, at which time it is least of all. When the line of the nodes has passed the quadratures, and is in the first and third quarters, as in the position *mn*, it is easily shown by the same kind of argument, that the inclination is increased while the moon passes from *m* to Q, then diminishes for the remainder of the first 90°, or Q*a*, and is afterwards increased for the other 90°, or *an*; and the same may be proved for the other half revolution *n*R*m*. Consequently, while the nodes are moving from the quadratures to the conjunction and opposition, the inclination is increased by the same degrees as it before was diminished, till they arrive at the conjunction and opposition; at which time it returns to its first quantity, being then greatest of all.

"The line of the nodes in the course of one entire revolution with respect to the sun, is twice in the quadratures and twice in the conjunction and opposition. Therefore the inclination of the moon's orbit to the ecliptic is diminished and increased by turns twice in every revolution of the nodes.

"All the irregularities of the moon's motion are a little greater when in the half of its orbit nearest the sun, than when it is in the other half; the chief reason of which is, that the difference between the squares of the moon's and earth's distances from the sun is greater in proportion to the squares themselves, in the former than in the latter case at equal elongations from the quadrature; and consequently the disturbing forces must be more considerable.

"Although the moon in reality revolves about the common centre of gravity between her and the earth, and not about the earth itself, and consequently their motions and irregularities are similar, and not confined to the moon alone; yet it may be easily conceived, that the conclusions are not affected in any degree that may be here regarded, when, for the sake of conciseness, we suppose one of the two bodies to be quiescent, and the other to revolve about it.

"Irregularities of the same kind take place among the primary planets, by their mutual actions on each other; but the quantities are not considerable. Hence the apsides of the planets are found to move in consequentia, but so very slowly that some have doubted whether they move at all. The motions of the aphelia of Saturn, Jupiter, Mars, the Earth, Venus, and Mercury, as deduced from the comparison of distant observations, are respectively 2° 30′, 1° 43′ 20″, 1° 51′ 40″, 1° 49′ 10″, 4° 10′, 1° 57′ 40″, in a century.

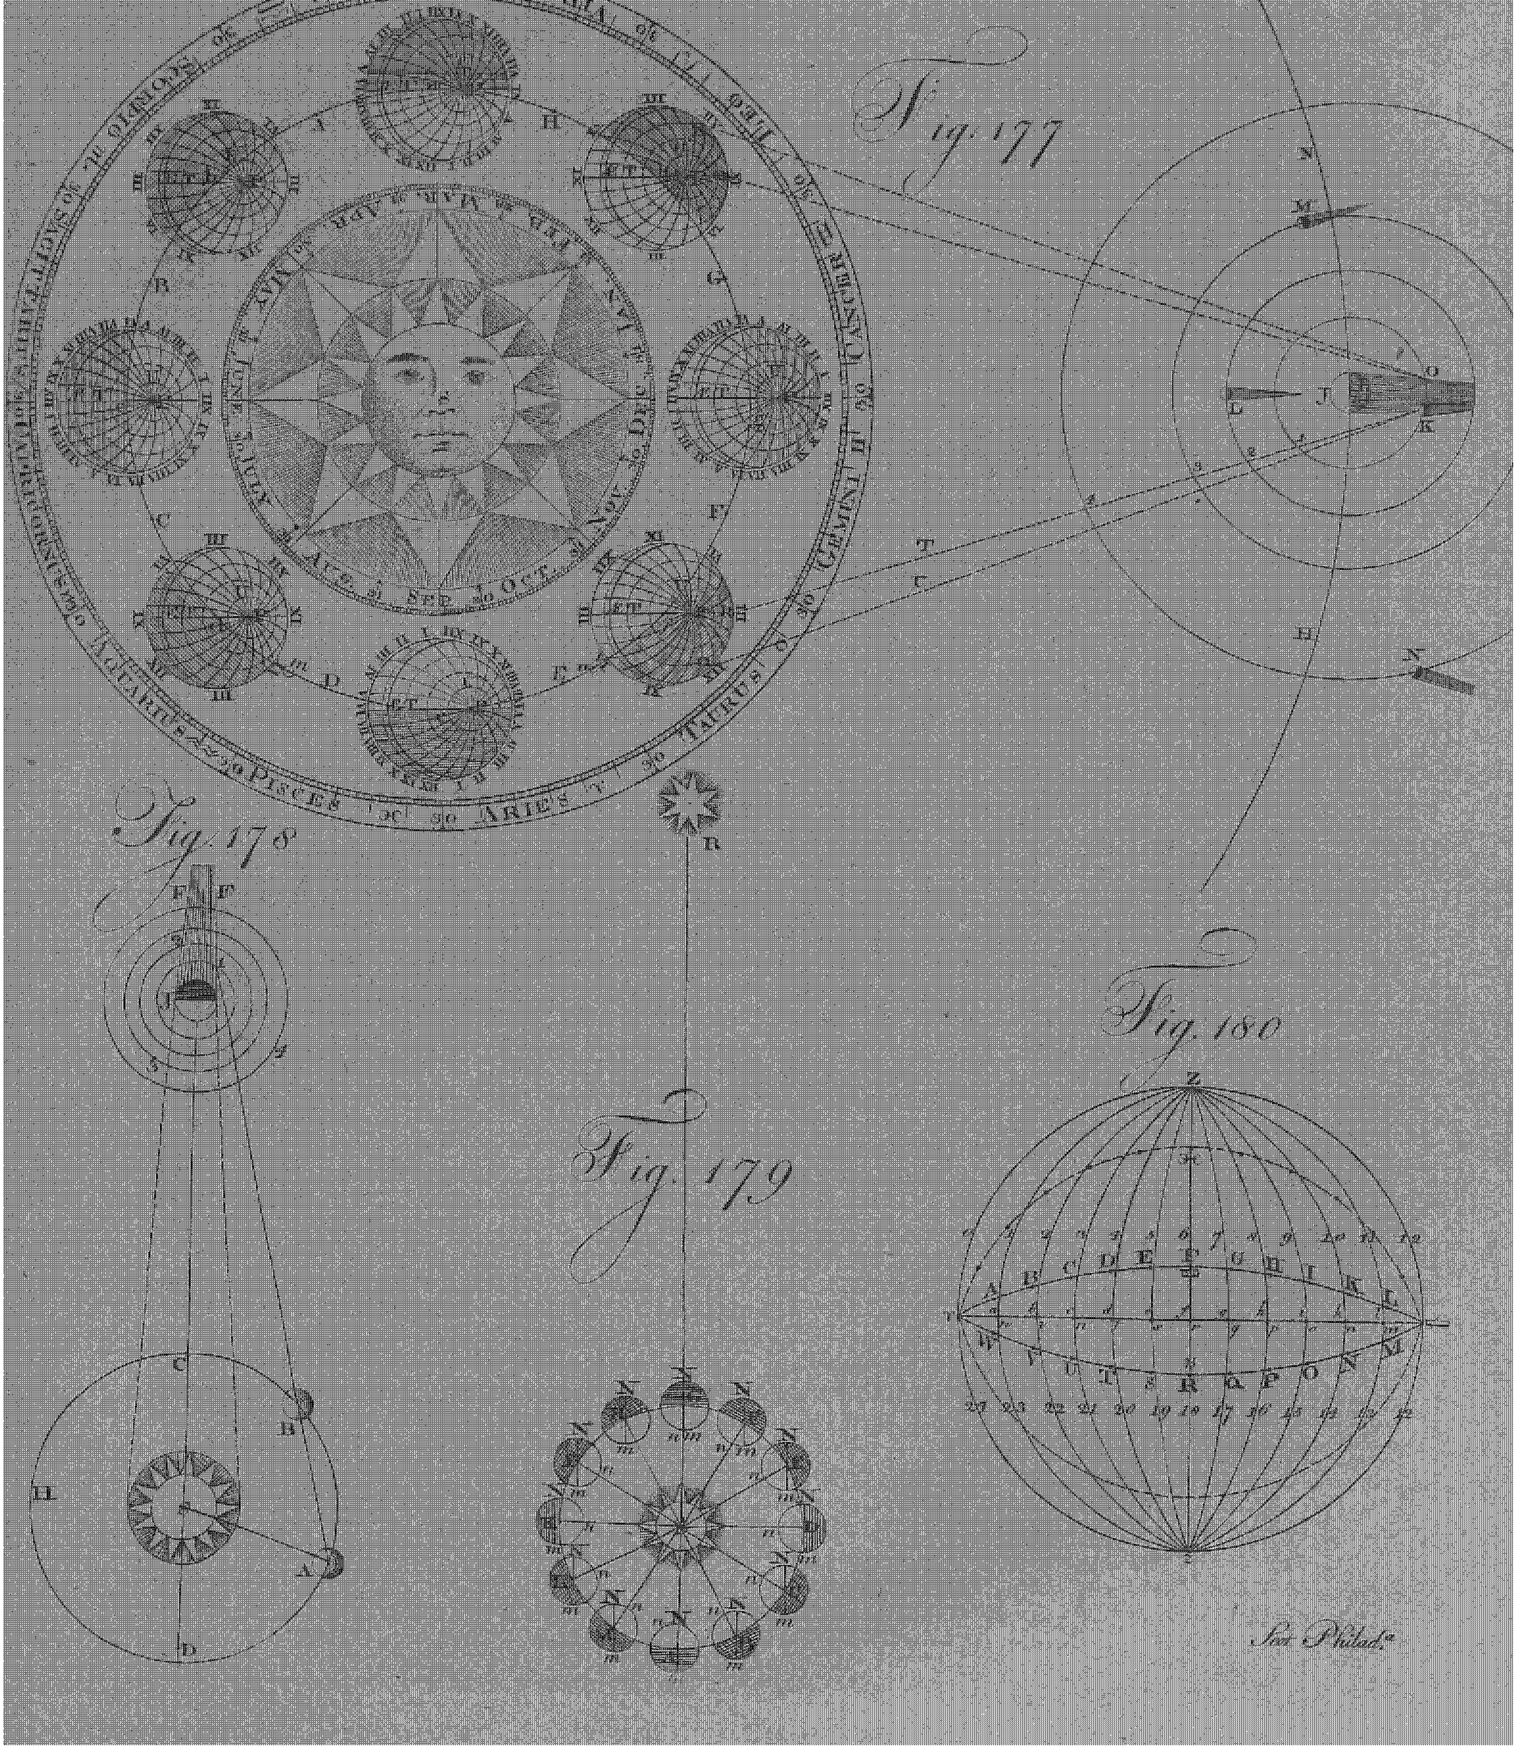
"The actions of the inferior planets on each other are very minute, on account of the smallness of their bulks; but those of Jupiter and Saturn are not altogether insensible. When Jupiter is between the Sun and Saturn, its whole attraction acts upon the latter and increases the gravity of that planet towards the sun. This is found by comparing the respective masses of Jupiter and the Sun; and the respective squares of their distances from Saturn, to be equal to $\frac{1}{211}$ of the Sun's action upon Saturn. That planet, on the other hand, at the conjunction, acts upon Jupiter and the Sun in the same direction; and therefore disturbs their relative position only so far as its actions on each are not equal. The difference of these actions is found, by the same principles, to be $\frac{1}{1523}$ of Jupiter's whole gravity."

Sect. VI. *Of the Ebbing and Flowing of the Sea, and the Phenomena of the Harvest and Horizontal Moon.*

THE cause of the tides was discovered by Kepler, who, in his *Introduction to the Physic of the Heavens*, thus explains it: "The orb of the attracting power, which is in the moon, is extended as far as the earth; and draws the waters under the torrid zone, acting upon places where it is vertical, insensibly on confined seas and bays, but sensibly on the ocean whose beds are large and where the waters have the liberty of reciprocation, that is, of rising and falling." And in the 70th page of his *Lunar Astronomy*—"But the cause of the tides of the sea appears to be the bodies of the sun and moon drawing the waters of the sea." This hint being given, the immortal Sir Isaac Newton improved it,

336 Cause of the tides discovered by Kepler.

ASTRONOMY Plate LXXIX



Ebbing and flowing of the Sea.

and wrote so amply on the subject, as to make the theory of the tides in a manner quite his own, by discovering the cause of their rising on the side of the earth opposite to the moon. For Kepler believed that the presence of the moon occasioned an impulse which caused another in her absence.

It has been already observed, that the power of gravity diminishes as the square of the distance increases; and therefore the waters at Z on the side of the earth ABCDEFGH next the moon M are more attracted than the central parts of the earth O by the moon, and the central parts are more attracted by her than the waters on the opposite side of the earth at *n*: and therefore the distance between the earth's centre and the waters on its surface under and opposite to the moon will be increased. For, let there be three bodies at H, O, and D: if they are all equally attracted by the body M, they will all move equally fast toward it, their mutual distances from each other continuing the same. If the attraction of M is unequal, then that body which is most strongly attracted will move fastest, and this will increase its distance from the other body. Therefore, by the law of gravitation, M will attract H more strongly than it does O, by which the distance between H and O will be increased; and a spectator on O will perceive H rising higher toward Z. In like manner, O being more strongly attracted than D, it will move farther towards M than D does: consequently, the distance between O and D will be increased; and a spectator on O, not perceiving his own motion, will see D receding farther from him towards *n*: all effects and appearances being the same, whether D recedes from O, or O from D.

Fig. 189.

Suppose now there is a number of bodies, as A, B, C, D, E, F, G, H, placed round O, so as to form a flexible or fluid ring: then, as the whole is attracted towards M, the parts at H and D will have their distance from O increased; whilst the parts at B and F being nearly at the same distance from M as O is, these parts will not recede from one another; but rather, by the oblique attraction of M, they will approach nearer to O. Hence, the fluid ring will form itself into an ellipse ZIBL*n*KFNZ, whose longer axis *n* OZ produced will pass through M, and its shorter axis BOF will terminate in B and F. Let the ring be filled with fluid particles, so as to form a sphere round O; then, as the whole moves towards M, the fluid sphere being lengthened at Z and *n*, will assume an oblong or oval form. If M is the moon, O the earth's centre, ABCDEFGH the sea covering the earth's surface, it is evident, by the above reasoning, that whilst the earth by its gravity falls toward the moon, the water directly below her at B will swell and rise gradually towards her, also the water at D will recede from the centre [strictly speaking, the centre recedes from D], and rise on the opposite side of the earth; whilst the water at B and F is depressed, and falls below the former level. Hence as the earth turns round its axis from the moon to the moon again in $24\frac{3}{4}$ hours, there will be two tides of flood and two of ebb in that time, as we find by experience.

364 Why the tides are high at full moon.

As this explanation of the ebbing and flowing of the sea is deduced from the earth's constantly falling towards the moon by the power of gravity, some may find a difficulty in conceiving how this is possible, when the moon is full, or in opposition to the sun; since the earth revolves about the sun, and must continually fall towards it, and therefore cannot fall contrary ways at the same time: or if the earth is constantly falling towards the moon, they must come together at last. To remove this difficulty, let it be considered, that it is not the centre of the earth that describes the annual orbit round the sun, but the (E) common centre of gravity of the earth and moon together: and that whilst the earth is moving round the sun, it also describes a circle round that centre of gravity; going as many times round it in one revolution about the sun as there are lunations or courses of the moon round the earth in a year: and therefore the earth is constantly falling towards the moon from a tangent to the circle it describes round the said common centre of gravity. Let M be the moon, TW part of the moon's orbit, and C the centre of gravity of the earth and moon; whilst the moon goes round her orbit, the centre of the earth describes the circle *d g e* round C, to which circle *g a k* is a tangent; and therefore when the moon has gone from M to a little past W, the earth has moved from *g* to *e*; and in that time has fallen towards the moon, from the tangent at *a* to *e*: and so on, round the whole circle. Fig. 190.

365 Influence of the sun in raising tides.

The sun's influence in raising the tides is but small in comparison of the moon's; for though the earth's diameter bears a considerable proportion to its distance from the moon, it is next to nothing when compared to its distance from the sun. And therefore the difference of the sun's attraction on the sides of the earth under and opposite to him, is much less than the difference of the moon's attraction on the sides of the earth under and opposite to her; and therefore the moon must raise the tides much higher than they can be raised by the sun.

366 Why they are not highest when the moon is in the meridian.

On this theory, the tides ought to be highest directly under and opposite to the moon; that is, when the moon is due north and south. But we find, that in open seas, where the water flows freely, the Moon M is generally past the north and south meridian, as at *p*, when it is high water at Z and at *n*. The reason is obvious: for though the moon's attraction was to cease altogether when she was past the meridian, yet the motion of ascent communicated to the water before that time would make it continue to rise for some time after; much more must it do so when the attraction is only diminished; as a little impulse given to a moving ball will cause it still to move farther than otherwise it could

(E) This centre is as much nearer the earth's centre than the moon's as the earth is heavier, or contains a greater quantity of matter than the moon, namely, about 40 times. If both bodies were suspended on it, they would hang *in æquilibrio*. So that dividing 240,000 miles, the moon's distance from the earth's centre, by 40, the excess of the earth's weight above the moon's the quotient will be 6000 miles, which is the distance of the common centre of gravity of the earth and moon from the earth's centre.

Ebbing and flowing of the Sea.

could have done; and as experience shows, that the day is hotter about three in the afternoon, than when the sun is on the meridian, because of the increase made to the heat already imparted.

The tides answer not always to the same distance of the moon from the meridian at the same places; but are variously affected by the action of the sun, which brings them on sooner when the moon is in her first and third quarters, and keeps them back later when she is in her second and fourth: because, in the former case, the tide raised by the sun alone would be earlier than the tide raised by the moon; and, in the latter case, later.

The moon goes round the earth in an elliptic orbit; and therefore, in every lunar month, she approaches nearer to the earth than her mean distance, and recedes farther from it. When she is nearest, she attracts strongest, and so raises the tides most; the contrary happens when she is farthest, because of her weaker attraction. When both luminaries are in the equator, and the moon in perigee, or at her least distance from the earth, she raises the tides highest of all, especially at her conjunction and opposition; both because the equatorial parts have the greatest centrifugal force from their describing the largest circle, and from the concurring actions of the sun and moon. At the change, the attractive forces of the sun and moon being united, they diminish the gravity of the waters under the moon, and their gravity on the opposite side is diminished by means of a greater centrifugal force. At the full, whilst the moon raises the tide under and opposite to her, the sun, acting in the same line, raises the tide under and opposite to him; whence their conjoint effect is the same as at the change; and, in both cases, occasion what we call the *Spring Tides*. But at the quarters the sun's action on the waters at O and H diminishes the effect of the moon's action on the water at Z and N; so that they rise a little under and opposite to the sun at O and H, and fall as much under and opposite to the moon at Z and N; making what we call the *Neap Tides*, because the sun and moon then act cross-wise to each other. But these tides happen not till some time after; because in this, as in other cases, the actions do not produce the greatest effect when they are at the strongest, but some time afterwards.

The sun, being nearer the earth in winter than in summer, is of course nearer to it in February and October than in March and September; and therefore the greatest tides happen not till some time after the autumnal equinox, and return a little before the vernal.

The sea, being thus put into motion, would continue to ebb and flow for several times, even though the sun and moon were annihilated, or their influence should cease; as, if a bason of water were agitated, the water would continue to move for some time after the bason was left to stand still; or like a pendulum, which, having been put in motion by the hand, continues to make several vibrations without any new impulse.

When the moon is in the equator, the tides are equally high in both parts of the lunar day, or time of the moon's revolving from the meridian to the meridian again, which is 24 hours 50 minutes. But as the moon declines from the equator towards either pole, the tides are alternately higher and lower at places having north or south latitude. For one of the highest elevations, which is that under the moon, follows her towards the pole to which she is nearest, and the other declines towards the opposite pole; each elevation describing parallels as far distant from the equator, on opposite sides, as the moon declines from it to either side; and consequently the parallels described by these elevations of the water are twice as many degrees from one another as the moon is from the equator; increasing their distance as the moon increases her declination, till it be at the greatest, when the said parallels are, at a mean state, 47 degrees from one another: and on that day, the tides are most unequal in their heights. As the moon returns towards the equator, the parallels described by the opposite elevations approach towards each other, until the moon comes to the equator, and then they coincide. As the moon declines towards the opposite pole, at equal distances, each elevation describes the same parallel in the other part of the lunar day, which its opposite elevation described before. Whilst the moon has north declination, the greatest tides in the northern hemisphere are when she is above the horizon; and the reverse whilst her declination is south. Let NESQ be the earth, NSC its axis, EQ the equator, T ♋ the tropic of Cancer, *t* ♑ the tropic of Capricorn, *a b* the arctic circle, *c d* the antarctic, N the north pole, S the south pole, M the moon, F and G the two eminences of water, whose lowest parts are at *a* and *d*, at N and S, and at *b* and *c*, always 90 degrees from the highest. Now, when the moon is in her greatest north declination at M, the highest elevation G under her is on the tropic of Cancer T ♋, and the opposite elevation F on the tropic of Capricorn *t* ♑; and these two elevations describe the tropics by the earth's diurnal rotation. All places in the northern hemisphere ENQ have the highest tides when they come into the position *b* ♋ Q, under the moon: and the lowest tides when the earth's diurnal rotation carries them into the position *a* TE, on the side opposite to the moon; the reverse happens at the same time in the southern hemisphere ESQ, as is evident to sight. The axis of the tides *a* C *d* has now its poles *a* and *d* (being always 90 degrees from the highest elevations) in the arctic and antarctic circles; and therefore it is plain, that at these circles there is but one tide of flood, and one of ebb, in the lunar day. For, when the point *a* revolves half round to *b*, in 12 lunar hours, it has a tide of flood; but when it comes to the same point *a* again in 12 hours more, it has the lowest ebb. In seven days afterward, the moon M comes to the equinoctial circle, and is over the equator EQ, when both elevations describe the equator; and in both hemispheres, at equal distances from the equator, the tides are equally high in both parts of the lunar day. The whole phenomena being reversed, when the moon has south declination, to what they were when her declination was north, require no farther description. Fig. 192, 193, 194.

In the three last-mentioned figures, the earth is orthographically projected on the plane of the meridian; but in order to describe a particular phenomenon, we now project it on the plane of the ecliptic. Let HZON be the earth and sea, FED the equator, T the tropic of Cancer, C the arctic circle, P the north pole, and the curves, 1, 2, 3, &c. 24 meridians or Fig. 191.

Ebbing and flowing of the Sea.

hour-circles, intersecting each other in the poles; AGM is the moon's orbit, S the sun, M the moon, Z the water elevated under the moon, and N the opposite equal elevation. As the lowest parts of the water are always 90 degrees from the highest, when the moon is in either of the tropics (as at M), the elevation Z is on the tropic of Capricorn, and the opposite elevation N on the tropic of Cancer; the low-water circle HCO touches the polar circles at C; and the high-water circle ETP6 goes over the poles at P, and divides every parallel of latitude into two equal segments. In this case, the tides upon every parallel are alternately higher and lower; but they return in equal times: the point T, for example, on the tropic of Cancer (where the depth of the tide is represented by the breadth of the dark shade), has a shallower tide of flood at T than when it revolves half round from thence to 6, according to the order of the numeral figures; but it revolves as soon from 6 to T as it did from T to 6. When the moon is in the equinoctial, the elevations Z and N are transferred to the equator at O and H, and the high and low-water circles are got into each other's former places; in which case the tides return in unequal times, but are equally high in both parts of the lunar day: for a place at I (under D) revolving as formerly, goes sooner from I to II (under F) than from II to I, because the parallel it describes is cut into unequal segments by the high water circle HCO: but the points I and II being equidistant from the pole of the tides at C, which is directly under the pole of the moon's orbit MGA, the elevations are equally high in both parts of the day.

367 Tides turn on the axis of the moon's orbit.

And thus it appears, that as the tides are governed by the moon, they must turn on the axis of the moon's orbit, which is inclined $23\frac{1}{2}$ degrees to the earth's axis at a mean state: and therefore the poles of the tides must be so many degrees from the poles of the earth, or in opposite points of the polar circles, going round these circles in every lunar day. It is true, that according to fig. 194. when the moon is vertical to the equator ECQ, the poles of the tides seem to fall in with the poles of the world N and S: but when we consider that FGH is under the moon's orbit, it will appear, that when the moon is over H, in the tropic of Capricorn, the north pole of the tides (which can be no more than 90 degrees from under the moon) must be at C in the arctic circle, not at P the north pole of the earth; and as the moon ascends from H to G in her orbit, the north pole of the tides must shift from *c* to *a* in the arctic circle, and the south poles as much in the antarctic.

It is not to be doubted, but that the earth's quick rotation brings the poles of the tides nearer to the poles of the world, than they would be if the earth were at rest and the moon revolved about it only once a month; for otherwise the tides would be more unequal in their heights and times of their return, than we find they are. But how near the earth's rotation may bring the poles of its axis and those of the tides together, or how far the preceding tides may affect those which follow, so as to make them keep up nearly to the same heights and times of ebbing and flowing, is a problem more fit to be solved by observation than by theory.

Those who have opportunity to make observations, and choose to satisfy themselves whether the tides are really affected in the above manner by the different positions of the moon, especially as to the unequal times of their returns, may take this general rule for knowing when they ought to be so affected. When the earth's axis inclines to the moon, the northern tides, if not retarded in their passage through shoals and channels, nor affected by the winds, ought to be greatest when the moon is above the horizon, least when she is below it; and quite the reverse when the earth's axis declines from her: but in both cases, at equal intervals of time. When the earth's axis inclines sidewise to the moon, both tides are equally high, but they happen at unequal intervals of time. In every lunation the earth's axis inclines once to the moon, once from her, and twice sidewise to her, as it does to the sun every year; because the moon goes round the ecliptic every month, and the sun but once in a year. In summer, the earth's axis inclines towards the moon when new; and therefore the day-tides in the north ought to be highest, and night-tides lowest, about the change: at the full, the reverse. At the quarters, they ought to be equally high, but unequal in their returns; because the earth's axis then inclines sidewise to the moon. In winter, the phenomena are the same at full moon as in summer at new. In autumn, the earth's axis inclines sidewise to the moon when new and full; therefore, the tides ought to be equally high and uneven in their returns at these times. At the first quarter, the tides of flood should be least when the moon is above the horizon, greatest when she is below it: and the reverse at her third quarter. In spring, the phenomena of the first quarter answer to those of the third quarter in autumn; and *vice versa*. The nearer any time is to either of these seasons, the more the tides partake of the phenomena of these seasons; and in the middle between any two of them the tides are at a mean state between those of both.

In open seas, the tides rise but to very small heights in proportion to what they do in wide-mouthed rivers, opening in the direction of the stream of tide. For in channels growing narrower gradually, the water is accumulated by the opposition of the contracting bank: like a gentle wind, little felt on an open plane, but strong and brisk in a street; especially if the wider end of the street be next the plain, and in the way of the wind.

268 Irregularities of tides accounted for.

The tides are so retarded in their passage thro' different shoals and channels, and otherwise so variously affected by striking against capes and headlands, that to different places they happen at all distances of the moon from the meridian, consequently at all hours of the lunar day. The tide propagated by the moon in the German ocean, when she is three hours past the meridian, takes 12 hours to come from thence to London bridge; where it arrives by the time that a new tide is raised in the ocean. And therefore, when the moon has north declination, and we should expect the tide at London to be greatest when the moon is above the horizon, we find it is least; and the contrary when she has south declination. At several places it is high-water three hours before the moon comes to the meridian; but that tide which the moon pushes as it were before her, is only the tide opposite to that which was raised by her when she was nine hours past the opposite meridian.

There are no tides in lakes, because they are generally

Ebbing and flowing of the Sea.

rally so small, that when the moon is vertical she attracts every part of them alike, and therefore by rendering all the water equally light, no part of it can be raised higher than another. The Mediterranean and Baltic seas have very small elevations, because the inlets by which they communicate with the ocean are so narrow, that they cannot, in so short a time, receive or discharge enough to raise and sink their surfaces sensibly.

369
Why the moon does not affect the barometer.

Air being lighter than water, and the surface of the atmosphere being nearer to the moon than the surface of the sea, it cannot be doubted that the moon raises much higher tides in the air than in the sea. And therefore many have wondered why the mercury does not sink in the barometer when the moon's action on the particles of air makes them lighter as she passes over the meridian. But we must consider, that as these particles are rendered lighter, a greater number of them are accumulated, until the deficiency of gravity be made up by the height of the column; and then there is an equilibrium, and consequently an equal pressure upon the mercury as before; so that it cannot be affected by the aerial tides. It is very probable, however, that the stars which are seen through an aerial tide of this kind will have their light more refracted than those which are seen through the common depth of the atmosphere; and this may account for the supposed refractions by the lunar atmosphere that have been sometimes observed.

370
Of the harvest moon.

It is generally believed that the moon rises about 50 minutes later every day than on the preceding; but this is true only with regard to places on the equator. In places of considerable latitude there is a remarkable difference, especially in the harvest time. Here the autumnal full moon rises very soon after sun-set for several evenings together. At the polar circles, where the mild season is of very short duration, the autumnal full moon rises at sun-set from the first to the third quarter. And at the poles, where the sun is for half a year absent, the winter full-moons shine constantly without setting from the first to the third quarter.

All these phenomena are owing to the different angles made by the horizon and different parts of the moon's orbit; and may be explained in the following manner.

The plane of the equinoctial is perpendicular to the earth's axis; and, therefore as the earth turns round its axis, all parts of the equinoctial make equal angles with the horizon both at rising and setting: so that equal portions of it always rise or set in equal times. Consequently, if the moon's motions were equable, and in the equinoctial, at the rate of 12 degrees 11 min. from the sun every day, as it is in her orbit, she would rise and set 50 minutes later every day than on the preceding: for 12 deg. 11 min. of the equinoctial rise or set in 50 minutes of time in all latitudes.

But the moon's motion is so nearly in the ecliptic, that we may consider her at present as moving in it. Now the different parts of the ecliptic, on account of its obliquity to the earth's axis, make very different angles with the horizon as they rise or set. Those parts or signs which rise with the smallest angles set with the greatest, and *vice versa*. In equal times, whenever this angle is least, a greater portion of the ecliptic rises than when the angle is larger; as may be seen by elevating the pole of a globe to any considerable latitude, and then turning it round its axis in the horizon. Consequently, when the moon is in those signs which rise or set with the smallest angles, she rises or sets with the least difference of time; and with the greatest difference in those signs which rise or set with the greatest angles.

Let FUP be the axis of a globe, ♋ TR the tropic of Cancer, L*t* ♑ the tropic of Capricorn, ♋ EU ♑ the ecliptic touching both the tropics, which are 47 degrees from each other, and AB the horizon. The equator, being in the middle between the tropics, is cut by the ecliptic into two opposite points, which are the beginnings of Aries and Libra, K is the hour-circle with its index, F the north pole of the globe elevated to a considerable latitude, suppose 40 degrees above the horizon; and P the south pole depressed as much below it. Because of the oblique position of the sphere in this latitude, the ecliptic has the high elevation N ♋ above the horizon, making the angle NU ♋ of $73\frac{1}{2}$ degrees with it when Cancer is on the meridian, at which time Libra rises in the east. But let the globe be turned half round it axis, till Capricorn comes to the meridian and Aries rises in the east; and then the ecliptic will have the low elevation NL above the horizon, making only an angle NUL of $26\frac{1}{2}$ degrees with it; which is 47 degrees less than the former angle, equal to the distance between the tropics. Fig. 187.

In Northern latitudes, the smallest angle made by the ecliptic and horiz is when Aries rises, at which time Libra sets; the greatest when Libra rises, at which time Aries sets. From the rising of Aries to the rising of Libra (which is twelve (A) sidereal hours) the angle increases; and from the rising of Libra to the rising of Aries, it decreases in the same proportion. By this article and the preceding, it appears, that the ecliptic rises fastest about Aries, and slowest about Libra.

On the parallel of London, as much of the ecliptic rises about Pisces and Aries in two hours as the moon goes through in six days: and therefore, whilst the moon is in these signs, she differs but two hours in rising for six days together; that is, about 20 minutes later every day or night than on the preceding, at a mean rate, But in 14 days afterwards the moon comes to Virgo and Libra, which are the opposite signs to Pisces and Aries; and then she differs almost four times as much in rising; namely, one hour and about fifteen minutes later every day or night than the former, whilst she is in these signs.

As the moon can never be full but when she is opposite to the sun, and the sun is never in Virgo and Libra but in our autumnal months, it is plain that the moon

(A) The ecliptic, together with the fixed stars, make $366\frac{1}{4}$ apparent diurnal revolutions about the earth in a year; the sun only $365\frac{1}{4}$. Therefore the stars gain 3 minutes 56 seconds upon the sun every day: so that a sidereal day contains only 23 hours 56 minutes of mean solar time, and a natural or solar day 24 hours. Hence 12 sidereal hours are 11 minutes 58 seconds shorter than 12 solar.

Fig. 181

Scot Philada

Harvest and Horizontal Moon.

moon is never full in the opposite signs, Pisces and Aries, but in those two months. And therefore we can have only two full moons in the year, which rise so near the time of sun-set for a week together as abovementioned. The former of these is called the *harvest moon*, and the latter the *hunter's moon*.

371
Why the same phenomenon is not observed at other times.

Here it will probably be asked, why we never observe this remarkable rising of the moon but in harvest, seeing she is in Pisces and Aries twelve times in the year besides; and must then rise with as little difference of time as in harvest? The answer is plain; for in winter these signs rise at noon; and being then only a quarter of a circle distant from the sun, the moon in them is in her first quarter: but when the sun is above the horizon, the moon's rising is neither regarded nor perceived. In spring, these signs rise with the sun, because he is then in them; and as the moon changeth in them at that time of the year, she is quite invisible. In summer they rise about midnight; and the sun being then three signs, or a quarter of a circle, before them, the moon is in them about her third quarter; when rising so late, and giving but very little light, her rising passes unobserved. And in autumn, these signs, being opposite to the sun, rise when he sets, with the moon in opposition, or at the full, which makes her rising very conspicuous.

At the equator, the north and south poles lie in the horizon; and therefore the ecliptic makes the same angle southward with the horizon when Aries rises, as it does northward when Libra rises. Consequently, as the moon rises and sets nearly at equal angles with the horizon all the year round, and about 50 minutes later every day or night than on the preceding, there can be no particular harvest-moon at the equator.

The farther that any place is from the equator, if it be not beyond the polar circle, the more the angle is diminished which the ecliptic and horizon make when Pisces and Aries rise: and therefore when the moon is in these signs, she rises with a nearly proportionable difference later every day than on the former; and is for that reason the more remarkable about the full, until we come to the polar circles, or 66 degrees from the equator; in which latitude the ecliptic and horizon become coincident every day for a moment, at the same sidereal hour (or 3 minutes 56 seconds sooner every day than the former), and the very next moment one half of the ecliptic, containing Capricorn, Aquarius, Pisces, Aries, Taurus, and Gemini, rises, and the opposite half sets. Therefore, whilst the moon is going from the beginning of Capricorn to the beginning of Cancer, which is almost 14 days, she rises at the same sidereal hour; and in autumn just at sun-set, because all that half of the ecliptic, in which the sun is at that time, sets at the same sidereal hour, and the opposite half rises; that is, 3 minutes 56 seconds of mean solar time, sooner every day than on the day before. So whilst the moon is going from Capricorn to Cancer, she rises earlier every day than on the preceding; contrary to what she does at all places between the polar circles. But during the above 14 days, the moon is 24 sidereal hours later in setting: for the six signs which rise all at once on the eastern side of the horizon are 24 hours in setting on the western side of it.

In northern latitudes the autumnal full moons are in Pisces and Aries, and the vernal full moons in Virgo and Libra; in southern latitudes, just the reverse, because the seasons are contrary. But Virgo and Libra rise at as small angles with the horizon in southern latitudes, as Pisces and Aries do in the northern; and therefore the harvest-moons are just as regular on one side of the equator as on the other.

Harvest and Horizontal Moon.

As these signs, which rise with the least angles, set with the greatest, the vernal full moons differ as much in their times of rising every night as the autumnal full moons differ in their times of setting; and set with as little difference as the autumnal full moons rise; the one being in all cases the reverse of the other.

Hitherto, for the sake of plainness, we have supposed the moon to move in the ecliptic, from which the sun never deviates. But the orbit in which the moon really moves is different from the ecliptic; one half being elevated $5\frac{1}{3}$ degrees above it, and the other half as much depressed below it. The moon's orbit therefore intersects the ecliptic in two points diametrically opposite to each other; and these intersections are called the *Moon's Nodes*. So the moon can never be in the ecliptic but when she is in either of her nodes, which is at least twice every course from change to change, and sometimes thrice: For, as the moon goes almost a whole sign more than around her orbit from change to change; if she passes by either node about the time of change, she will pass by the other in about 14 days after, and come round to the former node two days again before the next change. That node from which the moon begins to ascend northward, or above the ecliptic, in northern latitudes, is called the *Ascending Node;* and the other the *Descending Node*, because the moon, when she passes by it, descends below the ecliptic southward.

The moon's oblique motion with regard to the ecliptic causes some difference in the times of her rising and setting from what is already mentioned. For when she is northward of the ecliptic, she rises sooner and sets later than if she moved in the ecliptic: and when she is southward of the ecliptic, she rises later and sets sooner. This difference is variable, even in the same signs, because the nodes shift backward about $19\frac{2}{3}$ degrees in the ecliptic every year; and so go round it contrary to the order of the signs in 18 years 225 days.

When the ascending node is in Aries, the southern half of the moon's orbit makes an angle of $5\frac{1}{3}$ degrees less with the horizon than the ecliptic does, when Aries rises in northern latitudes: for which reason the moon rises with less difference of time whilst she is in Pisces and Aries, than she would do if she kept in the ecliptic. But in 9 years and 112 days afterward, the descending node comes to Aries; and then the moon's orbit makes an angle $5\frac{1}{3}$ degrees greater with the horizon when Aries rises, than the ecliptic does at that time; which causes the moon to rise with greater difference of time in Pisces and Aries than if she moved in the ecliptic.

To be a little more particular: When the ascending node is in Aries, the angle is only $9\frac{2}{3}$ degrees on the parallel of London when Aries rises; but when the descending node comes to Aries, the angle is $20\frac{1}{3}$ degrees. This occasions as great a difference of the

moon's

Harvest and Horizontal Moon.

moon's rising in the same signs every nine years, as there would be on two parallels $10\frac{1}{2}$ degrees from one another, if the moon's course were in the ecliptic.

372 Revolution of the moon's nodes.

As there is a complete revolution of the nodes in $18\frac{2}{3}$ years, there must be a regular period of all the varieties which can happen in the rising and setting of the moon during that time. But this shifting of the nodes never affects the moon's rising so much, even in her quickest descending latitude, as not to allow us still the benefit of her rising nearer the time of sun-set for a few days together about the full in harvest, than when she is full at any other time of the year.

373 Long moon-light in winter at the poles.

At the polar circles, when the sun touches the summer tropic, he continues 24 hours above the horizon; and 24 hours below it, when he touches the winter tropic. For the same reason, the full moon neither rises in summer nor sets in winter, considering her as moving in the ecliptic. For the winter full moon being as high in the ecliptic as the summer sun, must therefore continue as long above the horizon; and the summer full moon being as low in the ecliptic as the winter sun, can no more rise than he does. But these are only the two full moons which happen about the tropics, for all the others rise and set. In summer, the full moons are low, and their stay is short above the horizon, when the nights are short, and we have least occasion for moon light: in winter they go high, and stay long above the horizon, when the nights are long, and we want the greatest quantity of moon-light.

At the poles, one half of the ecliptic never sets, and the other half never rises: and therefore, as the sun is always half a year in describing one half of the ecliptic, and as long in going through the other half, it is natural to imagine that the sun continues half a year together above the horizon of each pole in its turn, and as long below it; rising to one pole when he sets to the other. This would be exactly the case if there were no refraction: but by the atmosphere's refracting the sun's rays, he becomes visible some days sooner, and continues some days longer in sight, than he would otherwise do: so that he appears above the horizon of either pole before he has got below the horizon of the other. And, as he never goes more than $23\frac{1}{2}$ degrees below the horizon of the poles, they have very little dark night; it being twilight there, as well as at other places, till the sun be 18 degrees below the horizon. The full moon, being always opposite to the sun, can never be seen while the sun is above the horizon, except when she is in the northern half of her orbit; for whenever any point of the ecliptic rises, the opposite point sets. Therefore, as the sun is above the horizon of the north pole from the 20th of March till 23d of September, it is plain that the moon, when full, being opposite to the sun, must be below the horizon during that half of the year. But when the sun is in the southern half of the ecliptic, he never rises to the north pole; during which half of the year, every full moon happens in some part of the northern half of the ecliptic which never sets. Consequently, as the polar inhabitants never see the full moon in summer, they have her always in the winter, before, at, and after, the full, shining for 14 of our days and nights. And when the sun is at his greatest depression below the horizon, being then in Capricorn, the moon is at her third quarter in Aries, full in Cancer, and at her first quarter in Libra. And as the beginning of Aries is the rising point of the ecliptic, Cancer the highest, and Libra the setting point, the moon rises at her first quarter in Aries; is most elevated above the horizon, and full, in Cancer; and sets at the beginning of Libra, in her third quarter, having continued visible for 14 diurnal rotations of the earth. Thus the poles are supplied one-half of the winter-time with constant moon-light in the sun's absence; and only lose sight of the moon from her third to her first quarter, while she gives but very little light and could be but of little and sometimes of no service to them. A bare view of the figure will make this plain: in which let S be the sun; e, the earth in summer, when its north pole *n* inclines towards the sun; and E the earth in winter, when its north pole declines from him. SEN and NWS is the horizon of the north pole, which is coincident with the equator; and, in both these positions of the earth, ♈ ♋ ♎ ♑ is the moon's orbit, in which she goes round the earth, according to the order of the letters *a b c d*, A B C D. When the moon is at *a* she is in her third quarter to the earth at e, and just rising to the north pole *n*; at *b* she changes, and is at the greatest height above the horizon, as the sun likewise is; at *c* she is in her first quarter, setting below the horizon; and is lowest of all under it at *d*, when opposite to the sun, and her enlightened side toward the earth. But then she is full in view to the south pole *p*: which is as much turned from the sun as the north pole inclines toward him. Thus, in our summer, the moon is above the horizon of the north pole whilst she describes the northern half of the ecliptic ♈ ♋ ♎, or from her third quarter to her first; and below the horizon during her progress through the southern half ♎ ♑ ♈; highest at the change, most depressed at the full. But in winter, when the earth is at E, and its north pole declines from the sun, the new moon at D is at her greatest depression below the horizon NWS, and the full moon at B at her greatest height above it; rising at her first quarter A, and keeping above the horizon till she comes to her third quarter C. At a mean state she is $23\frac{1}{2}$ degrees above the horizon at B and *b*, and as much below it at D and *d*, equal to the inclination of the earth's axis F. S ♋, or S ♑, are, as it were, a ray of light proceeding from the sun to the earth; and shows that when the earth is at e, the sun is above the horizon, vertical to the tropic of Cancer; and when the earth is at E, he is below the horizon, vertical to the tropic of Capricorn. Fig. 188.

374 Horizontal moon accounted for by Mr Ferguson.

The sun and moon generally appear larger when near the horizon than when at a distance from it; for which there have been various reasons assigned. The following account is given by Mr Ferguson: "These luminaries although at great distances from the earth, appear floating as it were on the surface of our atmosphere, HGF*fc*C, a little way beyond the clouds; of which, those about F, directly over our heads at E, are nearer us than those about H or c in the horizon HEc. Therefore, when the sun or moon appear in the horizon at *e*, they are not only seen in a part of the sky which is really farther from us than if they were at any considerable altitude, as about *f*; but they are also seen through a greater quantity of air and vapours at c than at *f*. Here we have two concurring appear- Fig. 170.

ances

Harvest and Horizontal Moon.

ances which deceive our imagination, and cause us to refer the sun and moon to a greater distance at their rising or setting about c, than when they are considerably high, as at *f*: first, their seeming to be on a part of the atmosphere at c, which is really farther than *f* from a spectator at E; and, secondly, their being seen through a grosser medium when at c than when at *f*, which, by rendering them dimmer, causes us to imagine them to be at a yet greater distance. And as, in both cases, they are seen much under the same angle, we naturally judge them to be largest when they seem farthest from us.

"Any one may satisfy himself that the moon appears under no greater angle in the horizon than on the meridian, by taking a large sheet of paper, and rolling it up in the form of a tube, of such a width, that, observing the moon through it when she rises, she may as it were just fill the tube; then tie a thread round it to keep it of that size; and when the moon comes to the meridian, and appears much less to the eye, look at her again through the same tube, and she will fill it just as much, if not more, than she did at her rising.

"When the full moon is in her perigee, or at her least distance from the earth, she is seen under a larger angle, and must therefore appear bigger than when she is full at other times: And if that part of the atmosphere where she rises be more replete with vapours than usual, she appears so much the dimmer; and therefore we fancy her to be still the bigger, by referring her to an unusually great distance, knowing that no objects which are very far distant can appear big unless they really be so."

375 By Mr Dunn.

To others this solution has appeared unsatisfactory; and accordingly Mr Dunn has given the following dissertation on this phenomenon, Phil. Transf. Vol. LXIV.

"1. The sun and moon, when they are in or near the horizon, appear to the naked eye of the generality of persons, so very large in comparison with their apparent magnitudes when they are in the zenith, or somewhat elevated, that several learned men have been led to inquire into the cause of this phenomenon; and after endeavouring to find certain reasons, founded on the principles of physics, they have at last pronounced this phenomenon a mere optical illusion.

"2. The principal dissertations which I have seen conducing to give any information on this subject, or helping to throw any light on the same, have been those printed in the Transactions of the Royal Society, the Academy of Sciences at Paris, the German Acts, and Dr Smith's Optics; but as all the accounts which I have met with in these writings any way relative to this subject, have not given me that satisfaction which I have desired, curiosity has induced me to inquire after the cause of this singular phenomenon in a manner somewhat different from that which others have done before me, and by such experiments and observations as have appeared to me pertinent; some of which have been as follows, viz.

"3. I have observed the rising and setting sun near the visible horizon, and near rising grounds elevated above the visible horizon about half a degree, and found him to appear largest when near to the visible horizon; and particularly a considerable alteration of his magnitude and light has always appeared to me from the time of his being in the horizon at rising, to the time of his being a degree or two above the horizon, and the contrary at his setting; which property I have endeavoured to receive as a prejudice, and an imposition on my sight and judgment, the usual reasons for this appearance.

Harvest and Horizontal Moon.

"4. I have also observed that the sun near the horizon appears to put on the figure of a spheroid, having its vertical diameter appearing to the naked eye shorter than the horizontal diameter; and, by measuring those diameters in a telescope, have found the vertical one shorter than the other.

"5. I have made frequent observations and comparisons of the apparent magnitude of the sun's disk, with objects directly under him, when he has been near the horizon, and with such objects as I have found by measurement to be of equal breadth with the sun's diameter; but in the sudden transition of the eye from the sun to the object, and from the object to the sun, have always found the sun to appear least; and that when two right lines have been imaginarily produced by the sides of those equal magnitudes, they have not appeared to keep parallel, but to meet beyond the sun.

"6. From these and other like circumstances, I first began to suspect that a sudden dip of the sun into the horizontal vapours, might some how or other be the cause of a sudden apparent change of magnitude; although the horizontal vapours had been disallowed to be able to produce any other than a refraction in a vertical direction; and, reducing things to calculation, found, that from the time when the sun is within a diameter or two of the horizon, to the time when he is a semidiameter below the horizon, the sun's rays become passable through such a length of medium, reckoning in the direction of the rays, that the total quantity of medium (reckoning both depth and density) through which the rays pass, being compared with the like total depth and density through which they pass at several elevations, it was proportionable to the difference of apparent magnitude, as appearing to the naked eye.

"7. This circumstance of sudden increase and decrease of apparent magnitude, and as sudden decrease and increase of light (for they both go together), seemed to me no improbable cause of the phenomenon, although I could not then perceive how such vapours might contribute towards enlarging the diameter of the sun in a horizontal direction.

"8. I therefore examined the sun's disk again and again, by the naked eye and by telescopes, at different altitudes; and, among several circumstances, found the solar maculæ to appear larger and plainer to the naked eye, and through a telescope, the sun being near the horizon, than they had appeared the same days when the sun was on the meridian, and to appearance more strongly defined, yet obscured.

"9. A little before sun-setting, I have often seen the edge of the sun with such protuberances and indentures as have rendered him in appearance a very odd figure; the protuberances shooting out far beyond, and the indentures pressing into the disk of the sun; and always, through a telescope magnifying 55 times, the the lower limb has appeared with a red glowing arch beneath it, and close to the edge of the sun, while the other parts have been clear.

"10. At

Harvest and Horizontal Moon.

" 10. At sun-setting, these protuberances and indentures have appeared to slide along the vertical limbs, from the lower limb to the higher, and their vanishing, so as often to form a segment of the sun's upper limb apparently separated from the disk for a small space of time.

" 11. At sun-rising I have seen the like protuberances, indentures and slices, above described; but with this difference of motion, that at sun-rising they first appear to rise in the sun's upper limb, and slide or move downward to the lower limb; or which is the same thing, they always appear at the rising and setting of the sun, to keep in the same parallels of altitude by the telescope. This property has been many times so discernable, even by the naked eye, that I have observed the sun's upper limb to shoot out towards right and left, and move downwards, forming the upper part of the disk an apparent portion of a lesser spheroid than the lower part at rising, and the contrary at setting. Through the telescope this has appeared more plain in proportion to the power of magnifying.

" 11. These protuberances and indentures so easily measurable by the micrometer, whilst the telescope wires appeared strait, enabled me to conclude, that certain strata of the atmosphere have different refractive powers; and, lying horizontally across the conical or cycloidal space traced out by the rays between the eye and that part of the atmosphere first touched by the rays, must have been the cause of such apparent protuberances and indentures in an horizontal direction across the sun's vertical limbs; and also that the bottoms of those protuberances and indentures must be considerably enlarged, and removed to appearance farther from the centre of the disk than they would have been had there been no such strata to refract.

" 13. Before sun-rising, when the sun has been near the tropic; and the sky, at the utmost extent of the horizon which appeared very clear; and when certain fogs have appeared in strata placed alternately between the hills, and over intervening rivers, valleys, &c. so as to admit a sight of the rising sun over those fogs; I have observed with admiration the most distant trees and bushments, which at other times have appeared small to the naked eye, but while the sun has been passing along a little beneath the horizon obliquely under them, just before sun-rising, when the sun has been thus approaching towards trees and bushments, they have grown apparently very large to the naked eye, and also through a telescope; and they have lost that apparent largeness as the sun has been passed by them. Thus a few trees standing together on the rising ground, at the distance of a few miles, have appeared to grow up into an apparent mountain. Such apparent mountains formed from trees put on all forms and shapes, as sloping, perpendicular, over-leaning, &c. but soon recover their natural appearance when the sun is past by them, or got above the horizon.

" 14. Mountains themselves, at a distance, sometimes appear larger than at other times. Beasts and cattle in the midst of, and being surrounded with, water, appear nearer to us than when no water surrounds them. Cattle, houses, trees, all objects on the summit of a hill, when seen through a fog, and at a proper distance, appear enlarged. All bodies admit of larger apparent magnitudes when seen through some mediums than others.

Harvest and Horizontal Moon.

" But more particularly,

" 15. I took a cylindrical glass-vessel about two feet high; and having graduated its sides to inches, I placed it upright on a table, with a piece of paper under the bottom of the glass, on which paper were drawn parallel right lines at proper distances from each other; and having placed a shilling at the bottom of the vessel, it was nearly as low as the paper. Pouring water into the vessel, and viewing the shilling through the medium of water with one eye, whilst I beheld with the other eye where the edges of the shilling were projected on the paper and its parallels, I found the shilling appear larger at every additional inch depth of the water; and this was the case if either eye was used; and the same when the eye was removed far from the surface or near to it, or in any proportion thereto.

" 16. I took large vessels; and, filling them with water, placed different bodies at the bottoms of those vessels. It always followed, that the greater depth of water I looked through, in a direction from my eye to the objects in the water, the nearer those objects appeared to me. Thus light bodies appeared more mellow and faint, and dark bodies rather better defined, than out of the water, when they were not deeply immersed. And thus they appeared under whatever directions or positions I viewed the bodies.

" 17. I placed different bodies in proper vessels of fair water, and immersed my face in the water; viewing the bodies in and through the water. They all appeared to me plain, when not too far from the eye; and altho' a little hazy at the edges, they appeared much enlarged, and always larger through a greater depth of water. Thus a shilling appeared nearly as large as half a crown, with a red glowing arch on that side opposite to the sun, when the sun shined on the water. From this experiment I concluded, that divers see light objects not only larger, but very distinctly, in the water."

From these experiments he draws a confirmation of his doctrine, that the appearances treated of arise from the different strata of the atmosphere; and then concludes that the rays coming from the sun are by the horizontal vapours " first obstructed, and many of them totally absorbed; the rest proceeding with a retarded motion, are thereby first reflected, and then less refracted through the humours of the eye; and, lastly, that hereby the image on the retina becomes enlarged."

Sect. VII. *Of drawing a Meridian Line. Of Solar and Sidereal Time, and of the Equation of Time.*

The foundation of all astronomical observations is a knowledge of the exact time when the sun, or any other of the celestial bodies, comes to the meridian; and therefore astronomers have been very attentive to the most proper methods of drawing a meridian line, by which only this can be exactly known. The easiest method of doing this is the following, recommended by Mr Ferguson, and is found a very good method of placing a sun-dial horizontally on its pedestal.

Make four or five concentric circles (fig. 5.) about a quarter of an inch from one another, on a flat board about a foot in breadth; and let the utmost circle be but little 376 Ferguson's method of drawing a meridian line.

Equation of time, &c.

little less than the board will contain. Fix a pin perpendicularly in the centre, and of such a length that its whole shadow may fall within the innermost circle for at least four hours in the middle of the day. The pin ought to be about an eighth part of an inch thick, and to have a round blunt point. The board being set exactly level in the place where the sun shines, suppose from eight in the morning till four in the afternoon, about which hours the end of the shadow should fall without all the circles; watch the times in the forenoon when the extremity of the shortening shadow just touches the several circles, and there make marks. Then, in the afternoon of the same day, watch the lengthening shadow; and where its end touches the several circles in going over them, make marks also. Lastly, with a pair of compasses, find exactly the middle point between the two marks on any circle, and draw a straight line from the centre to that point; which line will be covered at noon by the shadow of a small upright wire, which should be put in the place of the pin. The reason for drawing several circles is that in case one part of the day should prove clear, and the other part somewhat cloudy, if you miss the time when the point of the shadow should touch one circle, you may perhaps catch it in touching another. The pin is usually about five inches in length. The best time for drawing a meridian line in this manner is about the summer solstice; because the sun changes his declination slowest, and his altitude fastest, in the longest days.

If the casement of a window on which the sun shines at noon be quite upright, you may draw a line along the edge of its shadow on the floor, when the shadow of the pin is exactly on the meridian line of the board: and as the motion of the shadow of the casement will be much more sensible on the floor than that of the shadow of the pin on the board, you may know to a few seconds when it touches the meridian line on the floor.

377
Another from the Phil. Transf.

This method may suffice for ordinary purposes, but for astronomers the following is preferable. Take the gnomon of an horizontal dial for the latitude of the place, and to the hypotenusa fix two sights, whose centres may be parallel to the same: let the eye-sight be a small hole, but the other's diameter must be equal to the tangent of the double distance of the north-star from the pole; the distance of the sights being made radius, let the stile be rivetted to the end of a straight ruler; then when you would make use of it, lay the ruler on an horizontal plane, so that the end to which the stile is fixed may overhang; then look through the eye-sight, moving the instrument till the north-star appears to touch the circumference of the hole in the other sight, on the same hand with the girdle of Cassiopeia, or on the opposite side to that whereon the star in the Great Bear's rump is at that time; then draw a line by the edge of the ruler, and it will be a true meridian line.

378
To find the exact time of noon.

A meridian line being by either of these methods exactly drawn, the time when the sun or any other of the celestial bodies is exactly in the meridian may be found by a common quadrant, placing the edge of it along the line, and observing when the sun or other luminary can be seen exactly through its two sights, and noting exactly the time; which, supposing the luminary viewed to be the sun, will be exactly noon, or 12 o'clock; but as the apparent diameter of the sun is pretty large, it ought to be known exactly when his centre is in the meridian, which will be some short space after his western limb has arrived at it, and before his eastern limb come thither. It will be proper, therefore, to observe exactly the time of the two limbs being seen through the sights of the quadrant; and the half of the difference between these times added to the one or subtracted from the other, will give the exact time when the sun's centre is in the meridian. What we say with regard to the sun, is also applicable to the moon; but not to the stars, which have no sensible diameter. To render this more intelligible, the following short description of the quadrant, and method of taking the altitudes of celestial bodies by it, is subjoined.

379
To take the altitudes of the celestial bodies.

Let HOX (fig. 195.) be a horizontal line, supposed to be extended from the eye at A to X, where the sky and earth seem to meet at the end of a long and level plain: and let S be the sun. The arc XY will be the sun's height above the horizon at X, and is found by the instrument EDC, which is a quadrantal board, or plate of metal, divided into 90 equal parts or degrees on its limb DPC; and has a couple of little brass plates, as *a* and *b*, with a small hole in each of them, called *sight-holes*, for looking through, parallel to the edge of the quadrant whereon they stand. To the centre E is fixed one end of a thread F, called the *plumb-line*, which has a small weight or plummet P fixed to its other end. Now, if an observer holds the quadrant upright, without inclining it to either side, and so that the horizon at X is seen through the sight-holes *a* and *b*, the plumb-line will cut or hang over the beginning of the degrees at o, in the edge EC; but if he elevates the quadrant so as to look through the sight-holes at any part of the heavens, suppose to the sun at S; just so many degrees as he elevates the sight-hole *b* above the horizontal line HOX, so many degrees will the plumb-line cut in the limb CP of the quadrant. For, let the observer's eye at A be in the centre of the celestial arc XYV (and he may be said to be in the centre of the sun's apparent and diurnal orbit, let him be on what part of the earth he will), in which arc the sun is at that time, suppose 25 degrees high, and let the observer hold the quadrant so that he may see the sun through the sight-holes; the plumb-line freely playing on the quadrant will cut the 25th degree in the limb CP, equal to the number of degrees of the sun's altitude at the time of observation. (N. B. Whoever looks at the sun, must have a smoked glass before his eyes, to save them from hurt. The better way is, not to look at the sun through the sight-holes, but to hold the quadrant facing the eye, at a little distance, and so that, the sun shining through one hole, the ray may be seen to fall on the other.)

380
Difference between solar and sidereal days.

By observation made in the manner above directed, it is found, that the stars appear to go round the earth in 23 hours 56 minutes 5 seconds, and the sun in 24 hours: so that the stars gain three minutes 56 seconds upon the sun every day, which amounts to one diurnal revolution in a year; and therefore, in 365 days as measured by the returns of the sun to the meridian, there are 366 days as measured by the stars returning to it: the former are called *solar days*, and the latter *sidereal*.

If the earth had only a diurnal motion, without an annual, any given meridian would revolve from the sun to the sun again in the same quantity of time as from any star to the same star again; because the sun would never change his place with respect to the stars. But, as

Equation of Time, &c.

as the earth advances almost a degree eastward in its orbit in the time that it turns eastward round its axis, whatever star passes over the meridian on any day with the sun, will pass over the same meridian on the next day when the sun is almost a degree short of it; that is, 3 minutes 56 seconds sooner. If the year contained only 360 days, as the ecliptic does 360 degrees, the sun's apparent place, so far as his motion is equable, would change a degree every day; and then the sidereal days would be just 4 minutes shorter than the solar.

Let ABCDEFGHIKLM (fig. 179.) be the earth's orbit, in which it goes round the sun every year, according to the order of the letters, that is, from west to east; and turns round its axis in the same way from the sun to the sun again in every 24 hours. Let S be the sun, and R a fixed star at such an immense distance, that the diameter of the earth's orbit bears no sensible proportion to that distance. Let N*m* be any particular meridian of the earth, and N a given point or place upon that meridian when the earth is at A, the sun S hides the star R, which would always be hid if the earth never removed from A; and consequently, as the earth turns round its axis, the point N would always come round to the sun and star at the same time. But when the earth has advanced, suppose a twelfth part of its orbit, from A to B, its motion round its axis will bring the point N a twelfth part of a natural day, or two hours, sooner to the star than to the sun; for the angle of NB*n* is equal to the angle ASB: and therefore any star, which comes to the meridian at noon with the sun when the earth is at A, will come to the meridian at 10 in the forenoon when the earth is at B. When the earth comes to C, the point N will have the star on its meridian at 8 in the morning, or four hours sooner than it comes round to the sun: for it must revolve from N to *n*, before it has the sun in its meridian. When the earth comes to D, the point N will have the star on its meridian at 6 in the morning; but that point must revolve six hours more from N to *n*, before it has mid-day by the sun; for now the angle ASD is a right angle, and so is ND*n*; that is, the earth has advanced 90 degrees in its orbit, and must turn 90 degrees on its axis to carry the point N from the star to the sun: for the star always comes to the meridian when N*m* is parallel to RSA; because DS is but a point in respect of RS. When the earth is at E, the star comes to the meridian at 4 in the morning; at F, at two in the morning; and at G, the earth having gone half round its orbit, N points to the star R at midnight, it being then directly opposite to the sun; and therefore, by the earth's diurnal motion, the star comes to the meridian 12 hours before the sun. When the earth is at H, the star comes to the meridian at 10 in the evening; at I, it comes to the meridian at 8, that is, 16 hours before the sun; at K, 18 hours before him; at L, 20 hours; at M, 22; and at A, equally with the sun again.

381 Sidereal year contains 366 days.

Thus it is plain, than an absolute turn of the earth on its axis (which is always completed when any particular meridian comes to be parallel to its situation at any time of the day before) never brings the same meridian round from the sun to the sun again; but that the earth requires as much more than one turn on its axis to finish a natural day, as it has gone forward in that time; which, at a mean state, is a 365th part of a circle. Hence, in 365 days, the earth turns 366 times round its axis; and therefore, as a turn of the earth on its axis completes a sidereal day, there must be one sidereal day more in a year than the number of solar days, be the number what it will, on the earth or any other planet. One turn being lost with respect to the number of solar days in a year, by the planet's going round the sun; just as it would be lost to a traveller, who, in going round the earth, would lose one day by following the apparent diurnal motion of the sun; and consequently would reckon one day less at his return (let him take what time he would to go round the earth) than those who remained all the while at the place from which he set out. So if there were two earths revolving equally on their axes, and if one remained at A until the other had gone round the sun from A to A again, that earth which kept its place at A would have its solar and sidereal days always of the same length; and so would have one solar day more than the other at its return. Hence, if the earth turned but once round its axis in a year, and if that turn was made the same way as the earth goes round the sun, there would be continual day on one side of the earth, and continual night on the other.

382 Inequality of solar time.

The earth's motion on its axis being perfectly uniform, and equal at all times of the year, the sidereal days are always precisely of an equal length; and so would the solar or natural days be, if the earth's orbit were a perfect circle, and its axis perpendicular to its orbit. But the earth's diurnal motion on an inclined axis, and its annual motion in an elliptic orbit, cause the sun's apparent motion in the heavens to be unequal: for sometimes he revolves from the meridian to the meridian again in somewhat less than 24 hours, shown by a well-regulated clock; and at other times in somewhat more: so that the time shown by an equal going clock and a true sun-dial is never the same but on the 15th of April, the 16th of June, the 31st of August, and the 24th of December. The clock, if it goes equably and true all the year round, will be before the sun from the 24th of December till the 15th of April; from that time till the 16th of June, the sun will be before the clock; from the 16th of June till the 31st of August, the clock will be again before the sun; and from thence to the 24th of December, the sun will be faster than the clock.

393 Equation of time explained.

As the equation of time, or difference between the time shown by a well-regulated clock and a true sun-dial, depends upon two causes, namely, the obliquity of the ecliptic, and the unequal motion of the earth in it, we shall first explain the effects of these causes separately considered, and then the united effects resulting from their combination.

The earth's motion on its axis being perfectly equable, or always at the same rate, and the plane of the equator being perpendicular to its axis, it is evident that in equal times equal portions of the equator pass over the meridian; and so would equal portions of the ecliptic, if it were parallel to, or coincident with, the equator. But, as the ecliptic is oblique to the equator, the equable motion of the earth carries unequal portions of the ecliptic over the meridian in equal times, the difference being proportionate to the obliquity; and as some parts of the ecliptic are much

more

more oblique than others, those differences are unequal among themselves. Therefore, if two suns should start from the beginning either of Aries or Libra, and continue to move through equal arcs in equal times, one in the equator and the other in the ecliptic, the equatorial sun would always return to the meridian in 24 hours time, as measured by a well regulated clock: but the sun in the ecliptic would return to the meridian sometimes sooner and sometimes later than the equatorial sun; and only at the same moments with him on four days of the year; namely, the 20th of March, when the sun enters Aries; the 21st of June, when he enters Cancer; the 23d of September, when he enters Libra; and the 21st of December, when he enters Capricorn; and to this fictitious sun the motion of a well-regulated clock always answers.

Fig. 180. Let Z ♈ *z* ♎ be the earth; ZFR*z*, its axis; *abcde*, &c. the equator; ABCDE, &c. the northern half of the ecliptic from ♈ to ♎ on the side of the globe next the eye; and MNOP, &c. the southern half on the opposite side from ♎ to ♈. Let the points at A, B, C, D, E, F, &c. quite round from ♈ to ♈ again bound equal portions of the ecliptic, gone through in equal times by the real sun; and those at *a*, *b*, *c*, *d*, *e*, *f*, &c. equal portions of the equator described in equal times by the fictitious sun; and let Z ♈ *z* be the meridian.

As the real sun moves obliquely in the ecliptic, and the fictitious sun directly in the equator, with respect to the meridian; a degree, or any number of degrees, between ♈ and F on the ecliptic, must be nearer the meridian Z ♈ *z*, than a degree, or any corresponding number of degrees, on the equator from ♈ to *f*; and the more so, as they are the more oblique: and therefore the true sun comes sooner to the meridian every day whilst he is in the quadrant ♈ F, than the fictitious sun does in the quadrant ♈ *f*; for which reason, the solar noon precedes noon by the clock, until the real sun comes to F, and the fictitious to *f*; which two points, being equidistant from the meridian, both suns will come to it precisely at noon by the clock.

Whilst the real sun describes the second quadrant of the ecliptic FGHIKL from Cancer to ♎, he comes later to the meridian every day than the fictitious sun moving through the second quadrant of the equator from *f* to ♎; for the points at G H, I, K, and L, being farther from the meridian, their corresponding points at *g*, *h*, *i*, and *l*, must be later of coming to it: and as both suns come at the same moment to the point ♎ they come to the meridian at the moment of noon by the clock.

In departing from Libra, through the third quadrant, the real sun going through MNOPQ towards ♑ at R, and the fictitious sun through *mnopq* towards *r*, the former comes to the meridian every day sooner than the latter, until the real sun comes to ♑, and the fictitious to *r* and then they come both to the meridian at the same time.

Lastly, as the real sun moves equably thro' STUVW, from ♑ towards ♈; and the fictitious sun thro' *stuvw*, from *r* towards ♈, the former comes later every day to the meridian than the latter, until they both arrive at the point ♈, and then they make it noon at the same time with the clock.

Having explained one cause of the difference of time shown by a well-regulated clock and a true sun-dial, and considered the sun, not the earth, as moving in the ecliptic; we now proceed to explain the other cause of this difference, namely, the inequality of the sun's apparent motion, which is showed in summer, when the sun is farthest from the earth, and swiftest in winter when he is nearest to it. But the earth's motion on its axis is equable all the year round, and is performed from west to east; which is the way that the sun appears to change his place in the ecliptic.

If the sun's motion were equable in the ecliptic, the whole difference between the equal time as shown by the clock, and the unequal time as shown by the sun, would arise from the obliquity of the ecliptic. But the sun's motion sometimes exceeds a degree in 24 hours, though generally it is less: and when his motion is slowest, any particular meridian will revolve sooner to him than when his motion is quickest; for it will overtake him in less time when he advances a less space than when he moves through a larger.

Now, if there were two suns moving in the plane of the ecliptic, so as to go round it in a year; the one describing an equal arc every 24 hours, and the other describing sometimes a less arc in 24 hours, and at other times a larger, gaining at one time of the year what is lost at the opposite; it is evident, that either of these suns would come sooner or later to the meridian than the other, as it happened to be behind or before the other; and when they were both in conjunction, they would come to the meridian at the same moment.

As the real sun moves unequably in the ecliptic, let us suppose a fictitious sun to move equably in a circle coincident with the plane of the ecliptic. Let ABCD (fig. 181.) be the ecliptic or orbit in which the real sun moves, and the dotted circle *abcd* the imaginary orbit of the fictitious sun: each going round in a year according to the order of letters, or from west to east. Let HIKL be the earth turning round its axis the same way every 24 hours; and suppose both suns to start from A and *a*, in a right line with the plane of the meridian EH, at the same moment: the real sun at A, being then at his greatest distance from the earth, at which time his motion is slowest; and the fictitious sun at *a*, whose motion is always equable, because his distance from the earth is supposed to be always the same. In the time that the meridian revolves from H to H again, according to the order of the letters HIKL, the real sun has moved from A to F; and the fictitious with a quicker motion from *a* to *f*, through a large arc: therefore the meridian EH will revolve sooner from H to *h* under the real sun at F, than from H E to *k* under the fictitious sun at *f*; and consequently it will then be noon by the sun-dial sooner than by the clock.

As the real sun moves from A towards C, the swiftness of his motion increases all the way to C, where it is at the quickest. But notwithstanding this, the fictitious sun gains so much upon the real, soon after his departing from A, that the increasing velocity of the real sun does not bring him up with the equally moving fictitious sun till the former comes to C, and the latter to *c*, when each has gone half round its respective orbit; and then being in conjunction, the meridian EH, revolving to EK, comes to both suns at the same time, and

Calculating the Distances, &c. of the Planets.

and therefore it is noon by them both at the same moment.

But the increased velocity of the real sun, now being at the quickest, carries him before the fictitious one; and therefore, the same meridian will come to the fictitious sun sooner than to the real: for whilst the fictitious sun moves from *c* to *g*, the real sun moves through a greater arc from C to G: consequently the point K has its noon by the clock when it comes to *k*, but not its noon by the sun till it comes to *l*. And although the velocity of the real sun diminishes all the way from C to A, and the fictitious sun by an equable motion is still coming nearer to the real sun, yet they are not in conjunction till the one comes to A and the other to *a*, and then it is noon by them both at the same moment.

Thus it appears, that the solar noon is always later than noon by the clock whilst the sun goes from C to A; sooner, whilst he goes from A to C; and at these two points the sun and clock being equal, it is noon by them both at the same moment.

The point A is called the sun's *apogee*, because when he is there he is at his greatest distance from the earth; the point C his *perigee*, because when in it he is at his least distance from the earth: and a right line, as AEC, drawn through the earth's centre, from one of the points to the other, is called the *line of the Apsides*.

The distance that the sun has gone in any time from his apogee (not the distance he has to go to it, though ever so little) is called his *mean anomaly*, and is reckoned in signs and degrees, allowing 30 degrees to a sign. Thus, when the sun has gone suppose 174 degrees from his apogee at A, he is said to be 5 signs 14 degrees from it, which is his mean anomaly; and when he is gone suppose 355 degrees from his apogee, he is said to be 11 signs 25 degrees from it, although he be but 5 degrees short of A in coming round to it again.

From what was said above, it appears, that when the sun's anomaly is less than 6 signs, that is, when he is any where between A and C, in the half ABC of his orbit, the solar noon precedes the clock noon; but when his anomaly is more than 6 signs, that is, when he is any where between C and A, in the half CDA of his orbit, the clock noon precedes the solar. When his anomaly is 0 signs 0 degrees, that is, when he is in his apogee at A; or 6 signs 0 degrees, which is when he is in his perigee at C; he comes to the meridian at the moment that the fictitious sun does, and then it is noon by them both at the same instant.

Sect. VIII. *Of calculating the Distances, Magnitudes, &c. of the Sun, Moon, and Planets.*

384

To find the moon's horizontal parallax.

This is accomplished by finding out the horizontal parallax of the body whose distance you desire to know; that is, the angle under which the semidiameter of the earth would appear provided we could see it from that body; and this is to be found out in the following manner.

Let BAG (fig. 171.) be one half of the earth, AC its semidiameter, S the sun, *m* the moon, and EKOL a quarter of the circle described by the moon in revolving from the meridian to the meridian again. Let CRS be the rational horizon of an observer at A, extended to the sun in the heavens; and HAO, his sensible horizon extended to the moon's orbit. ALC is the angle under which the earth's semidiameter AC is seen from the moon at L; which is equal to the angle OAL, because the right lines AO and CL which include both these angles are parallel. ASC is the angle under which the earth's semidiameter AC is seen from the sun at S: and is equal to the angle OA*f*, because the lines AO and CRS are parallel. Now, it is found by observation, that the angle OAL is much greater than the angle OA*f*; but OAL is equal to ALC, and OA*f* is equal to ASC. Now as ASC is much less than ALC, it proves that the earth's semidiameter AC appears much greater as seen from the moon at L than from the sun at S; and therefore the earth is much farther from the sun than from the moon. The quantities of these angles may be determined by observation in the following manner.

Let a graduated instrument, as DAE (the larger the better), having a moveable index with sight-holes, be fixed in such a manner, that its plane surface may be parallel to the plane of the equator, and its edge AD in the meridian: so that when the moon is in the equinoctial, and on the meridian ADE, she may be seen through the sight-holes when the edge of the moveable index cuts the beginning of the divisions at o, on the graduated limb DE; and when she is so seen, let the precise time be noted. Now as the moon revolves about the earth from the meridian to the meridian again in about 24 hours 48 minutes, she will go a fourth part round it in a fourth part of that time, viz. in 6 hours 12 minutes, as seen from C, that is, from the earth's centre or pole. But as seen from A, the observer's place on the earth's surface, the moon will seem to have gone a quarter round the earth when she comes to the sensible horizon at O; for the index through the sights of which she is then viewed will be at *d*, 90 degrees from D, where it was when she was seen at E. Now let the exact moment when the moon is seen at O (which will be when she is in or near the sensible horizon) be carefully noted (G), that it may be known in what time she has gone from E to O; which time subtracted from six hours 12 minutes (the time of her going from E to L) leaves the time of her going from O to L, and affords an easy method for finding the angle OAL (called *the moon's horizontal parallax*, which is equal to the angle ALC) by the following analogy: As the time of the moon's describing the arc EO is to 90 degrees, so is 6 hours 12 minutes to the degrees of the arc D *d* E, which measures the angle EAL; from which subtract 90 degrees, and there remains the angle OAL, equal to the angle ALC, under which the earth's semidiameter AC is seen from the the moon. Now, since all the angles of a right-lined triangle are equal to 180 degrees, or to two right angles,

(G) Here proper allowance must be made for the refraction, which being about 34 minutes of a degree in the horizon, will cause the moon's centre to appear 34 minutes above the horizon when her centre is really in it.

Calculating the Distances, &c. of the Planets.

angles, and the sides of a triangle are always proportional to the sines of the opposite angles, say, by the Rule of Three, as the sine of the angle ALC at the moon L, is to its opposite side AC, the earth's semidiameter, which is known to be 3985 miles; so is radius, viz. the sine of 90 degrees, or of the right angle ACL to its opposite side AL, which is the moon's distance at L from the observer's place at A on the earth's surface; or, so is the sine of the angle CAL to its opposite side CL, which is the moon's distance from the earth's centre, and comes out at a mean rate to be 240,000 miles. The angle CAL is equal to what OAL wants of 90 degrees.

385 Another method.

Other methods have been fallen upon for determining the moon's parallax; of which the following is recommended as the best, by Mr Fergusson, though hitherto it has not been put in practice. Let two observers be placed under the same meridian, one in the northern hemisphere and the other in the southern, at such a distance from each other, that the arc of the celestial meridian included between their two zenith's may be at least 80 or 90 degrees. Let each observer take the distance of the moon's centre from his zenith, by means of an exceeding good instrument, at the moment of her passing the meridian: and these two zenith distances of the moon together, and their excess above the distance between the two zeniths, will be the distance between the two apparent places of the moon. Then, as the sum of the natural sines of the two zenith-distances of the moon is to radius, so is the distance between her two apparent places to her horizontal parallax: which being found, her distance from the earth's centre may be found by the analogy mentioned above.

Thus, in fig. 199. let VECQ be the earth, M the moon, and *Zbaz* an arc of the celestial meridian. Let V be Vienna, whose latitude EV is 48° 20′ north; and C the Cape of Good Hope, whose latitude EC is 34° 30′ south: both which latitudes we suppose to be accurately determined beforehand by the observers. As these two places are on the same meridian *n*VEC*s*, and in different hemispheres, the sum of their latitudes 82° 50′ is their distance from each other. Z is the zenith of Vienna, and z the zenith of the Cape of Good Hope; which two zeniths are also 82° 50′ distant from each other, in the common celestial meridian Zz. To the observer at Vienna, the moon's centre will appear at *a* in the celestial meridian; and at the same instant, to the observer at the Cape, it will appear at *b*. Now suppose the moon's distance Z *a* from the zenith of Vienna to be 38° 1′ 53″, and her distance *z b* from the zenith of the Cape of Good Hope to be 46° 4′ 41″: the sum of these two zenith distances (*Za*+*zb*) is 84° 6′ 34″; from which subtract 82° 50″, the distance of Zz between the zeniths of these two places, and there will remain 1° 16′ 34″ for the arc *ba*, or distance between the two apparent places of the moon's centre, as seen from V and from C. Then, supposing the tabular radius to be 10,000,000, the natural sine of 38° 1. 53″ (the arc *Za*) is 6,160,816, and the natural sine of 46′ 4′ 41″ the arc *zb*) is 7,202,821: the sum of both these sines is 13,363,637. Say therefore, As 13,363,637 is to 10,000,000, so is 1° 16′ 34″ to 57′ 18″, which is the moon's horizontal parallax.

If the two places of observation be not exactly under the same meridian, their difference of longitude must be accurately taken, that proper allowance may be made for the moon's declination whilst she is passing from the meridian of the one to the meridian of the other.

The parallax, and consequently the distance and bulk, of any primary planet, might be found in the above manner, if the planet was near enough to the earth, so as to make the difference of its two apparent places sufficiently sensible: but the nearest planet is too remote for the accuracy required.

386 Parallax of the sun difficult to be found.

The sun's distance from the earth might be found the same way, though with more difficulty, if his horizontal parallax, or the angle OAS equal to the angle ASC (fig. 171.), were not small so as to be hardly perceptible, being found in this way to be scarce 10 seconds of a minute, or the 360th part of a degree. Hence all astronomers, both ancient and modern have failed in taking the sun's parallax to a sufficient degree of exactness; but as some of the methods used are very ingenious, and show the great acuteness and sagacity of the ancient astronomers, we shall here give an account of them. The first method was invented by Hipparchus; and has been made use of by Ptolemy and his followers, and many other astronomers. It depends on an observation of an eclipse of the moon: And the principles on which it is founded, are, 1*st*, In a lunar eclipse, the horizontal parallax of the sun is equal to the difference between the apparent semidiameter of the sun, and half the angle of the conical shadow; which is easily made out in this manner. Let the circle AFG (fig. 87.) represent the sun, and DHC the earth; let DHM be the shadow, and DMC the half angle of the cone. Draw from the centre of the sun the right line SD touching the earth, and the angle DS is the apparent semidiameter of the earth, seen from the sun, which is equal to the horizontal parallax of the sun; and the angle ADS is the apparent semidiameter of the sun seen from the earth: The external angle ADS is equal to the two internals DMS and DSM, by the 32d Prop. Elem. I. And therefore the angle DSM, or DSC, is equal to the difference of the angles ADS and DMS. 2*dly*, Half the angle of the cone is equal to the difference of the horizontal parallax of the moon and the apparent semidiameter of the shadow, seen from the earth at the distance of the moon. For let CTE be the earth, CME the shadow, which at the distance of the moon being cut by a plane, the section will be the circle FLK, whose semidiameter is FG, and is seen from the centre of the earth under the angle FTG. But by the 32d Prop. Elem. I. the angle CFT is equal to the two internals FMT and FTM. Wherefore the angle FMT is the difference of the two angles CFT and GTF: But the angle CFT is the angle under which the semidiameter of the earth is seen from the moon, and this is equal to the horizontal parallax of the moon; and the angle GTF is the apparent semidiameter of the shadow seen from the earth's centre. It is therefore evident that the half angle of the cone is equal to the difference of the horizontal parallax of the moon, and the apparent semidiameter of the shadow seen from the earth. Wherefore, if to the apparent semidiameter of the sun there be added the apparent semidiameter of the shadow, from the sum you take away the horizontal parallax of the moon, there will

387 Hipparchus's method of finding it.

Fig. 89.

Fig. 173.

Calculating the Distances, &c. of the Planets.

will remain the horizontal parallax of the sun; which therefore, if these were accurately known, would be likewise known accurately: But none of them can be so exactly and nicely obtained, as to be sufficient for determining the parallax of the sun; for very small errors, which cannot be easily avoided in measuring these angles will produce very great errors in the parallax; and there will be a prodigious difference in the distances of the sun when drawn from these parallaxes. For example, Suppose the horizontal parallax of the moon to be 60′ 15″, the semidiameter of the sun 16′, and the semidiameter of the shadow 44′ 30″, we shall conclude from thence, that the parallax of the sun was 15″, and his distance from the earth about 13,700 semidiameters of the earth. But if there be an error committed in determining the semidiameter of the shadow, of 12″ in defect (and certainly the semidiameter of the shadow cannot be had so precisely as not to be liable to such an error), that is, if instead of 44′ 30″ we put 44′ 18″ for the apparent diameter of the shadow, all the others remaining as before, we shall have the parallax of the sun 3″, and its distance from the earth almost 70,000 semidiameters of the earth, which is five times more than what it was by the first position. But if the fault were in excess, or the diameter of the shadow exceeded the true by 12″, so that we should put in 44′ 42″, the parallax would arise to 27″, and the distance of the sun only 7700 of the earth's semidiameters; which is nine times less than what it comes to by a like error in defect. If an error in defect was committed of 15″, which is still but a small mistake, the sun's parallax would be equal to nothing, and his distance infinite. Wherefore, since from so small mistakes the parallax and distance of the sun vary so much, it is plain that the distance of the sun cannot be obtained by this method.

388 This method insufficient.

389 Aristarchus's method.

Since therefore, the angle that the earth's semidiameter subtends at the sun is so small that it cannot be determined by any observation, Aristarchus Samius, an ancient and great philosopher and astronomer, contrived a very ingenious way for finding the angle which the semidiameter of the moon's orbit subtends when seen from the sun: This angle is about 60 times bigger than the former, subtended only to the earth's semidiameter. To find this angle, he lays down the following principles.

From the phases of the moon, it hath been demonstrated, that if a plane passed through the moon's centre, to which the line joining the sun and moon's centre was perpendicular, this plane would divide the illuminated hemisphere of the moon from the dark one: And therefore, if this plane should likewise pass through the eye of a spectator on the earth, the moon would appear bisected, or like half a circle; and a right line, drawn from the earth to the centre of the moon, would be in the plane of illumination, and consequently would be perpendicular to the right line which joins the centres of the sun and moon. Let S be be the sun, and T the earth, ALq a quadrant of the moon's orbit; and let the line SL, drawn from the sun, touch the orbit of the moon in L; the angle TLS will be a right angle: And therefore, when the moon is seen in L, it will appear bisected, or just half a circle. At the same time take the angle LTS, the elongation of the moon from the sun, and then we shall have the angle LST, its complement to a right angle. But we have the side TL, by which we can find the side ST, the distance of the sun from the earth.

Fig. 90.

390 This method insufficient.

But the difficult point is to determine exactly the moment of time when the moon is bisected, or in its true dichotomy; for there is a considerable space of time both before and after the dichotomy, nay even in the quadrature, when the moon will appear bisected, or half a circle; so that the exact moment of bisection cannot be known by observation, as experience tells us: And consequently, the true distance of the sun from the earth cannot be obtained by this method.

391 Ricciolus's method.

Since the moment in which the true dichotomy happens is uncertain, but it is certain that it happens before the quadrature; Ricciolus takes that point of time which is in the middle, between the time that the phasis begins to be doubtful whether it be bisected or not, and the time of quadrature: but he had done better, if he had taken the middle point between the time when it becomes doubtful whether the moon's side is concave or straight, and the time again when it is doubtful whether it is straight or convex; which point of time is after the quadrature: and if he had done this, he would have found the sun's distance a great deal more than he has made it.

392 Another by Dr Keil.

There is no need to confine this method to the phasis of a dichotomy, or bisection, for it can be as well performed when the moon has any other phasis bigger or less than a dichotomy: for observe by a very good telescope, with a micrometer, the phasis of the moon, that is, the proportion of the illuminated part of the diameter to the whole; and at the same moment of time take her elongation from the sun: The illuminated part of the diameter, if it be less than the semidiameter, is to be subducted from the semidiameter; but if it be greater, the semidiameter is to be subducted from it, and mark the residue: then say, As the semidiameter of the moon is to the residue, so is the radius to the sine of an angle, which is therefore found: this angle added to, or subtracted from, a right angle, gives the exterior angle of the triangle at the moon: but we have the angle at the earth, which is the elongation observed; which therefore being subducted from the exterior angle, leaves the angle at the sun. And in the triangle SLT, having all the angles and one side LT, we can find the other side ST, the distance of the sun from the earth. But it is almost impossible to determine accurately the quantity of the lunar phasis, so that there may not be an error of a few seconds committed; and consequently, we cannot by this method find precisely enough the true distance of the sun. However, from such observations, we are sure, that the sun is above 7000 semidiameters of the earth distant from us. Since therefore the true distance of the sun can neither be found by eclipses nor by the phases of the moon, the astronomers are forced to have recourse to the parallaxes of the planets that are next to us, as Mars and Venus, which are sometimes much nearer to us than the sun is. Their parallaxes they endeavour to find by some of the methods above explained; and if these parallaxes were known, then the parallax and distance of the sun, which cannot directly by any observations be attained, would easily be deduced from them. For from the theory of the motions of the earth and planets, we know at any time the proportion of

393 All these methods insufficient.

Calculating the Distances, &c. of the Planets.

of the distances of the sun and planets from us; and the horizontal parallaxes are in a reciprocal proportion to these distances. Wherefore, knowing the parallax of a planet we may from thence find the parallax of the sun.

394 Another method from the parallax of Mars.

Mars, when he is in an achronycal position, that is opposite to the sun, is twice as near to us as the sun is; and therefore his parallax will be twice as great. But Venus, when she is in her inferior conjunction with the sun, is four times nearer to us than he is, and her parallax is greater in the same proportion: Therefore, though the extreme smallness of the sun's parallax renders it unobservable by our senses, yet the parallaxes of Mars or Venus, which are twice or four times greater, may become sensible. The astronomers have bestowed much pains in finding out the parallax of Mars; but some time ago Mars was in his opposition to the sun, and also in his perihelion; and consequently in his nearest approach to the earth: And then he was most accurately observed by two of the most eminent astronomers of our age, who have determined his parallax to have been scarce 30 seconds; from whence it was inferred, that the parallax of the sun is scarce 11 seconds, and his distance about 19,000 semidiameters of the earth.

395 From that of Venus.

As the parallax of Venus is still greater than that of Mars, Dr Halley proposed a method by it of finding the distance of the sun to within a 500th part of the whole. The times of observation were at her transits over the sun in 1761 and 1769. At these times the greatest attention was given by astronomers, but it was found impossible to observe the exact times of immersion and emersion with such accuracy as had been expected; so that the matter is not yet determined so exactly as could be wished. The method of calculating the sun's distance by means of these transits is as follows.

In fig. 91. let DBA be the earth, V Venus, and TSR the eastern limb of the sun. To an observer at B, the point *t* of that limb will be on the meridian, its place referred to the heaven will be at E, and Venus will appear just within it at S. But at the same instant, to an observer at A, Venus is east of the sun, in the right line AVF; the point *t* of the sun's limb appears at *e* in the heaven; and if Venus were then visible she would appear at F. The angle CVA is the horizontal parallax of Venus, which we seek; and is equal to the opposite angle FVE, whose measure is the arc FE. ASC is the sun's horizontal parallax, equal to the opposite angle *e* SE, whose measure is the arc *e* E; and FA*e* (the same as VA*v*) is Venus's horizontal parallax from the sun, which may be found by observing how much later in absolute time her total ingress on the sun is, as seen from A than as seen from B, which is the time she takes to move from V to *v* in her orbit OV*v*. Fig. 6.

It appears by the tables of Venus's motion and the sun's, that at the time of her transit in 1761 she moved 4′ of a degree on the sun's disk in 60 minutes of time: and consequently 4″ of a degree in one minute of time.

Now, let us suppose that A is 90° west of B, so that when it is noon at B it will be six in the morning at A; that the total ingress as seen from B is at one minute past 12, but that as seen from A it is at seven minutes 30 seconds past six; deduct six hours for the difference of meridians of A and B, and the remainder will be six minutes 30 seconds for the time by which the total ingress of Venus on the sun at S, is later as seen from A than as seen from B; which time being converted into parts of a degree is 26″, or the arc F*e* of Venus's horizontal parallax from the sun; for, as 1 minute of time is to 4 seconds of a degree, so is $6\frac{1}{2}$ minutes of time to 26 seconds of a degree.

The times in which the planets perform their annual revolutions about the sun are already known by observation.—From these times, and the universal power of gravity by which the planets are retained in their orbits, it is demonstrable, that if the earth's mean distance from the sun be divided into 100,000 equal parts, Mercury's mean distance from the sun must be equal to 38,710 of these parts—Venus's mean distance from the sun to 72,333——Mars's mean distance, 152,369—Jupiter's, 520,096—and Saturn's 954,006. Therefore when the number of miles contained in the mean distance of any planet from the sun is known, we can by these proportions find the mean distance in miles of all the rest.

At the time of the abovementioned transit, the earth's distance from the sun was 1015 (the mean distance being here considered as 1000), and Venus's distance from the sun 726 (the mean distance being considered as 723), which differences from the mean distances arise from the elliptical figure of the planets orbits—Subtracting 726 parts from 1015, there remain 289 parts for Venus's distance from the earth at that time.

Now, since the horizontal parallaxes of the planets are inversely as their distances from the earth's centre, it is plain, that as Venus was between the earth and the sun on the day of her transit, and consequently her parallax at that time greater than the sun's, if her horizontal parallax was then ascertained by observation, the sun's horizontal parallax might be found, and consequently his distance from the earth.—Thus, suppose Venus's horizontal parallax was found to be 36″.3480, then, As the sun's distance 1015 is to Venus's distance 289, so is Venus's horizontal parallax 36″.3480 to the sun's horizontal parallax 10″.3493 on the day of her transit. And the difference of these two parallaxes, viz. 25″.9987 (which may be esteemed 26″), will be the quantity of Venus's horizontal parallax from the sun.

To find the sun's horizontal parallax at the time of his mean distance from the earth, say, As 1000 parts of the sun's mean distance from the earth's centre, is to 1015, his distance therefrom on the day the transit, so is 10″.3493, his horizontal parallax on that day, to 10″.5045, his horizontal parallax at the time of his mean distance from the earth's centre.

396 Method of computing the sun's distance from his parallax.

The sun's parallax being thus (or any other way supposed to be) found, at the time of his mean distance from the earth, we may find his true distance therefrom, in semidiameters of the earth, by the following analogy. As the sine (or tangent of so small an arc as that) of the sun's parallax 10″.5045 is to radius, so is unity or the earth's semidiameter to the number of semidiameters of the earth that the sun is distant from its centre; which number, being multiplied by 3985, the number of miles contained in the earth's semidiameter, will give the number of miles by which the sun is distant from the earth's center.

Calculating the Distances, &c. of the Planets.

Then, As 100,000, the earth's mean distance from the sun in parts, is to 38,710, Mercury's mean distance from the sun in parts, so is the earth's mean distance from the sun in miles to Mercury's mean distance from the sun in miles.—And,

397 Distances of the other planets, how found.

As 100,000 is to 72,333, so is the earth's mean distance from the sun in miles to Venus's mean distance from the sun in miles.—Likewise,

As 100,000 is to 152,369, so is the earth's mean distance from the sun in miles to Mars's mean distance from the sun in miles.—Again.

As 100,000 is to 520,096, so is the earth's mean distance from the sun in miles to Jupiter's mean distance from the sun in miles. Lastly,

As 100,000 is to 954,006, so is the earth's mean distance from the sun in miles to Saturn's mean distance from the sun in miles.

And thus, by having found the distance of any one of the planets from the sun, we have sufficient data for finding the distances of all the rest. And then from their apparent diameters at these known distances, their real diameters and bulks may be found. According to the calculations made from the transit in 1769, we have given the distance of each of the primary and secondary planets from one another, and from the sun, in fig. 119. In fig. 153. their proportional bulks are shown, according to former culculations by Mr Ferguson; and in fig. 18. their relative magnitudes according to the latest calculations by Mr Dunn. The proportional distances of the satellites of Jupiter and Saturn, with the magnitudes of the sun, and orbit of our moon, by Mr Ferguson, are represented fig. 186.

398 Distances of the fixed stars immeasurable.

With regard to the fixed stars, no method of ascertaining their distance hath hitherto been found out. Those who have formed conjectures concerning them, have thought that they were at least 400,000 times farther from us than we are from the sun.

They are said to be fixed, because they have been generally observed to keep at the same distances from each other; their apparent diurnal revolutions being caused solely by the earth's turning on its axis. They

399 Why they seem so big to our naked eye.

appear of a sensible magnitude to the bare eye, because the retina is affected not only by the rays of light which are emitted directly from them, but by many thousands more, which falling upon our eye-lids, and upon the aerial particles about us, are reflected in our eyes so strongly as to excite vibrations not only in those points of the retina where the real images of the stars are formed, but also in other points at some distance round about. This makes us imagine the stars to be much bigger than they would appear if we saw them only by the few rays which come directly from them, so as to enter our eyes without being intermixed with others. Any one may be sensible of this, by looking at a star of the first magnitude through a long narrow tube; which, though it takes in as much of the sky as would hold 1000 such stars, yet scarce renders that one visible.

The more a telescope magnifies, the less is the aperture through which the star is seen; and consequently the fewer rays it admits into the eye. Now, since the stars appear less in a telescope which magnifies 200 times, than they do to the bare eye, insomuch that they seem to be only indivisible points, it proves at once that the stars are at immense distances from us, and that they shine by their own proper light. If they shone by borrowed light, they would be as invisible without telescopes as the satellites of Jupiter are; for these satellites appear bigger when viewed with a good telescope than the largest fixed stars do.

Dr. Herschel has proposed a method of ascertaining the parallax of the fixed stars, something similar, but more complete, than that mentioned by by Galileo and others; for it is by the parallax of the fixed stars that we should be best able to determine their distance. The method pointed out by Galileo; and first attempted by Hook, Flamstead, Mollineux and Bradley, of taking distances of stars from the zenith that pass very near it, has given us a much juster idea of the immense distance of the stars, and furnished us with an approximation to the knowledge of their parallax, that is much nearer the truth than we ever had before. But Dr Herschel mentions the insufficiency of their instruments, which were similar to the present zenith sectors, the method of zenith distances being liable to considerable errors on account of refraction, the change of position of the earth's axis arising from nutation, precession of the equinoxes, and other causes, and the aberration of light. The method of his own is by means of double stars; which is exempted from these errors, and of such a nature that the annual parallax, even if it should not exceed the tenth part of a second, may still become more visible, and be ascertained, at least to a much greater degree of approximation than it has ever been done. This method is capable of every improvement which the telescope and mechanism of micrometers can furnish. The method and its theory will be seen by the following investigation, extracted from his paper on the subject. Let O, E. (fig. 164.) be two opposite points in the annual orbit, taken in the same plane with two stars *a*, *b*, of unequal magnitudes. Let the angle *a* O *b* be observed when the earth is at O, and *a* E *b* be observed when the earth is at E. From the difference of these angles, if there should be any, we may calculate the parallax of the stars, according to the theory subjoined. These two stars ought to be as near each other as possible, and also to differ as much in magnitude as we can find them.

Phil. Tran. vol. lxxii. p. 82.

Dr Herschel's theory of the annual parallax of double stars, with the method of computing from thence what is generally called the parallax of the fixed stars, or of single stars of the first magnitude, such are nearest to us, supposes, *first*, that the stars, one with another, are about the size of the sun; and, *secondly*, that the difference of their apparent magnitude is owing to their different distances; so that the star of the second, third, or fourth magnitude, is two, three, or four times as far off as one of the first. These principles, which he premises as postulata, have so great a probability in their favour, that they will hardly be objected to by those who are in the least acquainted with the doctrine of chances. Accordingly, let OE (fig. 165.) be the whole diameter of the earth's annual orbit; and let *a*, *b*, *c*, be three stars situated in the ecliptic, in such a manner that they may be seen all in one line O *a*, *b*, *c*, when the earth is at O. Let the line O *a b c* be perpendicular to OE. and draw PE parallel to *c* O: then, if O *a*, *a b*, *b c*, are equal to each other, *a* will be a star of the first magnitude, *b* of the second, and *c* of

Scot Philad:

Calculating the Diſtances, &c. of the Planets.

c of the third. Let us now ſuppoſe the angle O a E, or parallax of the whole orbit of the earth, to be 1″ of a degree; then we have P E a = O a E = 1″: and becauſe very ſmall angles, having the ſame ſubtenſe OE, may be taken to be in the inverſe ratio of the lines O a, O b, O c, &c. we ſhall have O b E = $\frac{1}{2}$″, O c E = $\frac{1}{3}$″, &c. Now when the earth is removed to E, we ſhall have P E b = E b o = $\frac{1}{2}$″, and P E a — P E b = a E b = $\frac{1}{2}$″: i. e. the ſtars a, b, will appear to be $\frac{1}{2}$″ diſtant. We alſo have P E c = E c O = $\frac{1}{3}$″, and P E a — P E c = a E c = $\frac{2}{3}$″; i. e. the ſtars a, c, will appear to be $\frac{2}{3}$″ diſtant when the earth is at E. Now, ſince we have b E P = $\frac{1}{2}$″, and c E P = $\frac{1}{3}$″, therefore b E P — c E P = b E c = $\frac{1}{2}$″ — $\frac{1}{3}$″ = $\frac{1}{6}$″; i. e. the ſtars b, c, will appear to be only $\frac{1}{6}$″ removed from each other when the earth is at E. Whence we may deduce the following expreſſion, to denote the parallax that will become viſible in the change of diſtance between the two ſtars, by the removal of the earth from one extreme of its orbit to the other. Let P expreſs the total parallax of a fixed ſtar of the firſt magnitude, M the magnitude of the largeſt of the two ſtars, m the magnitude of the ſmalleſt, and p the partial parallax to be obſerved by the change in the diſtance of a double ſtar; then will $p = \frac{m - M}{M m} P$; and p, being found by obſervation, will give us $P = \frac{p M m}{m - M}$. *E. G.* Suppoſe a ſtar of the firſt magnitude ſhould have a ſmall ſtar of the twelfth magnitude near it; then will the partial parallax we are to expect to ſee be $\frac{12 \times 1 P}{12 - 1}$, or $\frac{12}{11}$ of the total parallax of a fixed ſtar of the firſt magnitude; and if we ſhould, by obſervation, find the partial parallax between two ſuch ſtars to amount to 1″, we ſhall have the total parallax $P = \frac{1 \times 1 \times 12}{12 - 1} = 1''.0909$. If the ſtars are of the third and twenty-fourth magnitude, the partial parallax will be $\frac{24 - 3}{3 \times 24} = \frac{21}{72} P$; and if, by obſervation, p is found to be a tenth of a ſecond, the whole parallax will come out $\frac{.1 \times 3 \times 24}{24 - 3} = 0''.3428$.

Farther, ſuppoſe the ſtars being ſtill in the ecliptic, to appear in one line, when the earth is in any other part of its orbit between O and E; then will the parallax ſtill be expreſſed by the ſame algebraic formula, and one of the maxima will ſtill lie at O, the other at E; but the whole effect will be divided into two parts, which will be in proportion to each other as radius — ſine to radius + ſine of the ſtars diſtance from the neareſt conjunction or oppoſition.

When the ſtars are any where out of the ecliptic, ſituated ſo as to appear in one line O a b c perpendicular to O E, the maximum of parallax will ſtill be expreſſed by $\frac{m - M}{M m} P$; but there will ariſe another additional parallax in the conjunction and oppoſition, which will be to that which is found 90° before or after the ſun, as the ſine (S) of the latitude of the ſtars ſeen at O is to the radius (R); and the effect of this parallax will be divided into two parts; half of it lying on one ſide of the large ſtar, the other half on the other ſide of it. This latter parallax, moreover, will be compounded with the former, ſo that the diſtance of the ſtars in the conjunction and oppoſition will then be repreſented by the diagonal of a parallelogram, whereof the two ſemiparallaxes are the ſides; a general expreſſion for which will be $\sqrt{\left(\frac{m - M}{2 m M} P\right)^2 \times \frac{SS}{RR} + 1}$; for the ſtars will apparently deſcribe two ellipſes in the heavens, whoſe tranſverſe axis will be to each other in the ratio of M to m (fig. 167.), and A a, B b, C c, D d, will be the cotemporary ſituations. Now, if b Q be drawn parallel to A C, and the parallelogram b q B Q be completed, we ſhall have b Q = $\frac{1}{2}$ C A — $\frac{1}{2}$ c a = $\frac{1}{2}$ C c = $\frac{1}{2}$ p, or ſemiparallax 90° before or after the ſun, and B b may be reſolved into, or is compounded of, b Q and b q; but b q = $\frac{1}{2}$ B D — $\frac{1}{2}$ b d = the ſemiparallax in the conjunction or oppoſition. We alſo have R : S : : b Q : b q = $\frac{p S}{2 R}$; therefore the diſtance B b (or D d) = $\sqrt{\left(\frac{p}{2}\right)^2 + \left(\frac{p S}{2 R}\right)^2}$; and by ſubſtituting the value of p into this expreſſion, we obtain $\sqrt{\left(\frac{m - M}{2 M m} P\right)^2 \times \frac{S S}{RR} + 1}$, as above. When the ſtars are in the pole of the ecliptic, b q will become equal to b Q, and B b will be 7071 P $\frac{m - M}{M m}$. Again, let the ſtars be at ſome diſtance, *e. g.* 5″ from each other, and let them both be in the ecliptic. This caſe is reſolvable into the firſt; for imagine the ſtar a (fig. 166.) to ſtand at x, and in that ſituation the ſtars x, b, c, will be in one line, and their parallax expreſſed by $\frac{m - M}{M m}$ P. But the angle a E x may be taken to be equal to a O x; and as the foregoing formula gives us the angles x E b, x E c, we are to add a E x or 5″ to x E b, and we ſhall have a E b. In general, let the diſtance of the ſtars be d, and let the obſerved diſtance at E be D, then will D = $d + p$, and therefore the whole parallax of the annual orbit will be expreſſed by $\frac{D M m - d M m}{m - M} = P$.

Suppoſe the two ſtars now to differ only in latitude, one being in the ecliptic, the other, *e. g.* 5 north, when ſeen at O. This caſe may alſo be reſolved by the former; for imagine the ſtars b, c, (fig. 165.) to be elevated at right angles above the plane of the figure, ſo that a O b, or a O c, may make an angle of 5″ at O; then, inſtead of the lines O a b c, E a, E b, E c, E P, imagine them all to be planes at right angles to the figure; and it will appear that the parallax of the ſtars in longitude muſt be the ſame as if the ſmall ſtar had been without latitude. And ſince the ſtars b, c, by the motion of the earth from O to E, will not change their latitude, we ſhall have the following conſtruction for finding the diſtance of the ſtars a b, a c, at E, and from thence the parallax P. Let the triangle a b β (fig. 168.) repreſent the ſituation of the ſtars; a b is the ſubtenſe of 5″, the angle under which they are ſuppoſed to be ſeen at O. The quantity b β by the former theorem is found, $\frac{m - M}{M m}$ P, which is the partial parallax that would have been ſeen by the earth's

Calculating the Distances, &c. of the Planets.

earth's moving from O to E, if both stars had been in the ecliptic; but on account of the difference in latitude, it will be now represented by $a\beta$, the hypothenuse of the triangle $a\, b\, \beta$: therefore, in general, putting $a\, b = d$, and $a\, \beta = D$, we have $\sqrt{\dfrac{DD - dd \times Mm}{m - M}} = P$. Hence D being taken by observation, and d, M, and m, given, we obtain the total parallax.

If the situation of the stars differs in longitude as well as latitude, we may resolve this case by the following method. Let the triangle $a\, b\, \beta$ (fig. 169.) represent the situation of the stars, $a\, b = d$ being their distance seen at O, $a\, \beta = D$ their distance seen at E. That the change $b\, \beta$, which is produced by the earth's motion will be truly expressed by $\dfrac{m - M}{M\, m} P$ may be proved as before, by supposing the star a to have been placed at α. Now let the angle of position $b\, a\, \alpha$ be taken by a micrometer, or by any other method sufficiently exact; then, by solving the triangle $a\, b\, \alpha$, we shall have the longitudinal and latitudinal differences $a\, \alpha$ and $b\, \alpha$ of the two stars, Put $a\, \alpha = x$, $b\, \alpha = y$, and it will be $x + b\, \beta = aq$, whence $D = \sqrt{\overline{x + \dfrac{m-M}{M\,m} P}\Big| + y\, y}$; and

$$\frac{\sqrt{\overline{D^2 - y^2} \times M^2 m} - x M m}{m - M} = P.$$

If neither of the stars should be in the ecliptic, nor have the same longitude or latitude, the last theorem will still serve to calculate the total parallax whose maximum will lie in E. There will, moreover, arise another parallax, whose maximum will be in the conjunction and opposition, which will be divided, and lie on different sides of the large star; but as we know the whole parallax to be exceedingly small, it will not be necessary to investigate every particular case of this kind; for by reason of the division of the parallax, which renders observations taken at any other times, except where it is greatest, very unfavourable, the formulæ would be of little use. Dr Herschel closes his account of this theory with a general observation on the time and place where the maxima of parallax will happen.

When two unequal stars are both in the ecliptic, or, not being in the ecliptic, have equal latitudes, north or south; and the largest star has most longitude, the maximum of the apparent distance will be when the sun's longitude is 90 degrees more than the stars, or when observed in the morning; and the maximum when the longitude of the sun is 90 degrees less than that of the stars, or when observed in the evening. When the small star has most longitude, the maximum and minimum, as well as the time of observation, will be the reverse of the former. When the stars differ in latitudes, this makes no alteration in the place of the maximum or minimum, nor in the time of observation; i. e. it is immaterial whether the largest star has the least or the greatest distance of the two stars.

400 Different magnitudes of the stars.

The stars, on account of their apparently various magnitudes, have been distributed into several classes, or orders. Those which appear largest are called *stars of the first magnitude;* the next to them in lustre, *stars of the second magnitude;* and so on to the *sixth*, which are the smallest that are visible to the bare eye. This distribution having been made long before the invention of telescopes, the stars which cannot be seen without the assistance of these instruments are distinguished by the name of *telescopic stars*.

Calculating the Distances, &c. of the Planets.

401 Telescopic stars.

The ancients divided the starry sphere into particular constellations, or systems of stars, according as they lay near one another, so as to occupy those spaces which the figures of different sorts of animals or things would take up, if they were there delineated. And those stars which could not be brought into any particular constellation were called *unformed stars*.

402 Unformed stars.

403 Use of their division into constellations.

This division of the stars into different constellations, or asterisms, serves to distinguish them from one another, so that any particular star may be readily found in the heavens by means of a celestial globe; on which the constellations are so delineated as to put the most remarkable stars into such parts of the figures as are most easily distinguished. The number of the ancient constellations is 48, and upon our present globes about 70. On Senex's globes are inserted Bayer's letters; the first in the Greek alphabet being put to the biggest star in each constellation, the second to the next, and so on: by which means, every star is as easily found as if a name were given to it. Thus, if the star γ in the constellation of the ram be mentioned, every astronomer knows as well what star is meant as if it were pointed out to him in the heavens. See fig. 205, 206. where the stars are represented with the figures of the animals from whence the constellations are marked.

404 Division of the heavens. Fig. 26, 29.

There is also a division of the heavens into three parts. 1. The zodiac (ζωδιακος), from ζωδιον *zodion*, "an animal," because most of the constellations in it, which are 12 in number, have the names of animals: As *Aries* the ram, *Taurus* the bull, *Gemini* the twins, *Cancer* the crab, *Libra* the balance, *Scorpio* the scorpion, *Sagittarius* the archer, *Capricornus* the goat, *Aquarius* the water-bearer, and *Pisces* the fishes. The zodiac goes quite round the heavens: it is about 16 degrees broad, so that it takes in the orbits of all the planets, and likewise the orbit of the moon. Along the middle of this zone or belt is the ecliptic, or circle which the earth describes annually as seen from the sun, and which the sun appears to describe as seen from the earth. 2. All that region of the heavens which is on the north side of the zodiac, containing 21 constellations. And, 3. That on the south side, containing 15.

405 Zodiac how divided.

The ancients divided the zodiac into the above 12 constellations or signs in the following manner. They took a vessel with a small hole in the bottom, and, having filled it with water, suffered the same to distil drop by drop into another vessel set beneath to receive it; beginning at the moment when some star rose, and continuing till it rose the next following night. The water falling down into the receiver, they divided into twelve equal parts; and having two other small vessels in readiness, each of them fit to contain one part, they again poured all the water into the upper vessel; and, observing the rising of some star in the zodiac, they at the same time suffered the water to drop into one of the small vessels; and as soon as it was full, they shifted it, and set an empty one in its place. When each vessel was full, they took notice what star of the zodiac rose; and though this could not be done in

Calculating the Distances, &c. of the Planets.

in one night, yet in many they observed the rising of 12 stars or points, by which they divided the zodiac into 12 parts.

The name of the constellations, and the number of stars observed in each of them by different astronomers, are as follow.

407 Change in the obliquity of the ecliptic.

The obliquity of the ecliptic to the equinoctial is found at present to be above the third part of a degree less than Ptolemy found it. And most of the observers after him found it to decrease gradually down to Tycho's time. If it be objected, that we cannot depend on the observations of the ancients, because of the incorrectness of their instruments; we have to answer, that both Tycho and Flamstead are allowed to have been very good observers; and yet we find that Flamstead makes this obliquity 2½ minutes of a degree less than Tycho did about 100 years before him: and as Ptolemy was 1324 years before Tycho, so the gradual decrease answers nearly to the difference of time between these three astronomers. If we consider, that the earth is not a perfect sphere, but an oblate spheroid, having its axis shorter than its equatorial diameter; and that the sun and moon are constantly acting obliquely upon the greater quantity of matter about the equator, pulling it, as it were, towards a nearer and nearer coincidence with the ecliptic; it will not appear improbable that these actions should gradually diminish the angle between those planes. Nor is it less probable that the mutual attractions of all the planets should have a tendency to bring their orbits to a coincidence: but this change is too small to become sensible in many ages.

SECT. IX. *Of calculating the periodical Times, Places, &c. of the Sun, Moon, and Planets: Delineation of the Phases of the Moon for any particular Time; and the Construction of Astronomical Tables.*

THIS title includes almost all of what may be called the *Practical part of Astronomy*; and as it is by far the most difficult and abstruse, so the thorough investigation of it would necessarily lead us into very deep geometrical demonstrations. The great labours of former astronomers have left little for succeeding ones to do in this respect: tables of the motions of all the celestial bodies have been made long ago, the periodical times, eccentricities, &c. of the planets determined; and as we suppose few will desire to repeat these laborious operations, we shall here content ourselves with giving some general hints of the methods by which these things have been originally accomplished, that so the operations of the young astronomer who makes use of tables already formed to his hand may not be merely mechanical.

Of calculating the periodical Times of the Planets, &c.

It hath been already observed, that the foundation of all astronomical operations was the drawing a meridian line. This being done, the next thing is to find out the latitude of the place where the observations are to be made, and for which the meridian line is drawn. From what hath been said, n° 39. it will easily be understood that the latitude of a place must always be equal to the elevation either of the north or south pole above the horizon; because when we are exactly on the equator, both poles appear on the horizon. There is, however, no star exactly in either of the celestial poles; therefore, to find the altitude of that invisible point called the *Pole of the heavens*, we must chose some star near it which does not set; and having by several observations, according to the directions given n° 377, found its greatest and least altitudes, divide their difference by 2; and half that difference added to the least, or subtracted from the greatest, altitude of the star, gives the exact altitude of the pole or latitude of the place. Thus, suppose the greatest altitude of the star observed is 60° and its least 50°, we then know that the altitude of the place where the observation was made is exactly 55°. 308 Latitude of any place how found.

The latitude being once found, the obliquity of the ecliptic, or the angle made by the sun's annual path with the earth's equator, is easily obtained by the following method. Observe, about the summer solstice, the sun's meridian distance from the zenith, which is easily done by a quadrant with a moveable index furnished with sights; if this distance is subtracted from the latitude of the place, provided the sun is nearer the equator than the place of observation, the remainder will be the obliquity of the ecliptic: But if the place of observation is nearer the equator than the sun at that time, the zenith distance must be added. By this method, the obliquity of the ecliptic hath been determined to be 23° 29′. 409 Obliquity of the ecliptic found.

By the same method the declination of the sun from the equator for any day may be found; and thus a table of his declination for every day in the year might be constructed: thus also the declination of the stars might be found. 410 Sun's declination.

Having the declination of the sun, his right ascension and place in the ecliptic may be geometrically found by the solution of a case in spherical trigonometry. For let EQ represent the celestial equator, *y* the sun, and *y* X the ecliptic; then, in the right-angled spherical triangle EC*y*, we have the side E*y*, equal to the sun's declination: the angle EC*y* is always 23° 29′, being the angle of the ecliptic with the equator; and the angle *y*EC is 90°, or a right angle. From these data we can find the side EC the right ascension; and C*y* the sun's place in the ecliptic, or his distance from the equinoctial point; and thus a table of the sun's place for every day in the year, answerable to his declination, may be formed. 411 His place in the ecliptic how found. Fig. 156.

Having the sun's place in the ecliptic, the right ascension of the stars may be found by the help of it and a good pendulum clock: For which purpose, the motion of the clock must be so adjusted that the hand may run through the 24 hours in the same time that a star leaving the meridian will arrive at it again; which time is somewhat shorter than the natural day, because of the space the sun moves through in the mean time eastward. 412 To find the right ascension of the stars.

Of Calculating the periodical Times of the Planets, &c.

ward. The clock being thus adjusted, when the sun is in the meridian, fix the hand to the point from whence we are to begin to reckon our time; and then observe when the star comes to the meridian, and mark the hour and minute that the hand then shows: The hours and minutes described by the index, turned into degrees and minutes of the equator, will give the difference between the right ascension of the sun and stars; which difference, being added to the right ascension of the sun will give the right ascension of the star. Now, if we know the right ascension of any one star, we may from it find the right ascensions of all the others which we see, by marking the time upon the clock between the arrival of the star whose right ascension we know to the meridian, and another star whose ascension is to be found. This time converted into hours and minutes of the equator, will give the difference of right ascensions; from whence, by addition, we collect the right ascension of the star which was to be found out.

413 Their longitudes and latitudes found.

The right ascension and declination of a star being known, its longitude and latitude, or distance from the first star of Aries, and north or south from the ecliptic, may thence be easily found, from the solution of a case in spherical trigonometry, similar to that already mentioned concerning the sun's place; and the places of the fixed stars being all marked in a catalogue according to their longitudes and latitudes, it may thence be conceived how the longitude and latitude of a planet or a comet may be found for any particular time by comparing its distances from them, and it apparent path may thus be traced; and thus the paths of Mercury and Venus were traced by M. Cassini, though Mr Ferguson made use of an orrery for that purpose.

414 To find the periodical times of the planets.

With regard to the planets, the first thing to be done is to find out their periodical times, which is done by observing when they have no latitude. At that time the planet is in the ecliptic, and consequently in one of its nodes; so that by waiting till it returns to the same node again, and keeping an exact account of the time, the periodical time of its revolution round the sun may be known pretty exactly. By the same observations, from the theory of the earth's motion we can find the position of the line of the nodes; and when once the position of this line is found, the angle of inclination of that planet's orbit to the earth may also be known.

415 Eccentricity of the earth's orbit how determined.

The eccentricity of the earth's orbit may be determined by observing the apparent diameters of the sun at different times: when the sun's diameter is least, the earth is at the greatest distance; and when this diameter is greatest, the earth is at its least distance from him. But as this method must necessarily be precarious, another is recommended by Dr Keil, by observing the velocity of the earth in its orbit, or the apparent velocity of the sun, which is demonstrated to be always reciprocally as the square of the distance.

416 Of the other planets.

The eccentricities of the orbits of the other planets may be likewise found by observing their velocities at different times; for all of them observe the same proportions with regard to the increase or decrease of their velocity that the earth does; only, in this case, care must be taken to observe the real, not the apparent, velocities of the planets, the last depending on the motion of the earth at the same time. Their aphelia, or points of their orbits where they are farthest from the sun, may be known by making several observations of their distances from him, and thus perceiving when these distances cease to increase.

417 To find their places in their orbits.

The position of the aphelion being determined, the planet's distance from it at any time may also be found by observation, which is called its *true* or *coequated* anomaly; but by supposing the motion of the planet to be regular and uniform, tables of that motion may be easily constructed. From thence the planet's mean place in its orbit may be found for any moment of time; and one of these moments being fixed upon as an epocha or beginning of the table, it is easy to understand, that from thence tables of the planet's place in its orbit for any number of years either preceding or consequent to that period may be constructed. These tables are to be constructed according to the meridian of equal time, and not true or apparent time, because of the inequalities of the earth's motion as well as that of the planet, and equations must be made to be added to or subtracted from the mean motion of the planet as occasion requires; which will be readily understood from what we have already mentioned concerning the unequal motion of the earth in its orbit. When all the necessary tables are constructed by this or similar methods, the calculating of the planetary places becomes a mere matter of mechanism, and consists only in the proper additions and subtractions according to the directions always given along with such tables.

418 Inaccuracies from the mutual attraction of the planets.

It must be observed, however, that the accidental interference of the planets with one another by their mutual attractions render it impossible to construct any tables that shall remain equally perfect; and therefore frequent actual observations and corrections of the tables will be necessary. This disturbance, however, is inconsiderable, except in the planets Jupiter and Saturn, and they are in conjunction only once in 800 years.

419 Difficulties with regard to the moon.

What hath been already mentioned with regard to the planets, is also applicable to the moon; but with more difficulty, on account of the greater inequalities of her motions, the cause of which has been already explained. She indeed moves in an ellipse as the rest do, and its eccentricity may be better computed from observing her diameter at different times than that of the earth's orbit; but that eccentricity is not always the same. The reason of this, and indeed of all the other lunar inequalities, is, that the sun has a sensible effect upon her by his attraction, as well as the earth. Consequently, when the earth is at its least distance from the sun, her orbit is dilated, and she moves more slowly; and, on the contrary, when the earth is in its aphelion, her orbit contracts, and she moves more swiftly. The eccentricity is always greatest when the line of the apsides coincides with that of the syzygies, and the earth at its least distance from the sun. When the moon is in her syzygies, i. e. in the line that joins the centres of the earth and sun, which is either in her conjunction or opposition, she moves swifter, *cæteris paribus*, than in the quadratures. According to the different distances of the moon from the syzygies, she changes her motion: from the conjunction to her first quadrature, she moves somewhat slower; but recovers her velocity in the second quarter. In the third quarter she again loses, and in the last again recovers it.

The

Of calculating the periodical Times of the Planets, &c.

The apogeon of the moon is alſo irregular; being found to move forward when it coincides with the line of the ſyzygies, and backwards whent it cuts that line at right angles. Nor is this motion in any degree equal: in the conjunction or oppoſition, it goes briſkly forwards, and in the quadratures moves either ſlowly forwards, ſtands ſtill, or goes backward. The motion of the nodes has been already taken notice of: but this motion is not uniform more than the reſt; for when the line of the nodes coincides with that of the ſyzygies, they ſtand ſtill; when their line cuts that at right angles, they go backwards with the velocity, as Sir Iſaac Newton hath ſhown, of 16″ 19‴ 24⁗ an hour.

420 Moves equably on her axis. The only equable motion the moon has, is her revolution on her axis, which ſhe always performs exactly in the ſpace of time in which ſhe moves round the earth. From hence ariſes what is called the *moon's libration*; for as the motion round her axis is equable, and that in her orbit unequal, it follows, that when the moon is in her perigee, where ſhe moves ſwifteſt, that part of her ſurface, which on account of the motion in her orbit would be turned from the earth, is not ſo, by reaſon of the motion on her axis. Thus ſome parts in the limb or margin of the moon ſometimes recede from, and ſometimes approach towards, the centre of the diſk. Yet this equable rotation produces an apparent irregularity; for the axis of the moon not being perpendicular but a little inclined to its orbit, and this axis maintaining its paralleliſm round the earth, it muſt neceſſarily change its ſituation with reſpect to an obſerver on the earth, to whom ſometimes the one and ſometimes the other pole of the moon becomes viſible; whence it appears to have a kind of wavering or vacillatory motion.

421 Lunar irregularities accounted for by Sir Iſaac Newton. From all theſe irregularities it may well be concluded, that the calculation of the moon's place in her orbit is a very difficult matter; and indeed, before Sir Iſaac Newton, aſtronomers in vain laboured to ſubject the lunar irregularities to any rule. By his labours, however, and thoſe of other aſtronomers, theſe difficulties are in a great meaſure overcome; and calculations with regard to this luminary may be made with as great certainty as concerning any other.

422 Her periodical time determined by Copernicus. Her periodical time may be determined from the obſervation of two lunar eclipſes, at as great a diſtance from one another as poſſible; for in the middle of every lunar eclipſe, the moon is exactly in oppoſition to the ſun. Compute the time between theſe two eclipſes or oppoſitions, and divide this by the number of lunations that have intervened, and the quotient will be the ſynodical month, or time the moon takes to paſs from one conjunction to another, or from one oppoſition to another. Compute the ſun's mean motion in the time of the ſynodical month, and add this to the entire circle deſcribed by the moon. Then, As that ſum is to 360°, ſo is the quantity of the ſynodical month to the periodical, or time that the moon takes to move from one point of her orbit to the ſame point again. Thus, Copernicus, in the year 1500, November 6th, at 2 hours 20 minutes, obſerved an eclipſe of the moon at Rome; and Auguſt 1ſt 1523, at 4 hours 25 minutes, another at Cracow: hence the quantity of the ſynodical month is thus determined

	Y.	D.	H.	M.
Obſerv. 2d	1523	237	4	25
Obſerv. 1ſt	1500	310	2	20
Interval of time	22	292	2	5
Add the intercalary days for leap years.		5		
Exact interval	22	297	2	5, or 11991005′.

This interval divided by 282, the number of months elapſed in that time, gives 29 days 12 hours 41 minutes for the length of the ſynodical month. But from the obſervations of two other eclipſes, the ſame author more accurately determined the quantity of the ſynodical month to be 29 degrees 11 hours 45 minutes 3 ſeconds: from whence the mean periodical time of the moon comes to be 27 degrees 7 hours 43 minutes 5 ſeconds, which exactly agrees with the obſervations of later aſtronomers.

The quantity of the periodical month being given, by the Rule of Three, we may find the moon's diurnal and horary motion; and thus may tables of the moon's mean motion be conſtructed; and if from the moon's mean diurnal motion that of the ſun be ſubtracted, the remainder will be the moon's mean diurnal motion from the ſun. 423 Her diurnal and horary motion.

Having the moon's diſtance from the ſun, her phaſes for that time may be eaſily delineated by the following method laid down by Dr Keil. "Let the circle COBP repreſent the diſk of the moon, which is turned towards the earth; and let OP be the line in which the ſemicircle OMP is projected, which ſuppoſe to be cut by the diameter BC, at right angles; and making LP the radius, take LF equal to the coſine of the elongation of the moon from the ſun: And then upon BC, as the great axis, and LF the leſſer axis, deſcribe the ſemi-ellipſe BFC. This ellipſe will cut off from the diſk of the moon the portion BFCP of the illuminated face, which is viſible to us from the earth." 424 Her phaſes delineated. Fig. 30. 31.

Since in the middle of a total eclipſe the moon is exactly in the node, if the ſun's place be found for that time, and ſix ſigns added to it, if the eclipſe is a lunar one the ſun will give the place of the node, or if the eclipſe obſerved is a ſolar one, the place of the node and of the ſun are the ſame. From comparing two eclipſes together, the mean motion of the nodes will thus be found out. The apogee of the moon may be known from her apparent diameter, as already obſerved; and by comparing her place when in the apogee at different times, the motion of the apogee itſelf may alſo be determined. 425 Place of the nodes how found.

Theſe ſhort hints will be ſufficient to give a general knowledge of the methods uſed for the ſolution of ſome of the moſt difficult problems in aſtronomy. As for the proper equations to be added or ſubtracted, in order to find out the true motion and place of the moon, together with the particular methods of conſtructing tables for calculating eclipſes, they are given from Mr Ferguſon, in the following ſection.

SECT. X. *Of Eclipſes: With Tables for their Calculation: the Method of conſtructing them: Rules for Calculation, and Directions for the Delineation of Solar and Lunar Eclipſes.*

EVERY planet and ſatellite is illuminated by the ſun; and caſts a ſhadow towards that point of the heavens which is oppoſite to the ſun. This ſhadow is nothing but a privation of light in the ſpace hid from the ſun by the opaque body that intercepts his rays.

426 Eclipſe defined.

When the ſun's light is ſo intercepted by the moon, that to any place of the earth the ſun appears partly or wholly covered, he is ſaid to *undergo an eclipſe*; though, properly ſpeaking, it is only an eclipſe of that part of the earth where the moon's ſhadow or penumbra falls. When the earth comes between the ſun and moon, the moon falls into the earth's ſhadow; and having no light of her own, ſhe ſuffers a real eclipſe from the interception of the ſun's rays. When the ſun is eclipſed to us, the moon's inhabitants, on the ſide next the earth, ſee her ſhadow like a dark ſpot travelling over the earth, about twice as faſt as its equatorial parts move, and the ſame way as they move. When the moon is in an eclipſe, the ſun appears eclipſed to her, total to all thoſe parts on which the earth's ſhadow falls, and of as long continuance as they are in the ſhadow.

427 Figure of the earth ſpherical.

That the earth is ſpherical (for the hills take off no more from the roundneſs of the earth, than grains of duſt do from the roundneſs of a common globe) is evident from the figure of its ſhadow on the moon; which is always bounded by a circular line, although the earth is inceſſantly turning its different ſides to the moon, and very ſeldom ſhows the ſame ſide to her in different eclipſes, becauſe they ſeldom happen at the ſame hours. Were the earth ſhaped like a round flat plate, its ſhadow would only be circular when either of its ſides directly faced the moon, and more or leſs elliptical as the earth happened to be turned more or leſs obliquely towards the moon when ſhe is eclipſed.

428 Moon's figure the ſame.

The moon's different phaſes prove her to be round; for as ſhe keeps ſtill the ſame ſide towards the earth, if that ſide were flat, as it appears to be, ſhe would never be viſible from the third quarter to the firſt; and from the firſt quarter to the third, ſhe would appear as round as when we ſay *ſhe is full*; becauſe, at the end of her firſt quarter, the ſun's light would come as ſuddenly on all her ſide next the earth, as it does on a flat wall, and go off as abruptly at the end of her third quarter.

429 Shadows of the earth and moon conical.

If the earth and ſun were equally large, the earth's ſhadow would be infinitely extended, and all of the ſame bulk; and the planet Mars, in either of its nodes and oppoſite to the ſun, would be eclipſed in the earth's ſhadow. Were the earth larger than the ſun, its ſhadow would increaſe in bulk the farther it extended, and would eclipſe the great planets Jupiter and Saturn, with all their moons, when they were oppoſite to the ſun. But as Mars, in oppoſition, never falls into the earth's ſhadow, altho' he is not then above 42,000,000 miles from the earth, it is plain that the earth is much leſs than the ſun; for otherwiſe its ſhadow could not end in a point at ſo ſmall a diſtance. If the ſun and moon were equally large, the moon's ſhadow would go on to the earth with an equal breadth, and cover a portion of the earth's ſurface more than 2000 miles broad, even if it fell directly againſt the earth's centre, as ſeen from the moon; and much more if it fell obliquely on the earth: But the moon's ſhadow is ſeldom 150 miles broad at the earth, unleſs when it falls very obliquely on the earth, in total eclipſes of the ſun. In annular eclipſes, the moon's real ſhadow ends in a point at ſome diſtance from the earth. The moon's ſmall diſtance from the earth, and the ſhortneſs of her ſhadow, prove her to be leſs than the ſun. And, as the earth's ſhadow is large enough to cover the moon, if her diameter were three times as large as it is (which is evident from her long continuance in the ſhadow when ſhe goes through its centre), it is plain that the earth is much bigger than the moon.

430 Why there are ſo few eclipſes.

Though all opaque bodies, on which the ſun ſhines, have their ſhadows, yet ſuch is the bulk of the ſun, and the diſtances of the planets, that the primary planets can never eclipſe one another. A primary can eclipſe only its ſecondary, or be eclipſed by it; and never but when in oppoſition or conjunction with the ſun. The primary planets are very ſeldom in theſe poſitions, but the ſun and moon are ſo every month: Whence one may imagine, that theſe two luminaries ſhould be eclipſed every month. But there are few eclipſes in reſpect of the number of new and full moons; the reaſon of which we ſhall now explain.

If the moon's orbit were coincident with the plane of the ecliptic, in which the earth always moves and the ſun appears to move, the moon's ſhadow would fall upon the earth at every change, and eclipſe the ſun to ſome parts of the earth. In like manner, the moon would go through the middle of the earth's ſhadow, and be eclipſed at every full; but with this difference, that ſhe would be totally darkened for above an hour and an half; whereas the ſun never was above four minutes totally eclipſed by the interpoſition of the moon. But one half of the moon's orbit is elevated $5\frac{1}{3}$ degrees above the ecliptic, and the other half as much depreſſed below it; conſequently, the moon's orbit interſects the ecliptic in two oppoſite points called the *moon's nodes*, as has been already taken notice of. When theſe points are in a right line with the centre of the ſun at new or full moon, the ſun, moon, and earth, are all in a right line; and if the moon be then new, her ſhadow falls upon the earth; if full, the earth's ſhadow falls upon her. When the ſun and moon are more than 17 degrees from either of the nodes at the time of conjunction, the moon is then generally too high or too low in her orbit to caſt any part of her ſhadow upon the earth; when the ſun is more than 12 degrees from either of the nodes at the time of full moon, the moon is generally too high or too low in her orbit to go through any part of the earth's ſhadow: and in both theſe caſes there will be no eclipſe. But when the moon is leſs than 17 degrees from either node at the time of conjunction, her ſhadow or penumbra falls more or leſs upon the earth, as ſhe is more or leſs within this limit. And when ſhe is leſs than 12 degrees from either node at the time of oppoſition, ſhe goes through a greater or leſs portion of the earth's ſhadow, as ſhe is more or leſs within this limit. Her orbit contains 360 degrees; of which 17, the limit of ſolar eclipſes on either ſide of the nodes, and 12, the limit of lunar eclipſes, are but ſmall portions: And as the ſun commonly paſſes

Of calculating eclipses, &c.

by the nodes but twice in a year, it is no wonder that we have so many new and full moons without eclipses.

To illustrate this (fig. 196.), let ABCD be the ecliptic, RSTU a circle laying in the same plane with the ecliptic, and VXYZ the moon's orbit, all thrown into an oblique view, which gives them an elliptical shape to the eye. One half of the moon's orbit, as VWX, is always below the ecliptic, and the other half XYV above it. The points V and X, where the moon's orbit intersects the circle RSTU, which lies even with the ecliptic, are the moon's nodes; and a right line, as XEV, drawn from one to the other, through the earth's centre, is the line of the nodes, which is carried almost parallel to itself round the sun in a year.

If the moon moved round the earth in the orbit RSTU, which is coincident with the plane of the ecliptic, her shadow would fall upon the earth every time she is in conjunction with the sun, and at every opposition she would go through the earth's shadow. Were this the case, the sun would be eclipsed at every change, and the moon at every full, as already mentioned.

But although the moon's shadow N must fall upon the earth at *a*, when the earth is at E, and the moon in conjunction with the sun at *i*, because she is then very near one of her nodes; and at her opposition *n* she must go through the earth's shadow I, because she is then near the other node; yet, in the time that she goes round the earth to her next change, according to the order of the letters XYVW, the earth advances from E to *e*, according to the order of the letters EFGH; and the line of the nodes VEX, being carried nearly parallel to itself, brings the point *f* of the moon's orbit in conjunction with the sun at that next change: and then the moon being at *f*, is too high above the ecliptic to cast her shadow on the earth: and as the earth is still moving forward, the moon at her next opposition will be at *g*, too far below the ecliptic to go through any part of the earth's shadow; for by that time the point *g* will be at a considerable distance from the earth as seen from the sun.

When the earth comes to F, the moon in conjunction with the sun Z is not at *k* in a plane coincident with the ecliptic, but above it at Y in the highest part of her orbit; and then the point *b* of her shadow O goes far above the earth. (as in fig. 2. which is an edge view of fig. 1.). The moon at her next opposition, is not at *o* (fig. 1.), but at W, where the earth's shadow goes far above her (as in fig. 2.). In both these cases the line of the nodes VEX (fig. 1) is about ninety degrees from the sun, and both luminaries are as far as possible from the limits of the eclipses.

When the earth has gone half round the ecliptic, from E to G, the line of the nodes VGX is nearly, if not exactly, directed towards the sun at Z; and then the new moon *l* casts her shadow P on the earth G; and the full moon *p* goes through the earth's shadow L; which brings on eclipses again, as when the earth was at E.

When the earth comes to H, the new moon falls not at *m* in a plane coincident with the ecliptic CD, but at W in her orbit below it; and then her shadow Q (see fig. 197.) goes far below the earth. At the next full she is not at *q* (fig. 196.), but at Y in her orbit $5\frac{1}{3}$ degrees above *q*, and at her greatest height above the ecliptic CD; being then as far as possible, at any opposition, from the earth's shadow M, as in fig. 197.

So, when the earth is at E and G, the moon is about her nodes at new and full, and in her greatest north and south declination (or latitude as it is generally called) from the ecliptic at her quarters; but when the earth is at F or H, the moon is in her greatest north and south declination from the ecliptic at new and full, and in the nodes about her quarters.

The point X, where the moon's orbit crosses the ecliptic, is called the *ascending node*, because the moon ascends from it above the ecliptic; and the opposite point of intersection V called the *descending node*, because the moon descends from it below the ecliptic. When the moon is at Y in the highest point of her orbit, she is in her greatest north latitude; and when she is at W in the lowest point of her orbit, she is in her greatest south latitude.

431 Appearance of eclipses determined from the motion of the nodes.

If the line of the nodes, like the earth's axis, was carried parallel to itself round the sun, there would be just half a year between the conjunctions of the sun and nodes. But the nodes shift backwards, or contrary to the earth's annual motion, $19\frac{1}{3}$ deg. every year; and therefore the same node comes round the sun 19 days sooner every year than on the year before. Consequently, from the time that the ascending node X (when the earth is at E) passes by the sun as seen from the earth, it is only 173 days (not half a year) till the descending node V passes by him. Therefore in whatever time of the year we have eclipses of the luminaries about either node, we may be sure that in 173 days afterward we shall have eclipses about the other node. And when at any time of the year the line of the nodes is in the situation VGX, at the same time next year it will be in the situation *r*G*s*; the ascending node having gone backward, that is, contrary to the order of signs, from X to *s*, and the descending node from V to *r*; each $19\frac{1}{3}$ deg. At this rate, the nodes shift through all the signs and degrees of the ecliptic in 18 years and 225 days; in which time there would always be a regular period of eclipses, if any complete number of lunations were finished without a fraction. But this never happens; for if both the sun and moon should start from a line of conjunction with either of the nodes in any point of the ecliptic, the sun would perform 18 annual revolutions and 222 degrees over and above, and the moon 230 lunations and 85 degrees of the 231st, by the time the node came round to the same point of the ecliptic again; so that the sun would then be 138 degrees from the node, and the moon 85 degrees from the sun.

But, in 223 mean lunations, after the sun, moon, and nodes, have been once in a line of conjunction, they return so nearly to the same state again, as that the same node, which was in conjunction with the sun and moon at the beginning of the first of these lunations, will be within 28′ 12″ of a degree of a line of conjunction with the sun and moon again, when the last of these lunations is completed. And therefore in that time there will be a regular period of eclipses, or return of the same eclipse, for many ages.——In this period (which was first discovered by the Chaldeans) there are 18 Julian years 11 days 7 hours 43 minutes 20 seconds, when the last day of February in leap years is four times included; but when it is five times included,

Scot Philad.a

Of calculating Eclipſes, &c.

ded, the period conſiſts of only 18 years 10 days 7 hours 43 minutes 20 ſeconds. Conſequently, if to the mean time of any eclipſe, either of the ſun or moon, you add 18 Julian years 11 days 7 hours 43 minutes 20 ſeconds, when the laſt day of February in leap-years comes in four times, or a day leſs when it comes in five times, you will have the mean time of the return of the ſame eclipſe.

432 When the ſame eclipſe returns again.

But the falling back of the line of conjunctions or oppoſitions of the ſun and moon 28′ 12″ with reſpect to the line of the nodes in every period, will wear it out in proceſs of time; and after that, it will not return again in leſs than 12,492 years.—Theſe eclipſes of the ſun, which happen about the aſcending node, and begin to come in at the north pole of the earth, will go a little ſoutherly at each return, till they go quite off the earth at the ſouth pole; and thoſe which happen about the deſcending node, and begin to come in at the ſouth pole of the earth, will go a little northerly at each return, till at laſt they quite leave the earth at the north pole.

433 Hiſtory of the ſolar eclipſe in 1764.

To exemplify this matter, we ſhall firſt conſider the ſun's eclipſe (March 21ſt old ſtyle, April 1ſt new ſtyle), A. D. 1764, according to its mean revolutions, without equating the times, or the ſun's diſtance from the node; and then according to its true equated times.

This eclipſe fell in open ſpace at each return, quite clear of the earth, ever ſince the creation, till A. D. 1295, June 13th old ſtyle, at 12h. 52m. 59 ſec. *poſt meridiem*, when the moon's ſhadow firſt touched the earth at the north pole; the ſun being then 17° 48′ 27″ from the aſcending node. In each period ſince that time, the ſun has come 28′ 12″ nearer and nearer the ſame node, and the moon's ſhadow has therefore gone more and more ſoutherly.—In the year 1962, July 18th old ſtyle, at 19 h. 36 m. 21 ſec. *p. m.* when the ſame eclipſe will have returned 38 times, the ſun will be only 24′ 45″ from the aſcending node, and the centre of the moon's ſhadow will fall a little northward of the earth's centre.—At the end of the next following period, A. D. 1980, July 28th old ſtyle, at 18 h. 19 m. 41 ſec. *p. m.* the ſun will have receded back 3′ 27″ from the aſcending node, and the moon will have a very ſmall degree of ſouthern latitude, which will cauſe the centre of her ſhadow to paſs a very ſmall matter ſouth of the earth's centre.—After which, in every following period, the ſun will be 28′ 12″ farther back from the aſcending node than in the period laſt before; and the moon's ſhadow will go ſtill farther and farther ſouthward, until September 12th old ſtyle, at 23 h. 46 m. 22 ſec. *p. m.* A. D. 2665; when the eclipſe will have completed its 77th periodical return, and will go quite off the earth at the ſouth pole (the ſun being then 17° 55′ 22″ back from the node), and cannot come in at the north pole, ſo as to begin the ſame courſe over again, in leſs than 12,492 years afterwads.—And ſuch will be the caſe of every other eclipſe of the ſun: For, as there is about 18 degrees on each ſide of the node within which there is a poſſibility of eclipſes, their whole revolution goes through 36 degrees about that node, which, taken from 360 degrees, leaves remaining 324 degrees for the eclipſes to travel *in expanſum*. And as this 36 degrees is not gone through in leſs than 77 periods, which takes up 1388 years, the remaining 324 degrees cannot be ſo gone through in leſs than 12,492 years. For, as 36 is to 1388, ſo is 324 to 12,492.

434 Of the eclipſe in 1748.

To illuſtrate this a little farther, we ſhall examine ſome of the moſt remarkable circumſtances of the returns of the eclipſe which happened July 14th 1748, about noon. This eclipſe, after traverſing the voids of ſpace from the creation, at laſt began to enter the Terra Auſtralis Incognita about 88 years after the conqueſt, which was the laſt of king Stephen's reign: every Chaldean period it has crept more northerly, but was ſtill inviſible in Britain before the year 1622; when, on the 30th of April, it began to touch the ſouth parts of England about two in the afternoon; its central appearance riſing in the American ſouth ſeas, and traverſing Peru and the Amazon's country, through the Atlantic ocean into Africa, and ſetting in the Æthiopian continent, not far from the beginning of the Red ſea.

Its next viſible period was, after three Chaldean revolutions, in 1676, on the firſt of June, riſing central in the Atlantic ocean, paſſing us about nine in the morning, with four digits eclipſed on the under limb, and ſetting in the gulph of Cochinchina in the Eaſt Indies.

It being now near the ſolſtice, this eclipſe was viſible the very next return in 1694, in the evening; and in two periods more, which was in 1730, on the 4th of July, was ſeen about half eclipſed juſt after ſun-riſe, and obſerved both at Wirtemberg in Germany, and Pekin in China, ſoon after which it went off.

Eighteen years more afforded us the eclipſe which fell on the 14th of July 1748.

The next viſible return happened on July 25th 1766 in the evening, about four digits eclipſed; and, after two periods more, will happen on Auguſt 16th 1802, early in the morning, about five digits, the centre coming from the north frozen continent, by the capes of Norway, through Tartary, China, and Japan, to the Ladrone iſlands, where it goes off.

Again, in 1820, Auguſt 26th, between one and two, there will be another great eclipſe at London, about 10 digits; but, happening ſo near the equinox, the centre will leave every part of Britain to the weſt, and enter Germany at Embden, paſſing by Venice, Naples, Grand Cairo, and ſet in the gulf of Baſſora near that city.

It will be no more viſible till 1874, when five digits will be obſcured (the centre being now about to leave the earth) on September 28th. In 1892, the ſun will go down eclipſed in London: and again, in 1928, the paſſage of the centre will be in the *expanſum*, though there will be two digits eclipſed at London, October the 31ſt of that year, and about the year 2090 the whole penumbra will be wore off; whence no more returns of this eclipſe can happen till after a revolution of 10,000 years.

435 Period in which the phenomena of an eclipſe are completed.

From theſe remarks on the entire revolution of this eclipſe, we may gather, that a thouſand years more or leſs (for there are ſome irregularities that may protract or lengthen this period 100 years), complete the whole terreſtrial phenomena of any ſingle eclipſe: and ſince 20 periods of 54 years each, and about 33 days, comprehend the entire extent of their revolution, is is evident, that the times of the returns will paſs through a circuit of one year and ten months, every Chaldean period

being

being 10 or 11 days later, and of the equable appearances, about 32 or 33 days. Thus, though this eclipse happens about the middle of July, no other subsequent eclipse of this period will return till the middle of the same month again; but wear constantly each period 10 or 11 days forward, and at last appear in winter, but then it begins to cease from affecting us.

436 Seldom more than two great eclipses in this period.

Another conclusion from this revolution may be drawn, that there will seldom be any more than two great eclipses of the sun in the interval of this period, and these follow sometimes next return, and often at greater distances. That of 1715 returned again in 1733 very great; but this present eclipse will not be great till the arrival of 1820, which is a revolution of four Chaldean periods: so that the irregularities of their circuits must undergo new computations to assign them exactly.

437 Eclipses come in by the north and south poles.

Nor do all eclipses come in at the south pole: that depends altogether on the position of the lunar nodes, which will bring in as many from the expansum one way as the other; and such eclipses will wear more southerly by degrees, contrary to what happens in the present case.

The eclipse, for example, of 1736 in September, had its centre in the expansum, and set about the middle of its obscurity in Britain; it will wear in at the north pole, and in the year 2600, or thereabouts, go off into the expansum on the south side of the earth.

The eclipses therefore which happened about the creation are little more than half way yet of their etherial circuit; and will be 4000 years before they enter the earth any more. This grand revolution seems to have been entirely unknown to the ancients.

438 Very ancient eclipses cannot be calculated by our tables.

It is particularly to be noted, that eclipses which have happened many centuries ago will not be found by our present tables to agree exactly with ancient observations, by reason of the great anomalies in the lunar motions; which appears an incontestable demonstration of the non-eternity of the universe. For it seems confirmed by undeniable proofs, that the moon now finishes her period in less time than formerly, and will continue, by the centripetal law, to approach nearer and nearer the earth, and to go sooner and sooner round it: nor will the centrifugal power be sufficient to compensate the different gravitations of such an assemblage of bodies as constitute the solar system, which would come to ruin of itself, without some regulation and adjustment of their original motions.

We are credibly informed from the testimony of the ancients, that there was a total eclipse of the sun predicted by Thales to happen in the fourth year of the 48th Olympiad, either at Sardis or Miletus in Asia, where Thales then resided. That year corresponds to the 585th year before Christ; when accordingly there happened a very signal eclipse of the sun, on the 28th of May, answering to the present 10th of that month, central through North America, the south parts of France, Italy, &c. as far as Athens, or the isles in the Ægean sea; which is the farthest that even the Caroline tables carry it; and consequently make it invisible to any part of Asia, in the total character; though there are good reasons to believe that it extended to Babylon, and went down central over that city. We are not however to imagine, that it was set before it passed Sardis and the Asiatic towns, where the predictor lived; because an invisible eclipse could have been of no service to demonstrate his ability in astronomical sciences to his countrymen, as it could give no proof of its reality.

For a further illustration, Thucydides relates, That a solar eclipse happened on a summer's day, in the afternoon, in the first year of the Peloponnesian war, so great, that the stars appeared. Rhodius was victor in the Olympic games the fourth year of the said war, being also the fourth year of the 87th Olympiad, on the 428th year before Christ. So that the eclipse must have happened in the 431st year before Christ; and by computation it appears, that on the third of August there was a signal eclipse which would have passed over Athens, central about six in the evening, but which our present tables bring no farther than the ancient Syrtes on the African coast, above 400 miles from Athens; which, suffering in that case but nine digits, could by no means exhibit the remarkable darkness recited by this historian: the centre therefore seems to have passed Athens about six in the evening, and probably might go down about Jerusalem, or near it, contrary to the construction of the present tables. These things are only mentioned by way of caution to the present astronomers, in recomputing ancient eclipses; and they may examine the eclipse of Nicias, so fatal to the Athenian fleet; that which overthrew the Macedonian army, &c.

439 Number of eclipses in a year.

In any year, the number of eclipses of both luminaries cannot be less than two, nor more than seven; the most usual number is four, and it is very rare to have more than six. For the sun passes by both the nodes but once a-year, unless he passes by one of them in the beginning of the year; and if he does, he will pass by the same node again a little before the year be finished; because, as these points move $19\frac{1}{3}$ degrees backwards every year, the sun will come to either of them 173 days after the other. And when either node is within 17 degrees of the sun at the time of new moon, the sun will be eclipsed. At the subsequent opposition, the moon will be eclipsed in the other node, and come round to the next conjunction again ere the former node be 17 degrees past the sun, and will therefore eclipse him again. When three eclipses fall about either node, the like number generally falls about the opposite; as the sun comes to it in 173 days afterward; and six lunations contain but four days more. Thus, there may be two eclipses of the sun and one of the moon about each of her nodes. But when the moon changes in either of the nodes, she cannot be near enough the other node at the next full to be eclipsed; and in six lunar months afterwards she will change near the other node: in these cases, there can be but two eclipses in a year, and they are both of the sun.

A longer period than the abovementioned, for comparing and examining eclipses which happen at long intervals of time, is 557 years, 21 days, 18 hours, 30 minutes, 11 seconds; in which time there are 6890 mean lunations; and the sun and node meet again so nearly as to be but 11 seconds distant; but then it is not the same eclipse that returns, as in the shorter period abovementioned.

Eclipses

Eclipſes of the ſun are more frequent than of the moon, becauſe the ſun's ecliptic limits are greater than the moon's; yet we have more viſible eclipſes of the moon than of the ſun, becauſe eclipſes of the moon are ſeen from all parts of that hemiſphere of the earth which is next her, and are equally great to each of thoſe parts; but the ſun's eclipſes are viſible only to that ſmall portion of the hemiſphere next him whereon the moon's ſhadow falls.

440 Why more eclipſes of the moon than of the ſun are obſerved.

The moon's orbit being elliptical, and the earth in one of its focuſes, ſhe is once at her leaſt diſtance from the earth, and once at her greateſt, in every lunation.

441 Total and annular eclipſes.

When the moon changes at her leaſt diſtance from the earth, and ſo near the node that her dark ſhadow falls upon the earth, ſhe appears big enough to cover the whole diſk of the ſun from that part on which her ſhadow falls; and the ſun appears totally eclipſed there for ſome minutes: but when the moon changes at her greateſt diſtance from the earth, and ſo near the node that her dark ſhadow is directed towards the earth, her diameter ſubtends a leſs angle than the ſun's; and therefore ſhe cannot hide his whole diſk from any part of the earth, nor does her ſhadow reach it at that time; and to the place over which the point of her ſhadow hangs, the eclipſe is annular, the ſun's edge appearing like a luminous ring all around the body of the moon.

When the change happens within 17 degrees of the node, and the moon at her mean diſtance from the earth, the point of her ſhadow juſt touches the earth, and ſhe eclipſeth the ſun totally to that ſmall ſpot whereon her ſhadow falls; but the darkneſs is not of a moment's continuance.

The moon's apparent diameter, when largeſt, exceeds the ſun's, when leaſt, only 1 minute 38 ſeconds of a degree; and in the greateſt eclipſe of the ſun that can happen at any time and place, the total darkneſs continues no longer than whilſt the moon is going 1 minute 38 ſeconds from the ſun in her orbit, which is about 3 minutes and 13 ſeconds of an hour.

442 Extent of the moon's ſhadow and penumbra.

The moon's dark ſhadow covers only a ſpot on the earth's ſurface about 180 Engliſh miles broad, when the moon's diameter appears largeſt, and the ſun's leaſt; and the total darkneſs can extend no farther than the dark ſhadow covers. Yet the moon's partial ſhadow or penumbra may then cover a circular ſpace 4900 miles in diameter, within all which the ſun is more or leſs eclipſed, as the places are leſs or more diſtant from the centre of the penumbra. When the moon changes exactly in the node, the penumbra is circular on the earth at the middle of the general eclipſe; becauſe at that time it falls perpendicularly on the earth's ſurface; but at every other moment it falls obliquely, and will therefore be elliptical: and the more ſo, as the time is longer before or after the middle of the general eclipſe; and then much greater portions of the earth's ſurface are involved in the penumbra.

443 Beginning, ending, &c. of a ſolar eclipſe.

When the penumbra firſt touches the earth, the general eclipſe begins; when it leaves the earth, the general eclipſe ends: from the beginning to the end the ſun appears eclipſed in ſome part of the earth or other. When the penumbra touches any place, the eclipſe begins at that place, and ends when the penumbra leaves it. When the moon changes in the node, the penumbra goes over the centre of the earth's diſk as ſeen from the moon; and conſequently by deſcribing the longeſt line poſſibly on the earth, continues the longeſt upon it; namely, at a mean rate, 5 hours 50 minutes; more, if the moon be at her greateſt diſtance from the earth, becauſe ſhe then moves ſloweſt; leſs, if ſhe be at her leaſt diſtance, becauſe of her quicker motion.

To make ſeveral of the above and other phenomena plainer, let S be the ſun, E the earth, M the moon, and AMP the moon's orbit. Draw the right line W e from the weſtern ſide of the ſun at W, touching the weſtern ſide of the moon at c, and the earth at e: draw alſo the right line V d from the eaſtern ſide of the ſun at V, touching the eaſtern ſide of the moon at d, and the earth at e: the dark ſpace $c e d$ included between thoſe lines is the moon's ſhadow, ending in a point at e, where it touches the earth; becauſe in this caſe the moon is ſuppoſed to change at M in the middle between A the apogee, or fartheſt point of her orbit from the earth, and P the perigee, or neareſt point to it. For, had the point P been at M, the moon had been nearer the earth; and her dark ſhadow at e would have covered a ſpace upon it about 180 miles broad, and the ſun would have been totally darkened, with ſome continuance: but had the point A been at M, the moon would have been farther from the earth, and her ſhadow would have ended in a point a little above e, and therefore the ſun would have appeared like a luminous ring all around the moon. Draw the right lines WX d b and VX c g, touching the contrary ſides of the ſun and moon, and ending on the earth at a and b: draw alſo the right line SXM, from the centre of the ſun's diſk, through the moon's centre, to the earth; and ſuppoſe the two former lines WXdb and VXcg to revolve on the line SXM as an axis, and their points a and b will deſcribe the limits of the penumbra TT on the earth's ſurface, including the large ſpace $a b a$; within which the ſun appears more or leſs eclipſed, as the places are more or leſs diſtant from the verge of the penumbra $a b$. Fig. 198.

Draw the right line y 12 acroſs the ſun's diſk, perpendicular to SXM the axis of the penumbra: then divide the line y 12 into 12 equal parts, as in the figure, for the twelve digits or equal parts of the ſun's diameter; and, at equal diſtances from the centre of the penumbra at e (on the earth's ſurface at YY) to its edge $a b$, draw twelve concentric circles, marked with the numeral figures 1 2 3 4, &c. and remember that the moon's motion in her orbit AMP is from weſt to eaſt, as from s to t. Then,

To an obſerver on the earth at b, the eaſtern limb of the moon at d ſeems to touch the weſtern limb of the ſun at W, when the moon is at M; and the ſun's eclipſe begins at b, appearing as at A, fig. 203. at the left hand; but at the ſame moment of abſolute time, to an obſerver at a in fig. 198. the weſtern edge of the moon at c leaves the eaſtern edge of the ſun at V, and the eclipſe ends, as at the right hand C fig. 203. At the very ſame inſtant, to all thoſe who live on the circle marked 1 on the earth E, in fig. 198. the moon M cuts off or darkens a twelfth part of the ſun S, and eclipſes him one digit, and at 1 in fig. 203.: to thoſe who live on the circle marked 2 in fig. 198. the moon cuts off two-twelfth parts of the ſun, as at 2 in fig. 203.: to thoſe on the circle 3, three parts; and ſo

Of calculating Eclipses, &c.

on to the centre at 12 in fig. 198. where the sun is centrally eclipsed, as at B in the middle of fig. 203.; under which figure there is a scale of hours and minutes, to show at a mean state how long it is from the beginning to the end of a central eclipse of the sun on the parallel of London; and how many digits are eclipsed at any particular time from the beginning at A to the middle at B, or the end at C. Thus, in 16 minutes from the beginning, the sun is two digits eclipsed; in an hour and five minutes, eight digits; and in an hour and 37 minutes, 12 digits.

By fig. 198. it is plain, that the sun is totally or centrally eclipsed but to a small part of the earth at any time, because the dark conical shadow *e* of the moon M falls but on a small part of the earth; and that the partial eclipse is confined at that time to the space included by the circle *a b*, of which only one half can be projected in the figure, the other half being supposed to be hid by the convexity of the earth E: and likewise that no part of the sun is eclipsed to the large space YY of the earth, because the moon is not between the sun and any of that part of the earth; and therefore to all that part of the eclipse is invisible. The earth turns eastward on its axis, as from *g* to *h*, which is the same way that the moon's shadow moves; but the moon's motion is much swifter in her orbit from *s* to *t*: and therefore, although eclipses of the sun are of longer duration on account of the earth's motion on its axis than they would be if that motion was stopped, yet, in four minutes of time at most, the moon's swifter motion carries her dark shadow quite over any place that its centre touches at the time of greatest obscuration. The motion of the shadow on the earth's disk is equal to the moon's motion from the sun, which is about 30½ minutes of a degree every hour at a mean rate; but so much of the moon's orbit is equal to 30½ degrees of a great circle on the earth; and therefore the moon's shadow goes 30½ degrees, or 1830 geographical miles, on the earth in an hour, or 30½ miles in a minute, which is almost four times as swift as the motion of a cannon-ball.

As seen from the sun or moon, the earth's axis appears differently inclined every day of the year, on account of keeeping its parallelism throughout its annual course. In fig. 205. let EDON be the earth at the two equinoxes and the two solstices, NS its axis, N the north pole, S the south pole, ÆQ the equator, T the tropic of Cancer, *t* the tropic of Capricorn, and ABC the circumference of the earth's enlightened disk as seen from the sun or new moon at these times. The earth's axis has the position NES at the vernal equinox, lying towards the right hand, as seen from the sun or new moon; its poles N and S being then in the circumference of the disk; and the equator and all its parallels seen to be straight lines, because their planes pass through the observer's eye looking down upon the earth from the sun or moon directly over E, where the ecliptic FG intersects the equator Æ. At the summer solstice, the earth's axis has the position NDS; and that part of the ecliptic FG, in which the moon is then new, touches the tropic of Cancer T at D. The north pole at that time inclining 23½ degrees towards the sun, falls so many degrees within the earth's enlightened disk, because the sun is then vertical to D 23½ degrees north of the equator ÆQ; and the equator with all its parallels seem elliptic curves bending downward, or towards the south pole, as seen from the sun; which pole, together with 23½ degrees all round it, is hid behind the disk in the dark hemisphere of the earth. At the autumnal equinox, the earth's axis has the position NOS, lying to the left hand as seen from the sun or new moon, which are then vertical to O, where the ecliptic cuts the equator ÆQ. Both poles now lie in the circumference of the disk, the north pole just going to disappear behind it, and the south pole just entering into it; and the equator, with all its parallels, seem to be straight lines, because their planes pass through the observer's eye, as seen from the sun, and very nearly so as seen from the moon. At the winter solstice, the earth's axis has the position NNS, when its south pole S inclining 23½ degrees towards the sun, falls 23½ degrees within the enlightened disk, as seen from the sun or new moon, which are then vertical to the tropic of Capricorn *t*, 23½ degrees south of the equator ÆQ; and the equator, with all its parallels, seem elliptic curves bending upward; the north pole being as far behind the disk in the dark hemisphere as the south pole is come into the light. The nearer that at any time of the year is to the equinoxes or solstices, the more it partakes of the phenomena relating to them.

Thus it appears, that from the vernal equinox to the autumnal, the north pole is enlightened; and the equator and all its parallels appear elliptical as seen from the sun, more or less curved as the time is nearer to, or farther from, the summer solstice; and bending downwards, or towards the south pole; the reverse of which happens from the autumnal equinox to the vernal. A little consideration will be sufficient to convince the reader, that the earth's axis inclines towards the sun at the summer solstice; from the sun at the winter solstice: and sidewise to the sun at the equinoxes; but towards the right hand, as seen from the sun at the vernal equinox; and towards the left hand at the autumnal. From the winter to the summer solstice, the earth's axis inclines more or less to the right hand, as seen from the sun; and the contrary from the summer to the winter solstice.

444 Eclipses affected by the position of the earth's axis.

The different positions of the earth's axis, as seen from the sun at different times of the year, affect solar eclipses greatly with regard to particular places; yea, so far as would make central eclipses which fall at one time of the year invisible if they fell at another, even though the moon should always change in the nodes, and at the same hour of the day; of which indefinitely various affections, we shall only give examples for the times of the equinoxes and solstices.

In the same diagram, let FG be part of the ecliptic, and IK, *i k*, *i k*, *i k*, part of the moon's orbit; both seen edgewise, and therefore projected into right lines; and let the intersections NODE be one and the same node at the above times, when the earth has the forementioned different positions; and let the spaces included by the circles P *p p p* be the penumbra at these times, as its centre is passing over the centre of the earth's disk. At the winter solstice, when the earth's axis has the position NNS, the centre of the penumbra P touches the tropic of Capricorn *t* in N at the middle of the general eclipse; but no part of the penumbra touches the tropic of Cancer T. At the sum

Of calculating Eclipses, &c.

summer solstice, when the earth's axis has the position NDS (*i* D *k* being then part of the moon's orbit whose node is at D), the penumbra *p* has its centre at D, on the tropic of Cancer T, at the middle of the general eclipse, and then no part of it touches the tropic of Capricorn *t*. At the autumnal equinox, the earth's axis has the position NOS (*i* O *k* being then part of the moon's orbit), and the penumbra equally includes part of both tropics T and *t* at the middle of the general eclipse: at the vernal equinox it does the same, because the earth's axis has the position NES; but, in the former of these two last cases, the penumbra enters the earth at A, north of the tropic of Cancer T, and leaves it at *m*, south of the tropic of Capricorn *t*; having gone over the earth obliquely southward, as its centre described the line AO*m*: whereas, in the latter case, the penumbra touches the earth at *n*, south of the equator ÆQ, and describing the line *n*E*q* (similar to the former line AO*m* in open space), goes obliquely northward over the earth, and leaves it at *q*, north of the equator.

In all these circumstances the moon has been supposed to change at noon in her descending node: Had she changed in her ascending node, the phenomena would have been as various the contrary way, with respect to the penumbra's going northward or southward over the earth. But because the moon changes at all hours, as often in one node as in the other, and at all distances from them both at different times as it happens, the variety of the phases of eclipses are almost innumerable, even at the same places; considering also how variously the same places are situated on the enlightened disk of the earth, with respect to the penumbra's motion, at the different hours when eclipses happen.

When the moon changes 17 degrees short of her descending node, the penumbra P 18 just touches the northern part of the earth's disk, near the north pole N; and as seen from that place, the moon appears to touch the sun, but hides no part of him from sight. Had the change been as far short of the ascending node, the penumbra would have touched the southern part of the disk near the south pole S. When the moon changes 12 degrees short of the descending node, more than a third part of the penumbra P12 falls on the northern part of the earth at the middle of the general eclipse: Had she changed as far past the same node, as much of the other side of the penumbra about P would have fallen on the southern part of the earth; all the rest in the expansum, or open space. When the moon changes 6 degrees from the node, almost the whole penumbra P6 falls on the earth at the middle of the general eclipse. And lastly, when the moon changes in the node at N, the penumbra PN takes the longest course possible on the earth's disk; its centre falling on the middle thereof, at the middle of the general eclipse. The farther the moon changes from either node, within 17 degrees of it, the shorter is the penumbra's continuance on the earth, because it goes over a less portion of the disk, as is evident by the figure.

445 Duration of eclipses in different parts of the earth.

The nearer that the penumbra's centre is to the equator at the middle of the general eclipse, the longer is the duration of the eclipse at all those places where it is central; because, the nearer that any place is to the equator, the greater is the circle it describes by the earth's motion on its axis: and so the place moving quicker, keeps longer in the penumbra, whose motion is the same way with that of the place, though faster, as has been already mentioned. Thus (see the earth at D, and the penumbra at 12) whilst the point *b* in the polar circle *a b c d* is carried from *b* to *c* by the earth's diurnal motion, the point *d* on the tropic of Cancer T is carried a much greater length from *d* to D; and therefore, if the penumbra's centre goes one time over *c* and another time over D, the penumbra will be longer in passing over the moving place *d* than it was in passing over the moving place *b*. Consequently, central eclipses about the poles are of the shortest duration; and about the equator, of the longest.

In the middle of summer, the whole frigid zone, included by the polar circle *abcd*, is enlightened; and if it then happens that the penumbra's centre goes over the north pole, the sun will be eclipsed much the same number of digits at *a* as at *c*; but whilst the penumbra moves eastward over *c*, it moves eastward over *a*; because, with respect to the penumbra, the motions of *a* and *c* are contrary: for *c* moves the same way with the penumbra towards *d*, but *a* moves the contrary way towards *b*; and therefore the eclipse will be of longer duration at *c* than at *a*. At *a* the eclipse begins on the sun's eastern limb, but at *c* on his western: at all places lying without the polar circles, the sun's eclipses begin on his western limb, or near it, and end on or near his eastern. At those places where the penumbra touches the earth, the eclipse begins with the rising sun, on the top of his western or uppermost edge; and at those places where the penumbra leaves the earth, the eclipse ends with the setting sun, on the top of his eastern edge, which is then uppermost, just at its disappearing in the horizon.

If the moon were surrounded by an atmosphere of any considerable density, it would seem to touch the sun a little before the moon made her appulse to his edge, and we should see a little faintness on that edge before it were eclipsed by the moon: but as no such faintness has been observed, it seems plain, that the moon has no such atmosphere as that of the earth. The faint ring of light surrounding the sun in total eclipses, called by Cassini *la chevelure du soliel*, is said to be the atmosphere of the sun; because it has been observed to move equally with the sun, not with the moon. See n° 147.

446 Lunar eclipses explained.

Having been so prolix concerning eclipses of the sun, we shall drop that subject at present, and proceed to the doctrine of lunar eclipses; which, being more simple, may be explained in less time.

That the moon can never be eclipsed but at the time of her being full, and the reason why she is not eclipsed at every full, has been shown already. In fig. 198. let S be the sun, E the earth, RR the earth's shadow, and B the moon in opposition to the sun: In this situation the earth intercepts the sun's light in its way to the moon; and when the moon touches the earth's shadow at *v*, she begins to be eclipsed on her eastern limb *x*, and continues eclipsed until her western limb *y* leaves the shadow at *w*: At B she is in the middle of the shadow, and consequently in the middle of the eclipse.

The moon, when totally eclipsed, is not invisible if she

Of calculating Eclipses, &c.

she be above the horizon and the sky be clear; but appears generally of a dusky colour, like tarnished copper, which some have thought to be the moon's native light. But the true cause of her being visible is the scattered beams of the sun, bent into the earth's shadow by going through the atmosphere; which, being more or less dense near the earth than at considerable heights above it, refracts or bends the sun's rays more inward, the nearer they are passing by the earth's surface, than those rays which go through higher parts of the atmosphere, where it is less dense according to its height, until it be so thin or rare as to lose its refractive power. Let the circle $f\ g\ h\ i$, concentric to the earth, include the atmosphere whose refractive power vanishes at the heights f and i; so that the rays Wfw and Viv go on straight without suffering the least refraction: but all those rays which enter the atmosphere between f and k, and between i and l, on opposite sides of the earth, are gradually more bent inward as they go thro' a greater portion of the atmosphere, until the rays Wk and Vl touching the earth at m and n, are bent so much as to meet at q, a little short of the moon; and therefore the dark shadow of the earth is contained in the space $m\ o\ q\ p\ n$, where none of the sun's rays can enter; all the rest RR, being mixed by the scattered rays which are refracted as above, is in some measure enlightened by them; and some of those rays falling on the moon, give her the colour of tarnished copper, or of iron almost red hot. So that if the earth had no atmosphere, the moon would be as visible in total eclipses as she is when new. If the moon were so near the earth as to go into its dark shadow, suppose about $p\ o$, she would be invisible during her stay in it; but visible before and after in the fainter shadow RR.

447 Why the moon is visible when eclipsed.

When the moon goes thro' the centre of the earth's shadow, she is directly opposite to the sun; yet the moon has been often seen totally eclipsed in the horizon when the sun was also visible in the opposite part of it: for the horizontal refraction being almost 34 minutes of a degree, and the diameter of the sun and moon being each at a mean state but 32 minutes, the refraction causes both luminaries to appear above the horizon when they are really below it.

When the moon is full at 12 degrees from either of her nodes, she just touches the earth's shadow, but enters not into it. In fig. 204. let GH be the ecliptic, ef the moon's orbit where she is 12 degrees from the node at her full; $c\ d$ her orbit where she is 6 degrees from the node, $a\ b$ her orbit where she is full in the node, AB the earth's shadow, and M the moon. When the moon describes the line $e\ f$, she just touches the shadow, but does not enter into it; when she describes the line $c\ d$, she is totally, though not centrally, immersed in the shadow; and when she describes the line $a\ b$, she passes by the node at M in the centre of the shadow, and takes the longest line possible, which is a diameter, through it: and such an eclipse being both total and central is of the longest duration, namely, 3 hours 57 minutes 6 seconds from the beginning to the end, if the moon be at her greatest distance from the earth; and 3 hours 37 minutes 26 seconds, if she be at her least distance. The reason of this difference is, that when the moon is farthest from the earth, she moves slowest; and when nearest to it, quickest.

The moon's diameter, as well as the sun's, is supposed to be divided into 12 equal parts, called *digits*; and so many of these parts as are darkened by the earth's shadow, so many digits is the moon eclipsed. All that the moon is eclipsed above 12 digits, shows how far the shadow of the earth is over the body of the moon, on that edge to which she is nearest at the middle of the eclipse.

448 Lunar eclipses difficultly observed.

It is difficult to observe exactly either the beginning or ending of a lunar eclipse, even with a good telescope, because the earth's shadow is so faint and ill-defined about the edges, that when the moon is either just touching or leaving it, the obscuration of her limb is scarce sensible; and therefore the nicest observers can hardly be certain to four or five seconds of time. But both the beginning and ending of solar eclipses are visibly instantaneous; for the moment that the edge of the moon's disk touches the sun's, his roundness seems a little broke on that part; and the moment she leaves it, he appears perfectly round again.

449 Eclipses useful in determining longitudes, &c.

In astronomy, eclipses of the moon are of a great use for ascertaining the periods of her motions; especially such eclipses as are observed to be alike in all her circumstances, and have long intervals of time between them. In geography, the longitudes of places are found by eclipses: but for this purpose eclipses of the moon are more useful than those of the sun, because they are more frequently visible, and the same lunar eclipse is of equal largeness and duration at all places where it is seen. In chronology, both solar and lunar eclipses serve to determine exactly the time of any past event: for there are so many particulars observable in every eclipse, with respect to its quantity, the places where it is visible (if of the sun), and the time of the day or night, that it is impossible there can be two solar eclipses in the course of many ages which are alike in all circumstances.

450 Darkness of our Saviour's crucifixion supernatural.

From the above explanation of the doctrine of eclipses, it is evident, that the darkness at our Saviour's crucifixion was supernatural. For he suffered on the day on which the passover was eaten by the Jews, on which day it was impossible that the moon's shadow could fall on the earth; for the Jews kept the passover at the time of full moon: nor does the darkness in total eclipses of the sun last above four minutes in any place; whereas the darkness at the crucifixion lasted three hours, Math. xxviii. 15. and overspread at least all the land of Judea.

451 Construction of tables for calculating eclipses.

The theory of eclipses being now, we hope, pretty plainly laid down, the construction of tables for their calculation will be understood from the following considerations.

The motions of the sun and moon are observed to be continually accelerated from the apogee to the perigee, and as gradually retarded from the perigee to the apogee; being slowest of all when the mean anomaly is nothing, and swiftest of all when it is six signs.

When the luminary is in its apogee or perigee, its place is the same as it would be if its motion were equable in all parts of its orbit. The supposed equable motions are called *mean*; the unequable are justly called the *true*.

The mean place of the sun or moon is always forwarder than the true place, whilst the luminary is moving from its apogee to its perigee: and the true

place

Of calculating Eclipses, &c.

place is always forwarder than the mean, whilst the luminary is moving from its perigee to its apogee. In the former case the anomaly is always less than six signs; and in the latter case, more.

It has been found by a long series of observations, that the sun goes through the ecliptic, from the vernal equinox to the same equinox again, in 365 days, 5 hours 48 minutes 55 seconds; from the first star of Aries to the same star again, in 365 days 6 hours 9 minutes 24 seconds; and from his apogee to the same again, in 365 days 6 hours 14 minutes 0 seconds.—The first of these is called the *solar year*; the second the *sidereal year*; and the third the *anomalistic year*. So that the solar year is 20 minutes 29 seconds shorter than the sidereal; and the sidereal year is 4 minutes 36 seconds shorter than the anomalistic. Hence it appears, that the equinoctial point, or intersection of the ecliptic and equator at the beginning of Aries, goes backward with respect to the fixed stars, and that the sun's apogee goes forward.

It is also observed that the moon goes through her orbit, from any given fixed star to the same star again, in 27 days 7 hours 43 minutes 4 seconds at a mean rate; and from her apogee to her apogee again, in 27 days 13 hours 18 minutes 43 seconds; and from the sun to the sun again, in 29 days 12 hours 44 minutes $3\frac{1}{10}$ seconds. This shows that the moon's apogee moves forward in the ecliptic, and that at a much quicker rate than the sun's apogee does: since the moon is 5 hours 55 minutes 39 seconds longer in revolving from her apogee to her apogee again, than from any star to the same star again.

The moon's orbit crosses the ecliptic in two opposite points, which are called her *Nodes*: and it is observed, that she revolves sooner from any node to the node again, than from any star to the star again, by 2 hours 38 minutes 27 seconds; which shows that her nodes move backward, or contrary to the order of signs in the ecliptic.

The time in which the moon revolves from the sun to the sun again (or from change to change) is called the *Lunation*; which according to Dr Pound's mean measures, would always consist of 29 days 12 hours 44 minutes 3 seconds 2 thirds 58 fourths, if the motions of the sun and moon were always equable. Hence 12 mean lunations contain 354 days 8 hours 48 minutes 36 seconds 35 thirds 40 fourths, which is 10 days 21 hours 11 minutes 23 seconds 24 thirds 20 fourths less than the length of a common Julian year, consisting of 365 days 6 hours; and 13 mean lunations contain 383 days 21 hours 32 minutes 39 seconds 38 thirds 38 fourths, which exceeds the length of a common Julian year, by 18 days 15 hours 32 minutes 39 seconds 38 thirds 38 fourths.

The mean time of new moon being found for any given year and month, as suppose for March 1700, old style, if this mean new moon falls later than the 11th day of March, then 12 mean lunations added to the time of this mean new moon will give the time of the mean new moon in March 1701, after having thrown off 365 days. But when the mean new moon happens to be before the 11th of March, we must add 13 mean lunations, in order to have the time of mean new moon in March the year following; always taking care to subtract 365 days in common years, and 366 days in leap years, from the sum of this addition.

Thus A. D. 1700, old style, the time of mean new moon in March was the 8th day, at 16 hours 11 minutes 25 seconds after the noon of that day (viz. at 11 minutes 25 seconds past four in the morning of the 9th day, according to common reckoning. To this we must add 13 mean lunations, or 383 days 21 hours 32 minutes 39 seconds 38 thirds 38 fourths, and the sum will be 392 days 13 hours 44 minutes 4 seconds 38 thirds 38 fourths: from which subtract 365 days, because the year 1701 is a common year, and there will remain 27 days 13 hours 44 minutes 4 seconds 38 thirds 38 fourths for the time of a mean new moon in March, A. D. 1701.

Carrying on this addition and subtraction till A. D. 1703, we find the time of mean new moon in March that year to be on the 6th day, at 7 hours 21 minutes 17 seconds 49 thirds 46 fourths past noon; to which add 13 mean lunations, and the sum will be 390 days 4 hours 53 minutes 57 seconds 28 thirds 20 fourths; from which subtract 366 days, because the year 1704 is a leap year, and there will remain 24 days 4 hours 53 minutes 57 seconds 28 thirds 20 fourths, for the time of mean new moon in March, A. D. 1704.

In this manner was the first of the following tables constructed to seconds, thirds, and fourths; and then wrote out to the nearest seconds. The reason why we chose to begin the year with March, was to avoid the inconvenience of adding a day to the tabular time in leap-years after February, or subtracting a day therefrom in January and February in those years; to which all tables of this kind are subject, which begin the year with January, in calculating the times of new or full moons.

The mean anomalies of the sun and moon, and the sun's mean motion from the ascending node of the moon's orbit, are set down in Table III. from 1 to 13 mean lunations. These numbers, for 13 lunations, being added to the radical anomalies of the sun and moon, and to the sun's mean distance from the ascending node, at the time of mean new moon in March 1700 (Table I.), will give their mean anomalies, and the sun's mean distance from the node, at the time of mean new moon in March 1701; and being added for 12 lunations to those for 1701, give them for the time of mean new moon in March 1702. And so on as far as you please to continue the table (which is here carried on to the year 1800), always throwing off 12 signs when their sum exceeds 12, and setting down the remainder as the proper quantity.

If the numbers belonging to A. D. 1700 (in Table I.) be subtracted from those belonging to 1800, we shall have their whole differences in 100 complete Julian years; which accordingly we find to be 4 days 8 hours 10 minutes 52 seconds 15 thirds 40 fourths, with respect to the time of mean new moon. These being added together 60 times (always taking care to throw off a whole lunation when the days exceed $29\frac{1}{2}$) make up 60 centuries, or 6000 years, as in Table VI. which was carried on to seconds, thirds, and fourths; and then wrote out to the nearest seconds. In the same manner were the respective anomalies and the sun's distance from the node found, for these centurial

1

Of calculating Eclipses, &c.

turial years; and then (for want of room) wrote out only to the nearest minutes, which is sufficient in whole centuries. By means of these two tables, we may find the time of any mean new moon in March, together with the anomalies of the sun and moon, and the sun's distance from the node, at these times within the limits of 6000 years, either before or after any given year in the 18th century; and the mean time of any new or full moon in any given month after March, by means of the third and fourth tables, within the same limits, as shown in the precepts for calculation.

Thus it would be a very easy matter to calculate the time of any new or full moon, if the sun and moon moved equably in all parts of their orbits. But we have already shown, that their places are never the same as they would be by equable motions, except when they are in apogee or perigee; which is, when their mean anomalies are either nothing, or six signs: and that their mean places are always forwarder than their true places, whilst the anomaly is less than six signs; and their true places are forwarder than the mean, whilst the anomaly is more.

Hence it is evident, that while the sun's anomaly is less than six signs, the moon will overtake him, or be opposite to him, sooner than she could if his motion were equable; and later whilst his anomaly is more than six signs. The greatest difference that can possibly happen between the mean and true time of new or full moon, on account of the inequality of the sun's motion, is 3 hours 48 minutes 28 seconds: and that is, when the sun's anomaly is either 3 signs 1 degree, or 8 signs 29 degrees; sooner in the first case, and later in the last.—In all other signs and degrees of anomaly, the difference is gradually less, and vanishes when the anomaly is either nothing or six signs.

The sun is in his apogee on the 30th of June, and in his perigee on the 30th of December, in the present age: so that he is nearer the earth in our winter than in our summer.—The proportional difference of distance, deduced from the difference of the sun's apparent diameter at these times, is as 983 to 1017.

The moon's orbit is dilated in winter, and contracted in summer; therefore the lunations are longer in winter than in summer. The greatest difference is found to be 22 minutes 29 seconds; the lunations increasing gradually in length whilst the sun is moving from his apogee to his perigee, and decreasing in length whilst he is moving from his perigee to his apogee.—On this account, the moon will be later every time in coming to her conjunction with the sun, or being in opposition to him, from December till June, and sooner from June till December, than if her orbit had continued of the same size all the year round.

As both these differences depend on the sun's anomaly, they may be fitly put together into one table, and called *The annual or first equation of the mean to the true syzygy*, (see Table VII.) This equational difference is to be subtracted from the time of the mean syzygy when the sun's anomaly is less than six signs, and added when the anomaly is more.—At the greatest it is 4 hours 10 minutes 57 seconds, viz. 3 hours 48 minutes 28 seconds, on account of the sun's unequal motion, and 22 minutes 29 seconds, on account of the dilatation of the moon's orbit.

This compound equation would be sufficient for reducing the mean time of new or full moon to the true time thereof, if the moon's orbit were of a circular form, and her motion quite equable in it. But the moon's orbit is more elliptical than the sun's, and her motion in it so much the more unequal. The difference is so great, that she is sometimes in conjunction with the sun, or in opposition to him, sooner by 9 hours 47 minutes 54 seconds, than she would be if her motion were equable; and at other times as much later. The former happens when her mean anomaly is 9 signs 4 degrees, and the latter when it is 2 signs 26 degrees. See Table IX.

At different distances of the sun from the moon's apogee, the figure of the moon's orbit becomes different. It is longest of all, or most eccentric, when the sun is in the same sign and degree either with the moon's apogee or perigee; shortest of all, or least eccentric, when the sun's distance from the moon's apogee is either three signs or nine signs; and at a mean state when the distance is either 1 sign 15 degrees, 4 signs 15 degrees, 7 signs 15 degrees, or 10 signs 15 degrees. When the moon's orbit is at its greatest eccentricity, her apogeal distance from the earth's centre is to her perigeal distance therefrom, as 1067 is to 933; when least eccentric, as 1043 is to 957; and when at the mean state, as 1055 is to 945.

But the sun's distance from the moon's apogee is equal to the quantity of the moon's mean anomaly at the time of new moon, and by the addition of six signs it becomes equal in quantity to the moon's mean anomaly at the time of full moon. Therefore, a table may be constructed so as to answer to all the various inequalities depending on the different eccentricities of the moon's orbit, in the syzygies, and called *The second equation of the mean to the true syzygy*. (See Table IX.): and the moon's anomaly, when equated by Table VIII. may be made the proper argument for taking out this second equation of time; which must be added to the former equated time, when the moon's anomaly is less than six signs, and subtracted when the anomaly is more.

There are several other inequalities in the moon's motion, which sometimes bring on the true syzygy a little sooner, and at other times keep it back a little later, than it would otherwise be: but they are so small, that they may be all omitted except two; the former of which (see Table X.) depends on the difference between the anomalies of the sun and moon in the syzygies, and the latter (see Table XI.) depends on the sun's distance from the moon's nodes at these times.—The greatest difference arising from the former is 4 minutes 48 seconds; and from the latter, 1 minute 34 seconds.

452 Directions for the use of those tables.

The tables here inserted being calculated by Mr Fergusson according to the methods already given, he gives the following directions for their use.

To calculate the true Time of New or full Moon.

Precept I. If the required time be within the limits of the 18th century, write out the mean time of new moon in March, for the proposed year, from Table I. in the old style, or from Table II. in the new; together with the mean anomalies of the sun and moon, and the sun's mean distance from the moon's ascending node. If you want the time of full moon in March, add the half lunation at the foot of Table III. with its

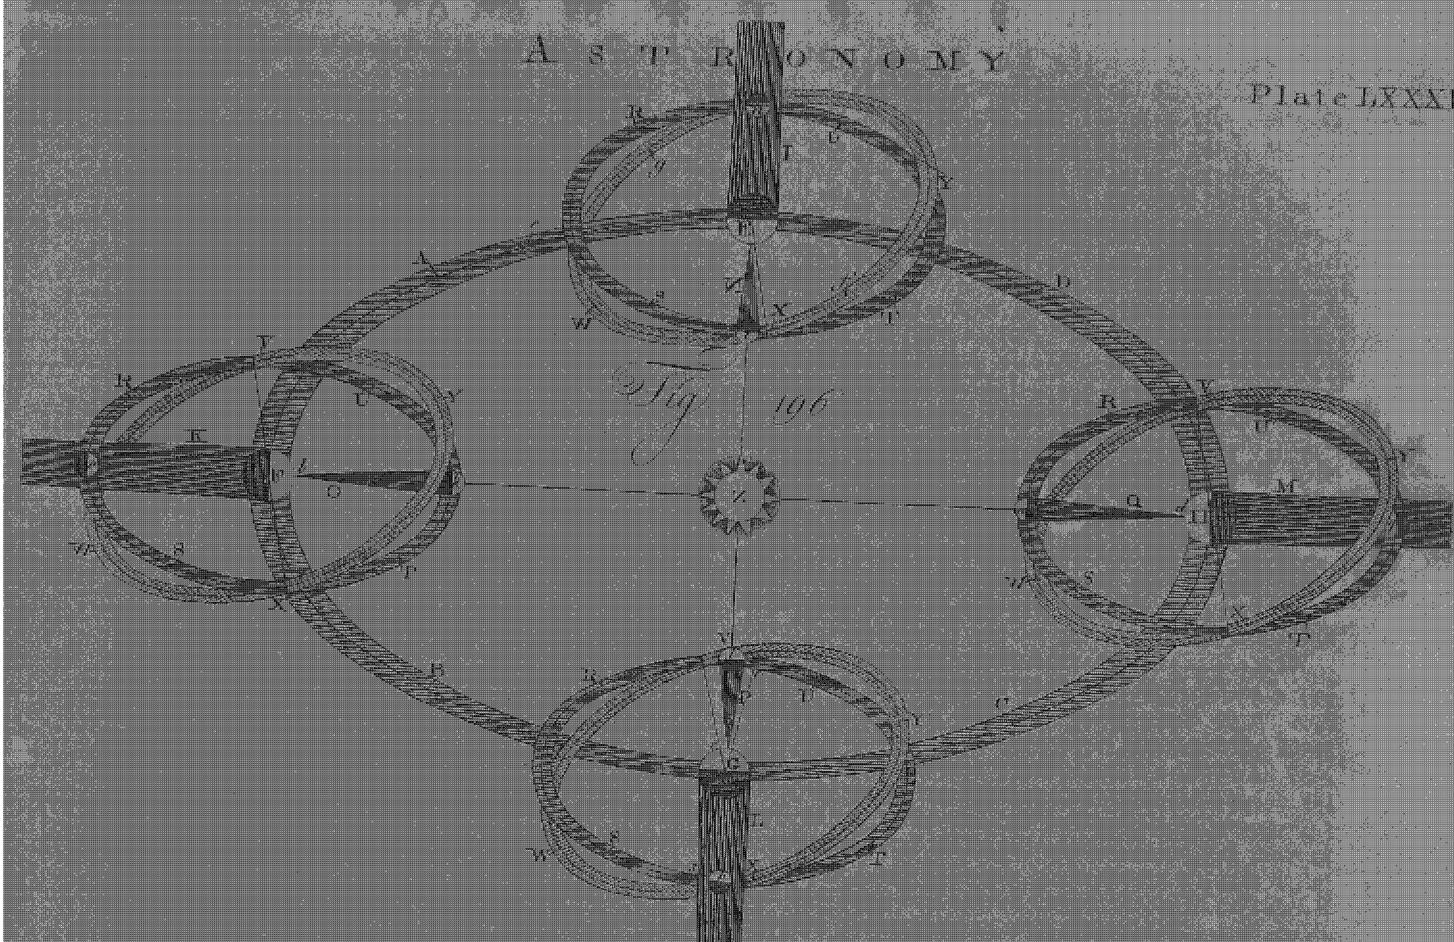

Fig. 196

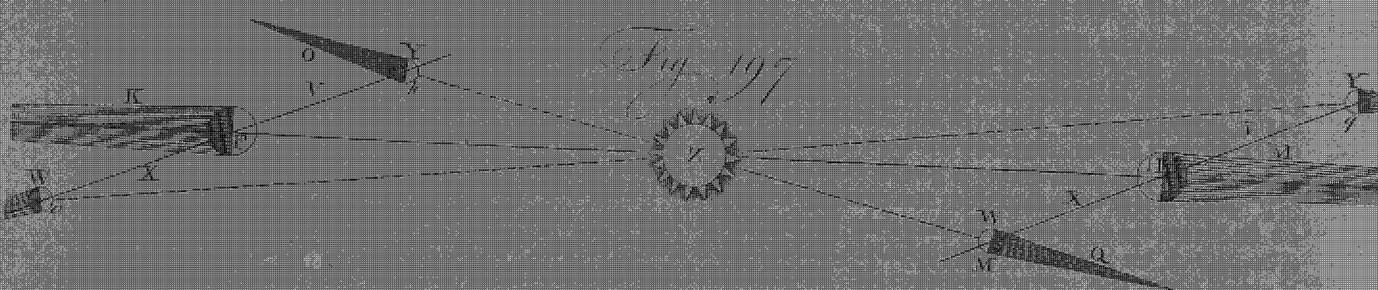

Fig. 197

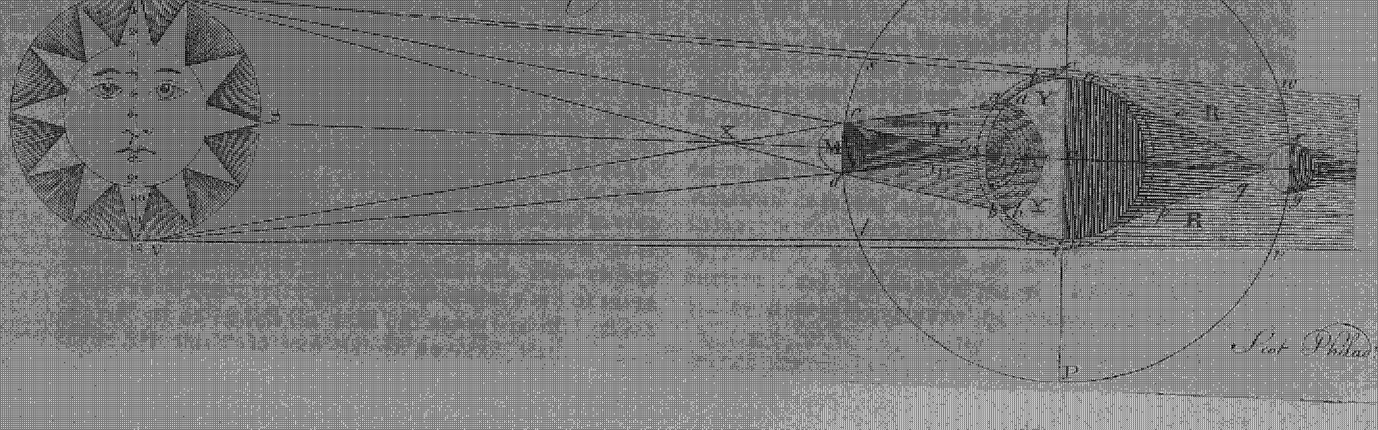
Fig. 198



Scot Philada

Of calculating Eclipses, &c.

its anomalies, &c. to the former numbers, if the new moon falls before the 15th of March; but if it falls after, subtract the half lunation, with the anomalies, &c. belonging to it, from the former numbers, and write down the respective sums or remainders.

II. In these additions or subtractions, observe, that 60 seconds make a minute, 60 minutes make a degree, 30 degrees make a sign, and 12 signs make a circle. When you exceed 12 signs in addition, reject 12, and set down the remainder. When the number of signs to be subtracted is greater than the number you subtract from, add 12 signs to the lesser number, and then you will have a remainder to set down. In the tables signs are marked thus ^{s}, degrees thus $^\circ$, minutes thus $'$, and seconds thus $''$.

III. When the required new or full moon is in any given month after March, write out as many lunations with their anomalies, and the sun's distance from the node from Table III. as the given month is after March, setting them in order below the numbers taken out for March.

IV. Add all these together, and they will give the mean time of the required new or full moon, with the mean anomalies and sun's mean distance from the ascending node, which are the arguments for finding the proper equations.

V. With the number of days added together, enter Table IV. under the given month; and against that number you have the day of mean new or full moon in the left-hand column, which set before the hours, minutes, and seconds, already found.

But (as it will sometimes happen) if the said number of days fall short of any in the column under the given month, add one lunation and its anomalies, &c. (from Table III.) to the foresaid sums, and then you will have a new sum of days wherewith to enter Table IV. under the given month, where you are sure to find it the second time, if the first falls short.

VI. With the signs and degrees of the sun's anomaly, enter Table VII. and therewith take out the annual or first equation for reducing the mean syzygy to the true; taking care to make proportions in the table for the odd minutes and seconds of anomaly, as the table gives the equation only to whole degrees.

Observe, in this and every other case of finding equations, that if the signs are at the head of the table, their degrees are at the left hand, and are reckoned downwards; but if the signs are at the foot of the table, their degrees are at the right hand, and are counted upward; the equation being in the body of the table, under or over the signs, in a collateral line with the degrees. The titles *Add* or *Subtract* at the head or foot of the tables where the signs are found, show whether the equation is to be added to the mean time of new or full moon, or to be subtracted from it. In this table the equation is to be subtracted, if the signs of the sun's anomaly are found at the head of the table; but it is to be added, if the signs are at the foot.

Of calculating Eclipses, &c.

VII. With the signs and degrees of the sun's mean anomaly, enter Table VIII. and take out the equation of the moon's mean anomaly; subtract this equation from her mean anomaly, if the signs of the sun's anomaly be at the head of the table, but add it if they are at the foot; the result will be the moon's equated anomaly, with which enter table IX. and take out the second equation for reducing the mean to the true time of new or full moon; adding this equation, if the signs of the moon's anomaly are at the head of the table, but subtracting it if they are at the foot; and the result will give you the mean time of the required new or full moon twice equated, which will be sufficiently near for common almanacs.—But when you want to calculate an eclipse, the following equations must be used: thus,

VIII. Subtract the moon's equated anomaly from the sun's mean anomaly, and with the remainder in signs and degrees enter Table X. and take out the third equation, applying it to the former equated time, as the titles *Add* or *Subtract* do direct.

IX. With the sun's mean distance from the ascending node enter Table XI. and take out the equation answering to that argument, adding it to, or subtracting it from, the former equated time, as the titles direct, and the result will give the time of new or full moon, agreeing with well regulated clocks or watches very near the truth. But to make it agree with the solar, or apparent time, you must apply the equation of natural days, taken from an equation-table, as it is leap-year, or the first, second, or third after. This, however, unless in very nice calculations, needs not be regarded, as the difference between true and apparent time is never very considerable.

The method of calculating the time of any new or full moon without the limits of the 18th century, will be shown further on. And a few examples compared with the precepts will make the whole work plain.

N. B. The tables begin the day at noon, and reckon forward from thence to the noon following.—Thus, March the 31st, at 22 ho. 30 min. 25 sec. of tabular time, is April 1st (in common reckoning) at 30 min. 25 sec. after 10 o'clock in the morning.

Time once equated,	32	1	50	19	9	20	27	1	11	10	59	18	Sun from Node, and Arg. 4th equation.			
Second Equation,	—	3	24	49	Arg. 3d. equation				Arg. 2d equation.							
Time twice equated,	31	22	25	30												
Third Equation,		+	4	37												
Time thrice equated,	31	22	30	7												
Fourth Equation,			+	18												
True New Moon,	31	22	30	25												
Equation of days,		—	3	48												
Apparent time,	31	22	26	37												

So the true time is 22 h. 30 min. 25 sec. after the noon of the 31st March; that is, April 1st, at 30 min. 25 sec. after ten in the morning. But the apparent time is 26 min. 37 sec. after ten in the morning.

EXAMPLE II.

454 Qu. *The true time of the Full Moon in* May 1762, *New Style?*

By the Precepts,	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s	°	'	"	s	°	'	"	s	°	'	"
March 1762,	24	15	18	24	8	23	48	16	1	23	59	11	10	18	49	14
Add 2 Lunations,	59	1	28	6	1	28	12	39	1	21	38	1	2	1	20	28
New Moon, May,	22	16	46	30	10	22	0	55	3	15	37	12	0	20	9	42
Subt. ½ Lunation,	14	18	22	2	0	14	33	10	6	12	54	30	0	15	20	7
Full Moon, May,	7	22	24	28	10	7	27	45	9	2	42	42	0	4	49	35
First equation,	+	3	16	36	9	3	57	18	+	1	14	36				
Time once equated,	8	1	41	4	1	3	30	27	9	3	57	18	Sun from Node, and Arg. fourth equation.			
Second Equation,	—	9	47	53	Arg. 3d equation.				Arg. 2d equation.							
Time twice equated,	7	15	53	11												
Third Equation,		—	2	36												
Time thrice equated,	7	15	50	35												
Fourth Equation,			+	15												
The Full Moon,	7	15	50	50												

Ans. May 7th at 15 h. 50 min. 50 sec. past noon, *viz.* May 8th at 3 h. 50 min. 50 sec. in the morning.

455 *To calculate the time of New and Full Moon in a given year and month of any particular century, between the Christian æra and the 18th century.*

Precept I. Find a year of the same number in the 18th century with that of the year in the century proposed, and take out the mean time of new moon in March, old style, for that year, with the mean anomalies and sun's mean distance from the node at that time, as already taught.

II. Take as many complete centuries of years from Table VI. as, when subtracted from the abovesaid year in the 18th century, will answer to the given year; and take out the first mean new moon and its anomalies, &c. belonging to the said centuries, and set them below those taken out for March in the 18th century.

III. Subtract the numbers belonging to these centuries from those of the 18th century, and the remainders will be the mean time and anomalies, &c. of new moon, in March, in the given year of the century proposed,—Then, work in all respects for the true time of new or full moon, as shown in the above precepts and examples.

IV. If the days annexed to these centuries exceed the number of days from the beginning of March taken out in the 18th century, add a lunation and its anomalies, &c. from Table III. to the time and anomalies of new moon in March, and then proceed in all respects as above.—This circumstance happens in Example V.

EXAMPLE

Of calculating Eclipses, &c.

EXAMPLE III.

Required the true time of Full Moon, in April, Old Style, A. D. 30?

From 1730 subtract 1700 (or 17 centuries) and there remains 30.

By the Precepts.	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s.	o.	'	''	s.	o.	'	''	s.	o.	'	''
March 1730,	7	12	34	16	8	18	4	31	9	0	32	17	1	23	17	16
Add ½ Lunation,	14	18	22	2	0	14	33	10	6	12	54	30	0	15	20	7
Full Moon,	22	6	56	18	9	2	37	41	3	13	26	47	2	8	37	23
1700 years subtr.	14	17	36	42	11	28	46	0	10	29	36	0	4	29	23	0
Full ☽ March A. D. 30.	7	13	19	36	9	3	51	41	4	13	50	47	9	9	14	23
Add 1 Lunation,	29	12	44	3	0	29	6	19	0	25	49	0	1	0	40	14
Full Moon, April,	6	2	3	39	10	2	58	0	5	9	39	47	10	9	54	37
First Equation,	+	3	28	4	5	10	58	40	+	1	18	53	Sun from Node, and Arg. fourth equation.			
Time once equated,	6	5	31	43	4	21	59	20	5	10	58	40				
Second Equation,	+	2	57	48	Arg. 3d equation.				Arg. 2d equation.							
Time twice equated,	6	8	29	31												
Third Equation,		—	2	54												
Time thrice equated,	6	8	26	37												
Fourth Equation,		—	1	33												
True Full Moon, April,	6	8	25	4												

Hence it appears, that the true time of Full Moon in April, A. D. 30, old style, was on the 6th day at 25 m. 4 s. past eight in the evening.

456 *To calculate the true time of New or Full Moon in any given year and month before the Christian æra.*

Precept I. Find a year in the 18th century, which being added to the given number of years before Christ diminished by one, shall make a number of complete centuries.

II. Find this number of centuries in Table VI. and subtract the time and anomalies belonging to it from those of the mean new moon in March, the above-found year of the 18th century; and the remainder will denote the time and anomalies, &c. of mean new moon in March, the given year before Christ.—Then, for the true time thereof in any month of that year, proceed as above taught.

EXAMPLE IV.

Required the true time of New Moon in May, *Old Style, the year before Christ* 585?

The years 584 added to 1716, makes 2300, or 23 centuries.

By the Precepts.	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s.	o	'	''	s.	o	'	''	s.	o	'	''
March 1716,	11	17	33	29	8	22	50	39	4	4	14	2	4	27	17	5
2300 years subtract,	11	5	57	53	11	19	47	0	1	5	59	0	7	25	27	0
March before Christ 585,	0	11	35	36	9	3	3	39	2	28	15	2	9	1	50	5
Add 3 Lunations,	88	14	12	9	2	27	18	58	2	17	27	1	3	2	0	42
May before Christ 585,	28	1	47	45	0	0	22	37	5	15	42	3	0	3	50	47
First Equation,		—	1	37	5	15	41	17			—	46	Sun from Node, and Arg. fourth equation.			
Time once equated,	28	1	46	8	6	14	41	20	5	15	41	17				
Second Equation,	+	2	15	1	Arg. 3d equation.				Arg. 2d equation.							
Time twice equated,	28	4	1	9												
Third Equation,		+	1	9												
Time thrice equated,	28	4	2	18												
Fourth Equation,			+	12												
True New Moon,	28	4	2	30												

So the true time was May 28th, at 2 minutes 30 seconds past four in the afternoon.

These Tables are calculated for the meridian of London; but they will serve for any other place, by subtracting four minutes from the tabular time, for every degree that the meridian of the given place is westward of London, or adding four minutes for every degree that the meridian of the given place is eastward: as in

Of calculating Eclipses, &c.

Of calculating Eclipses, &c.

EXAMPLE V.

Required the true time of Full Moon at Alexandria *in* Egypt *in* September, *Old Style, the year before Christ* 201?
The years 200 added to 1800, make 2000, or 20 centuries.

By the Precepts.	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M.	S.	s	°	′	″	s	°	′	″	s	°	′	″
March 1800,	13	0	22	17	8	23	19	55	10	7	52	36	11	3	58	24
Add 1 Lunation,	29	12	44	3	0	29	6	19	0	25	49	0	1	0	40	14
From the sum,	42	13	6	20	9	22	26	14	11	3	41	36	0	4	38	38
Subtract 2000 years,	27	18	9	19	0	8	50	0	0	15	42	0	6	27	45	0
N. M. bef. Chr. 201,	14	18	57	1	9	13	36	14	10	17	59	36	5	6	53	38
Add { 6 Lunations,	177	4	24	18	5	24	37	56	5	4	54	3	6	4	1	24
{ half Lunations,	14	18	22	2	0	14	33	10	6	12	54	30	0	15	20	7
Full Moon, September,	22	17	43	21	3	22	47	20	10	5	48	9	11	26	15	9
First Equation,	—	3	52	6	10	4	19	55	—	1	28	14	Sun from Node, and Argument fourth equation.			
Time once equated,	22	13	51	15	5	18	27	25	10	4	19	55				
Second Equation,	—	8	25	4	Arg. 3d equation.				Arg. 2d equation.							
Time twice equated,	22	5	26	11												
Third Equation,			—	58												
Time thrice equated,	22	5	25	13												
Fourth Equation,			—	12												
True time at London,	22	5	25	1												
Add for Alexandria,		2	1	27												
True time there,	22	7	26	28												

Thus it appears, that the true time of Full Moon at Alexandria, in September, old style, the year before Christ 201, was the 22d day, at 26 minutes 28 seconds after seven in the evening.

EXAMPLE VI.

Required the true time of Full Moon at Babylon *in* October, *Old Style, the* 4008 *year before the first year of Christ, or* 4007 *before the year of his birth?*
The years 4007 added to 1793, make 5800, or 58 centuries.

By the Precepts.	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H.	M	S.	s	°	′	″	s	°	′	″	s	°	′	″
March 1793,	30	9	13	55	9	10	16	11	8	7	37	58	7	6	18	26
Subtract 5800 years,	15	12	38	7	10	21	35	0	6	24	43	0	9	13	1	0
N. M. bef. Chr. 4007,	14	20	35	48	10	18	41	11	1	12	54	58	9	23	17	26
Add { 7 Lunations,	206	17	8	21	6	23	44	15	6	0	43	3	7	4	41	38
{ half Lunations.	14	18	22	2	0	14	33	10	6	12	54	30	0	15	20	7
Full Moon, October,	22	8	6	11	5	26	58	36	1	26	32	31	5	13	19	11
First Equation,		—	13	26	1	26	27	26		—	5	5	Sun from Node, and Argument fourth equation.			
Time once equated,	22	7	52	45	4	0	31	10	1	26	27	26				
Second Equation,	+	8	29	21	Arg. 3d equation.				Arg. 2d equation.							
Time twice equated,	22	16	22	6												
Third Equation,		—	4	10												
Time thrice equated,	22	16	17	56												
Fourth Equation,			—	51												
Full Moon at London,	22	16	17	5												
Add for Babylon,		2	25	41												
True time there,	22	18	42	46												

So that, on the meridian of London, the true time was October 23d, at 17 minutes 5 seconds past four in the morning; but at Babylon, the true time was October 23d, at 42 minutes 46 seconds past six in the morning.—This is supposed by some to have been the year of the creation.

EXAMPLE

458 *To calculate the true time of New or Full Moon in any given year and month after the 18th century.*

Precept I. Find a year of the same number in the 18th century with that of the year proposed, and take out the mean time and anomalies, &c. of new moon in March, old style, for that year, in Table I.

II. Take so many years from Table VI. as when added to the abovementioned year in the 18th century will answer to the given year in which the new or full moon is required; and take out the first new moon, with its anomalies for these complete centuries.

III. Add all these together, and then work in all respects as above shown, only remember to subtract a lunation and its anomalies, when the abovesaid addition carries the new moon beyond the 31st of March; as in the following example.

EXAMPLE VII.

Required the true time of New Moon in July, *Old Style*, A. D. 2180?

Four centuries (or 400 years) added to A. D. 1780, make 2180.

By the Precepts.	New Moon.				Sun's Anomaly.				Moon's Anomaly.				Sun from Node.			
	D.	H	M.	S.	s	°	′	″	s	°	′	″	s	°	′	″
March 1780,	23	23	1	44	9	4	18	13	1	21	7	47	10	18	21	1
Add 400 years.	17	8	43	29	0	13	24	0	10	1	28	0	6	17	49	0
From the sum	41	7	45	13	9	17	42	13	11	22	35	47		6	10	1
Subtract 1 Lunation,	29	12	44	3	0	29	6	19	0	25	49	0		0	40	14
New Moon March 2180,	11	19	1	10	8	18	35	54	10	26	46	47	4	5	29	47
Add 4 Lunations,	118	2	56	12	3	26	25	17	3	13	16	2	4	2	40	56
New Moon July 2180.	7	21	57	22	0	15	1	11	2	10	2	49	8	8	10	43
First Equation,	—	1	3	39	3	9	38	37		—	24	12	Sun from Node, and Argument fourth equation.			
Time once equated,	7	20	53	43	10	5	22	34	2	9	38	37				
Second Equation,	+	9	24	8	Arg. 3d equation.				Arg. 2d equation.							
Time twice equated,	8	6	17	51												
Third Equation,		+	3	56												
Time thrice equated,	8	6	21	47												
Fourth Equation,		+	1	8												
True time, July,	8	6	22	55												

True time, July 8th, at 22 minutes 55 seconds past six in the evening.

In keeping by the old style, we are always sure to be right, by adding or subtracting whole hundreds of years to or from any given year in the 18th century. But in the new style we may be very apt to make mistakes, on account of the leap-year's not coming in regularly every fourth year: and therefore, when we go without the limits of the 18th century, we had best keep to the old style, and at the end of the calculation reduce the time to the new. Thus, in the 22d century there will be fourteen days difference between the styles; and therefore the true time of new moon in this last example being reduced to the new style, will be the 22d of July, at 22 minutes 55 seconds past six in the evening.

459 *To calculate the true place of the Sun for any given moment of time.*

Precept I. In Table XII. find the next lesser year in number to that in which the sun's place is sought, and write out his mean longitude and anomaly answering thereto: to which add his mean motion and anomaly for the complete residue of years, months, days, hours, minutes and seconds, down to the given time, and this will be the sun's mean place and anomaly at that time, in the old style, provided the said time be in any year after the Christian æra. *See the first following Example.*

II. Enter Table XIII. with the sun's mean anomaly, and making proportions for the odd minutes and seconds thereof, take out the equation of the sun's centre: which, being applied to his mean place as the title *Add* or *Subtract* directs, will give his true place or longitude from the vernal equinox, at the time for which it was required.

III. To calculate the sun's place for any time in a given year before the Christian æra, take out his mean longitude and anomaly for the first year thereof, and from these numbers subtract the mean motions and anomalies for the complete hundreds or thousands next above the given year; and to the remainders, add those for the residue of years, months, &c. and then work in all respects as above. *See the second Example following.*

EX-

Of Calculating Eclipses, &c.

EXAMPLE I.

Required the Sun's true place, March 20th *Old Style,* 1764, *at* 22 *hours* 30 *minutes* 25 *seconds past noon? In common reckoning,* March 21st, *at* 10 *hours* 30 *minutes* 25 *seconds in the forenoon.*

Equation of the sun's centre subtract - - - -				3	4	Sun's Anomaly.			
Sun's true place at the same time - - - - -		6	0	0	0 or ♎	0	0	0	

So that in the meridian of London, the sun was then just entering the sign ♎ Libra, and consequently was upon the point of the autumnal equinox.

If to the above time of the autumnal equinox at London, we add 2 hours 25 minutes 41 seconds for the longitude of Babylon, we shall have for the time of the same equinox, at that place, October 23d, at 19 hours 22 minutes 41 seconds; which, in the common way of reckoning, is October 24th, at 22 minutes 41 seconds past seven in the morning.

And it appears by Example VI. that in the same year, the true time of full moon at Babylon was October 23d, at 42 minutes 46 seconds after six in the morning; so that the autumnal equinox was on the day next after the day of full moon.—The dominical letter for that year was G, and consequently the 24th of October was on a Wednesday.

To find the Sun's distance from the Moon's ascending node, at the time of any given new or full moon; and consequently to know whether there is an eclipse at that time, or not. 460

The sun's distance from the moon's ascending node is the argument for finding the moon's fourth equation in the syzygies, and therefore it is taken into all the foregoing examples in finding the times thereof. Thus, at the time of mean new moon in April 1764, the sun's mean distance from the ascending node, is $0^s\ 5^\circ\ 35'\ 2''$. See Example I. p. 562.

The

Of calculating Eclipses, &c.

The descending node is opposite to the ascending one, and they are just six signs distant from each other.

When the sun is within 17 degrees of either of the nodes at the time of new moon, he will be eclipsed at that time: and when he is within 12 degrees of either of the nodes at the time of full moon, the moon will be then eclipsed. Thus we find, that there was an eclipse of the sun at the time of new moon in April 1764.

But the true time of that new moon comes out by the equations to be 50 minutes 46 seconds later than the mean time thereof, by comparing these times in the above example: and therefore we must add the sun's motion from the node during that interval to the above mean distance $0^s\ 5°\ 35'\ 2''$, which motion is found in Table XII. for 50 minutes 46 seconds, to be $2'\ 12''$. And to this we must apply the equation of the sun's mean distance from the node in Table XV. found by the sun's anomaly, which at the mean time of new moon in Example I. is $9^s\ 1°\ 26'\ 19''$; and then we shall have the sun's true distance from the node, at the true time of new moon, as follows:

	Sun from Node.			
	s	o	′	″
At the mean time of new moon in April 1764	0	5	35	2
Sun's motion from the node for { 50 minutes			2	10
{ 46 seconds				2
Sun's mean distance from node at true new moon	0	5	37	14
Equation of mean distance from node, add		2	5	0
Sun's true distance from the ascending node	0	7	42	14

Which being far within the above limit of 17 degrees, shows that the sun must then have been eclipsed.

And now we shall show how to project this, or any other eclipse, either of the sun or moon.

461 *To project an Eclipse of the Sun.*

In order to this, we must find the 10 following elements, by means of the tables.

1. The true time of conjunction of the sun and moon; and at that time. 2. The semidiameter of the earth's disk, as seen from the moon, which is equal to the moon's horizontal parallax. 3. The sun's distance from the solstitial colure to which he is then nearest. 4. The sun's declination. 5. The angle of the moon's visible path with the ecliptic. 6. The moon's latitude. 7. The moon's true horary motion from the sun. 8. The sun's semidiameter. 9. The moon's. 10. The semidiameter of the penumbra.

We shall now proceed to find these elements for the sun's eclipse in April 1764.

462 *To find the true time of new moon.* This, by Example I. p. 562, is found to be on the first day of the said month, at 30 minutes 25 seconds after ten in the morning.

463 2. *To find the moon's horizontal parallax, or semidiameter of the earth's disk, as seen from the moon.* Enter Table XVII. with the signs and degrees of the moon's anomally (making proportions, because the anomaly is in the table only to every 6th degree), and thereby take out the moon's horizontal parallax; which for the above time, answering to the anomaly $11^s\ 9°\ 24'\ 21''$, is $54'\ 43''$.

3. *To find the sun's distance from the nearest solstice, viz. the beginning of Cancer, which is 3^s or 90° from the beginning of Aries.* It appears by Example I. in p. 566 (where the sun's place is calculated to the above time of new moon), that the sun's longitude from the beginning of Aries is then $0^s\ 12°\ 10'\ 12''$; that is, the sun's place at that time is ♈ Aries, $12°\ 10'\ 12''$. 464

	s	o	′	″
Therefore from - -	3	0	0	0
Subtract the Sun's longitude or place	0	12	10	12
Remains the sun's distance from the solstice ♋ =	2	17	49	48

Or $77°\ 49'\ 48''$; each sign containing 30 degrees.

5. *To find the sun's declination.* Enter Table XIV. with the signs and degrees of the sun's true place, viz. $0^s\ 12°$, and making proportions for the $10'\ 12''$, take out the sun's declination answering to his true place, and it will be found to be $4°\ 49'$ north. 465

5. *To find the moon's latitude.* This depends on her distance from her ascending node, which is the same as the sun's distance from it at the time of new moon; and is thereby found in Table XVI. 466

But we have already found, that the sun's equated distance from the ascending node, at the time of new moon in April 1764, is $0^s\ 7°\ 42'\ 14''$. See above.

Therefore, enter Table XVI. with 0 signs at the top, and 7 and 8 degrees at the left hand, and take out $36'$ and $39''$, the latitude for 7°; and $41'\ 51''$, the latitude for 8°: and by making proportions between these latitudes for the $42'\ 14''$, by which the moon's distance from the node exceeds 7 degrees; her true latitude will be found to be $40'\ 18''$ north ascending.

6. *To find the moon's true horary motion from the sun.* With the moon's anomaly, viz. $11^s\ 9°\ 24'\ 21''$, Table XVII. and take out the moon's horary motion; which, by making proportions in that table, will be found to be $30'\ 22''$. Then, when the sun's anomaly, $9^s\ 1°\ 26'\ 19''$, take out his horary motion $2'\ 28''$ from the same table: and subtracting the latter from the former, there will remain $27'\ 54''$ for the moon's true horary motion from the sun. 467

7. *To find the angle of the moon's visible path with the ecliptic.* This, in the projection of eclipses, may be always rated at $5°\ 35'$, without any sensible error. 468

8, 9. *To find the semidiameters of the sun and moon.* These are found in the same table, and by the same arguments, as their horary motions. In the present case, the sun's anomaly gives his semidiameters $16'\ 6''$, and the moon's anomaly gives her semidiameter $14'\ 57''$. 469

10. *To find the semidiameter of the penumbra.* Add the moon's semidiameter to the sun's, and their sum will be the semidiameter of the penumbra, viz. $31'\ 3''$. 470

Now collect these elements, that they may be found the more readily when they are wanted in the construction of this eclipse.

Of calculating Eclipses, &c.

		°	′	″
1. True time of new moon in April, 1764 - -	I	10	30	25
2. Semidiameter of the earth's disk		0	54	53

7. Angle of the moon's visible path with the ecliptic		5	35	0
8. Sun's semidiameter			16	6
9. Moon's semidiameter			14	57
10. Semidiameter of the penumbra			31	3

To project an Eclipse of the Sun geometrically.

Make a scale of any convenient length, as AC, and divide it into as many equal parts as the earth's semidisk contains minutes of a degree; which, at the time of the eclipse in April 1764, is 54′ 53″. Then, with the whole length of the scale as a radius, describe the semicircle AMB upon the centre C; which semicircle shall represent the northern half of the earth's enlightened disk, as seen from the sun.

Upon the centre C raise the straight line CH, perpendicular to the diameter ACB; so ACB shall be a part of the ecliptic, and CH its axis.

Being provided with a good sector, open it to the radius CA in the line of chords; and taking from thence the chord of 23½ degrees in your compasses, set it off both ways from H, to *g* and to *h*, in the periphery of the semidisk; and draw the straight line *g* V *h*, in which the north pole of the disk will be always found.

When the sun is in Aries, Taurus, Gemini, Cancer, Leo, and Virgo, the north pole of the earth is enlightened by the sun; but whilst the sun is in the other six signs, the south pole is enlightened, and the north pole is in the dark.

And when the sun is in Capricorn, Aquarius, Pisces, Aries, Taurus, and Gemini, the northern half of the earth's axis C XII P lies to the right hand of the axis of the ecliptic, as seen from the sun; and to the left hand, whilst the sun is in the other six signs.

Open the sector till the radius (or distance of the two 90's) of the sines be equal to the length of V *h*, and take the sine of the sun's distance from the solstice (77° 49′ 48″) as nearly as you can guess, in your compasses, from the line of sines, and set off that distance from V to P in the line *g* V *h*, because the earth's axis lies to the right hand of the axis of the ecliptic in this case, the sun being in Aries; and draw the straight line C XII P for the earth's axis, of which P is the north pole. If the earth's axis had lain to the left hand from the axis of the ecliptic, the distance VP would have been set off from V towards *g*.

To draw the parallel of latitude of any given place, as suppose London, or the path of that place on the earth's enlightened disk as seen from the sun, from sunrise till sun-set, take the following method.

Subtract the latitude of London, 51½°, from 90°, and the remainder 38½° will be the co-latitude, which take in your compasses from the line of chords, making CA or CB the radius, and set it from *h* (where the earth's axis meets the periphery of the disk) to VI and VI, and draw the occult or dotted line VI K VI. Then, from the points where this line meets the earth's disk, set off the chord of the sun's declination 4° 49′ to D and F, and to E and G, and connect these points by the two occult lines F XII G and DLE.

Bisect LK XII in K, and through the point K draw the black line VI K VI. Then making CB the radius of a line of sines on the sector, take the co-latitude of London 38½° from the sines in your compasses, and set it both ways from K to VI and VI. These hours will be just in the edge of the disk at the equinoxes, but at no other time in the whole year.

With the extent K VI taken into your compasses, set one foot in K (in the black line below the occult one) as a centre, and with the other foot describe the semicircle VI 7 8 9 10, &c. and divide it into 12 equal parts. Then from these points of division draw the occult lines 7*p*, 8*o*, 9*n*, &c. parallel to the earth's axis C XII P.

With the small extent K XII as a radius, describe the quadrantal arc XII*f*, and divide it into six equal parts, as XII *a*, *ab*, *bc*, *cd*, *de*, and *ef*; and through the division-points *a*, *b*, *c*, *d*, *e*, draw the occult lines VII *e* V, VIII *d* IV, IX *c* III, X *b* II, and XI *a* I, all parallel to VI K VI, and meeting the former occult lines 7 *p* 8 *o*, &c. in the points VII VIII IX X XI, V IV III II and I: which points shall mark the several situations of London on the earth's disk, at these hours respectively, as seen from the sun; and the elliptic curve VI VII VII, &c. being drawn through these points, shall represent the parallel of latitude, or path of London on the disk, as seen from the sun, from its rising to its setting.

N. B. If the sun's declination had been south, the diurnal path of London would have been on the upper side of the line VI K VI, and would have touched the line DLE in L. It is requisite to divide the horary spaces into quarters (as some are in the figure), and, if possible, into minutes also.

Make CB the radius of a line of chords on the sector, and taking therefrom the chord of 5° 35′, the angle of the moon's visible path with the ecliptic, set it off from H to M on the left hand of CH, the axis of the ecliptic, because the moon's latitude is north ascending. Then draw CM for the axis of the moon's orbit, and bisect the angle MCH by the right line C*z*. If the moon's latitude had been north descending, the axis of her orbit would have been on the right hand from the axis of the ecliptic.——N. B. The axis of the moon's orbit lies the same way when her latitude is south ascending as when it is north ascending, and the same way when south descending as when north descending.

Take the moon's latitude 40′ 18″ from the scale C A in your compasses, and set it from *i* to *x* in the bisecting line C*z*, making *ix* parallel to C*y*: and thro' *x*, at right angles to the axis of the moon's orbit CM, draw the straight line N *wxy*S for the path of the penumbra's centre over the earth's disk.—The point *w*, in the axis of the moon's orbit, is that where the penumbra's centre approaches nearest to the centre of the earth's disk, and consequently is the middle of the general eclipse: the point *x* is that where the conjunction

I of

Fig. 199

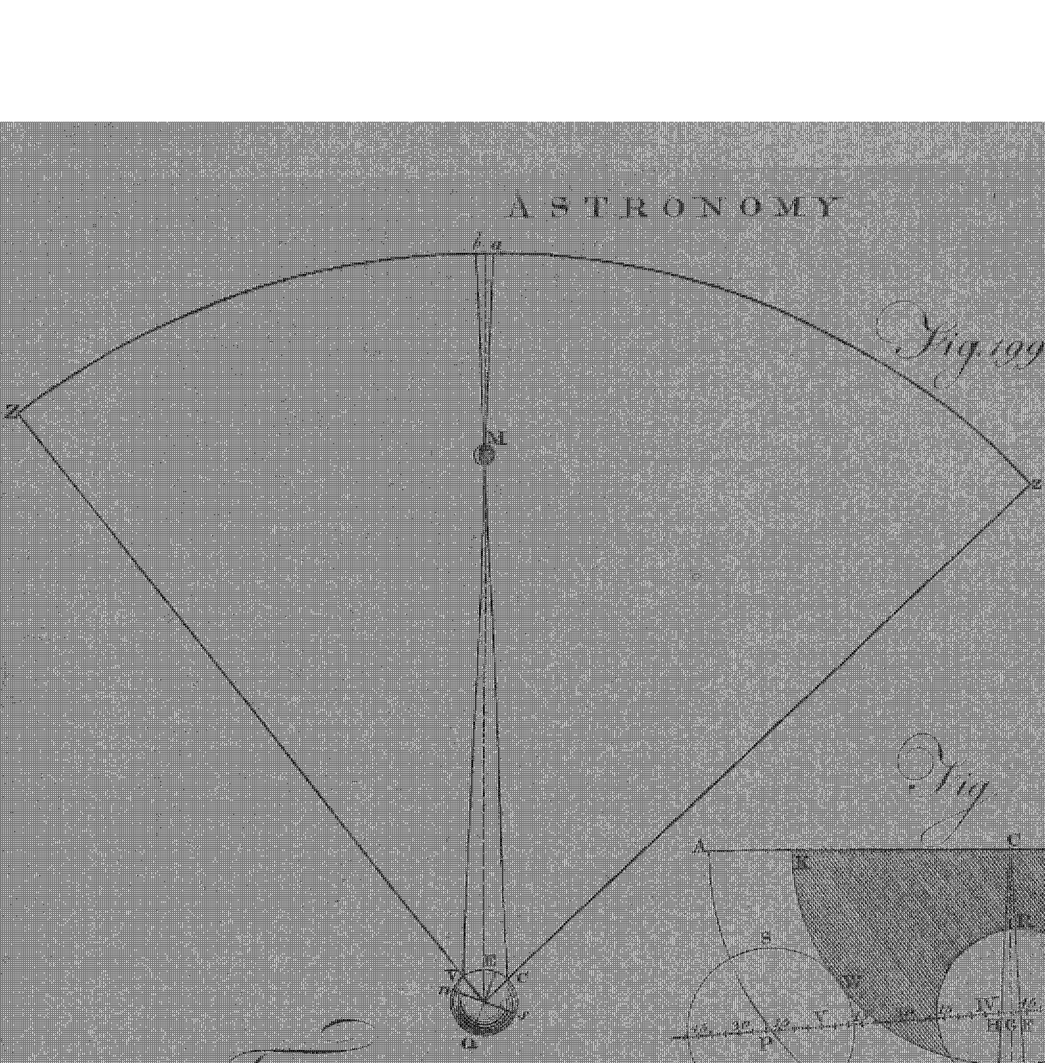

Fig. 202

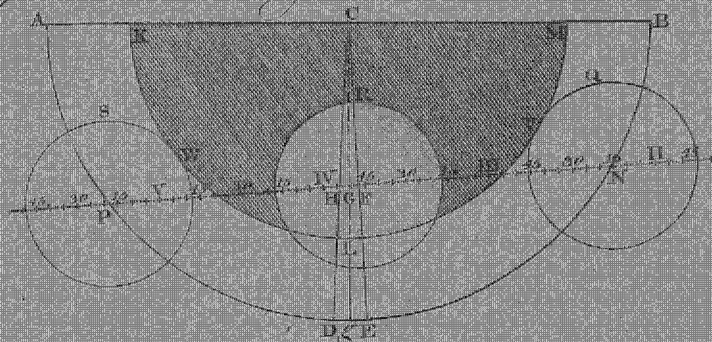

Fig. 201

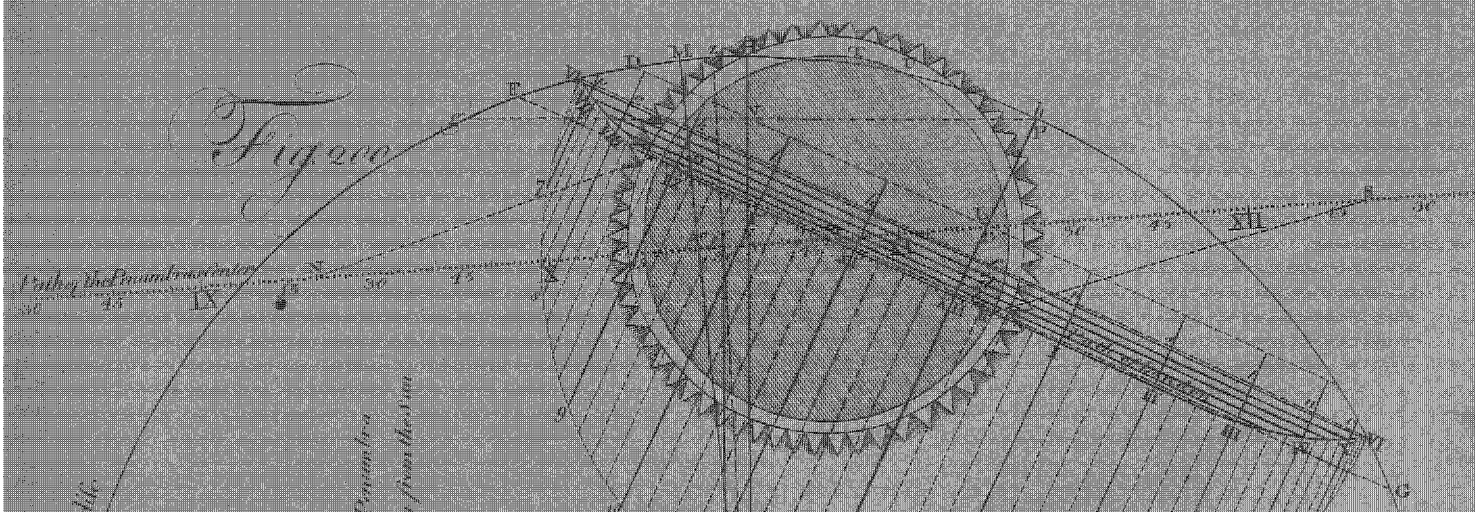
Fig. 200



Of calculating Eclipses, &c.

of the sun and moon falls, according to equal time by the tables; and the point y is the ecliptical conjunction of the sun and moon.

Take the moon's true horary motion from the sun, 27′ 54″, in your compasses, from the scale CA (every division of which is a minute of a degree), and with that extent make marks along the path of the penumbra's centre; and divide each space from mark to mark into sixty equal parts or horary minutes, by dots; and set the hours to every 60th minute in such a manner, that the dot signifying the instant of new moon by the tables, may fall into the point x, half way between the axis of the moon's orbit and the axis of the ecliptic; and then, the rest of the dots will show the points of the earth's disk, where the penumbra's centre is at the instants denoted by them, in its transit over the earth.

Apply one side of a square to the line of the penumbra's path, and move the square backwards and forwards until the other side of it cuts the same hour and minute (as at m and m) both in the path of London and in the path of the penumbra's centre; and the particular minute or instant which the square cuts at the same time in both paths, shall be the instant of the visible conjunction of the sun and moon, or greatest obscuration of the sun, at the place for which the construction is made, namely, London, in the present example; and this instant is at 47½ minutes past ten o'clock in the morning; which is 17 minutes five seconds later than the tabular time of true conjunction.

Take the sun's semidiameter, 16′ 6″, in your compasses, from the scale CA, and setting one foot in the path of London, at m, namely at 47½ minutes past ten, with the other foot describe the circle UY, which shall represent the sun's disk as seen from London at the greatest obscuration.—Then take the moon's semidiameter, 14′ 57″, in your compasses from the same scale; and setting one foot in the path of the penumbra's centre at m, in the 47½ minute after ten, with the other foot describe the circle TY for the moon's disk, as seen from London, at the time when the eclipse is at the greatest, and the portion of the sun's disk which is hid or cut off by the moon's will show the quantity of the eclipse at that time; which quantity may be measured on a line equal to the sun's diameter, and divided into 12 equal parts for digits.

Lastly, take the semidiameter of the penumbra, 31′ 3″, from the scale CA in your compasses; and setting one foot in the line of the penumbra's central path, on the left hand from the axis of the ecliptic, direct the other foot toward the path of London; and carry that extent backwards and forwards till both the points of the compasses fall into the same instants in both the paths: and these instants will denote the time when the eclipse begins at London.—Then, do the like on the right hand of the axis of the ecliptic; and where the points of the compasses fall into the same instants in both of the paths, they will show at what time the eclipse ends at London.

These trials give 20 minutes after nine in the morning for the beginning of the eclipse at London, at the points N and O; 47½ minutes after ten, at the points m and n, for the time of greatest obscuration; and 18 minutes after twelve, at R and S, for the time when the eclipse ends; according to mean or equal time.

From these times we may subtract the equation of natural days, &c. 3 minutes 48 seconds, in leap-year April 1, and we shall have the apparent times; namely, 9 hours 16 minutes 12 seconds for the beginning of the eclipse, 10 hours 43 minutes 42 seconds for the time of greatest obscuration, and 12 hours 14 minutes 12 seconds for the time when the eclipse ends. But the best way is to apply this equation to the true equal time of new moon, before the projection be begun; as is done in Example I. For the motion or position of places on the earth's disk answer to apparent or solar time.

In this construction it is supposed, that the angle under which the moon's disk is seen, during the whole time of the eclipse, continues invariably the same; and that the moon's motion is uniform and rectilineal during that time. But these suppositions do not exactly agree with the truth; and therefore, supposing the elements given by the tables to be accurate, yet the times and phases of the eclipse, deduced from its construction, will not answer exactly to what passeth in the heavens; but may be at least two or three minutes wrong, though done with the greatest care. Moreover, the paths of all places of considerable latitudes, are nearer the centre of the earth's disk, as seen from the sun, than those constructions make them: because the disk is projected as if the earth were a perfect sphere although it is known to be a spheroid. Consequently, the moon's shadow will go farther northward in all places of northern latitude, and farther southward in all places of southern latitude, than it is shown to do in these projections.—According to Meyer's Tables, this eclipse was about a quarter of an hour sooner than either these tables, or Mr Flamstead's or Dr Halley's, make it, and was not annular at London. But M. de la Caille's make it almost central.

The projection of lunar eclipses.

When the moon is within 12 degrees of either of her nodes at the time when she is full, she will be eclipsed, otherwise not. 471

We find by example second, page 562, that at the time of mean full moon in May 1762, the sun's distance from the ascending node was only 4° 49′ 35″; and the moon being then opposite to the sun, must have been just as near her descending node, and was therefore eclipsed.

The elements for constructing an eclipse of the moon, are eight in number, as follow:

1. The true time of full moon; and at that time. 472
2. The moon's horizontal parallax. 3. The sun's semidiameter. 4. The moon's. 5. The semidiameter of the earth's shadow at the moon. 6. The moon's latitude. 7. The angle of the moon's visible path with the ecliptic. 8. The moon's true horary motion from the sun.——Therefore,

1. *To find the true time of new or full moon.* Work as already taught in the precepts.—Thus we had the true time of full moon in May 1762 (See Example II. page 562) on the 8th day, at 50 minutes 50 seconds past three o'clock in the morning. 473

2. *To find the moon's horizontal parallax.* Enter Table XVII. with the moon's mean anomaly (at the above full) 9ˢ 2° 42′ 42″, and thereby take out her horizontal parallax, which by making the requisite proportions, will be found to be 57′ 23″. 474

3, 4. *To find the semidiameters of the sun and moon.* Enter Table XVII. with their respective anomalies, the sun's being 10ˢ 7° 27′ 45″ (by the above example) and the moon's 9ˢ 2° 42′ 42″; and thereby take out their respective semidiameters; the sun's 15′ 56″, and the moon's 15′ 38″. 475

476 5. *To find the semidiameter of the earth's shadow at the moon.* Add the sun's horizontal parallax, which is always 10″, to the moon's which in the present case is 57′ 23″, the sum will be 57′ 33″, from which subtract the sun's semidiameter 15′ 56″, and there will remain 41′ 36″ for the semidiameter of that part of the earth's shadow which the moon then passes through.

477 6. *To find the moon's latitude.* Find the sun's true distance from the ascending node (as already taught in page 566) at the true time of full moon; and this distance increased by six signs, will be the moon's true distance from the same node; and consequently the argument for finding her true latitude, as shown in p. 566.

478 Thus, in Example II. the sun's mean distance from the ascending node was 0s 4° 49′ 35″, at the time of mean full moon: but it appears by the example, that the true time thereof was six hours 33 minutes 38 seconds sooner than the mean time; and therefore we must subtract the sun's motion from the node (found in Table XII.) during this interval, from the above mean distance 0s 4° 49′ 35″, in order to have his mean distance from it at the true time of full moon. Then to this apply the equation of his mean distance from the node, found in Table XV. by his mean anomaly 10s 7° 27′ 45″; and lastly add six signs: so shall the moon's true distance from the ascending node be found as follows:

	S	°	′	″
Sun from node at mean full moon	0	4	49	35
His motion from it in { 6 hours			15	35
33 minutes			1	26
38 seconds				2
Sum, subtract from the uppermost line			17	3
Remains his mean distance at true full moon	0	4	32	32
Equation of his mean distance, add		1	38	0
Sun's true distance from the node	0	6	10	32
To which add	6	0	0	0
And the sum will be	6	6	10	32

Which is the moon's true distance from her ascending node at the true time of her being full; and consequently the argument for finding her true latitude at that time.—Therefore, with this argument, enter Table XVI. making proportions between the latitudes belonging to the 6th and 7th degree of the argument at the left hand (the signs being at top) for the 10′ 32″ and it will give 32′ 21″ for the moon's true latitude, which appears by the table to be south descending.

479 7. *To find the angle of the moon's visible path with the ecliptic.* This may be stated at 5° 35′, without any error of consequence in the projection of the eclipse.

480 8. *To find the moon's true horary motion from the sun.* With their respective anomalies take out their horary motions from Table XVII. and the sun's horary motion subtracted from the moon's leaves remaining the moon's true horary motion from the sun: in the present case 30′ 52″.

481 Now collect these elements together for use.

	D.	H.	M.	S.
1. True time of full moon in May, 1762	8	3	50	50
		°	′	″
2. Moon's horizontal parallax		0	57	23
3. Sun's semidiameter		0	15	56
4. Moon's semidiameter		0	15	38
5. Semidiameter of the earth's shadow at the moon		0	41	37
6. Moon's true latitude, south descending		0	32	21
7. Angle of her visible path with the ecliptic		5	35	0
8. Her true horary motion from the sun		0	30	52

These elements being found for the construction of the moon's eclipse in May 1762, proceed as follows:

Make a scale of any convenient length, as WX (fig. 201.), and divide it into 60 equal parts, each part standing for a minute of a degree.

Draw the right line ACB (fig. 202.) for part of the ecliptic, and CD perpendicular thereto for the southern part of its axis; the moon having south latitude.

Add the semidiameters of the moon and earth's shadow together, which in this eclipse will make 57′ 15″; and take this from the scale in your compasses, and setting one foot in the point C as a centre, with the other foot describe the semicircle ADB; in one point of which the moon's centre will be at the beginning of the eclipse, and in another at the end thereof.

Take the semidiameter of the earth's shadow, 41′ 37″, in your compasses from the scale, and setting one foot in the centre C, with the other foot describe the semicircle KLM for the southern half of the earth's shadow, because the moon's latitude is south in this eclipse.

Make CD equal to the radius of a line of chords on the sector, and set off the angle of the moon's visible path with the ecliptic, 5° 35′, from D to E, and draw the right line CFE for the southern half of the axis of the moon's orbit lying to the right hand from the axis of the ecliptic CD, because the moon's latitude is south descending.—It would have been the same way (on the other side of the ecliptic) if her latitude had been north descending; but contrary in both cases, if her latitude had been either north ascending or south ascending.

Bisect the angle DCE by the right line C*g*; in which line the true equal time of opposition of the sun and moon falls, as given by the tables.

Take the moon's latitude, 32′ 21″ from the scale with your compasses, and set it from C to G, in the line CG*g*; ond through the point G, at right angles to CFE, draw the right line PHGFN for the path of the moon's centre. Then, F shall be the point in the earth's shadow, where the moon's centre is at the middle of the eclipse: G, the point where her centre is at the tabular time of her being full; and H, the point where her centre is at the instant of her ecliptical opposition.

Take the moon's horary motion from the sun, 30′ 52″, in your compasses from the scale; and with that extent make marks along the line of the moon's path PGN: then divide each space from mark to mark, into 60 equal parts, or horary minutes, and set the hours to the proper dots in such a manner, that the dot signifying the instant of full moon (viz. 50 minutes 50 seconds after III in the morning) may be in the point G, where the line of the moon's path cuts the line that bisects the angle DCE.

Take the moon's semidiameter, 15′ 38″, in your compasses from the scale, and with that extent, as a radius, upon the points N, F, and P, as centres, describe the circle Q for the moon at the beginning of the eclipse, when she touches the earth's shadow at V; the circle R for the moon at the middle of the eclipse; and the circle S for the moon at the end of the eclipse, just leaving the earth's shadow at W.

The point N denotes the instant when the eclipse began, namely, at 15 minutes 10 seconds after II in the morning: the point F the middle of the eclipse at 47 minutes 44 seconds past III; and the point P the the end of the eclipse, at 18 minutes after V.—At the greatest obscuration the moon was 10 digits eclipsed.

TABLE I. *The mean Time of New Moon, in* March, *Old Style; with the mean Anomalies of the Sun and Moon, and the Sun's mean Distance from the Moon's ascending Node, from* A. D. 1700 *to* A. D. 1800 *inclusive.*

Fig. 205.

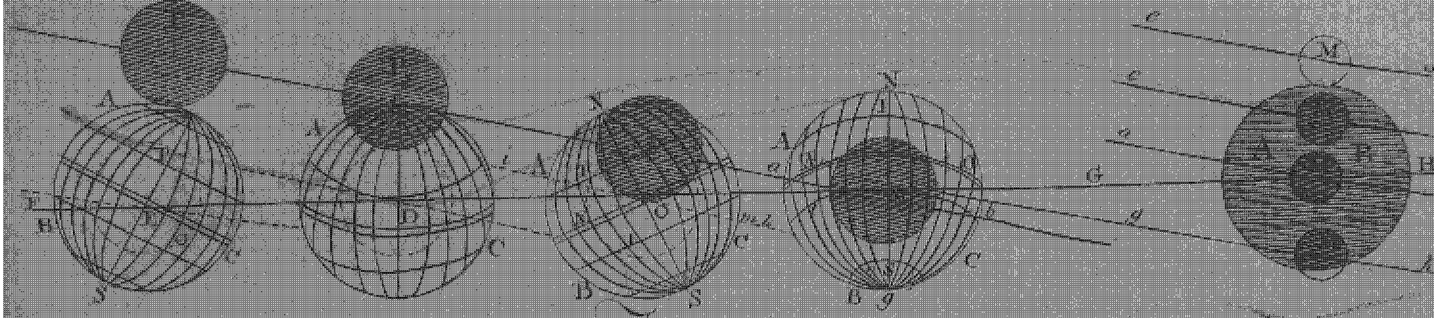

Fig. 206

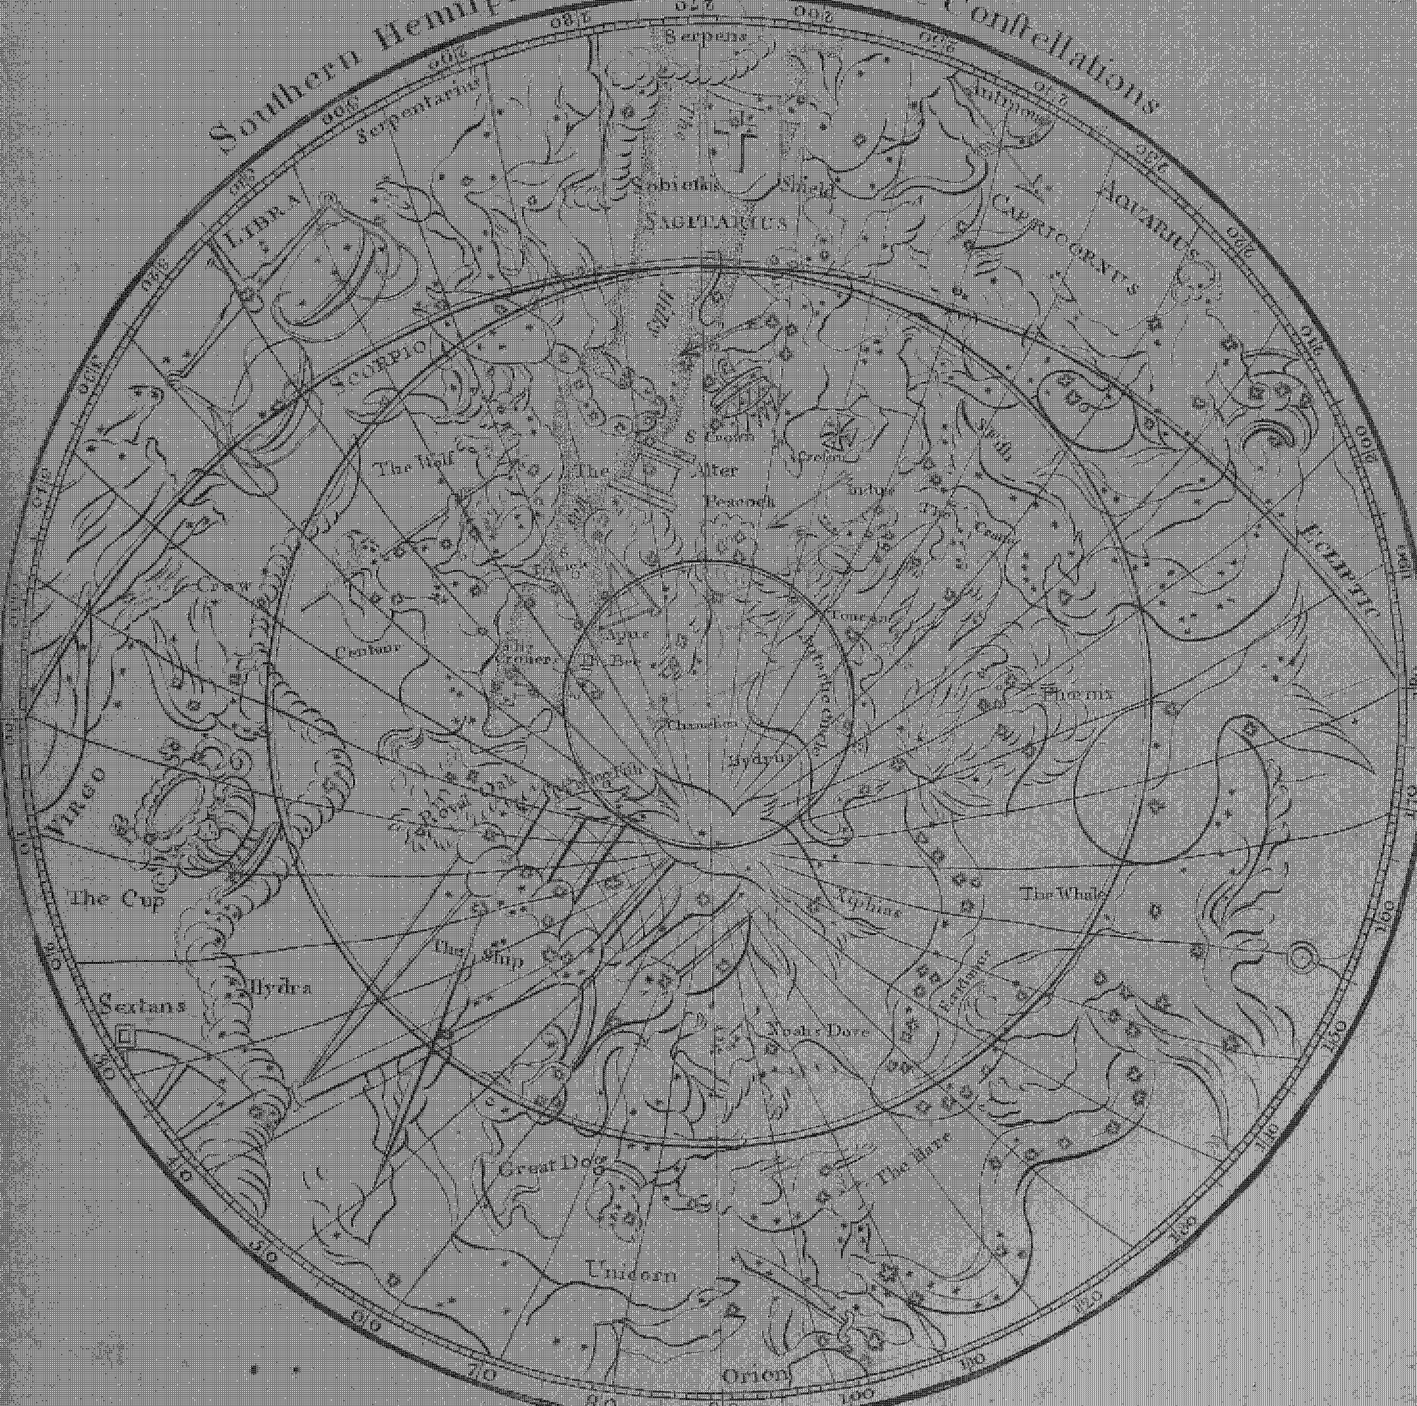
Southern Hemisphere with the Figures of the Constellations



EXPLANATION AND USE OF THE SOLAR AND LUNAR TABLES.

USE *of the* TABLES *of the* EQUATION *of* TIME.

PROBLEM I.

To convert apparent time into mean time, and the contrary.

SINCE the place of the Sun's apogee does not remain fixed in the ſame point of the ecliptic, but goes forward 1′ 6″ every year, and conſequently about a degree in 55 years, the ſame equation of time will not ſerve accurately for many years continuance. To remedy this defect, we have here given two tables, one adapted to the 16th year of this century, at which time the Sun's apogee was in 8° ♋, the other to the year 1771, when the Sun's apogee was in 9° ♋. Whence the equation of time may be readily found by proportion; and that with ſufficient accuracy, not only for any intermediate year, but alſo for thoſe preceding and following, provided they are not diſtant from theſe above 60 or 100 years. The uſe of tables of this kind is ſo familiar to aſtronomers, that it ſeems unneceſſary to enter into any further explanation of theſe; we ſhall therefore only remark, that the titles of the equation or algebraic ſigns ſtanding over them are what are to be uſed for turning apparent into mean time: but the contrary are to be uſed for turning mean into apparent time.

EXAMPLE.

In the year 1756, April 30, 23ʰ. 20′. 28″, apparent time, the Sun's place was obſerved 1ˢ. 11°. 25′ 8″,6; the equation of time and the mean time are required.

With the given place of the Sun, the equation of time anſwering to the year 1716 is had = — 3′. 18″; and anſwering to the year 1771 = — 3′ 12″; and conſequently to the given year it will be = —3′ 14″; and therefore the mean time is 23ʰ. 17′. 14″.

SCHOLIUM I.

But if the equation of time be required either more accurately or for a time above 100 years diſtant from the limits of the tables, the mean longitude of the Sun muſt be found reckoned from the true equinox, and his true right aſcenſion by Prob. III. and VII. which follow hereafter, and the difference between the two is to be converted into time of the *primum mobile*. And if the right aſcenſion is greater than the mean longitude, the equation ſo found is additive to apparent time, otherwiſe ſubſtractive.

SCHOLIUM II.

I ſay that the true equation of time is to be found by converting the difference abovementioned into time of the *primum mobile*, and not into mean ſolar time. For though the learned De La Caille preſcribes the latter method in his Solar Tables, yet it is eaſy to demonſtrate that the former method is the true one.

USE *of the* CATALOGUE *of* PLACES.

PROBLEM II.

To convert the time of the given place into the time of the meridian of the tables, or the contrary.

THERE is given in a ſelect catalogue the difference in time of the meridians of 60 famous places from the meridian of the tables, marked with the ſign + or —, the firſt of which denotes the place to be weſt of Greenwich, and the latter ſhews it to be eaſt of the ſame. Theſe ſigns are to be uſed if the time of the given place is to be reduced into Greenwich time; but the contrary if Greenwich time is to be reduced into time of the given place.

EXAMPLE.

Let the time at Gottingen be given 6ʰ. 9′. 38″, the time that anſwers to it under the meridian of Greenwich is required?

	h ′ ″
Since the difference in time of the meridians of Gottingen and Greenwich, by catalogue, is	0 . 39 . 32 —
Subtract it, on account of the ſign —, from the given time - - - - -	6 . 9 . 38
The remainder is the Greenwich time required	5 . 30 . 6

SCHOLIUM I.

I deduced the differences aſcribed to the cities of France and the Netherlands from the geometrical meaſure of the French mathematicians, making allowance at the ſame time for the ſpheroidical figure of the earth. The ſituation of the cities in Germany and ſome others I ſettled with particular care from eclipſes of the Sun and occultations of fixed ſtars by the Moon. The reſt I either determined from eclipſes of Jupiter's ſatellites and eclipſes of the Moon, or, where this could not be done, retained them as they are given in the *Connoiſſance des Temps*.

SCHOLIUM II.

In the ſame catalogue are inſerted the latitudes of the places, concerning the uſe of which, as well known, it is ſuperfluous to add any thing. The latitude of Gottingen, as given in the catalogue, is that of the obſervatory of this city; the latitude of Nuremberg is adjuſted to Hoffman's houſe, famous for the ſhop of geographical maps. I deduced both, but particularly that of Gottingen, from my own obſervations. Concerning that of Nuremberg, See Com. Soc. Reg. Gotting. tom. I. p. 373.

USE *and* EXPLANATION *of the* TABLES *of the* MOTION *of the* SUN.

PROBLEM III.

To find the true longitude of the Sun at any aſſigned time by the meridian of the Greenwich obſervatory.

1. FROM the table of epoches, take out the epoches of the mean longitude of the Sun, the apogee, and the numbers I, II, III, IV, for the given year; or, if that is not there to the neareſt year that is ſet down preceding the given year; underneath which place the mean motions anſwering to the number of years elapſed ſince the epoch to the given time.

2. Under theſe write down in order the mean motions for the day of the month, and for the hours, minutes, and ſeconds.

3. Add up the numbers of the ſeveral columns, rejecting 12 S. or any multiple thereof, if they ſhould occur, from the two firſt columns, and rejecting thouſands from num. I, II, III, IV, if they ariſe. And thus the mean longitude of the Sun will be obtained to the aſſigned time in the firſt column, the longitude of the Sun's apogee in the ſecond column, and in the others the numbers proper for finding the corrections ariſing from the actions of the Moon, Jupiter, and Venus.

4. Subſtract the longitude of the apogee from the mean longitude of the Sun, the remainder is the mean anomaly of the Sun.

5. With this anomaly enter the table of the equation of the Sun's centre, and take out the equation of the Sun's centre with its proper ſign, and place it under the Sun's mean longitude.

6. With the numbers I, II, III, IV, enter the tables, and having found the hundreds at the top or bottom, and the tens on the ſide, take out the correction or leſſer equations, each with their proper number reſpectively, without neglecting the proportional part, and let theſe alſo be written under the Sun's mean longitude.

7. Apply theſe equations according to their titles or ſigns to the mean longitude; the reſult is the true longitude of the Sun required.

Example.

If the Sun's true longitude be required to the year 1756, April 30, 23ʰ 17′. 14″, mean time at Greenwich; the calculation performed according to the foregoing precepts will be as follows:

	Mean Long. ☉	Long. ☉'s apog.	N. I.	N. II.	N. III.	N. IV.
	s ° ′ ″	s ° ′ ″				
Epoch of year 1756	9.10.33.18,8	3. 8.44.10	973	262	605	544
Mean Mot. April 30th	3.28.16.39,7	22	64	301	206	18
23ʰ	56.40,5		32	2	2	0
17′	41,9					
14″	0,6					
	1. 9.47.21,5	3. 8.44.32	69	565	813	562
Equat. of cent.	+ 1.37.54,0	Mean an. 10. 1. 2.49				
Equat. ☽ I.	+ 3,4					
♃ II.	— 1,2					
♀ III.	— 0,9					
☊ IV.	— 6,8					
True long. of the Sun.	1.11.25. 9,9					

Scholium I.

The longitude thus found is computed from the true vernal equinoctial point, becaufe of the equation of the equinoxes being applied, which was taken out with number IV. But, in computing the planet's and the moon's place, it is better to make ufe of the Sun's longitude as computed from the mean equinox, till their geocentric longitude is found; in which cafe therefore that equation taken out with number IV. fhould not be applied till then. Thus, in our example, the Sun's longitude reckoned from the mean equinox would be 1ˢ. 11°. 25′. 16″,7.

Scholium II.

When I was conftructing thefe folar tables, I had in my view the tables of that learned aftronomer Lewis de la Caille (who merits much commendation on this fubject) publifhed in the year 1758, and fent me as a prefent from him. Upon examining them I found that they very nearly agreed with the many and careful obfervations made by myfelf from the year 1756 forward with an excellent mural quadrant. Wherefore it did not feem neceffary for me to conftruct folar tables intirely new, but only (availing myfelf of the labours of this illuftrious aftronomer) to correct his tables as far as my obfervations feemed to require. Accordingly I found the excentricity of the Sun's orbit, and confequently the equation of the center, to require no fenfible correction. But, as to the epoches of the mean motion, particularly thofe of the Sun's longitude, I could not make them agree with my obfervations, till I had diminifhed the faid epoch by near feven feconds. Moreover a place of the apogee fomewhat different from his feemed to agree better at leaft with my obfervations, which why I fhould confide lefs in than thofe of others did not appear. Laftly, I had long before deduced from the theory of gravity the difturbances of the apparent motion of the Sun caufed by the Moon, Jupiter and Venus, and found them fuch as are here reprefented, befides fome other fmaller ones, which, being extremely difficult to obferve, I thought might be conveniently neglected in calculation. As to the form of the arguments of thefe fmall corrections, or numbers I, II, III, and IV, I have rendered it more fimple by fuppofing the circle to be divided into 1000 parts.

Scholium III.

I muft not pafs over without mentioning in this place, that all the mean motions both of the Sun and Moon in thefe tables fuppofe the annual motion of the fixed ftars or of the preceffion of the equinoxes to be exactly 50″,3, and to depend thereon fo much, that, if it fhould appear proper to ftate the motion of preceffion flower or quicker, the mean motions of the Sun muft be all made flower or quicker by the fame quantity: and therefore you cannot, without fubverting the whole fabric of the tables, increafe or diminifh one of thefe motions and at the fame time leave the reft unaltered. Thus, for inftance, if the mean motion of the Sun, which I make in 60 Julian years to be 0ˢ. 0°. 27′. 49″,8 over and above the intire revolutions, fhould feem proper to be corrected fo as to agree with the tables of the learned De la Caille, in which that motion is found lefs by 16″,4, this cannot be done except the preceffion of the equinoxes in 60 years, inftead of 50′. 18″ as it is in the tables, be reckoned lefs by the fame quantity or only 50′. 1″,6; and fo much ought the Moon's motion alfo to be corrected. To explain the matter briefly, I would have it obferved, that the mean motions of the Sun and Moon with refpect to the fixed ftars are laid down truly in thefe tables, fo that there fcarce remains a doubt of a few feconds in 60 years; but whether they are alfo laid down juftly with refpect to the equinoctial points muft be judged of from the motion of their preceffion, which being 50′. 18″ in 60 years, according to the opinion of moft modern aftronomers, the affirmative of the queftion cannot be doubted.

Scholium IV.

Whenever therefore any phenomenon is concerned depending on the relative fituation of a fixed ftar and the Sun and Moon; as for inftance, the occulation of a fixed ftar, the motion of preceffion affumed in thefe tables muft be made ufe of in computing the place of the ftar. For this purpofe that motion is added to the mean motion of the Sun, that the calculator may not be left in any uncertainty, nor have any occafion to feek for it elfewhere, or lofe any time in computing it.

Scholium V.

To the fame tables of the mean motions of the Sun, there is alfo added the motion of decreafe of the obliquity of the ecliptic, according to the quantity deduced from the theory of gravity. Hence the mean obliquity of the ecliptic is eafily found to any time, provided it be known for any one year. Now, from my obfervations made with great care with an excellent mural quadrant, at both folftices, in the years 1756, 57, and 58, I find the mean obliquity of the ecliptic to the beginning of the year 1756 to be 23°. 28′. 16″, which therefore fhould be made ufe of in the prefent cafe.

Problem IV.

To find the mean and true obliquity of the ecliptic to any affigned time.

1. From the column that lies fartheft to the right hand, take out the decreafe of the obliquity of the ecliptic, anfwering to the number of years intervening between the given time and the year 1756; which add to 23°. 28′. 16″, if the given time precedes 1756, but fubftract, if it follows the fame, and the mean obliquity

obliquity of the ecliptic will be obtained to the beginning of the year; which is easily reduced to the elapsed time of the given year, by substracting one tenth of a second for every three months.

2. By means of the tables of epoches and mean motions, find num. IV. with which take out the equation from the table intitled Nutation, and apply it according to its sign to the mean obliquity just found, and you have the true or apparent obliquity.

EXAMPLE.

What was the true obliquity of the ecliptic in the beginning of September 1671.

Because from this year to the year 1756 there are elapsed 85 years, the decrease of the obliquity will be found for 80 years - -	36″,8
For 5 years - -	2,3
And consequently for 85 years - -	39,1

Which added to 23°. 28′. 16″,0 gives the mean obliquity of the ecliptic 23°. 28′ 55″,1, and in the month of September 23°. 28′. 54″,8.

Now num. IV. to the epoch 1660 is - - -	386
The motion for 11 years - -	591
For the beginning of September -	36
Therefore num. IV. to the given time, rejecting 1000, is	13

To which the corresponding correction or nutation is +9″,6, which, being added to the mean obliquity 23°. 28′. 54″,8, gives the true obliquity 23°. 29′. 4″,4.

SCHOLIUM I.

But if the mean obliquity is to be found from the true, it is evident that the nutation must be applied with a contrary sign.

SCHOLIUM II.

The maximum of nutation 9″,6, according to which this table is constructed, exceeds a little that which is commonly assumed, the laws of attraction requiring such increase, and the observations at the same time favouring it.

PROBLEM V.

To find the logarithm of the Sun's distance from the earth at any assigned time.

1. If the mean anomaly of the Sun, with the numbers I, II, III, are not already known from a calculation of the Sun's longitude, they must be found by prob. III. 1. 2. 3. 4.

2. With the mean anomaly take out the logarithm of the distance in the ecliptic hypothesis.

3. To this apply the corrections taken with the numbers I. II. III, out of their respective tables, the result is the true logarithm of the distance.

EXAMPLE.

In the example of prob. III. the mean anomaly of the Sun was 10ˢ. 1°. 2′. 49″, wherefore the uncorrected logarithm is - - - -		0.003836
Num. I. 69. gives - - - -	+	15
Num. II. 565. - - - -	—	8
Num. III. 813. - - - -	—	5
Therefore the logarithm of the true distance		0.003838

SCHOLIUM.

These logarithms are adapted to a mean distance = 1, wherefore to prevent the logarithms of numbers less than unity from coming out negative, their index is supposed to be increased by ten, which therefore must be again rejected, when the case requires it.

PROBLEM VI.

To find the apparent semidiameter, and also the hourly motion of the Sun, to any assigned time.

Both are readily had, if the mean anomaly of the Sun to the given time be known or first found by prob. III.

EXAMPLE.

In the example of prob. III. the mean anomaly of the Sun was - - - -	° ′ ″ 10. 1. 2. 49
Wherefore the apparent semidiameter of the Sun is	15. 54,3
And his true hourly motion - -	2. 25,2

SCHOLIUM.

The semidiameter of the Sun, as here given, is suited to the supposition of the semidiameter at the mean distance being 16′. 2″,8; which quantity I have inferred from above 130 observations made with the mural quadrant, which did not seem ill-adapted for this purpose.

PROBLEM VII.

The longitude of the Sun or any point of the ecliptic, and the obliquity of the ecliptic being given, to find the corresponding right ascension.

1. With the given longitude look for the reduction and its mutation or change.

2. Say, as 60″ : is to this mutation : : so is the difference between 23°. 28′. 15″,0 and the given obliquity, to a fourth number, which added to the reduction just found, if the given obliquity be greater than 23°. 28′. 15″,0, or substracted from it, if the obliquity be less, will give the reduction corrected.

3. Therefore apply this according to its sign to the longitude, and you will have the right ascension required.

EXAMPLE.

Let the longitude of the Sun be given 1ˢ. 11°. 25′. 10″,3, and the obliquity 23°. 28′. 7″,0, the right ascension is required.

With the given longitude the reduction is found	—2°. 26′. 19″,0
And its mutation - - -	12,7

Since therefore the given obliquity differs 8″ from 23°. 28′. 15″,0, say, as 60″ : is to 12″,7 : : so is 8″,0 : to a 4th number, 1″,7, which being substracted, leaves the true reduction—0ˢ. 2° 26.′17″,3

And therefore the right ascension required	1 .8 .58 .53 ,0
Or, - -	38 .58 .53 ,0

PROBLEM VIII.

The right ascension of the Sun or a point of the ecliptic, and the obliquity of the ecliptic being given, to find the corresponding longitude.

1. With the right ascension increased by three signs, find the proper reduction in the very same manner as in the preceding problem, for the given obliquity of the ecliptic, and from the same table.

2. Apply this according to its sign to the given right ascension, and the required longitude will be found.

EXAMPLE.

If the given obliquity be 23°. 28′. 7″,0, and the right ascension 38°. 58′. 53″,0, or 1ˢ. 8°. 58′. 53″,0, adding three signs to this we shall have 4ˢ. 8°. 58′. 53″,0, and therefore by the reduction + 2°. 26′. 19″,1, with the mutation 12″,9. Then say, as 60″ : is to 12″,9 : : so is the difference of the obliquities, 8″ : to a fourth number, 1″,7, which, substracted from + 2°. 26′. 19″,1, leaves the true reduction + 2°. 26′. 17″,4; hence the longitude required is 1ˢ. 11°. 25′. 10″,4.

PROBLEM IX.

The obliquity of the ecliptic, and the longitude of the Sun or a point of the ecliptic being given, to find the corresponding declination.

1. With the given longitude find the declination with its mutation or change.

2. Say, as 60″ : is to this mutation : : so is the difference between 23°. 28′. 15″,0, and the given obliquity : to a fourth number, which added to or substracted from the declination just found, according as the given obliquity is greater or less than 23°. 28′. 15″,0, will give the declination required; which will be north if marked in the table with the sign +, but south if distinguished with the sign —.

EXAMPLE.

EXAMPLE.

Let the logitude be 1ˢ. 11°. 25′. 10″,3, and the obliquity 23°. 28′. 7″,0, the declination is + 15°. 16′. 38″,0, and the mutation 37″,7. And as 60″ : is to 37″,7 : : so is 8″,0 to a fourth number, 5″,0; which, becauſe the given obliquity is leſs than 23°. 28′ 15″,0, muſt be ſubſtracted from 15°. 16′. 38″,0; Hence the true declination is 15°. 16′. 33″,0 +, or north.

PROBLEM X.

The obliquity of the ecliptic and declination of the Sun being given, to find his longitude.

1. Enter the table, with the given declination, and take out the mutation anſwering to it.

2. With this mutation and the difference of the obliquities find, as in the preceding problems, a fourth number, which ſubſtract from the given declination, if the given obliquity be greater than 23°. 28′. 15″,0, or add, if it be leſs; the reſult will be the declination, ſuch as it would be if the obliquity was 23°. 28′. 15″.

3. With this declination enter the ſame table again, and by making proportion find the longitude.

EXAMPLE.

On the firſt day of May 1756, the Sun's declination was obſerved 15°. 16′. 34″,2 north, and the obliquity of the ecliptic was 23°. 28′. 7″.0, the longitude of the Sun is required.

Since this declination has the mutation 37″,7 aſcribed to it in the table: ſay, as 60″ : is to 37″,7 : : ſo is 8″ : to a fourth number, 5″,0; therefore the declination would be + 15° 16′.39″,2, if the obliquity was as great as it is ſuppoſed in the table; wherefore from the ſame table the longitude of the Sun will be found either 1s. 11°. 25′. 11″,4 or 4s. 18°. 34′. 48″,6; but ſince in the month of May the Sun is in the aſcending ſigns, the firſt only in this caſe is the true one.

PROBLEM XI.

The obliquity of the ecliptic, and the longitude or right aſcenſion of any point of the ecliptic being given, to find the angle between the ecliptic and the parallel to the equator paſſing thro' that point.

1. If it be the longitude which is given, firſt find the right aſcenſion by problem VII.

2. With the right aſcenſion ſo found, or given, and increaſed by three ſigns, find the declination by problem IX. which, only with the change of its name, will repreſent the angle between the ecliptic and the parallel. And according as the ſign is + or —, the ecliptic will aſcend above, or deſcend below the parallel.

EXAMPLE.

Let the given right aſcenſion be 38°. 58′. 53″,0, which, increaſed by three ſigns, becomes 4ˢ. 8°. 58′. 53″,0. Hence by problem IX. for the obliquity 23°. 28′. 7″,0, there will be found 18°. 2′. 1″,4 +, wherefore ſo much the ecliptic is inclined to the parallel, and aſcends above it, or towards the north.

PROBLEM XII.

The Sun's diſtance from the zenith being given to find his parallax in a vertical circle.

This, which is alſo called the parallax in altitude, is eaſily found from its proper table, and is uſeful either for converting the obſerved diſtance from the zenith into the true, or the contrary. In the firſt caſe it is to be ſubſtracted from, and in the latter added to, the diſtance from the zenith. 2

USE *and* EXPLANATION *of the* TABLE *of* ASTRONOMICAL REFRACTIONS.

PROBLEM XIII.

The apparent diſtance of a celeſtial object from the zenith, and the temperature of the air ſhewn by the barometer and thermometer being given, to find the refraction.

IT is not the buſineſs of this place to treat largely of the nature of the aſtronomical refractions, or to explain the whole theory of them. But ſo much it ſeems proper to premiſe, that the refractions greatly depend on the viciſſitudes of the atmoſphere, and on its heat and elaſticity; and therefore it is neceſſary for obſervers, at the ſame time that they obſerve the altitude or zenith diſtance of a ſtar, to take notice alſo of the ſtate of the atmoſphere as ſhewn by the barometer and thermometer, and write it down in their journal. For ſince the modern practical aſtronomy is brought to this pitch, as to be almoſt wholly employed in ſearching out little niceties, and correcting ſmall errors, formerly overlooked, ſo neither is it proper to diſregard thoſe, which may affect obſervations from the variableneſs of the refractions. My table, which ſerves for computing the true refractions to any temperature of the air, in any part of the earth, requires the height of the barometer to be noted to twelfths of an inch or lines of the Paris foot, and the height of the thermometer according to Reaumur's ſcale: ſo that if the obſerver ſhould make uſe of a different meaſure, it muſt be firſt reduced to this before the refraction is computed†.

The firſt column of the table of refraction contains the refraction anſwering to every degree of zenith-diſtance, for that ſtate of the air, in which the height of the mercury in the barometer is 28 inch. 0 lin. and that of Reaumur's thermometer 10 degrees above the freezing point. The ſecond and third columns ſhew the variations of the refraction, the former for 10 lines of the barometer, and the latter for as many degrees of the thermometer; whence the proportional part is eaſily had for any other number of lines or degrees. Now the refraction is greater than the tabular one, and therefore the proportional part is to be added if the barometer is higher than 28 inches; the refraction is alſo greater if the thermometer is lower than 10+; but in the oppoſite caſes the refraction is leſs than the tabular one. But the uſe of the table will better appear by an example than by any further explanation.

EXAMPLE.

Let the obſerved zenith-diſtance be 70°. 20′. 5″, the height of the barometer being 27 inc. 5l. and that of the thermometer 4 degrees above the freezing point; the refraction is required.

By the table, the refraction anſwering to the zenith diſtance 70°. 20′. 5″ is - - -	2′. 39″,2
And the variation hereof, for 10 lines of the barometer	4, 8
For 10 degrees of the thermometer	7, 4

But as the given height of the barometer wants 7 lines of 28 inc. 0 l. ſay, as 10 l. is to 4″,8, ſo is 7l. to a fourth number, 3″,4; further, ſince four degrees of the thermometer differ 6 degrees from 10 degrees, ſay, as 10 is to 7″,4, ſo is 6 to a fourth number, 4″,4. Hence the true refraction will be 2′. 39″,2 — 3″,4, +4″,4, or 2′. 40″,2; the firſt correction being ſubſtracted on account of the given height of the barometer being leſs, and the ſecond correction additive, becauſe the thermometer was lower than the tabluar ones.

In

† A note is added, at the bottom of the table, ſhewing its relation to the Engliſh meaſure of length, and to the ſcale of Fahrenheit's thermometer.

In a note at the bottom of the table of astronomical refractions, we have referred that table to the height of the barometer expressed in English measure, and to the scale of Fahrenheit's thermometer, to the following effect: "This table also answers to the height of "the barometer 29,6 inches, English measure, and to 50° of Fahrenheit's thermometer; or to the height of the barometer 30 "English inches, and 55° of Fahrenheit's thermometer. And the "column of variation of refraction for 10 lines of the barometer, "Paris measure, answers to a difference of 9-10ths of an inch English measure, from the given height 29,6 or 30,00 inches; and "the column of variation of refraction of 10° of Reaumur's thermometer answers to a difference of 20° of Fahrenheit's thermometer from the given degree 50 or 55°." But the author, in the 1st scholium of this problem, having observed, that it is not safe to use proportional parts in zenith-distances exceeding 80 degrees, and having therefore delivered the algebraic formula of refraction upon which the table was constructed, directs the refraction to be thence deduced by direct calculation in that case; it may therefore be useful to reduce the formula to the English measure of length, and the scale of Fahrenheit's thermometer. Therefore,

Let the apparent zenith-distance be put $= \delta$

The height of the barometer expressed in English inches $= \beta$

And the height of Fahrenheit's thermometer $= \theta$.

And substituting the values of $b =, 9383\,\beta$, and $t = \frac{\theta - 32}{2\frac{1}{4}}$ in the formula, we shall have

$$\text{Refr.} = \frac{74'',408\beta \text{ sin. } \delta}{(1+0,002483\theta)^{\frac{3}{2}}}\left[\sqrt{\left(1+\frac{(17,143 \text{ cos. } \delta)^2}{1+0,002483\,\theta}\right)} - \frac{17,143 \text{ cos. } \delta}{(1+0,002483\theta)^{\frac{1}{2}}}\right]$$

$$= \frac{74'',408\beta \text{ sin. } \delta}{\left(1+\frac{\theta}{400}-\frac{\theta}{60000}\right)^{\frac{3}{2}}}\left[\sqrt{\left(1+\frac{(17,143. \text{ cos. } \delta)^2}{1+\frac{\theta}{400}-\frac{\theta}{60000}}\right)} - \frac{17,143 \text{ cos. } \delta}{\left(1+\frac{\theta}{400}-\frac{\theta}{60000}\right)^{\frac{1}{2}}}\right]$$

The computation may be very conveniently made from this formula (in a similar manner to what Mayer has shewn with respect to the other formula) as follows: find an angle ω whose tangent is

$$= \frac{\left(1+\frac{\theta}{400}-\frac{\theta}{60000}\right)^{\frac{1}{2}}}{17,143 \text{ cos. } \delta};\quad \text{and the refraction is} = \frac{74'',408\,\beta \text{ sin. } \delta \text{ tang. } \frac{1}{2}\,\omega}{\left(1+\frac{\theta}{400}-\frac{\theta}{60000}\right)^{\frac{3}{2}}}.$$

EXAMPLE.

On the 5th day of July 1756, the barometer standing at 29,485 English inches, and Fahrenheit's thermometer at 56 degrees, the zenith-distance of λ ♏ was observed at Gottingen 88°. 7'. 34″,0; the refraction is required.

$$\theta \text{ being} = 56, \left(1+\frac{\theta}{400}-\frac{\theta}{60000}\right)^{\frac{1}{2}} = (1+,14-,00093)^{\frac{1}{2}} = \sqrt{(1,13907)} \text{ and}$$

Log. $\sqrt{1,13907}$		= 0.02827
Compl. ar. log. 17,143		= 8.76592
Compl. ar. log. cos. δ		= 1.48546
Therefore tang. ω		= 10.27965
And hence ω		= 62°. 17'. 26″
and $\frac{1}{2}\,\omega$		= 31 . 8 . 43
Moreover log. tang. $\frac{1}{2}\,\omega$	9.78126	
log. 74″,408	1.87162	
log. β or log. 29,485	1.46960	
log. sin. δ	9.99977	
Compl. ar. log. $(1.13907)^{\frac{3}{2}}$	9.91519	
Whence log. refr.	= 3.03744	
And the refraction sought	= 1090″,0 or = 18'. 10″,0

PRECEPTS *for Calculating the* Moon's Place *by Mr Mason's* Lunar Tables.

Example.

Let it be required to find the ☽'s longitude and latitude, with her horary motion and parallax for the year 1791 N. S. on the 4th of Feb. at 0h. 5′. 3″ mean time at Greenwich.

Precepts.

1. Find the true longitude of the Sun, by the solar tables preceding, to the assigned time, reckoned from the mean equinox; by omitting the last of the four small equations or the equation of the equinoxes, together with his mean anomaly. By these tables you will find the true longitude of the Sun for the given instant to be
   10ˢ. 15°. 43′. 2″. = ⊙ long. and
   7 5 12 30 = ⊙ mean anomaly.

2. From the tables of the epochs, take out the mean motions of the moon's mean longitude, mean anomaly, and mean long. of her ascending node, for the year, month, day, hour, minute and second of the given time; placing each in their respective columns, and under the moon's mean-longitude, place her acceleration found in the table of Epochs.

Add up the the numbers in the columns of mean long. and mean anomaly, rejecting twelve signs whenever they occur and setting down the remainder, and you will have the mean longitude of the moon and her mean anomaly. But from the epoch of the node in the third column, substract the sum of all the numbers placed under it, which you have collected from the tables for months, days, hours, &c. and you will have the mean longitude of of the moon's ascending node. Thus you will have in the proposed example.

10ˢ. 26°. 8′. 12″,2 = m. Long. ☽
9 12 58 36 5 = m. Anom.
6 25 28 33 = ☽'s ☊.

3. Make two columns for receiving the positive and negative equations of the moon's longitude to be collected from the tables with their proper arguments placing each in their proper columns, according to the signs of the tables.

4. The argument of the first table for the ☽'s long. is the mean anomaly of the Sun, viz. in this example 7ˢ. 5°. 12′. 30″, with which you will find — 6′. 31″,9 to be placed in the column of negative equations.

5. If you substract the true longitude of the Sun, viz. 10ˢ. 15°. 43′. 2″. from the mean long. of the Moon, you will have the mean distance of the Moon from the Sun = 0ˢ. 10°. 25′. 10″.; to and from the double of which, viz. 0ˢ. 20°. 50′. 20″, add and substract the first argument, or ☉'s m. anom. = 7ˢ. 5°. 12′. 30″. and you will have the second and third arguments respectively; that is, for the second argument 7ˢ. 26°. 2′. 50″, by which you will find in the second table for the Moon's longitude the equation + 46″,4 to be placed in the column of positive equations in this example; and for the third argument you will have 5ˢ. 15°. 37′. 50″, with which, you will find in table the third = — 18″.7, for the column of negative equations.

6. To and from twice the Moon's mean distance from the Sun = 0ˢ. 20°. 50′. 20″, add and substract the mean anomaly of the Moon and you have the fourth and fifth argument; that is, for argument 4th in this case, 10ˢ. 3°. 49′. 65″, to which you will find — 48″. in the fourth table; and for the fifth argument you will have 3s. 7°. 51′. 3″,3, by which you will have — 3°. 19′. 52″,5 from table 5th, called the Evections.

7. To and from the fifth argument, viz. 3ˢ. 7°. 51′ 33″.5, add and substract the first argument, and you will have 10ˢ. 13°. 4′. 6″5 for the sixth argument, and 8ˢ. 2°. 39′. 3″,5, for the seventh argument by the first of which you will find — 1ˢ. 30″,2, and by the latter — 41″,3.

8. From the mean anomaly of the Moon substract the first argument or the Sun's mean anomaly, and you will have 2ˢ. 7°. 46′. 16″,5, for the eighth argument, with which, entering table 8th, you will find + 38″,9, for the equation.

9. From the mean distance of the Moon from the Sun, substract the moon's mean anomaly and you will have 2ˢ. 27°. 26′. 24″. for the ninth argument, with which in table 9th, you will have + 17″,6.

10. From the mean long. of the Moon's node substract the true long. of the Sun and you will have the tenth argument, viz. 8ˢ. 19°. 45′. 31″, with which you have in table 10th, + 39″2.

11. To the Moon's mean distance from the Sun add the Sun's anomaly, and you will have 7ˢ. 15°. 37′. 40″, for the eleventh argument, with which entering table 11th, you will find + 12″,1.

12. From the Moon's mean distance from the Sun substract the Sun's mean anomaly, and you will have 5ˢ. 5°. 12′ 40″, for the twelfth argument, with which you will find in table 12th, — 1″,3.

13. To twice the Moon's mean distance from the Sun add twice the Moon's mean anomaly, and you will have the thirteenth argument, viz. 7ˢ. 16°. 48′, with which you will find in table 13th, the equation + 2″,7.

14. From four times the Moon's mean distance from the Sun substract the Moon's mean anomaly, and you will have 3ˢ. 28°. 42′ for the fourteenth argument, with which you will find in table 14th, the equation, + 10″,9.

15. Substract the longitude of the Moon's node from the ☽'s mean longitude, and you will have her mean distance from her node, viz. 4ˢ. 0°. 39′. 39″, from the double of which, viz. 8ˢ. 10° 19′. 18″, substract the double of the Moon's mean anomaly, viz. 6ˢ. 25°. 57′. 33″, and you will have 1ˢ. 5°. 21′ 45″, for the fifteenth argument, with which you will find — 3″,6 for the equation in table 15th.

16. From the fourth argument, viz. 10ˢ. 3°. 49′. 7″, substract twice the Moon's mean distance from her node, and you will have 2ˢ. 2°. 29′ 49″, for the sixteenth argument, with which you will find + 7″,4, for the equation in table 16th.

17. From the fifth argument 3ˢ. 7°. 57′. 33″,5 substract twice the Moon's mean distance from her node, viz. 8ˢ. 1°. 19′. 18″, and you will have 7ˢ. 6°. 32′. 15″,5 for the seventeenth argument, with which you will find + 3″,2 for the equation in table 17th.

18. The mean longitude of the Moon's node is the eighteenth argument, viz. 6ˢ. 25°. 28′. 33″, with which take out the equation 3″,3 from table 18th.

19. Now add up the two columns of positive and negative equations separately and the difference of these sums with the sign of the greater is the sum of these eighteen equations of longitude. In the present case, the sum of the positive equations is + 2′. 58″,4, and the sum of the negative equations is — 1°. 29′. 52″,8, and their difference with the sign of the greater is — 1°. 26′. 54″,4 for the result of the whole eighteen preceding equations.

20. The next thing to be done is to corrct the ☽'s mean anomaly, for which purpose you have a table at the beginning of the lunar tables, (the argument being the Sun's mean anomaly), which is called *the Annual Equation* of the Moon's mean anomaly. Enter this table with its proper argument, the Sun's mean anomaly, viz. 7ˢ. 5°. 12′. 30″, and you will find — 12′. 46″, which added to — 1°. 26′. 54″,4, the sum of the eighteen preceding equations found before, will give — 1°. 39′: 40″,40 for the total correction, which applied according to its sign to the Moon's mean anomaly will give 9ˢ. 11°. 19′. 6″,1 the Moon's anomaly corrected, which is the argument of table 19th, entitled, the Equation of the Moon's center, where you will find the equation of the center = + 6°. 5′. 23″,0, which add to the result of the eighteeen equations, and you will have + 4°. 38′. 28″,4 for the result of the nineteen preceding equations.

21. Apply this amount of the nineteen equations, viz. 4s. 38′. 28″,4 to the mean dist. of the Moon from the Sun, viz. 0ˢ. 10°. 25′. 10″, and you will have the argument of table 20th, entitled the Variation, viz. 0ˢ. 15°. 3′. 38″,4; or, which is the same thing, apply this result of the nineteen equations to the Moon's mean longitude, and from the corrected longitude substract the Sun's true longitude, and you will have the same argument of table 20th, with which enter table 20th, and you will find + 17′. 35″,4, which apply to the aforesaid sum + 4°. 38′. 28″,4, and the sum will be 4°. 56′, 3″,8, which applied to the mean longitude of the Moon, viz. 10ˢ. 26°. 8′. 12″,2 according to its sign, will give 11ˢ. 1°. 4′. 16″, for the correct longitude of the Moon, in her orbit.

22. Now correct the longitude of the Moon's node, by entering the table for this purpose at the beginning of the lunar tables, entitled, the annual equation of the Moon's node, with it proper argument, viz. the Sun's mean anomaly, viz. 7ˢ. 5°. 12′. 30″, and you will have 5′. 24″,7, which applied to the mean longitude of the node 6ˢ. 25°. 28′. 33″,4, according to its sign will give 6ˢ. 25°. 23′. 8″,3 for the equated long. of the Moon's asc. node.

23. From the correct longitude of the Moon, viz. 11ˢ. 1°. 4. 16″, substract the equated longitude of the Moon's node, viz. 6ˢ. 25°. 23′. 8″.3, and the remainder, viz. 4ˢ. 5°. 41′. 7″,7, will be the equated distance of the Moon from her node; from the double of which, viz. 8ˢ. 11°. 22′. 15″,4 substract the Moon's corrected anomaly, viz. 9ˢ. 11°. 19′. 6″,1, there will remain 11ˢ. 0°. 3′. 9″,3 for the twenty-first argument, with which enter the

the 21ſt table, and you will find — 42″,0 for the equation, which apply to the correct longitude of the Moon, viz. 11ˢ. 1°. 4′. 16″, and you will have her longitude in her orbit farther corrected, viz. 11ˢ. 1°. 3′. 34″.

24. From her longitude in her orbit now found, 11ˢ. 1°. 3′. 34″, ſubſtract the equated or correct longitude of her aſcending node, found by the 22d precept, viz. 6ˢ. 25°. 23′. 8″,3, and you will have 4ˢ. 5°. 40′. 25″.7 for the argument of the 22d table, entitled Reduction, in which you will find the equation + 6′. 26″,3.

25. Laſtly, with the mean longitude of the Moon's node, not corrected, viz. 6ˢ. 25°. 28′. 33″ as the argument, enter the table entitled, the equation of the equinoctial points, and you will find + 7″,7, which together with the equation laſt found + 6′. 26″,3 being added to the Moon's laſt corrected longitude in her orbit, viz. 11ˢ. 1°. 3′. 34″, will give 11ˢ. 1°. 10′. 8″ for the true longitude of the Moon reduced to the ecliptic, and computed from the apparent equinox.

See the Arguments and Equations in the following Table for finding the Longitude of the Moon at the time propoſed.

PRECEPT for computing the MOON'S LATITUDE.

1. The 22d argument of longitude 4ˢ. 5°. 40′. 25″,7 found by precept 24th is the 1ſt argument of latitude, by which you have from the 1ſt table of latitude the equation + 4°. 10′. 46″,4.

2. To the 20th argument of longitude apply the ſum of the 20th and 21ſt equations of longitude, having regard to their ſigns, viz.+ 16′. 53″,4 and you have the true diſtance of the Moon in her orbit from the Sun, viz. 0s. 15°. 20′. 31″,8, from the double of which 1s. 0°. 41′. 3″,6, ſubſtract the 1ſt argument of latitude 4s. 5°. 40′. 27″,5, and you will have 8s. 25°. 0′. 37″,9 for the 2d argument of latitude, by which you get in table 2d — 8′. 46″,4 for the 2d equation of latitude.

3. From the 1ſt argument of latitude 4s. 5°. 40′. 25″,7, ſubſtract the mean anomaly of the Sun 7s. 5°. 12. 30″, and there will remain 9s. 0°. 27′. 55″,7 for the 3d argument which gives — 3″,1.

4. From 1ſt argument 4s. 5°. 40′. 25″,7, ſubſtract the mean anomaly of the Moon 9s. 12°. 58′. 46″,5, and there remains 6s. 22°. 41′. 39″,2 for the 4th argument, with which you get from table 4th + 6″,8.

5. From the 4th argument ſubſtract the Moon's mean anomaly, or from the firſt argument ſubſtract twice the Moon's mean anomaly, and you have 9s. 9°. 42′. 52″,7 for the fifth argument of latitude, with which you find in table 5th + 24″,7.

6. From the 5th argument ſubſtract the Moon's mean anomaly; or, from the firſt argument ſubſtract three times the Moon's mean anomaly, and there remains 11ˢ. 26°. 44′. 6″,2 for the 6th argument, with which you get — 0″,1 from table 6th.

7. To argument the 2d 8ˢ. 25°. 0′. 37″,9 of latitude, add the mean anomaly of the Sun 7ˢ. 5°. 12′. 30″ and their ſum 4ˢ. 0°. 13′. 7″,9 will be the 7th argument; with which you get — 7″,8.

8. From the 2d argument of latitude 8ˢ. 25°. 0′. 37″,9 ſubſtract the mean anomaly of the Sun, and the remainder 1ˢ. 19°. 48′. 7″,9 will be the 8th argument, with which you get — 2″,8.

9. To the 2d argument of latitude 8ˢ. 25°. 0′. 37″,9, add the Moon's mean anomaly, 9s, 12°. 58′. 46″,5, and the Sum 6s. 7°. 59′. 24″,4 is the 9th argument, with which you have + 0″,3.

10. From the ſecond argument ſubſtract the Moon's mean anomaly, and the remainder 11s. 12°. 1′. 51″.4 is the 10th argument, with which you get — 4″,9.

11. From the 10th argument ſubſtract the mean anomaly of the Moon, and the remainder 1s. 29°. 3′. 4″,9 is the 11th argument, with which you find — 4″,5.

The ſum of the additive equations is 4°. 11′. 18″,2, and the ſum

sum of the substractive equations is 9′. 9″,6 and their amount or difference + 4°. 2′. 8″,6 is the true latitude of the Moon; and it is north latitude, because the sum of the positive equations exceeds the sum of the substractive or negative equations. Had the negative equations exceeded the positive the latitude would have been south.

PROBLEM.

To find the EQUATORIAL PARALLAX *of the* MOON.
Precepts for finding the horizontal Parallax of the Mooon at the Equator.

With the first ten arguments for the Moon's longitude take out so many equations from the first ten tables of parallax, and the three other equations from the remaining three tables, with the 19th, 20th, and 21st arguments of longitude, with their proper signs. From the sum of the affirmative numbers substract the sum of the negative numbers, and the remainder is the moon's equatorial parallax, or her horizontal parallax for a place under the equator. In our example you will find the sum of the positive numbers + 56′. 54″,3, and of the negative numbers — 2″,5, and their difference is 56′. 51″,8 for the equat. parallax.

To find the horizontal parallax for any latitude, and to reduce that latitude to the center of the earth, when the equat. parallax is given.

PRECEPT.

Enter the table entitled, *for finding the horizontal parallax from the equatorial parallax, and for reducing the latitude to the earth's center*, with its argument, viz. the latitude on the side, and the equatorial parallax on the top, and find the reduction of parallax, which substracted from the equatorial parallax leaves the horizontal parallax required. Take also the reduction of the latitude from the same table, which substracted from the given latitude, gives the latitude reduced to the earth's center.

N. B. The parallax and reduced latitude should be used in computing the moon's parallaxes in longitude, latitude, right ascension, and declination. For hereby they may be computed by the common rules upon the supposition of the earth's being a perfect sphere, as both are hereby referred to the center of the earth.

In our example you will find for the latitude 42°. and the equatorial parallax found above 6″,7 of a reduction to be substracted from it, to give the horizontal parallax in that latitude; and for the reduction of the latitude to the center of the earth — 14′ 51″.

The next table for finding the Moon's diameter from her equatorial parallax needs no explication, as you have her diameter answering to any parallax given. Or it may be found for any latitude from the horizontal parallax, by this proportion: as 54′ 56″. : 30′. 0″. : : the horizontal parallax for any latitude : to the moon's horizontal diameter required.

To find the horary motion of the Moon in longitude.

The first ten equations are taken from the tables of horary motion in longitude by the first ten arguments of longitude, and the other four with the arguments 19, 20, 21, 22. Find the sum of the first thirteen of these equations by substracting the sum of the negative from the sum of the positive, and the moon's horary motion in her orbit will be obtained. Then say, as 32′. 56″, is to the Moon's horary motion in her orbit just found, so is the number taken out of the last table, to a fourth, which will be the same equation corrected, to be applied according to its sign in the last table to the Moon's hourly motion in her orbit, to have her horary motion with respect to the ecliptic. In our example, you will find 32′. 40″,3 for the sum of the thirteen equations, and in the 14th table + 2″,5, the reduction of which by the above proportion will be insensible, and therefore, the horary motion with respect to the ecliptic will be 32′. 42,″8.

To find the Moon's horary motion in latitude.

With argument I. and II. of latitude, take out the two equations from the two tables of the Moon's horary motion in latitude, and the sum, if they have the same sign, or their difference, if they have contrary signs, with the sign of the greater will be the Moon's mean hourly motion in latitude. Then say, as 32′, 56″, is to the Moon's horary motion in her orbit, found by the last problem, so is the mean horary motion in latitude to her true hourly motion in latitude, which will be north, if marked with the sign +, but south if marked with the sign —.

EQUATION of TIME.

Sun's apogee in 8°. Cancer, agreeing with the year A. C. 1716.

Argu. Sun's true Longitude.

For right Ascension of a Point of the Ecliptic. Reduction of the Ecliptic to the Equator.

According to the obliquity of the Ecliptic 23° 28′ 15″,
With the change of reduction for the change of the obliquity one minute.

Argument. Longitude of a point in the Ecliptic.

Declination of the Points of the Ecliptic.

According to the Obliquity of the Ecliptic, 23°. 28′. 15″.

With the Change of Reduction, for the Change of the Obliquity, one Minute.

Argument. Longitude of the Point in the Ecliptic.

* This table alſo anſwers to the height of the barometer 29,6 inches, Engliſh meaſure, and to 50° of Fahrenheit's thermometer; or to the height of the barometer 30 Engliſh inches, and 55° of Fahrenheit's thermometer. And the column of variation of refraction for 10 lines of the barometer, Paris meaſure, anſwers to a difference of 9-10ths of an inch, Engliſh meaſure, from the given height 29,6 or 30,00 inches; and the column of variation of refraction of 10° of Reaumur's thermometer anſwers to a difference of 20° of Fahrenheit's thermometer from the given degree 50 or 55°.

Epochs of the mean Motion of the Moon.

Years current. Mean Time, for the Meridian of the Royal Obſervatory at Greenwich.
